This research addresses the legal challenges posed by the implementation of digital twin technology in public health. Digital twins are advanced computational models which aim to replicate human organ functions and biological processes. Their goal is to enable the simulation of the entire human body and to personalize the outputs with individual patient's health data. Digital twin technology promises to bridge gap between personalized medicine and precision public health. This research is based on a comprehensive review of the current European and Swiss legal frameworks for medical devices and data protection that apply to digital twin technology. Within these frameworks, digital twins are in a grey area, as they are only considered as medical device software when applied to individuals. They also incorporate artificial intelligence, machine learning, and data analytics, which are already a source of legal concern in a healthcare setting, but their effective use in public health raises additional issues. Preliminary findings suggest significant shortcomings in the legal frameworks regarding data privacy, and the potential for increased surveillance by health insurance systems, which could lead to human rights violations. The public health application of digital twins would require global data analysis of sensitive personal information, raising further questions about the secure storage, transmission, and processing of this data. The study concludes that current legal frameworks must be future proofed to manage the complexities introduced by digital twins in public health. In particular, it suggests that regulatory oversight of medical devices needs to be significantly improved in order to safely harness the potential of digital twin technologies for public health. Finally, the new European Union health data space and the forthcoming EU AI act will also play important roles in the implementation of digital twin technologies.

Key messages:

- Applying digital twin technology in public health faces considerable challenges, particularly the issues around data privacy, potential discrimination, and increased surveillance.
- We need to adapt and strengthen existing legal frameworks to effectively manage the complexities introduced by digital twins, ensuring that these technologies can be safely used for public health.

The corporate political activity of the food industry in Ireland: an analysis and proposed solutions

Melissa Mialon

N Campbell[1], *F Finucane*[2], *M Walsh*[3], *K Reilly*[4]
[1]Trinity Business School, Trinity College Dublin, Dublin, Ireland
[2]Galway University, Galway, Ireland
[3]Citizen Expert, Dublin, Ireland
[4]Irish Heart Foundation, Dublin, Ireland
Contact: melissa.mialon@inserm.fr

Background: The study consisted of mapping the corporate political activity (CPA) of the food industry in Ireland. Following that study, we plan to benchmark the efforts made by the Irish government to address any undue corporate influence on public health policy.

Methods: We followed the INFORMAS methods for studying the food industry's CPA (document analysis) and analysed the key commercial actors in Ireland and their activities over a 24-month period. We also conducted nine semi-structured interviews with key informants.

Results: We found a total of 147 CPA occurrences during the period of analysis. That data was triangulated and completed with information shared by our participants. We found examples of the food industry lobbying the government, shaping scientific evidence, and framing the problems and solutions on diet in ways that would not harm the industry. IBEC, a trade association, and the dairy sector were particularly active in trying to influence public health in Ireland.

Conclusions: Our study shows that the food industry uses its CPA to influence public policy, research, and practice in Ireland. The next step for our project will be to benchmark the Irish government against international standards for its efforts to limit the negative effects of the CPA on public health policy.

Key messages:

- In Ireland, as in other countries, the food industry uses its CPA to interfere with public health policy, research and practice.
- There is a need to address that influence, and we will benchmark the efforts of the Irish government in trying to limit the CPA, against international standards.

Abstract citation ID: ckae144.1512
Effect of plastic-free diet, education and Bisphenol A exposure feedback on urine BPA in adolescent

Sebahat Gözüm

F Ulusoy[1], *S Gozum*[2], *M Parlak*[3]
[1]Çamlıbel Public Education Center, Antalya Directorate of National Education, Antalya, Türkiye
[2]Public Health Nursing, Faculty of Nursing, Akdeniz University, Antalya, Türkiye
[3]Pediatric Endocrinology, School of Medicine, Akdeniz University, Antalya, Türkiye
Contact: sgozum@akdeniz.edu.tr

Background: BPA is an endocrine disrupting chemical and is mostly taken orally. Adolescence is the critical sensitivity to these chemicals is maximum. This study was conducted to compare the effects of a plastic-free diet program, plastic-free diet education program and BPA exposure feedback on urine BPA levels in adolescents with high use of packaged products.

Methods: The first phase of the two-phase study is descriptive, the second phase is a single-centre, single-blind, three-arm non-randomized experimental design. The study was conducted at Antalya/Türkiye in the 2022-2023 academic year, and in the first stage, adolescents with high use of plastic packaged products and low attitudes towards healthy nutrition were identified. In the second stage, participants were assigned to the group-1 ($n = 36$), group-2 ($n = 36$) and group-3 ($n = 36$) by simple random sampling method. An eight-week plastic-free diet program was applied to the group 1, plastic-free diet education program and BPA exposure feedback was given to the group-2, and only BPA exposure feedback was given to the group-3. Plastic Packaged Product Usage Survey, Attitude Scale towards Healthy Nutrition, and spot urine samples were used to collect data.

Results: It was found that 2% of adolescents used low plastic packaging, 34% medium, 57% high, and 7% very high. Pre-posttest urine BPA levels ng/ml (µg/g creatinine) were 1.98 (2.54), 1.43 (1.51) in the intervention1 group, respectively; 1.91 (2.35), 1.43 (1.47) in the intervention2 group; It was found to be 1.97 (2.49) and 1.49 (1.66) in the intervention3 group. The effect sizes of pre-posttest BPA/creatinine values were calculated as 1.38, 1.13 and 1.09 in intervention1-2-3 groups, respectively.

Conclusions: All three interventions (plastic-free diet program, plastic-free diet education program and BPA exposure feedback) were effective in reducing urinary BPA levels, reducing plastic-packaged product use levels, and increasing attitudes towards healthy eating.

Key messages:

- Since all three interventions are effective in reducing adolescents' urinary BPA levels, it may be recommended to use the intervention appropriate to the field conditions.
- In the post-tests, the use of plastic packaged products by adolescents in all three groups decreased and their attitudes towards healthy nutrition increased.

Determinants of appetite in the first year of life: Results from a prospective study of infants

Christiana Demetriou

CA Demetriou[1], *A Singhal*[2], *J Lanigan*[2], *P Iacovides*[3], *P Yiangou*[3], *D Hileti*[4]
[1]Department of Primary Care and Population Health, University of Nicosia Medical School, Nicosia, Cyprus
[2]Childhood Nutrition Research Centre, UCL GOS Institute of Child Health, London, UK
[3]Department of Basic and Clinical Sciences, University of Nicosia Medical School, Nicosia, Cyprus
[4]Department of Life Sciences, School of Life and Health Sciences, University of Nicosia, Nicosia, Cyprus
Contact: demetriou.chri@unic.ac.cy

Childhood obesity, a growing public health problem, was shown to be associated with appetite traits (ATs) in infancy but little research exists on the determinants of early appetite. We aimed to examine the association between parental, pregnancy and infant variables on ATs during the first year of life. We followed up 450 healthy term infants assessing Enjoyment of Food (EF), Food Responsiveness (FR), Satiety Responsiveness (SR) and Slowness in Eating (SE), using the Baby (at 2-4 weeks (wk) & 6m) and the Child (at 12m) Eating Behaviour Questionnaires. Associations between parental sociodemographic and lifestyle, pregnancy, infant feeding and anthropometric factors, and these ATs were investigated. Multivariable linear regression models were built for each AT, incorporating statistically significant variables from minimally adjusted models (sex, gestational age, and ethnicity).

Results primarily focus on ATs at 2-4wks, as later ATs were largely influenced by these values. Higher father's BMI ($\beta = 0.013$, $p = 0.022$) was associated with increased EF at 2-4wks. Later gestational age (β = 0.106, p = 0.032), and gestational diabetes (β = 0.538, p = 0.002) were associated with higher FR 2-4wk while mixed feeding compared to exclusively breast feeding (β =-0.281, p = 0.013) with lower FR 2-4wk. Female sex (β = 0.174, p = 0.009) was positively, while gestational age (β=-0.076, 0.022), father's educational attainment (β=-0.199, p = 0.003), father habitual smoking (β=-0.167, p = 0.020) and 4wk WFA z-score (β = 0.087, p = 0.037) were negatively associated with SR 2-4wk. Lastly, higher 4wk WFA z-score (β=-0.151, p = 0.012) and bottle feeding (β=-0.378, p = 0.003) were associated with decreased SE 2-4wk. Acknowledging that a causal association cannot be established in an observational study, this data suggests that parental lifestyle and pregnancy factors could influence infant ATs and hence risk of later obesity, highlighting the importance of preconception health in mitigating the problem of childhood obesity.

Key messages:

- Appetite traits in early infancy are influenced by infant feeding and anthropometric variables, but also by parental and pregnancy characteristics.
- The importance of preconception health is paramount in mitigating the problem of childhood obesity.

Abstract citation ID: ckae144.1514
Evaluation of food pattern behaviours following nutritional education for health professionals

Giulio Barocco

G Barocco[1], E Croci[1], FG Bucci[1], G Forciniti[1], T Longo[1], D Steinbock[1], R Fedele[1], A Marsi[1], E Occoni[1]
[1]Dipartimento di Prevenzione, Azienda Sanitaria Universitaria Giuliano Isontina, Trieste, Italy
Contact: giuliobarocco@gmail.com

Background: The "Work Programme - UN Decade of action on nutrition 2016-2025" highlights the importance of implementing Recommendation 19 of the Second International Conference on Nutrition of FAO and WHO related to nutrition education interventions (NEI) for health professionals (HP), in order to develop nutritional skills based on national dietary guidelines and coherent policies relating to food. The Local Health Agency integrated with Trieste University (ASUGI), since 2009, has performed 25 NEI with the formation of 910 HP. Post pandemic, the content of ASUGI's last 5 NEI, programmed by the prevention plan of the Autonomous Region of Friuli Venezia Giulia, was aligned with the principles of the European Farm to Fork Strategy linked to Sustainable Healthy Diets (SHD).

Objectives: The objectives of the training programme (TP), approved for Continuing Medical Education, was to change and evaluate food pattern behaviour (FPB) of HP (n = 200) to adhere to the SHD. TP was characterized by a systemic view on complex interconnections between nutritional and sensorial food value, sustainability of food chain systems, evolution of urban food environments, as contexts into which SHD choices can be applied. The 2 days training, spread over 14 hours with 40 participants, concluded with interactive work and experiences to applied knowledge and beginning to make informed healthy dietary choices in practice.

Results: 6 months after the conclusion of TP it was reported that the percentage of HP who consumed the recommended portions of fruits and vegetables had increased from 62% to 70% and from 28% to 35% respectively, while those who consumed no cured meats, red meats or legumes, changed from 24% to 35%, from 19% to 25%, from 6% to 3% respectively.

Conclusions: The evaluation of the TP systemic structure has shown its effectiveness in improving some healthy FPB of HP and the importance of applying a continuous improvement process of the program to better adhere to the whole SHD.

Key messages:

- The systemic and integrated structure of nutritional education intervention programs for health professionals contributes to improving their healthy food pattern behaviour.
- The relationships between complex policies of food systems and the 17 SDGs included in the training programs on nutrition education are useful for promoting adherence to healthy and sustainable diets.

Abstract citation ID: ckae144.1515
Proportions and types of different sweeteners in the Hungarian packaged food supply

Eszter Sarkadi-Nagy

E Sarkadi-Nagy[1], G Guba[1], L Zámbó[1], K Susovits[1], M Bakacs[1], M Bica[2], R Harrington[3], H Rippin[4], K Wickramasinghe[4], A Zentai[1]

[3]Nuffield Department of Primary Care Health Science, University of Oxford, Oxford, UK
[4]Special Initiative on NCDs and Innovation, WHO/Europe, Copenhagen, Denmark
Contact: sarkadinagy.eszter@nngyk.gov.hu

Branded food databases facilitate the analysis of sweetener use in commercial packaged food products. The purpose of this study was to map the use of sweeteners in relevant packaged food categories and to assess and compare the nutrient profile of non-sugar (including sugar alcohol) vs. added sugar sweetened food products in Hungary. The foodDB software, developed by University of Oxford, enables automated online data collection, and was used to compile data of all foods and drinks available from four major Hungarian supermarket websites, selected by market share in March 2021. Only products containing either added sugar and/or non-sugar sweeteners were included in the study. These were categorized into 12 food groups using specific search terms. After data cleaning the final product number was 2016. 72% of the products was sweetened with added sugars only, 15% of them with non-sugar sweeteners only and 13% contained both sugars and non-sugar sweeteners. Chewing gums (92%), soft drinks (60%), energy drinks (50%) and pickles (35%) contained non-sugar sweeteners in the largest proportion. More than 90% of flavoured alcoholic beers, chocolate bars, breakfast cereals and yogurts were sweetened with added sugar only. Nine categories included food items containing multiple non-sugar sweeteners per product. The most common non-sugar sweeteners were acesulfame-potassium, sucralose, aspartame present in 15%, 10%, 9% of the total products respectively. Muesli bars with non-sugar sweeteners contained less energy but also less fibre than muesli bars with added sugars only; whereas pickles with non-sugar sweeteners contained less energy but were significantly higher in salt than those products with added sugars only. The presence of non-sugar sweeteners is widespread in the Hungarian food supply; however, their use does not guarantee a more beneficial nutrient profile. Branded food databases are useful tools to analyse the nutrient composition of packaged foods.

Key messages:

- Branded food databases are useful tools to monitor the composition of the packaged food supply.
- The nutrition profile of foods with non-sugar sweeteners can be less favourable than foods with added sugars.

Abstract citation ID: ckae144.1516
Effect of unprocessed and minimally processed foods on blood pressure in children

Silmara Mastroeni

S Mastroeni[1,2], G Kasmirski[2], C Torres[3], M Mastroeni[1,2]
[1]Nutrition Course, University of Joinville Region, Joinville, Brazil
[2]Postgraduate Program in Health and Environment, University of Joinville Region, Joinville, Brazil
[3]Population Health Intervention Research Unit, School of Public Health, University of Alberta, Edmonton, Canada
Contact: silmara.mastroeni@univille.br

Background: The poor eating habits of children, including a decrease in the consumption of unprocessed foods and an increase in the consumption of processed foods, have been associated with excess body weight, which is a well-established risk factor for cardiovascular diseases (CVDs), especially high blood pressure (BP). We aimed to investigate whether the consumption of unprocessed and minimally processed foods is associated with high BP in children at nine years of age.

Methods: Cross-sectional study of 142 Brazilian children participating in a cohort study conducted at the participant's home. The child's food consumption markers were evaluated using the Brazilian Food and Nutrition Surveillance System (SISVAN) and were classified by NOVA. Using a standardized procedure for approaching the child, BP was measured by the auscultatory method. Biological, socioeconomical, demographic, and anthropometric data of the mother and child were also collected. Logistic regression analysis adjusting for important predictors was used to evaluate the association between food consumption and BP.

Results: The prevalence of high BP in children was 20.4%, and the mean systolic and diastolic BP were significantly ($p < 0.05$) higher in children classified as high BP (110.1 and 71.3 mmHg, respectively). An important proportion (44.8%) of children had excess body weight (>85th percentile) and high BP when compared to eutrophic children. Not consuming healthy foods was associated with high systolic BP, even after adjustment for other important covariates ($OR = 3.97$; $p = 0.028$).

Conclusions: Not consuming healthy foods was associated with increased odds of children having high BP at nine years of age. Interventions promoting a healthy diet and the consumption of fruits and vegetables in childhood may contribute to preventing diseases associated with CVD, a global public health problem.

Key messages:

- Educating parents to avoid processed foods and monitoring children's BP are essential actions to prevent associated chronic diseases throughout life.
- Public policies aimed at educating parents to encourage the consumption of healthy foods may significantly contribute to reducing adverse cardiovascular outcomes.

Abstract citation ID: ckae144.1517
Culinary medicine in type 2 diabetes management: co-designing the Cook2DIAbeat training program

Matina Kouvari

M Kouvari[1], A Dalma[1], D Zota[1], E Zioga[1], L Goni[2], A Acilu[2], B Chang[3], M Arrizabalaga-López[4], M Patsea[5], M Ruiz-Canela[2]
[1]Prolepsis Institute, Marousi, Athens, Greece
[2]Preventive Medicine and Public Health, University of Navarra, Pamplona, Spain
[3]The European Food Information Council, Brussels, Belgium
[4]Technology Center in Gastronomy, Basque Culinary Center, Donostia-San Sebastián, Spain
[5]CSI Center for Social Innovation LTD, Nicosia, Cyprus
Contact: m.kouvari@prolepsis.gr

Background: Type 2 diabetes (hereinafter diabetes) stands among the top ten drivers of disease burden. Globally, more than 59 million adults are living with diabetes with a projection of 15% increase by 2045. The Cook2DIAbeat project aims to develop a tailor-made nutrition training program based on culinary medicine, for patients with diabetes to achieve lifelong dietary changes. The aim of the present work was to reveal potential drivers and barriers related to lifelong dietary modifications.

Methods: The study was implemented in February-July 2023 in Spain, Belgium, Greece, and Cyprus. A mixed-method co-design methodology was conducted: co-creation sessions with individuals with diabetes, family members, and healthcare professionals, and an online survey with patients with diabetes.

Results: In total, 23 health professionals and 25 patients and family members participated in the co-creation sessions, and 212 patients in the online survey. Patients and health professionals recognized the added value of the culinary approach for diabetes management. The main perceived barriers for changing dietary habits included difficulties accessing reliable and non-conflicting information, lack of time, emotional and psychological issues, and limited social support. Individuals at an advanced age and of low socioeconomic status seem to demand specific educational approaches addressing the actual challenges of their daily life.

Conclusions: The study indicated that training should provide reliable information and address psychosocial aspects. The translation of the dietary guidelines through the culinary medicine approach seems to be well-received by the target group. Last, the content needs to be tailored to suit the specific age group and socioeconomic background of the patients.

Key messages:

- Reliability, practicability are three key characteristics of a nutrition training program in diabetes management.
- Cultural and socioeconomic barriers needs to be taken into consideration.

Abstract citation ID: ckae144.1518
Revealing the influence of food industry actors in relation to nutritional policies in Belgium

Silke Cnockaert

S Cnockaert[1], S Vandevijvere[1]
[1]Nutrition and Health, Sciensano, Anderlecht, Belgium
Contact: silke.cnockaert@sciensano.be

Unhealthy food is one of the prevailing risk factors of NCDs and cancers, making the food industry a key player in their prevention. However, evidence-based public health policies aimed at reducing consumption of unhealthy food, may threaten industry sales. In response, food industry actors try to influence the development and implementation of these nutritional policies by engaging in corporate political activities (CPA). As part of the Joint Action PreventNCD, the CPA of relevant food industry actors in relation to public health nutritional policies will be assessed. In Belgium, strategies of Fevia, the umbrella organization of the food industry, are examined. This study analyses publicly available information collected from Fevia's website, social media accounts (i.e. X and LinkedIn), newsletters and newspapers. A thematic qualitative analysis is conducted using established frameworks to categorize both framing and action strategies used by the industry. The categorization of framing strategies reveals how the food industry presents the actors, problems, and solutions. The framework of action strategies categorizes the CPA of the food industry under the following six strategies: information and messaging; financial incentives; constituency building; legal action; policy substitution; opposition fragmentation and destabilization. Preliminary results indicate that the

industry often frames itself as 'the good actor' and primarily uses strategies such as 'information and messaging', 'constituency building' and 'policy substitution' to influence policies in Belgium in their favor. In the next phase, interviews with stakeholders (e.g. policymakers, politicians,...) will be performed to collect undocumented information. Overall, this research sheds light on the ongoing CPA of the food industry and will increase transparency in their influence on the development and implementation of effective nutritional policies aimed at reducing the burden of NCDs and cancers.

Key messages:

- This study reveals how the umbrella organization of the food industry in Belgium influences public health nutritional policies through various corporate political action and framing strategies.
- Identifying these CPA increases awareness of the industry's influence, but also promotes their transparency and accountability, which is crucial for reliable and effective nutritional policy.

Abstract citation ID: ckae144.1519
Total sugar intake significantly associated with systolic blood pressure in small sample population

Claudia Viegas

[4]DIV-AV Instituto Português do Mar e Atmosfera, IPMA, Lisbon, Portugal
Contact: claudia.viegas@estesl.ipl.pt

Background: Hypertension contributes to 45% of all deaths from heart disease and up to 51% of deaths from strokes. Dietary factors, such as sodium (Na+) and potassium (K+) can play a role, but recent studies have also highlighted the importance of sugar intake on blood pressure. Very few studies have evaluated the impact of these factors and their ratio on cardiometabolic biomarkers. This study aims to assess the impact of dietary sugar intake, Na+, K+ and NA+/K+ ratio on hypertension and cardiometabolic biomarkers.

Methods: Fasting venous blood was collected to measure glucose, triacylglycerols (TAG), total cholesterol, HDL-c, ApoA1, ApoB, or hs-CRP, with enzymatic and turbidimetric techniques, and oxidized LDL by ELISA, and IL-6 and TNFa by Luminex system, the latter's in a subset sample. Blood pressure (SBP, DBP, and HR) was measured at least twice with an automatic recorder. Dietary intake was obtained using semi-quantitative FFQ, comprising 82 items, and reported to the previous year. Data was analysed using R software through descriptive analysis and partial correlations adjusted to the participant's BMI. A significant level of 0.05 was used.

Results: 78 participants, aged from 19 to 80 years old ($M = 48,5 \pm 13,5$) were evaluated, with 47% taking hypertensive medication. BMI ranged from 19,7 to 41,1 Kg/m2 ($M = 29,2 \pm 5,4$). The average intake of Na+, K+ and NA+/K+ ratio were 3805±1397 mg, 3980±1300 mg and 1.65±0,38, respectively. Total mean sugar intake (% energy) represents 21,4%. No significant correlation was found between Na+ or K+ with SBP, HR, and the cardiometabolic biomarkers ($p > 0.05$). A positive correlation was found between % sugar intake and SBP ($rs = 0,29$, $p < 0,05$), which remains significant after adjusting for BMI, and a positive correlation, in the borderline of significance, with TAG ($rs = 0,23$, $p = 0,0561$).

Conclusions: N+, K+, and their ratio do not associate with SBP, HR and cardiometabolic biomarkers. However, % of sugar intake is positively associated with SBP.

Key messages:

- Sodium and potassium may not always be associated with changes in blood pressure.
- Sugar intake might have an important role in the etiopathology of hypertension.

Contact: dcmalta@uol.com.br

Background: The double burden of malnutrition consists of the coexistence of nutritional deficiencies (malnutrition and overweight/obesity. Approximately 2.28 billion children and adults are overweight, and more than 150 million children are malnourished. The Decade of Action on UN Nutrition and SDGs that broaden the focus to both sides of malnutrition: overweight/obesity and nutritional deficiencies.

Objectives: To analyze the global burden of disease attributable to undernutrition and high body mass index (BMI) in Brazil and its 27 states, as well as its association with the socio-demographic index (SDI) from 1990 to 2019.

Methods: Study design: This is an epidemiological time-series study. This study analyzed the undernutrition and high BMI estimated by the Global Burden of Disease study conducted from 1990 to 2019 for Brazil and its states, using the following metrics: absolute number of deaths, standardized mortality rate, and disability-adjusted life years (DALYs). This study also analyzed the correlation between the percentage variation of mortality rates and SDI.

Results: A decrease in the number of deaths (75%), mortality rate (75.1%), and DALYS (72%) attributable to undernutrition was found in Brazil and in all regions. As regarding the high BMI, an increase in the number of deaths was found (139.6%); however, the mortality rate (9.7) and DALYs (6.4 %) declined in all regions, except in the North and Northeast regions, which showed an increase. A strong correlation was identified between undernutrition and high BMI with SDI.

Conclusions: Our study observed a double burden of malnutrition in Brazil, with a reduction in the burden of diseases due to malnutrition in Brazil and variation in the burden due to high BMI according to the socioeconomic status of the region. Public policies are necessary in order to guarantee the human right to a healthy and sustainable diet, together with food and nutrition security and a diminishing of social inequality.

Key messages:

- Overcome the malnutrition public policies are necessary to guarantee the human right to healthy and sustainable food, such as encouraging the production and commercialization of fruits & vegetables.
- Overcoming undernutrition and excess weight requires public policies aimed at reducing social inequality and providing access to healthy food for all, and taxation of ultra-processed foods.

Abstract citation ID: ckae144.1521
Overcoming barriers in implementing healthy school nutrition policies: insights from Ukraine

Tatiana Yurochko

T Yurochko[1], *L Heiko*[1]
[1]School of Public Health, National University of 'Kyiv-Mohyla Academy',
Kyiv, Ukraine
Contact: t.yurochko@ukma.edu.ua

The general mortality rate from NCDs in Ukraine exceeds that in European Union countries, (Yurochko et al., 2023) exacerbated by the ongoing war. Healthy nutrition plays a pivotal role in enhancing the overall quality of life and curbing the prevalence of non-communicable diseases (NCDs). Despite its significance, ensuring healthy eating habits, particularly during the early stages of life at the period of setting lifelong habits (Jackson et al., 2020; Riley et al., 2018), remains a challenge. Besides, school-based settings represent an ideal environment for effective intervention because they offer a shared common physical, academic, and social space (Tapia-Fonllem et al., 2020). Through a series of semi-structured interviews with key stakeholders, this study identifies barriers and facilitators to policy implementation, with a focus on educational institutions. Qualitative analysis reveals barriers such as inadequate human resources, funding constraints, resistance from the food industry, and ineffective communication strategies at the family level. Moreover, there exists a disjointed understanding of nutrition standards. However, collaborative efforts with civil society, empowerment of nursing roles, strategic utilization of grants and fundraising, engagement with the food industry, and the adoption of a family-oriented approach emerge as crucial enablers for successful policy implementation. These findings offer theoretical foundations for fostering healthier nutrition environments within schools. This research serves as a roadmap for policymakers and educators striving to create sustainable and effective strategies for promoting healthy eating among early school-age children in Ukraine and beyond. Study finds human resource shortages, funding constraints, and food industry resistance as major barriers to school nutrition policy. Recommendations include collaborative approaches, nurse involvement, and aligned standards for effective school nutrition policy.

Key messages:

- Healthy nutrition plays a pivotal role in enhancing the overall quality of life and curbing the prevalence of non-communicable diseases.
- Through a series of semi-structured interviews with key stakeholders, this study identifies barriers and facilitators to policy implementation, with a focus on educational institutions.

Abstract citation ID: ckae144.1522
The transition towards a healthy and sustainable food system at local level: the Brussels City case

Nora Lorenzo i Sunyer

N Lorenzo i Sunyer[1], *S Vandevijvere*[1]
[1]Health Information, Sciensano, Brussels, Belgium
Contact: nora.lorenzo@sciensano.be

Despite the European Union's political efforts to promote healthier and more sustainable food systems, challenges persist, with these systems not yet achieving sustainability and still exacerbating health inequalities. The EU-funded FEAST project aims to catalyse this transition through different actions including by focusing on mapping factors shaping food environments in five European cities, including Brussels. This study focuses on mapping existing policies and initiatives by the city government supporting healthier and more sustainable food systems in Brussels City. Policies were then categorized based on Food-EPI domains, types of policies (i.e. financial incentive) and role of the government (i.e. policy development). Results indicated that while Brussels City has a clear strategy (Good Food Strategy) and objectives (Climate Action Plan) to support the transition, there is a notable emphasis on sustainability over health which could be explained by the absence of a dedicated public health expert in the local government. While there are numerous policies focused on improving the school environment (i.e. healthy and sustainable canteens, banned sodas and snack provision, forbidden advertising inside and nearby of unhealthy foods), there is a lack of corresponding measures for public spaces. Furthermore legislative policies are practically inexistent possibly due to jurisdictional barriers from higher governmental levels. Stakeholder interviews will be conducted in the next phase to delve deeper into these issues and to explore potential facilitators and barriers faced in the development and implementation process of these policies. Overall, this research sheds light on the policy landscape in Brussels City, highlighting both progress, areas for improvement and policy gaps in advancing towards healthier and more sustainable food systems.

Key messages:

- Despite EU political efforts to prioritise more sustainable food systems, relevant barriers are still present at local level in Brussels City, hampering the development and implementation of policies.
- In Brussels relevant policies for healthier and more sustainable food systems have been implemented, especially in the school environment, but health seems to be overshadowed by sustainability.

Abstract citation ID: ckae144.1523
Avoiding hedonic contrast to increase acceptance of healthy sustainable school meals

Margarita Kokkorou

To promote sustainable eating in schools, new approaches for embracing plant-based (PB) meals are needed. Hedonic contrast (HC) describes how liking for one item is influenced by the recent experience of other items of different hedonic valence. Despite its established impact on liking, HC's effect on intake, particularly in repeated exposure experiments, is limited. Moreover, its effect on food-related emotions remains largely unexplored. Hence, this study investigated how HC influences liking, emotions and intake of an innovative co-created PB dish, served as part of a course meal, at school in a repeated exposure study. Two groups of students (N (HC) =71, mean age=14.5 and N (control) =57, mean age=15.3) were served the same neutrally liked main PB dish (pumpkin stuffed lentils balls (LPA)) after a starter dish (rice with vegetables) which was altered in taste through seasoning and cooking methods to be more (HC) or less (control) tasty. The exposure was repeated once/week for 5 consecutive weeks. Liking and emotional responses for the dishes were recorded through a questionnaire and food consumption by weighting plate waste. HC led to lower liking ($p = 0.037$) and lower positive emotions (cheerful, pleasure) with high arousal (surprise) for LPA, while increasing negative valence emotions (disappointed). Moreover, LPA consumption was significantly lower in the HC group vs the control (45% vs 60% respectively, $p = 0.040$), resulting in lower protein intake in the HC group ($p = 0.029$). The effects of HC remained stable with time. This study, for the first time, reveals a sustained rise in food-related positive high arousal emotions, when foods are presented following less liked food. Since new foods evoking positive valence and high arousal emotions have higher chances to be appreciated than foods evoking positive valence and low arousal emotions, this work opens new perspectives on how to propose new, healthier and more sustainable PB dishes in school canteens.

Key messages:

- Avoiding negative contrast between school meals is a promising strategy to ensure higher liking, intake and increased positive emotions over repeated exposure for innovative plant-based dishes.
- To enhance adolescent's acceptance and uptake of new plant-based dishes in school canteens, it is better to serve them after less tasty options.

Exploring the use of meal delivery services in Belgium

Laura Oostenbach

L Oostenbach[1], *L Thornton*[1]
[1]University of Antwerp, Antwerp, Belgium
Contact: laura.oostenbach@uantwerpen.be

Background: Ready-to-eat meal delivery services have become commonplace in recent years and their growth accelerated during the COVID-19 pandemic. However, the potential ramifications on dietary habits and subsequent health outcomes remain largely unexplored. Given the well-established links between unhealthy dietary patterns and chronic diseases such as obesity, type II diabetes, and cardiovascular diseases, understanding the determinants and public health implications of ready-to-eat meal delivery services use is imperative. This study aims to investigate the determinants associated with the use of ready-to-eat meal delivery services and their implications for health behaviours and outcomes.

Methods: This cross-sectional study is conducted amongst adults residing in Flanders or Brussels, Belgium. A quantitative online survey commenced in April 2024 and is scheduled to conclude by June 2024. Structural equation models will be used to assess determinants and implications of ready-to-eat meal delivery services use. Latent class analysis will be used to identify user profiles and subsequent structural equation modelling will assess determinants of these profiles and their associated health (behaviour) outcomes.

Results: Preliminary results suggest meal delivery usage was higher in younger and middle-income users. Main reasons of use amongst users ($n = 139$) were more time for leisure activities (66%) and supermarket avoidance (64%). Main reasons for non-use amongst non-users ($n = 69$) were not wanting to spend money with meal delivery services (70%) and preference to cook own meals (81%). Data collection is currently ongoing. Further analysis is planned, and full results will be available by November 2024.

Conclusions: This study will provide a better understanding of drivers of meal delivery services use in Belgium and their potential impact on public health. It will also help inform public health strategies targeted at improving dietary habits.

Key messages:

- Recognising that meal delivery services will become ever present in the future, insights into why people order meals for delivery and the potential health implications of such services are essential.
- The use of advanced statistical techniques highlights the potential of the study to offer novel insights into determinants and ramifications of meal delivery services usage.

Abstract citation ID: ckae144.1525
Promoting a sustainable diet among office workers in Sweden: A pilot Study

Katarina Balter

O Halling Ullberg[1], *S Toivanen*[1,2], *A Tillander*[3], *K Bälter*[1,4]
[1]School of Health, Care and Social Welfare, Mälardalen University, Västerås, Sweden
[2]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
[3]Department of Statistics and Machine Learning, Linköping University, Linköping, Sweden
[4]Department of Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden
Contact: katarina.balter@mdu.se

Background: Society is facing multiple challenges, including lifestyle-related diseases, alongside global climate change. Actions are needed to promote sustainable lifestyles advocating for healthy and environmentally friendly diets. This study aimed to assess how a sustainable lifestyle, compared to conventional healthy lifestyle education at work, affects participants' energy intake, nutrient consumption, and diet-related CO_2e.

Methods: An 8 week two-armed randomized trial was conducted, comprising a sustainable lifestyle arm ($n = 21$) and a healthy lifestyle arm ($n = 16$) based on the theoretical framework of the Behavioral Change Wheel, in total ($n = 33$) completed the trial. The office workers participated in 6 workshops during working hours. Linear mixed-effects models and analysis of variance tests were used for data analysis. Changes over time are presented as arms combined, along with their respective mean differences.

Results: A significant decrease in mean diet-related CO_2e was observed ($p < 0.001$), with a decrease on average of 0.74 and 0.71 kg CO_2e/day. The mean change in daily kilocalorie intake had a significant decrease over time ($p = 0.008$), on average of 192 and 386 Kcal. Moreover, a significant decrease in mean protein intake was observed ($p < 0.001$), with a decrease on average of 16 and 18 grams, possibly explaining the decrease in CO_2e. No significant differences were observed between the arms at any timepoint.

Conclusions: Promoting sustainable lifestyle habits has a similar impact to advocating for a conventional healthy lifestyle regarding diet. This supports the new Nordic Nutrition Recommendations 2023. Despite the small sample size, insights into facilitating sustainable behaviors can influence public health policies across Europe and the workplace as an arena for health promotion.

Key messages:

- The promotion of sustainable and healthy lifestyle habits at work can promote both individual and planetary health by decreasing diet-related CO_2e emissions.
- Here we demonstrate that the workplace has the potential to act as an arena to combat climate change.

Abstract citation ID: ckae144.1526
The negative health assessment and the different consumption of dietary supplements

Rokas Arlauskas

R Arlauskas[1], *D Austys*[1], *R Stukas*[1]
[1]Public Health, Vilnius University, Vilnius, Lithuania
Contact: rokas.arlauskas@mf.vu.lt

Background: There is an insufficient level of research carried on the consumption of dietary supplements among diverse social and demographic groups, especially among those with a negative assessment of personal health. Therefore, the aim of this study was to assess the consumption of dietary supplements among working-age residents of Lithuania in the period from 2021 to 2023 with respect to social and demographic factors and the assessment of personal health.

Materials and methods: The data for this study were collected after conducting three independent cross-sectional surveys in 2021, in 2022, and in 2023. Each of the samples included 1600 working-age adult residents of Lithuania. Distribution of the respondents by the assessment of personal health and gender, age, marital status, education level, place of residence, employment, income, and

COVID-19 cases among the respondents and members of their families was assessed.

Results: The consumption of dietary supplements differed each year and accounted for 78.1%, 71.6%, and 72.7% of the respondents, respectively ($p < 0.05$). In 2022, the prevalence of the consumption of dietary supplements was lower in the majority of social and demographic groups ($p < 0.05$). In 2023, it was higher among females, younger residents, and those from larger families, who suffered from COVID-19 ($p < 0.05$). Despite similar changes found in the consumption of dietary supplements among those who negatively assessed their health, this group showed more prevalent consumption of dietary supplements among residents with non-university education, unemployed respondents, and those with lower income ($p < 0.05$).

Conclusions: Despite a significantly lower prevalence in the consumption of dietary supplements in 2022, it was higher again in 2023. A negative assessment of personal health is associated with opposite tendencies in the prevalence of the consumption of dietary supplements in the general population.

Key messages:

- Despite a significantly lower prevalence in the consumption of dietary supplements in 2022, it was higher again in 2023.
- The negative assessment of personal health should be taken into account when planning nutritional interventions due to its association with different consumption of dietary supplements.

Abstract citation ID: ckae144.1527
Impact of MaNu dietary counselling on Oxidative Stress and Gestational Weight Gain during pregnancy

Samar El Sherbiny

S El Sherbiny[1]*, V Bellisario*[1]*, F Ghelli*[1]*, E Lenta*[2]*, C Dalla Costa*[2]*, R Bono*[1]
[1]Department of Public Health and Pediatrics, Università degli Studi di Torino, Turin, Italy
[2]Clinical Nutrition Unit, Michele and Pietro Ferrero Hospital, Verduno, Italy
Contact: samar.elsherbiny@unito.it

According to the WHO guidelines, to counteract the excessive weight gain during pregnancy and to mitigate the increase in oxidative stress (OS) which naturally increases during pregnancy, a healthy lifestyle and a correct diet are crucial as preventive measures to promote health. The MaNu project was conceived precisely to control these factors through dietary counselling. We expect that pregnant women who voluntarily undergo an educational program consisting of specific and accurate dietary advice will be able to emphasize weight control and contain the increase in OS. Our randomized controlled trial (RCT) has a parallel group design and takes place in the Obstetrics and Clinical Nutrition Departments of Michele and Pietro Ferrero Hospital (Verduno, north-western Italy), where physiological pregnant women are enrolled between 12-17 gestational weeks (GWs). The educational intervention takes place between 12-24 GWs. Dietary habits were collected with a questionnaire and urine samples were analysed to quantify the OS using 15-F2t-isoprostane, malondialdehyde and total antioxidant power. The descriptive analyses are based on paired t-tests. Preliminary analyses on 76 women who completed two out of three time points (T0 and T1) indicate that, of women who received the intervention, 35% experienced excessive weight gain (based on guidelines), compared to 39% shown by controls. Following the counselling, the 15-F2t-isoprostane decreased significantly (mean T0=5.1 ng/ml vs. mean T1=3.5 ng/ml, $p = 0.02$). Concerning nutrient intake, a statistically significant reduction in sugar consumption has been found in the intervention group (mean T0=92.2 g vs. mean T1=83.3 g, $p = 0.03$). Conversely, no correlations have been detected between OS and the main pro and anti-oxidant macronutrients. Although promising, our findings need further verification since the RCT is still ongoing, and it is imperative to attain the anticipated sample size before drawing any definitive conclusions.

Key messages:

- Dietary counselling during pregnancy should be implemented as a preventive strategy used to counteract potential pregnancy complications and ensure the well-being of both the mother and the baby.
- Healthy diet is essential to control the increase in oxidative stress levels during pregnancy and to prevent excessive weight gain, factors that can lead to the onset of pregnancy complications.

Abstract citation ID: ckae144.1528
Representativeness of disadvantaged pupils in a trial to improve beverage consumption in Belgium

Lucille Desbouys

L Desbouys[1]*, W Assakali*[1]*, I Thiébaut*[2]*, K Castetbon*[1]
[1]School of Public Health, Université Libre de Bruxelles, Brussels, Belgium
[2]Club Européen des Diététiciens de l'Enfance, Ath, Belgium
Contact: lucille.desbouys@ulb.be

Background: The cluster-randomized controlled trial DRINK was implemented in 2021 to evaluate the effect of interventions aimed at reducing sweetened beverages and increasing tap water consumption among children in French-speaking primary schools in Belgium. Multiple participation issues related to the implementation in the school setting were encountered. Our aim was to describe the individual characteristics of pupils at baseline and their participation in the data collection.

Methods: In 2021, out of a sample of 168 schools stratified by region and socioeconomic index (SEI), 46 were included. Children in grades 3 to 5 were asked to complete a 4-day diary to record all beverages consumed. Questionnaires were completed by children and parents, from which individual characteristics were summarised, such as the Family Affluence Scale (FAS; in three groups).

Results: School participation (overall: 29.0%) was higher in Wallonia (33.0%) than in Brussels (22.0%), and in schools with an intermediate SEI (33.0%). At baseline, a total of 3,631 children participated in the data collection, either through the 4-day diary, the child questionnaire, or the parent questionnaire; 2,013 completed all three instruments. Participating children were more likely to be girls, to have an intermediate FAS, to be born in Belgium, and to have two working parents. The proportion of children attending schools in the Brussels region was 27.9% of the total participating children and dropped to 11.5% for those who returned three valid questionnaires. The proportions of low FAS (14.4% to 11.8%), birth outside Belgium (11.8% to 8.7%), and low parents' schooling (35.3% to 33.8%) were lower among children who completed the three instruments.

Conclusions: The low participation of Brussels schools, possibly exacerbated by the Covid-19 impact, may explain why disadvantaged children were less represented in the baseline sample. Such knowledge is valuable for interpreting the findings of such a trial.

Key messages:

- Participation issues may have affected the representativeness of less advantaged children.
- Documenting such disparities is key to understanding the context in which interventions were implemented.

Abstract citation ID: ckae144.1529
Evaluation of Label Compliance to Allergens in Imported Asian Food Sold in Northern Italy

Laura Ragni

L Ragni[1]*, R Bertolassi*[1]*, G Magagna*[1]*, M Tilola*[1]*, B Bertasi*[1]*, E Pavoni*[1]*,*
G Finazzi[1,2]*, M-N Losio*[1]
[1]Food Safety, IZSLER, Brescia, Italy
[2]CRESA, IZSLER, Brescia, Italy
Contact: laura.ragni@izsler.it

Background: The import of Asian food is strongly increasing in the EU. In Italy, the Asian market has expanded over the last 3 decades. Unfortunately, the labelling of these products often implies errors, mainly due to linguistic differences. Consequently, it can become a consistent problem regarding food safety, in particular for allergens declaration. According to EU Reg. 1169/2011 (Annex II), allergens must be labelled in bold and translated in the current language of the Member State. Asian food non-compliant labelling could enhance the probability of allergic consumers to get adverse events; accordingly, it is important to increase controls on the imported products. The present work investigates the label compliance to allergens on Asiatic products imported in Northern Italy.

Methods: Totally, 39 foodstuffs were tested for gluten, 93 for white egg proteins and 118 for milk proteins by commercial ELISA kits according to manufacturers' instructions. Samples were considered non-compliant when the results were above 20 mg/Kg, the law limit for gluten, or above the milk LOD (10 µg/Kg) and the egg LOD (0.4 mg/Kg).

Results: Data showed 18% (CI 95% 0.09-0.32) of non-compliant samples for gluten: 6 samples $>$ 80 mg/Kg (snacks and ready to eat meal) and 1 sample containing 48 mg/Kg (snack). In addition, 19.4 % (CI 95% 0.13-0.28) showed presence of egg proteins (noodles, snacks, patties and pasty). Finally, 13.6% (CI 95% 0.08-0.21) samples were irregular for undeclared milk (noodles and snacks).

Conclusions: Products label report their content and represent an important element for food trading and tracing. The results obtained confirm a high percentage of non-compliant labels, underlining how the consumption of imported products can represent a health risk for allergic consumers. The present work highlights the importance of imported food monitoring to guarantee the consumers health, and of the implementation of standardized/international regulated labelling rules.

Key messages:

- Many non-compliant labels about allergens was observed on Asiatic products.
- Correct labelling of allergens in imported food should be monitored to avoid adverse events.

Abstract citation ID: ckae144.1530
Barriers to adopting a plant-based diet in various Finnish sociodemographic groups

Laura Sares-Jäske

L Sares-Jäske[1]*, L Paalanen*[1]*, H Tapanainen*[1]*, NE Kaartinen*[1]*, M Kaljonen*[2]*,*
H Konttinen[3]*, S Männistö*[1]
[1]THL, Helsinki, Finland
[2]Finnish Environment Institute, Helsinki, Finland
[3]University of Helsinki, Helsinki, Finland
Contact: laura.sares-jaske@thl.fi

Background: According to nutrition recommendations, plant-based diets are favorable for both climate and health. However, the adoption of such diets varies between sociodemographic groups. Aims of this study are to examine how large proportions of the population have shifted towards plant-based diets to combat climate change, and to identify perceived barriers to dietary changes by gender, age, urbanization level, education, and household income.

Methods: The study is based on the Healthy Finland Survey conducted in 2022-2023, including 5390 participants (56% women) aged 20-74 years. Questions related to plant-based diet had predefined response options.

Results: Women reported that they had changed their diets to be more plant-based more often than men (46% vs. 31%). Women and men living in urban areas, having high education, or belonging to the highest income quartile had made changes more often than those in other sociodemographic groups. Women and men reported barriers in shifting to more plant-based diets, such as uncertainty about nutritional value (20% and 24%) and lacking skills to prepare tasty vegetarian food (30% and 28%). Disliking vegetarian foods (23%) or not being interested in the topic (28%) were also frequent issues in men, while women commonly cited the preferences of their close ones as preventing them from making vegetarian food (17%). These perceived barriers also differed between sociodemographic groups. For example, while uncertainty about nutritiousness of plant-based diets was most common in the oldest age group (29%), lack of skills to prepare tasty vegetarian food was most common in the youngest age group (35%). One third of men living in remote rural areas or with basic education reported not being interested in the topic.

Conclusions: Understanding barriers that prevent people in different sociodemographic groups from changing their diets to more plant-based is critical in tailoring more targeted and effective health promotion and policy.

Key messages:

- Moving towards more plant-based diets to combat climate change and perceived barriers to dietary changes vary by gender, age, urbanization level, education, and household income.
- Understanding barriers preventing people in different sociodemographic groups from changing their diets to more plant-based is critical in tailoring targeted and effective health promotion and policy.

Abstract citation ID: ckae144.1532
Hip fracture in elderly: malnutrition and health outcomes. A systematic review and meta-analysis

Giorgia Maria Ricciotti

GM Ricciotti[1]*, A Genga*[1]*, M Chiavarini*[1]*, MI Faggi*[1]*, A Rinaldi*[1]*, OD Toscano*[1]*, MM D'Errico*[1]*, P Barbadoro*[1]
[1]Department of Public Health, Polytechnic University of the Marche Region, Ancona, Italy
Contact: giorgina.ricciotti@gmail.com

Background: Hip fracture is a common condition among elderly and one of the leading causes of disability. Malnutrition is widely present in older patients and has been identified in several studies as an important and modifiable prognostic factor for several medical conditions, including hip fracture. The aim of the present study is to evaluate the association between malnutrition, assessed by validated tools, and selected health outcomes for different follow-up intervals from hip fracture, in particular: mortality, changes in mobility/living arrangements and postoperative delirium.

Methods: A literature search on PubMed, Web of Science and Scopus databases up to September 2023, was conducted to identify all studies involving older subjects that reported an association between MNA/GNRI/PNI/CONUT score and health outcome after hip fracture. Meta-analysis was performed by a random-effects model using risk values (RR/OR/HR) extracted from 14 eligible selected studies.

Results: Malnutrition significantly increased the risk of any adverse outcome by 70% at 1 month, and up to 250% at 1 year, showing an increasing trend with longer follow-up periods. One month after hip fracture, malnutrition significantly increased the risk of postoperative delirium by 275% ($OR = 2.75$; 95% CI 1.80-4.18; $p \leq 0.05$), mortality by 342% ($OR = 3.42$; 95% CI 2.14-5.48; $p \leq 0.05$) and mortality hazard risk by 351% ($HR = 3.51$; 95% CI 1.63-7.55; $p \leq 0.05$). One year after hip fracture, malnutrition significantly increased the risk of transfer to more supported living arrangements by 218% ($OR = 2.18$; 95% CI 1.58-3.01; $p \leq 0.05$), declined mobility by 41% ($OR = 1.41$; 95% CI 1.14-1.75; $p \leq 0.05$), mortality by 368% ($OR = 3.68$; 95% CI 3.00-4.52; $p \leq 0.05$) and mortality hazard risk by 234% ($HR = 2.34$; 95% CI 1.91-2.87; $p \leq 0.05$).

Conclusions: These findings underscore that malnutrition worsens outcomes after hip fracture in elderly, emphasizing the importance of nutritional assessment to mitigate potential adverse consequences.

Key messages:
- The results of the present study underscore that malnutrition increases the risk of death and worsens mobility and independence after hip fracture in older adults.
- Routine nutritional status evaluation could prove beneficial in the management of hip fracture older patients in order to prevent potential adverse outcomes.

Abstract citation ID: ckae144.1533
Food depiction in posts of the most popular Lithuanian influencers on Instagram and Facebook

Robertas Basijokas

R Basijokas[1]*, D Austys*[1]
[1]Department of Public Health, Institute of Health Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania
Contact: robertas.basijokas@mf.stud.vu.lt

Background: Considering that content published in social networks might act as risk factor to health, we aimed to assess the prevalence of posts depicting food published by Lithuanian influencers on Facebook and Instagram.

Materials and methods: All publicly available posts (6425 in total) created by 21 most popular Lithuanian influencers on Facebook and Instagram in 2022 were included. The content analysis of the posts was performed and information about food and other health-related factors was registered. Distribution of the posts depicting food was assessed according to social networks, gender, age, and number of followers of influencers.

Results: Every fourth (22.6%) post presented foods. Among these posts, fast food was presented in 10.2%, sweets - in 35.5%, vegetables - in 59.5%, fruits and berries - in 40.7%, cereals - in 39.2%, dairy products - in 36.8%, meat - in 26.6%, sea food - in 12.1%. Overall, women, older influencers, influencers with higher number of followers more frequently posted posts depicting vegetables (respectively, 21.0% vs 5.5%, 18.6% vs 6.7%, 18.3% vs 9.3%), fruits and berries (respectively, 14.5% vs 3.8%, 12.0% vs 6.4%, 11.4% vs 8.3%), cereals (respectively, 13.7% vs 4.7%, 12.2% vs 5.6%, 11.2% vs 8.2%), dairy products (respectively, 13.0% vs 3.2%, 11.0% vs 5.0%, 10.8% vs 6.3%), meat (respectively, 8.6% vs 4.1%, 7.9% vs 4.4%). Women and older influencers more frequently depicted sweets (respectively, 13.3% vs 7.1%, 12.6% vs 7.1%), sea food (respectively, 4.4% vs 1.5%, 3.8% vs 2.0%). More posts portraying food in general, fast food, vegetables, milk and dairy products were posted on Instagram (respectively, 27.5% vs 19.8%, 3.4% vs 2.1%, 16.6% vs 13.4%, 10.0% vs 8.3%) ($p \leq 0.05$).

Conclusions: Every fourth post depict food, more frequently on Instagram. Healthy and unhealthy foods are presented with similar frequency. Female influencers, older influencers and influencers with higher number of followers more frequently depict foods.

Key messages:
- Both healthy and unhealthy foods are presented with similar frequency on social networks – this might lead to the overconsumption of unhealthy foods.
- Differences in depiction of foods between social networks and influencers with different gender, age and number of followers should be taken into account when implementing public health interventions.

Abstract citation ID: ckae144.1534
Adherence to Mediterranean diet and cardiometabolic risk among mountain communities in European Alps

Giulia Squillacioti

G Squillacioti[1], I Aguilar Palacio[2], A Bédard[3], S El Sherbiny[1], F Ghelli[1], M Panizzolo[1], V Bellisario[1], R Bono[1]
[1]Public Health and Pediatrics, University of Turin, Turin, Italy
[2]Public Health, Zaragoza University, Zaragoza, Spain
[3]Université Paris-Saclay - UVSQ, CESP - Inserm, Villejuif, France
Contact: giulia.squillacioti@unito.it

Background: The Mediterranean diet has emerged as a model promoting a better health status, particularly for cardiovascular diseases prevention. Adherence to the Mediterranean diet (AMD) may vary depending on geographical location and sociocultural factors. Mountains and rural communities may experience lower adherence, also depending on food provision-related services availability. Our cross-sectional study aims to investigate the association between AMD and cardiometabolic risk in a cohort of mountain dwellers. As a secondary aim, we will test if services availability may influence health status via AMD.

Methods: In spring/summer 2023, healthy volunteers from 5 small villages in Italian Alps were enrolled. Dietary habits were investigated by Medi-Lite standardized questionnaire. The waist-to-height ratio (WHtR) was calculated by dividing the waist circumference by height, then used as an anthropometric index for central adiposity and related cardiometabolic risk. Services availability was assessed by network analysis implemented in QGIS. A multilevel logistic regression model, with center as random intercept and adjusted for age, sex, BMI, education and physical activity was used to test the association between AMD and cardiometabolic risk. Ethical approval was provided by University of Turin.

Results: To date, 142 subjects (59.2% females, 49.9±14.0 y.o.) have been enrolled. Preliminary analyses showed that, as compared to the least adherent group, subjects reporting the highest AMD level (3rd tertile of Medi-Lite scoring) were strongly protected from cardiometabolic risk (OR: 0.07, 95% C.I.: 0.01, 0.67; $p = 0.021$). A similar trend was observed for the 2nd tertile.

Conclusions: Our preliminary findings suggest the beneficial role of the Mediterranean diet also in remotely located populations. We plan to investigate how service availability may impact AMD and, indirectly, cardiometabolic health to reinforce the importance of equity in services distribution for Public Health

Key messages:

- Independently of age, sex, BMI, education and physical activity, adherence to the Mediterranean diet can promote cardiometabolic health among rural and mountain communities.
- Mediterranean eating pattern can positively influence central adiposity and should be promoted to ensure more effective prevention strategies in mountain dwellers.

Abstract citation ID: ckae144.1535
Health disparities continue to report in DEIS schools: Irish COSI Round 6 study

Nandakumar Ravichandran

N Ravichandran[1], O Kilduff[1], J Slattery[1], C Lee[1], E Hunt[1], A Douglas[1], S O'Brien[2], C Murrin[1], C Kelleher[1]
[1]School of Public Health, Physiotherapy and Sports Science, University College Dublin, Dublin, Ireland
[2]Healthy Eating and Active Living Policy Programme, Health Service Executive, Dublin, Ireland
Contact: nanda14032001@gmail.com

Background: Previous reports have identified clear differences in the prevalence of overweight and obesity among children living with disadvantaged compared to those living in advantaged circumstances. Childhood obesity is influenced by factors in the home environment, including lifestyle behaviours and socio-economic status. The Childhood Obesity Surveillance Initiative (COSI) family survey provides insights into these factors, particularly in children that attend disadvantaged (DEIS) and non-disadvantaged (non-DEIS) schools.

Aim: This study aims to compare various demographic and socio-economic factors within the home environment of primary school children across DEIS and non-DEIS schools in Ireland, elucidating the differences in their performance with implications for health policy.

Methods: Parents of 1st and 2nd class children (mean age 7) from 121 sentinel schools invited to participate in the family survey, returned it by post or online using Lime Survey. Ethical approval was secured for COSI R6, with consent from families. Data on demographics, diet, transportation, activities, and clinical characteristics of children in Ireland were collected, anonymised and analysed in SPSS, comparing children from DEIS ($n = 147$) and non-DEIS ($n = 1014$) schools.

Results: Around 88% of respondents of returned surveys included in the study ($n = 1161$) were mothers. Significant disparity in families with diabetes diagnosis or treatment observed between DEIS and non-DEIS schools (10.6% vs. 5.4%, $p = 0.016$). Breastfeeding rates were higher in non-DEIS schools (57.0% vs. 46.9%, $p = 0.015$). Children consuming at least 3 portions of fruits and vegetables daily were also higher in non-DEIS schools (58.9% vs. 46.0%, $p < 0.001$). More children in non-DEIS schools engaged in physical activities outside of school hours (93.7% vs. 74.5%, $p < 0.001$).

Conclusions: The findings underscore the significant socioeconomic disparities between families whose children attend DEIS and non-DEIS schools in Ireland.

Key messages:

- Irish COSI R6 reveals disparities in health-related factors between disadvantaged and advantaged schools.
- Targeted interventions and policies are necessary to address factors influencing child health.

Abstract citation ID: ckae144.1536
The role of weight stigma and food literacy in eating behaviour

Vladimíra Timková

V Timkova[1], Z Katreniakova[1], P Mikula[1], I Nagyova[1]
[1]Department of Social and Behavioural Medicine, Faculty of Medicine, P.J. Safarik University in Kosice, Kosice, Slovakia
Contact: vladimira.timkova@upjs.sk

Background: Overweight/obesity is associated with negative health outcomes that may be caused by experience and internalization of weight stigma. Weight stigma seems to diminish weight control efforts and may be associated with unhealthy eating behaviours. Moreover, lack is known about the protective factors against stigmatization. We aimed to assess the role of weight stigma and food literacy in eating behaviour in people with overweight and obesity controlling for sociodemographic and clinical variables.

Methods: A total of 189 participants with overweight/obesity (52.9% female; mean age 48.8±14.5 years; body-mass index (BMI) 32.6±6.5 kg/m2; waist-to-height ratio (WHtR) 0.6±0.1) completed the Experienced Weight Stigma Questionnaire and the Weight Self-Stigma Questionnaire. To examine eating behaviours including cognitive restraint, uncontrolled eating, and emotional eating we used the Three Factor Eating Questionnaire. Multiple linear regression analyses were performed.

Results: Higher WHtR and BMI were associated with emotional eating and uncontrolled eating. Experienced weight stigma was associated with emotional eating but was no longer significant when self-stigmatization was added to the regression model. Self-stigmatization was associated with emotional eating and uncontrolled eating. This association attenuated when food literacy was added to the final models. Low food literacy was significantly associated with emotional and uncontrolled eating. No role of weight-related measures, stigma or food literacy in the cognitive restrain was found. The explained variance in the final regression models for emotional eating and uncontrolled eating was 41%, and 32.7%, respectively.

Conclusions: Emotional eating and uncontrolled eating may represent crucial components to address in health and weight management. Nutrition literacy may have a positive effect on diminishing associations between weight stigma and unhealthy eating patterns. [Funding: VEGA: 1/0748/22].

Key messages:

- Eating disorder symptoms and their association with obesity should be considered when designing public health interventions.
- Interventions targeting weight stigmatization and food literacy may mitigate the negative impact of weight stigma on eating behaviours.

Abstract citation ID: ckae144.1537
Disparities in Breastfeeding Patterns Persist Despite Improved Rates: Findings from Irish COSI R6

Nandakumar Ravichandran

N Ravichandran[1], O Kilduff[1], J Slattery[1], C Lee[1], E Hunt[1], A Douglas[1], S O'Brien[2], C Murrin[1], C Kelleher[1]
[1]School of Public Health, Physiotherapy and Sports Science, University College Dublin, Dublin, Ireland
[2]Healthy Eating and Active Living Policy Programme, Health Service Executive, Dublin, Ireland
Contact: nanda14032001@gmail.com

Background: Breastfeeding is crucial for reducing childhood obesity, recommended exclusively for 6 months by World Health Organisation (WHO). Previous reports have highlighted disparities in breastfeeding patterns between Irish and non-Irish mothers. The Irish Childhood Obesity Surveillance Initiative (COSI) family survey offers insights into breastfeeding rates and patterns in Ireland and their differences between Irish and non-Irish mothers.

Aims: This study aims to compare the breastfeeding rates in Ireland between COSI Round 6 (R6) and COSI R5, elucidating the differences between Irish and non-Irish mothers. Additionally, it aims to establish the association between breastfeeding pattern and socioeconomic factors involved in the Irish households.

Methods: Parents of 1st and 2nd class children (mean age 7) from 121 sentinel schools invited to participate in the family survey, returned it by post or online using Lime Survey. Ethical approval was secured for COSI R6, with consent from families. Data on breastfeeding rates and pattern were collected, anonymised, and analysed using SPSS version 29.

Results: Around 88% of respondents were mothers. The number of children breastfed for at least a month increased in R6 (55.7%) compared to R5 (45.6%). The mean duration of exclusive breastfeeding increased to 5.86 months in R6 from 4.91 months in R5, in line with WHO recommendations. Significant disparities were found in breastfeeding patterns, with higher rates among non-Irish mothers (67.8%) compared to Irish mothers (52.6%) ($p < 0.001$). Linear regression showed a significant association between breastfeeding duration and maternal birth country. Irish mothers exhibited a negative coefficient ($b1 = -2.442$; 95% CI -4.1 to -0.8; $p = 0.004$), suggesting shorter breastfeeding durations compared to non-Irish mothers.

Conclusions: Breastfeeding rates improved in COSI R6 compared to R5. There are significant disparities in breastfeeding pattern between Irish and non-Irish mothers.

Key messages:

- Improved breastfeeding rates indicate good feeding practices in Ireland.
- Targeted interventions and policies are necessary to address the disparities between Irish and non-Irish mothers in breastfeeding patterns.

[2]Environment Health Institute, School of Medicine - University of Lisbon, Lisbon, Portugal
[3]Association for Sustainable Development of the Saloia Region, Lisbon, Portugal
Contact: inescoutinho1808@gmail.com

Background: It is essential to address food sustainability (FS) within the school community to enhance both public and environmental health. In Portugal, in the scope of AML Alimenta, teachers' training on FS was identified as a priority. Therefore, local partners along with academia developed, implemented, monitored, and evaluated the SustentAÇÃO.

Objectives: SustentAÇÃO aimed to empower school teachers in the Lisbon Metropolitan Area to teach students between 6 and 14 years old on FS. The program consisted of 10 hours of asynchronous online learning (MoodleTM), structured in 4 modules, and 10 hours of autonomous learning (5 students' educational sessions), offering autonomy and flexible time management. The contents were adapted for different age groups. The teacher's performance was monitored and evaluated continuously. A process evaluation was conducted for both teachers and students.

Results: Of the 79 teachers enrolled, 47% completed the program. Teachers' performance (0-20) on the 4 evaluation questionnaires was on average 17,9±3,13. Most teachers found the program benefited their work (94%) and considered it essential for enhancing student's knowledge (98%). Considering overall satisfaction, 85% of teachers were satisfied or very satisfied with the training and 91% would recommend it to their colleagues. Additionally, 86% of students enjoyed the activities delivered, 76% considered that they were wasting less food, and 78% believed they had improved their ability to make healthier and more sustainable food choices.

Conclusions: Through a collaborative work between local partners and academia, an innovative e-learning training programme on FS was developed, implemented, monitored, and evaluated, responding to the local needs identified. SustentAÇÃO complies with national education guidelines and contributes to the sustainable development goals agenda.

Key messages:

- SustentAÇÃO E-learning training highlights the importance of collaborative work, based on an initial assessment to target local needs.
- SustentAÇÃO E-learning training improve teachers' knowledge on FS and benefit their students.

Abstract citation ID: ckae144.1539
Diets, ergogenic supplements, and microbiota in professional and non-professional athletes

Francesca Ubaldi

T Ghaffar[1], F Ubaldi[1], V Romano Spica[1], F Valeriani[1]
[1]Departement of Human Movement and Sports, University of Rome, Rome, Italy
Contact: f.ubaldi@studenti.uniroma4.it

Background: Regular physical activity has significant health benefits and can help prevent and manage non-communicable diseases. Intense exercise during training requires diet modulation to support health and performance. Anaerobic sports require high-protein diets, while aerobic sports prefer high-carbohydrate diets. Two-thirds of adult athletes take dietary supplements, and non-professional athletes also use supplements to enhance their appearance. However, dietary stress and imbalanced use of supplements leads the body to different diseases like gastrointestinal diseases and even multifactorial diseases e.g. cancer, cardiovascular diseases, and neurodegenerative diseases. Depending on the specific nutritional intake, supplementations, types of exercises the microbiota can be influenced positively or negatively. A systematic review meta-analysis and a pilot study were conducted to investigate the role of diet and supplementation about the microbial composition of the gut, under different types and intensities of physical activities.

Methods: The systematic review and meta-analysis were conducted according to the PRISMA guidelines, and the protocol was registered in PROSPERO (Number CRD42024500826). In a pilot study gut microbiota (16S amplicon sequencing), anthropometric data, and information on diet and supplementation, physical activity and sport habits were collected in a sample including professional and non-professional athletes.

Results: Out of 1318 studies, only 9 met the criteria for inclusion in the meta-analysis. The pilot study's meta-regression analysis and microbiota analysis highlight the role of physical activity type in changing the Bacillota/Bacteroidota ratio ($p = 0.001$).

Conclusions: As gut training becomes more popular among athletes, it is necessary to map interactions between microbiota and different personalized diets, physical activities, and the most popular ergogenic supplements to enhance performance and athletic wellness

Key messages:

- The microbiome can be influenced positively or negatively by the specific dietary intake, types of physical activities and ergogenic supplementations.
- To map interactions between microbiota and different diets, physical activities, and popular ergogenic supplements is needed to design new strategies to enhance performance and athletic wellness.

Abstract citation ID: ckae144.1540
Compliance of eating model of individuals with metabolic syndrome with Bulgarian dietary guidelines

Zdravka Radionova

Z Radionova[1], *V Birdanova*[2]
[1]Social Medicine and Health Management Department, Medical University - Pleven, Pleven, Bulgaria
[2]Department of Hygiene, Medical Ecology, Professional Diseases and Disaster Medicine, Medical University - Pleven, Pleven, Bulgaria
Contact: zradion@yahoo.com

Background: The incidence of metabolic syndrome progressively increases among the urban population of Europe. About 1/3 of the Bulgarian adults have metabolic syndrome. Changing the dietary pattern can be a modern approach to control it. The aim of the study is to investigate the eating model of people with metabolic syndrome according to the Bulgarian dietary guidelines.

Methods: Two hundred individuals with metabolic syndrome aged 54.6±10.5 y. were randomly selected from general practitioners' practices in Pleven region, Bulgaria. A Food Frequency Questionnaire method was applied to assess the eating pattern of the respondents. The frequency of food consumption of different foods was compared with the dietary guidelines for the Bulgarian population over 18 years of age. Data were processed with IBM SPSS v. 25.

Results: Grain consumption met the recommendations in almost all respondents. Only 29% consumed fresh fruits and 42% had intake of milk and milk products according to the requirements. Women ate more fresh vegetables and fruits and dairy products than men ($p = 0{,}032$). Risk meat consumption, 2-4 times a week, was found: men preferring more red meat (45%) and women - chicken and poultry (56%). Fish consumption met recommendation (once a week) in only 14.7% of the respondents. The food intake of eggs, vegetables, legumes and nuts were low. The preferred oils were sunflower and olive (once a day by 86% and 15% respectively), and butter (21% - 2-4 times a week). The intake of table salt corresponds to the recommendations in two thirds of the participants. One third consumed confectionery every day. Half did not drink alcohol, but 16% used concentrates once a day.

Conclusions: Foods that increase the nutritional risk for the development of metabolic syndrome and type 2 diabetes - high consumption of confectionery and red meat, low consumption of vegetables, fish and legumes were found. Unbalanced eating model requires new public initiatives to prevent metabolic syndrome.

Key messages:

- Men with metabolic syndrome have a higher consumption of unhealthy foods than women.
- Modern Bulgarian dietary guidelines are an important tool for prevention of metabolic syndrome.

Abstract citation ID: ckae144.1541
Mediterranean diet adherence and food waste among university students

Vincenza Gianfredi

V Gianfredi[1], *L Stacchini*[2], *A Catalini*[3], *C Passeri*[4], *N Romano*[4], *M Villa*[4], *R Ferranti*[4], *D Nucci*[4]

Contact: vincenza.gianfredi@unimi.it

Introduction: The Mediterranean diet (MD) is widely acknowledged as both a nutritious and sustainable dietary option. Growing research indicates that dietary habits can impact the amount of food waste produced. The aim of the study was to assess the correlation between adherence to the MD and food waste behavior among university students.

Methods: A cross-sectional study employing a validated, anonymous, online questionnaire was conducted among students at the University of Milan. Food waste was measured using the Italian version of the Household Food Waste Behavior (HFWB) questionnaire, while adherence to the MD was assessed through the Medi-Lite questionnaire. The questionnaire was developed in Microsoft Forms. Data were collected between July and October 2023. Responses to the HFWB were scored from 1 for disagreeing responses to 7 for agreeing resposes. Pearson correlation (ρ) between MD adherence and anti-waste behavior, stratified by gender and for the overall population was calculated.

Results: A total of 2,617 students (70% females, age 18-23 years 52%) completed the questionnaire. The average MD adherence score was 10.2 (± 2.2), with 65% of the sample being adherent to the MD. MD score was higher among female (10.4), compared to males (10.1, $p < 0.001$). Females show a more anti-waste behavior (score=5.3± 0.8) compared to males (score=5.2±0.7, $p < 0.001$). MD adherence statistically significant correlated with anti-waste behavior in the overall sample (ρ = 0.27; 95% CI 0.24-0.31, $p < 0.001$) and within each gender group (Females: ρ = 0.27; 95% CI 0.22-0.35, $p < 0.001$; Male: (ρ = 0.28; 95% CI 0.22-0.35, $p < 0.001$)

Conclusions: This study provides evidence of the weak, positive correlation between adherence to the MD and household food waste behavior. Advocating for the MD could enhance health while simultaneously lowering food waste levels, which may have beneficial effects on environmental sustainability and the management of food resources.

Key messages:

- Adherence to the Mediterranean diet linked to lower food waste among university students.
- Mediterranean diet promotes health and less waste, aiding environmental sustainability.

Contact: antonella.ruffatto@aulss6.veneto.it

Background: The psychosocial risks generated from difficult work conditions are damaging not only for the workers' health and safety, but also have a huge impact on the organization and management efficiency.

Description: Some of the primary challenges that health workers face are demanding schedules and stressful shift patterns which lead to higher levels of worker burnout. Ensuring the well-being of healthcare staff is crucial not only for the individual workers, but it also brings important lessons to the community creating an environment built on a culture of health.

Results: In the past year, the Hospital of Cittadella (Province of Padua) has launched a set of programmes structured to help the staff make better lifestyle choices that affect not only their personal life but also create a more sustainable work environment. One of the projects involved various meetings with a Physical Medicine-Rehabilitation physician, a physical therapist, an Occupational Medicine physician and a medical yoga teacher. The encounters, attended by nearly 10% of the hospital staff, were aimed to help healthcare workers create a more balanced lifestyle and to implement physical activity and posture exercises in their daily routine. Four nutrition classes were also organized with the help of a nutritional biologist. The aim of this course was to show the basics of healthy diets supported by scientific data and guide the participants towards realistic and healthy meal plans.

Lessons: In conclusion, increasing the general wellbeing within the healthcare context is not an easy task, especially when organizational circumstances like staff reduction are being faced. These projects represent a small step towards facing these difficulties. It is important to note that the motivation, collaboration, inclusivity, flexibility and reliance are all elements that contribute to better mental and physical health of the healthcare staff which is crucial on an individual, organizational and societal level.

Key messages:

- Increasing personal well being amongst healthcare workers can help create a more sustainable work environment.
- A healthy work environment is crucial for a better functioning organization.

Contact: Suzannah.Dhooghe@sciensano.be

Persons in socioeconomically disadvantaged situations (PSEDs) are more susceptible and disproportionally exposed to unhealthy food environments, resulting in poorer dietary outcomes. Food access plays an important role within the wider food environment. This qualitative paper explores the context-specific relationships between the dimensions of perceived food access within the local food environment among PSEDS. 23 participants were recruited through purposeful convenience sampling until data saturation was achieved in two municipalities in Flanders, Belgium. Utilizing the photovoice and photo-elicitation method, participants expressed their perceptions of food access within their local food environment and its role in their eating behaviour, both individually ($n = 16$) and in group ($n = 7$). Applying the access framework to our analysis, the dimensions of perceived food access among PSEDS were divided into the personal (acceptability and convenience), perceived external (accommodation and desirability) or both personal and perceived external (awareness, availability, accessibility and affordability) domain. Our results suggest that awareness (e.g. of local opportunities available) precedes the other dimensions and that affordability is related to all dimensions among PSEDs. This study underscores the importance of perceived food access in healthy eating among PSEDS. The identified food access dimensions can inform policy, urban planning and community-based interventions to promote equitable access to healthy food.

Key messages:

- Understanding perceived food access is essential to identify ways in which inequalities in food access can be addressed.
- Perceived food access interacts between external and personal domains.

Abstract citation ID: ckae144.1544
Influence of vegetable knowledge in preschooler's vegetable consumption: Veggies4myHeart project

Sara Simões Dias

R Novo[1], *J Edra*[2], *L Vieito*[1], *M Lages*[1], *MP Guarino*[1,2], *S Simões Dias*[1,2], *C Braga-Pontes*[1,2]
[1]ciTechCare - Center for Innovative Care and Health Technology, Polytechnic Institute of Leiria, Leiria, Portugal
[2]ESSLei - School of Health Sciences, Polytechnic Institute of Leiria, Leiria, Portugal
Contact: sara.dias@ipleiria.pt

Background: Vegetable consumption among children is below recommended. Food rejection, especially vegetables, is common in preschool-aged children. Impoverished food knowledge is associated with this rejection. The Veggies4myHeart project aims to promote vegetable consumption and knowledge among preschoolers'. This study assesses the project's effectiveness in increasing vegetable knowledge and consumption and whether increased knowledge influences vegetable consumption.

Methods: Veggies4myHeart is a prospective longitudinal study with children 2-6 years old attending preschools. Two preschools participated in a five-week intervention in the 2023/24 academic year. A distinctive pedagogical tool was tested in each preschool: a storybook and a digital game. Knowledge and vegetable consumption were assessed before and after the intervention. Knowledge was evaluated through a questionnaire with taxonomic categorization. Consumption was assessed by recording the portions of eight vegetables (carrot, lettuce, red cabbage, cucumber, tomato, onion, beetroot, and red bell pepper). Wilcoxon test was applied to compare vegetable knowledge and consumption before and after the intervention. Spearman's correlation was used to examine the association between knowledge and vegetable consumption before and after the intervention.

Results: 98 children (55.1% female, mean age 4.15 ± 0.868 years) participated. Statistically significant increases in both knowledge and total vegetable consumption were observed post-intervention in both preschools ($p < 0.001$). A moderate correlation of 0.412 ($p = 0.013$) in the storybook group post-intervention suggests that increased knowledge may contribute to increased vegetable consumption.

Conclusions: This study demonstrates the potential of the Veggies4myHeart project as an effective strategy to promote knowledge about vegetables among preschool children, highlighting the critical role of educational interventions in promoting healthier dietary patterns.

Key messages:

- To increase vegetable knowledge may lead to higher consumption in preschool children.
- Veggies4myHeart demonstrated its effectiveness as an educational project for preschool children.

Abstract citation ID: ckae144.1545
Lunchbox content and dietary outcomes of Dutch primary school children explored by sociodemographics

Annemieke Wargers

A Wargers[1], W Jansen[1,2]
[1]Public Health, Erasmus MC, Rotterdam, Netherlands
[2]Social Development, City of Rotterdam, Rotterdam, Netherlands
Contact: a.wargers@erasmusmc.nl

Background: Most children fail to meet recommended guidelines for a healthy diet. Children living in low socioeconomic areas are less likely to have healthy eating behaviours. In this study we investigated the food Dutch primary school children bring from home, and their dietary, health and school related outcomes explored by sociodemographics.

Methods: 5 primary schools, with high deprivation scores and a high percentage of overweight, have been included in this study (ClinicalTrials.gov NCT06058325). With observations in September 2023 we mapped the content of lunchboxes, including snacks, of children. Questionnaires for all parents and children in grade 5-8 focused on dietary and health outcomes of children and perceived class factors. Preliminary baseline data were analysed using descriptive statistics. Exploratory analyses will be conducted to show differences by sociodemographics (e.g. age, sex, parental financial stress).

Results: 297 lunchboxes were observed, 98.7% contained sandwiches, half being brown bread. Most children brought fruit from home for either lunch or morning snack, 13.8% not at all. 21.9% brought vegetables. 135 children completed the questionnaire: 43.0% boys, mean age 9.3 years old (SD 1.12). Children ate fruit and vegetables on an average of 5.9 (SD 1.69) and 4.9 (SD 2.23) days a week. Whereas 80% of children eats fruit every day at school, only 20% of children eats vegetables every day at school. Most children perceived their health as good (89.3%) and felt happy (89.6%). On a scale of 1 (low) to 5 (high), they rated concentration, social climate and comfort in class an average of 3.8 (SD 1.05), 4.3 (SD 1.07) and 4.3 (SD 0.92) respectively.

Conclusions: Lunchboxes of Dutch primary school children mainly contain sandwiches. Whereas most children eat fruit at school, the majority of children do not eat vegetables at school. A healthy school lunch might increase vegetable consumption of children and could affect health and school related outcomes.

Key messages:

- Most Dutch primary school children eat sandwiches during lunch at school, but in half of the cases this is not brown bread as recommended by nutritional guidelines.
- Most Dutch primary school children bring fruit to eat as snack or lunch, but no vegetables to eat at school. The majority also self-reported the lack of eating vegetables at school on a daily basis.

Abstract citation ID: ckae144.1546
Focus on food instead of nutrients improves consumers' understanding of meals' nutrition quality

Claudia Viegas

C Viegas[1], E Lamy[2], M Prada[3], A Rocha[4,5]
[1]Health & Technology Research Center, Escola Superior de Tecnologia da Saúde de Lisboa, IPL, Lisbon, Portugal
[2]MED - UEvora, Mediterranean Institute for Agriculture Environment and Development, Evora, Portugal
[3]Department of Social and Organizational Psychology, Iscte-Instituto Universitário de Lisboa, CIS_Iscte, Lisbon, Portugal
[4]GreenUPorto, Sustainable Agrifood Production Research Centre/Inov4Agro, Porto, Portugal
[5]FCNAUP, Faculty of Nutrition and Food Sciences University of Porto, Porto, Portugal
Contact: claudia.viegas@estesl.ipl.pt

Background: Nowadays, most of the information directed to consumers focuses on nutrients, ignoring the impact of the interactions between different foods, origin or degree of processing. The methodologies currently applied have led consumers to confuse foods with nutrients, meat and fish are often referred to as "proteins", grains and potatoes are referred to as "carbohydrates, forgetting that these foods are source of other nutrients, such as fat, proteins or fibre. Furthermore, its efficacy is compromised by the difficulties of reading labels among consumers.

Objectives: This study aimed to evaluate the understanding about food and nutritional information presented in menus to consumers, comparing the nutrient-focused approach (Nutrition Declaration) and the new food-focused approach (infographic - based on the Portuguese food Guide, from previous research).

Methods: 4 different meals were created, 2 balanced and complete in terms of food and nutrient content and 2 unbalanced and uncomplete. A questionnaire was applied, evaluating the understanding of the balance and healthiness of the meals, using the two approaches (nutrient-focused and food-focused). The order of presentation of the approaches and the meals was randomized for all participants. The questionnaire was distributed online through snowball sampling.

Results: 221 individuals participated, mostly female (67%), aged 25 to 54 years old. Evaluation of meals ("how balanced" and "how complete" the meal is) using the Nutrition Declaration did not allow to distinguish the quality of meals (Mb = 3,8;Mc=4,0), in opposite the Infographic returned significant differences between M1/M2 (Mb = 4,3;Mc=4,4) and M3/M4 (Mb = 2,5;Mc=2,6) ($p < 0.01$) allowing consumers to perceive differences between meals. The percentage of consumers that respond "I don't know" to these questions decreased using the food-focused tool (13% vs 2%).

Conclusions: The food-focused approach allows for better understanding of meals' nutritional balance.

Key messages:

- The infographic provides more information about the daily food portions and how different meals and types of food contribute for complying food and nutritional recommendations.
- The use of the infographic in menus, recipes, cookbooks and clinical advice may improve better food choices and a healthier lifestyle.

Abstract citation ID: ckae144.1547
Double-sided effect of selenium on blood lipids: A dose-response meta-analysis

Teresa Urbano

T Urbano[1]*, M Vinceti*[1,2]*, G Fiore*[1]*, LA Wise*[2]*, T Filippini*[1,3]
[1]Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy
[2]Department of Epidemiology, Boston University School of Public Health, Boston, USA
[3]School of Public Health, University of California Berkley, Berkley, USA
Contact: teresaurbano@unimore.it

Background: Selenium, a trace element with both nutritional and toxicological properties, has been suggested to increase cardiovascular risk, particularly concerning diabetes and blood pressure levels. However, the impact of selenium exposure on the risk of dyslipidemia remains uncertain. This meta-analysis explored the shape of the relation between selenium exposure and its effects on lipid profiles in the most relevant experimental human studies, randomized controlled trials (RCTs).

Materials and methods: The review was registered in PROSPERO (ID: CRD42022380432). Through a bibliographic search conducted on PubMed, Web of Science, Embase, and the Cochrane Library, we identified RCTs investigating the impact of selenium supplementation on lipid profile. We then compared the results between intervention and control groups and, whenever possible, evaluated the non-linear relationship using a dose-response approach.

Results: We could include 26 RCTs involving different populations, i.e. healthy individuals, pregnant women, and subjects with health conditions such as cardiovascular diseases and Alzheimer's dementia. Study endpoints were levels of total cholesterol, high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol, and triglycerides. Our dose-response analysis indicated that selenium supplementation exceeding 200 μg/day adversely affected total cholesterol, HDL, and triglyceride levels. Hence, a threshold for such a detrimental effect of selenium was observed on total and HDL cholesterol and triglycerides, while opposite and inconsistent results emerged for levels below 200 μg/day and for LDL-cholesterol. Blood selenium levels at the end of the studies were positively associated with adverse effects on all endpoints.

Conclusions: This first dose-response meta-analysis of the effects of selenium on blood lipids highlights the potentially adverse effects of this trace element, in the amount and the chemical forms used in the trials.

Key messages:

- Elevated selenium levels correlated with adverse effects on lipid profile.
- Selenium doses exceeding 200 μg/day showed adverse effects on total and HDL cholesterol and triglycerides levels.

Abstract citation ID: ckae144.1548
Evaluation of front-of-pack labeling's impact on unhealthy food consumption in Israeli households

Hadar Samuel

H Samuel[1]*, E Katz*[1]*, R Maoz Breuer*[1]*, M Blaychfeld Magnazi*[2]*, N Fliss Isakov*[2,3]*, R Endevelt*[2,4]
[1]Health Policy Research Team, Myers-JDC-Brookdale Institute, Jerusalem, Israel
[2]Nutrition Division, Ministry of Health, Jerusalem, Israel
[3]School of Public Health, Tel-Aviv University, Tel-Aviv, Israel
[4]School of Public Health, University of Haifa, Haifa, Israel
Contact: hadars@jdc.org

Background: In 2020, Israel introduced front-of-pack labeling (FOPL), marking unhealthy foods high in sugar/salt/saturated fat in red and Mediterranean diet-conforming foods in green, aiming to facilitate healthy choices through clear nutrition information.

Methods: Two cross-sectional telephone surveys assessed food purchasing, red/green food consumption frequency, label exposure, and perceived impact before labeling (944 households, 2019) and 3 years post-implementation (500 households, 2023).

Results: Over 90% of respondents in 2023 reported seeing red labels on packages. Nearly 70% checked for red labels when shopping, vs. only 48% who examined the full Nutrition Facts panel on the back of the package. 60% reported preferring unlabeled alternatives within unhealthy categories. Although 50% reported that compared to the period before the labeling, they purchased fewer red-labeled products, a significant decrease in purchasing rates between timepoints was found only for 2 out of 11 unhealthy food categories-sugary drinks (which during 2022 were also taxed by sugar content) and salty snacks. At both timepoints, rates of purchasing and consumption frequency of unhealthy foods were higher among households with children, compared to other households. Multivariate analysis showed that having children under 18, lower education and bigger household size predicted a higher overall unhealthy consumption score. Red label checking was associated with better scores.

Conclusions: FOPL raised awareness and shows potential for reducing unhealthy consumption, especially when combined with policies like sugar taxation. Their impact on reducing purchases of nutritionally valueless foods (snacks/sugary drinks) is highly valuable. However, red-labeled food consumption remained high among households with children, a strong predictor of higher unhealthy consumption scores. Continued label promotion, child-targeted interventions, and product reformulation incentives are recommended.

Key messages:

- FOPL shows potential of enhancing healthy choices especially when combined with supportive policies.
- Results regarding households with children highlight the need for continued promotion, child-targeted interventions, and product reformulation incentives for impacting long-term habits.

Abstract citation ID: ckae144.1549
When toxicity is not just from gluten: a systematic review on financial toxicity and celiac disease

Background: With an incidence of up to ∼2% globally, Celiac Disease (CD) is probably one of the most life-long common chronic conditions. Although 'Financial toxicity' (FT) has been mainly linked to oncology, significant financial burdens have been described across all healthcare domains, even in CD and to the unexpected economic effort resulting from illness and the need for treatments. This study aimed to investigate the potential relationship between CD and FT.

Methods: A systematic literature review was performed according to the PRISMA Statement 2020 guidelines. The search query queried the following databases: PubMed, Scopus, CINAHL and APA PsycInfo. No time and study design limits were included.

Results: 105 articles were found, and 25 were included in the review. The main results revealed that CD impacts physical health and imposes a significant financial burden on patients and their families. FT in CD is primarily due to the high costs of diagnosis, lifestyle changes, and expenses for gluten-free foods. Several studies highlighted the scarce adherence to the therapeutic diet due to the cost of food and poor acceptance of CD. Furthermore, since 2007, there has

been increased attention to the difficulty of finding gluten-free products and their expensive fees. All these aspects, even for low-income countries, were faced differently globally, as documented by the heterogeneity of government subsidy policies highlighting the health inequity.

Conclusions: Considering the prevalence, a comprehensive health assessment with a global health approach should consider clinical, social, and economic aspects. This regard could improve the quality of life for CD patients and ensure fair and personalised access to care, regardless of their geographical location or financial situation. This review has highlighted the fragmentation of resources available internationally, underlining the relevance from a public health point of view.

Key messages:

- Celiac Disease is one of the most common life-long disorders, and financial toxicity is an aspect that should be taken into account also from a public health point of view to ensure health equity.
- The gluten-free diet represents an important therapeutic choice in CD; the related expensive fees could increase scarce adherence and worse health outcomes.

Background: Post-bariatric weight loss varies substantially, and a large proportion of patients respond poorly. The literature highlights the importance of chrono-nutrition for weight regulation. This study aims to explore the chrono-related factors associated with poorer weight loss.

Methods: This study was conducted within the ChronoWise project, an ongoing prospective cohort study following patients undergoing bariatric surgery at the Santo António Local Health Unit, Porto. The sample included patients evaluated at both pre-surgery and 3 months post-surgery. Baseline information on meal timing was gathered through the Chrononutrition Profile-Questionnaire. The eating midpoint (midpoint between first and last meal) was calculated for work and free days. Chronotype was determined using the Munich Chronotype Questionnaire. Weight loss was expressed as the percent of total weight loss ($\%TWL = [(\text{initial weight} - \text{current weight})/(\text{initial weight})]\times 100$). Chrono-related variables were compared according to %TWL (dichotomized by the median) using the Mann-Whitney test.

Results: Sixty patients were included (72% female; mean age 45± 11.8). The mean baseline BMI was 44±5.6 kg/m2, which decreased to 35±5.3 kg/m2 at 3 months post-surgery, resulting in an average 20± 3.9 %TWL. On free days, participants with lower %TWL tend to do the first meal later in the day (9h45 vs. 9h10, p=0.367), and later lunch on workdays (12h45 vs 12h30, p=0.531) compared with individuals with higher %TWL. Lower %TWL is typically observed in individuals having later eating midpoints (15h00 vs. 14h15 for workdays, p=0.011; 15h07 vs. 14h44 for free days, p=0.205). A later chronotype (3h37 vs 3h30, p=0.347) was also linked with poorer weight loss.

Conclusions: Eating later during the day and later chronotype may contribute to poorer post-bariatric weight loss. Funding: This work was supported by FCT - Fundação para a Ciência e Tecnologia [2021.01096.CEECIND, UIDB/04750/2020,LA/P/0064/2020&SGITR 2023/EPIUnit].

Key messages:

- Recognizing meal timing as a modifiable lifestyle factor may optimize current approaches by aligning food intake with circadian clock.
- A later chronotype, i.e. a behavioural expression of an individual's internal circadian clock system as a preference for eveningness or later sleep timing, may negatively influence weight loss.

Abstract citation ID: ckae144.1551
Characterising users of community-based interventions designed to improve the food practices

Janet Kyle

O Petre[1], *J Allan*[3], *L Craig*[1], *F Douglas*[2], *J Kyle*[1], *A Stephen*[1], *F Thies*[1]
[1]University of Aberdeen, Aberdeen, UK
[2]Robert Gordon University, Aberdeen, UK
[3]University of Stirling, Stirling, UK
Contact: j.kyle@abdn.ac.uk

Promoting affordable ways to help low-income families improve dietary behaviours and achieve a healthy weight represents a priority for UK public health policy. For such interventions to be appropriately tailored and targeted, it is important to better understand the intended recipients. The present study aimed to assess the dietary practices and psychosocial characteristics of users of Aberdeen City community-based interventions (e.g., food banks, pantries, social cafés) designed to support low-income communities in accessing food and engaging in healthier food practices. From January to June 2023, a cross-sectional survey was conducted employing convenience sampling among users of community-based interventions ($N = 105$; 73 females). The questionnaire assessed diet quality (SFFQ), household food insecurity (HFIAS), mental health (PHQ-4), well-being (Cantril Ladder), intention and self-efficacy toward healthy eating, and sociodemographic variables. Data were analysed using descriptive statistics, group comparisons, correlations, and regression analyses. Results indicated that community-based food provision users are highly vulnerable to food insecurity. Among participants, 53.3% reported severe food insecurity, and 18.1% reported moderate levels. Service users' diets were high in discretionary foods and drinks (26% consume daily >1 portion of fizzy juice, 18.2% sweets, 16.7% crisps vs. 11.5% fruits and 10.6% vegetables). The mean dietary quality score was 9.48 ($SD = 1.90$) from a possible 15. Higher food insecurity and lower diet quality were significantly associated with greater mental distress ($r=.41$, $p<.001$; $r=-.287$, $p=.005$;) and poorer well-being ($r=-.460$, $p<.001$; $r=.19$, $p=.049$;). This study is part of a larger project aiming to optimise community-based dietary interventions for low-income populations. The results provide a clearer picture of the intended beneficiaries of such interventions and highlight user needs that can be prioritised in optimisation efforts.

Key messages:

- Community-based food provision users are highly vulnerable to food insecurity and related negative health experiences.

- The burden of poor diet and its associated health consequences disproportionately affect those living in the most deprived communities.

Background: Nutrition is one of the most important factors for a person that affects the quality and length of life. Nutrition has a fundamental influence on the maintenance of health or the development of disease and participates in the correct growth and development of an individual. Nutrition is especially important in the early stages of life, when a child's organism develops dramatically. Mothers have the greatest influence on a child's nutrition, and therefore it is advisable to educate them appropriately and also educate them early, from child birth or before. And early nutrition is provided through breastfeeding.

Objectives: To improve the knowledge of healthcare workers in the field of breastfeeding and nutrition of children up to one year of age. To strengthen the breastfeeding skills of mothers. To motivate healthcare workers to educate mothers in maternity wards and GP offices.

Results: Using a questionnaire, we analyzed the knowledge of 716 mothers of children under two years of age. 91 % of female respondents knew that the child should be breastfed according to his/her needs. Only 66 % of women were educated and informed about the importance and technique of breastfeeding. Educational material was prepared and distributed for midwives, nurses and doctors on breastfeeding and feeding children up to one year of age.

Conclusions: The level of awareness of health professionals about breastfeeding and nutrition is still insufficient. There is a need to continue to educate and support healthcare workers in this area and to motivate them in providing information to mothers.

Key messages:

- Breastfeeding and feeding children up to one year of age are important for a child's health.
- The advisory activity of healthcare workers is key to improving public health. Health workers should help mothers not only with advice but also with practical help with breastfeeding.

Abstract citation ID: ckae144.1553
The health profile of Lithuanian beekeepers and use of bee products for health purposes

Petras Sladkevicius

P Sladkevicius[1], M Jakubauskiene[1]
[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania
Contact: petras.sladkevicius@gmail.com

Background: There is little research about the health profile and attitude of beekeepers themselves who are the main suppliers of apitherapy products to the general public. The study aims to describe the health profile of Lithuanian bee keepers and identify their attitudes towards use of bee products for health purposes.

Methods: A cross-sectional survey was carried out from November 2023 to February 2024 among beekeepers in Lithuania. A representative sample of $N = 369$ (5% margin of error) has been enrolled in the study. A mixed-model approach was used for data collection. Research instrument consisted of a two-part questionnaire covering socio-demographic variables and questions on the use of bee products.

Results: 369 respondents participated in the study: 73% ($n = 270$) males and 27% ($n = 99$) of females. The mean age was 57.8 years ($SD = 14.4$). Beekeepers assessed their health as good and only 2% assessed it as bad, while the Lithuanian rate is 12%. 95% of the respondents used bee products for health purposes, 5% did not use at all. Large beekeepers (>100 beehives) were more likely not to choose bee products ($p < 0.001$). No correlation was found between chronic diseases and consumption of bee products, except for diabetes mellitus ($p = 0.001$). The most common reasons for choosing apitherapy products included respiratory (62%), digestive (31%) diseases, immunity boosting (77%), dermatological conditions (53%). Propolis was pointed out in the survey as being used by 74%. Elder beekeepers (>65 years) were found to be more likely to use propolis ($p < 0.001$). They were also more likely to use it for prevention ($p < 0.001$) and in case of toothache ($p = 0.001$).

Conclusions: The majority of beekeepers use bee products for health purposes. The most common reasons for consuming honey and other bee products are immunity boosting and colds. It was found that beekeepers over 65 years of age are more likely to use propolis for prevention and toothache treatment.

Key messages:

- Although the consumption of bee products is high among beekeepers, elder generation and owners of smaller apiaries are more likely to use bee products for health purposes.
- Chronic diseases are not associated with consumption of bee products, except for beekeepers with diabetes mellitus who do not consume it.

Abstract citation ID: ckae144.1554
Food insecurity and fruit and vegetable consumption in Belgium

Nicolas Berger

N Berger[1], T Lebacq[1], S Vandevijvere[1], K De Ridder[1], E Le Dieu[1], E Van Campenhout[1], MS Vasquez[1], S Bel[1], I Moyersoen[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
Contact: nicolas.berger@sciensano.be

Background: Food insecurity is a substantial and growing concern in many high-income countries. Yet, representative data on the extent of the issue in the general Belgian population is lacking. This study aims to assess the extent of food insecurity in Belgium, identify those at risk of food insecurity, and explore the relationship between food insecurity and fruit and vegetable consumption.

Methods: We used data from the Belgian National Food Consumption Survey 2022-2023, a representative sample of the Belgian population aged 3 years and older ($n = 2{,}800$). Food insecurity was assessed using the 3 screening questions derived from the USDA Household Food Security Survey Module. Frequencies of fruit and vegetable consumption were obtained from a food propensity questionnaire. Prevalence of food insecurity was estimated using post-stratification weights. Logistic regression models were used to determine the association between frequency of fruit and vegetable consumption and food insecurity, adjusting for gender, household composition, educational attainment, and income.

Results: Preliminary results indicate that 12.6% of population experienced some form of food insecurity. Those who experienced food insecurity consumed fruit and vegetables less frequently than others, after adjustment for other socio-economic variables (ORs$>$4.00, p-values$>$0.05).

Conclusions: This study confirms that food insecurity is a substantial concern in Belgium. Food insecurity should be routinely monitored at the national level. Experiencing food insecurity appears to be negatively associated with the consumption of healthy foods such as fruits and vegetables and thus with the overall quality of the diet. Further research should be supported to identify effective strategies to reduce food insecurity in Belgium. Policy attention should be given to ensure financial accessibility to healthy foods and their attractiveness, especially for people experiencing food insecurity.

Key messages:

- Food insecurity is an major concern in Belgium and should be routinely monitored.
- Financial accessibility to healthy foods should be improved, especially for those facing food insecurity.

Abstract citation ID: ckae144.1555
Accuracy of body weight perception: The Case of Türkiye

Emine Baran Deniz

E Baran Deniz[1], *N Çelikay*[2], *S Kocadağ*[2]
[1]Public Health, Kafkas University Faculty of Medicine, Kars, Türkiye
[2]General Directorate of Public Health, Ministry of Health, Ankara, Türkiye
Contact: eminibaran@yahoo.com

Background: Accuracy of body weight perception is defined as the extent to which an individual's self-assessment of their body weight aligns with their actual body weight. Our study evaluates the accuracy of body weight perception, an important factor in preventing and managing obesity and overweight, according to sociodemographic factors.

Methods: This study utilizes data from the nationwide cross-sectional 'Nutrition and Health Survey 2017'. The survey includes 12,266 participants who were interviewed face-to-face. Factors influencing the accuracy of body weight perception were evaluated using the chi-square test. Subsequently, the logistic regression models were constructed to assess factors that were statistically significant ($p < 0.05$).

Results: The prevalence of obesity and overweight was found to be 36.3% and 71.5%, respectively. The accuracy of body weight perception was 39.2%, underestimation was 57.0%, and overestimation was 3.8%. There was no significant difference in accuracy of body weight perception between sexes ($p = 0.94$). According to logistic regression analysis ($n = 12.168$), accuracy of body weight perception was higher among individuals who were not overweight compared to those who were overweight ($p < 0.001$, OR: 4.56, CI: 4.16-4.98), among those aged 15-44 compared to those aged 45 and over ($p < 0.001$, OR: 1.47, CI: 1.35-1.60), among those with high school and higher education compared to those with middle school education or less ($p < 0.001$, OR: 1.43, CI: 1.31-1.56), among unmarried individuals compared to married ones ($p = 0.011$, OR: 1.12, CI: 1.03-1.23), and in individuals with poor income status compared to good ($p = 0.005$, OR: 1.13, CI: 1.04-1.22).

Conclusions: In health promotion programs aiming to perceive body weight accurately, priority should be given to people with overweight, those with low education levels, married individuals, people aged 45 and over, and individuals with low income.

Key messages:

- Accuracy of body weight perception is important in fighting obesity.
- Individuals with overweight, have a low level of education, are married, aged 45 and over, and have low income are misperceive their body weight to a greater extent.

Abstract citation ID: ckae144.1556
Perception of fatphobia and pesocentrism within medical consultation

Samantha Denise Chávez Castillo

SD Chávez Castillo[1], *P Cordero García*[1], *KA Abonce Bautista*[1],
M Pérez Villanueva[1], *DK Morales Morales*[1], *D Hernández Valenzuela*[1],
OD León Barroso[1], *JE Villegas-Dominguez*[1]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
Contact: samc80543@gmail.com

Background: About 42% of adults living with overweight or obesity suffer a marked pattern of stigmatization and thanks to this discrimination the risk of death has increased up to 60%.

Objectives: To identify the factors that contribute to the perception of fatphobia and pesocentrism within the first level of medical care.

Methods: A prospective cross-sectional study was carried out. Statistical analysis was performed with X2 test and 95% confidence interval (OR/CI95%).

Results: 104 participants with obesity and overweight were included. The factors associated with the perception of pesocentrism were, started eating plans before the age of 10 years (3.38/1.12-10.7); being denied consultation for being a fat person (0.27/-0.16-0.46); perceiving mistreatment by the physician regarding weight (0. 2/0.13-0.3); perceiving physical harassment by the physician (0.23/0.16-0.82); perceiving discomfort on physical examination (0.44/0.23-0.82); perceiving fat-phobic behaviors by the physician (5.45/3.24-9.16). Factors associated with perceived fatphobia were, started eating plans before the age of 10 years (4.89/1.71-14.01); being denied consultation for being a fat person (0.19/-0.08-0.44); perceiving mistreatment by the physician regarding weight (0. 07/0.04-0.15); perceiving physical harassment by the physician (0.11/0.06-0.19); perceiving discomfort on physical examination (0.28/0.11-0.67); perceiving weight-centered behaviors by the physician (0.05/0.01-0.23). All with p value $<$0.05.

Conclusions: Factors such as the beginning of eating plans in childhood, refusal of consultation for being a fat person, mistreatment regarding weight, physical harassment by the physician, discomfort during physical examination are associated with and favor the perception of both fat-phobia and weight-centeredness in the medical consultation.

Key messages:

- It is of vital importance to know more about the concepts of fatphobia and pesocentrism, in order to promote non-discrimination around them.
- Fatphobia and pesocentrism are still little known issues within the medical community, the perception of them is due to discriminatory behaviors that have been normalized.

Abstract citation ID: ckae144.1557
Revealed and stated preferences for sharing of patient-reported data in Austria

Susanne Drexler

S Drexler[1]
[1]Health Economics and Policy, Vienna University of Economics and Business, Vienna, Austria
Contact: susanne.drexler@wu.ac.at

Objectives: Routine collection of health data is essential for creating sustainable, efficient, and equitable health systems. While administrative health data are collected automatically, successful routine collection of patient-reported outcome measures (PROMs) and patient-reported experience measures (PREMs) depends on voluntary participation. The aim of this study is to investigate how to increase participation in routine patient-reported data collection.

Methods: This mixed methods study used representative survey data from the Austrian population aged 18-70 ($N = 1260$) and 15 semi-structured narrative interviews with citizens and health data experts collected in 2024. Survey respondents were shown examples of PREMs and PROMs and indicated their willingness to share them, depending on the recipient and purpose. Interviewees answered the same questions while providing insight into their decision-making process, which was analyzed using thematic analysis. Wilcoxon rank sum tests were used to assess differences in willingness to share across recipients and data collection purposes.

Results: Survey respondents were more willing to share PREMs than PROMs ("rather yes" vs. "rather no", $p < 0.001$). One explanation given in the interviews is that PROMs are more personal and convey sensitive information. In terms of sharing PROMs, people were most likely to share with their GP (81%) and least likely to share with private companies (7%). Facilitators for sharing identified in the interviews were improving personal care and the health system, while barriers were use for profit generation and fear of negative consequences for the person sharing.

Conclusions: The results suggest handling the collection of PROMs demands greater caution compared to PREMs. Furthermore, clearly communicating personal and societal benefits arising from the collection and analysis of self-reported health data may increase participation in routine self-reported health data collection.

Key messages:

- The collection of self-reported health data depends on voluntary participation. Clearly communicating personal and societal benefits of sharing self-reported data can motivate participation.
- Self-reported data collection is essential for sustainable and efficient health systems. Compared to PREMs, people are more reluctant to share PROMs because they contain sensitive information.

Abstract citation ID: ckae144.1558
Health Impact Assessment (HIA): a tool to drive health in all policies?

Liz Green

L Green[1,2]
[1]Wales HIA Support Unit, Public Health Wales, Wrexham, UK
[2]International Health, University of Maastricht, Maastricht, Netherlands
Contact: liz.green@wales.nhs.uk

Health Impact Assessment (HIA) is often promoted as a tool to implement 'health in all policies' and sustainable development approaches to improve health and equity outcomes. However, is this truly the case? Currently global HIA practice is variable. This paper shares learning from the development and implementation of HIA in Wales to date to understand how HIA has been, and can be, used to inform policies and decisions and reduce health inequalities. The research investigated if, and how, HIA can be used as a tool to mobilise HiAP in reality. It followed a mixed methodological approach and investigated the contribution of HIA to practically advancing HiAP viewed through the lens of Wales and internationally. Primary and secondary evidence and statistics were collected and analysed. A literature review, stakeholder interviews, online statistical questionnaires and case studies were conducted. Thematic and content analysis techniques used. Findings include the importance of conceptual considerations i.e. the perspective on health - social determinant an equity or environmental determinant driven - taken by those carrying out or commissioning a HIA; the importance of centres of expertise to learn from; and practical considerations such as the political and regulatory environment, workforce and organisational knowledge and capacity. Wales has a dedicated expert HIA Unit, an enabling political environment and has led to HIA influencing policies and plans over 20 years. It has transferrable learning for other nations and the research including the online survey has been replicated by others, led to collaborations with nations such as Portugal and contributed to the reviewed literature by providing case studies on a topics like climate change which have influenced decision makers. Tangible ways forward for policy makers, researchers and academics include the need to develop more cross collaboration and fill gaps in the evidence i.e. on institutionalisation of HIA.

Key messages:

- HIA is a excellent process to drive Health in all policies approaches.
- HIA needs an enabling environment and workforce support such as that in Wales to thrive.

[3]Ludwig-Maximilians-Universität München, Munich, Germany
[4]University of Porto, Porto, Portugal
[5]Norwegian Institute for Public Health and the Environment, Trondheim, Norway
[6]National Institute for Health Development, Tallinn, Estonia
[7]Sciensano, Brussels, Belgium
[8]Scientific and Technical Centre for Building, Paris, France
Contact: axel.luyten@swisstph.ch

Background: Ambient air pollution and noise substantially impact public health and the economy. Different methods to quantify these impacts are described in the literature.

Objectives: Within the European project BEST-COST (Burden of disease-based methods for estimating the socio-economic cost of environmental stressors), we aim to develop an open-source R package to quantify and monetise the disease burden attributable to air pollution and noise, including the impact of social inequalities.

Methods: The developed code will allow for different calculation pathways including: single baseline health data vs. age-specific estimates from life tables; relative and absolute risk; scenario comparison based on the population attributable fraction vs. population impact fraction; single-pollutant vs. correlated exposures; and outdoor vs. indoor air pollution. Moreover, the package can digest a variety of input data formats for the exposure-response function (e.g. relative risk with fixed shape vs. user-defined function) and exposure data (e.g. population-weighted mean vs. categorical distribution, spatial data). Eligible impact metrics will include morbidity incidence and prevalence, number of deaths, years of life lost, and years lived with disability. Finally, the R package will enable quantifying social inequities (using a novel multiple deprivation index) and monetising the attributable disease burden (using a state-of-the-art approach).

Results: During development, the R package will be tested in BEST-COST case studies in 5 European countries (BE, EE, FR, NO, PT), compared with existing tools, and discussed with key users in a workshop. The final R package will be available on GitHub in 2026.

Conclusions: This tool will allow the quantification and monetisation of the health impact of air pollution and noise. The R package will be a flexible programming resource that can be used as a standalone or combined with existing tools to build a more solid basis for evidence-based policy making.

Key messages:

- This open-source tool will allow the quantification and monetisation of the health impact of air pollution and noise, including the impact of social inequalities.
- The R package will be a flexible programming resource that can be used as a standalone or combined with existing tools to build a more solid basis for evidence-based policy making.

Realising the health benefits of City Development Plan in Ireland: The process and influence of HIA

Tara Kenny

T Kenny[1], M O'Mullane[1], K Nash[1], B Harris-Roxas[2], P Kavanagh[3], S McHugh[1], L Green[4]
[1]School of Public Health, UCC, Cork, Ireland
[2]School of Population Health, UNSW Sydney, Sydney, Australia
[3]National Health Intelligence Unit, Health Service Executive, Dublin, Ireland
[4]Wales Health Impact Support Unit, Public Health Wales, Cardiff/Wrexham, Wales, UK
Contact: tarakenny@ucc.ie

Background: The built environment is a major determinant of health. This research examined the process of implementing a health impact assessment (HIA) of a city development plan, using HIA guidance developed by Institute of Public Health Ireland. HIA is an established approach to facilitate a Health for All Policy approach and is a practical tool used to appraise the potential health effects of a policy, programme or project prior to implementation.

Methods: This mixed methods study underpinned by action research and implementation science frameworks, explored the process and experiences of undertaking an HIA on the Cork City Development Plan (2022-2028). A total of 36 stakeholders across a variety of institutions, sectors, and including members of the public, were involved in the HIA.

Results: We found there was an appetite for HIA's use to facilitate cross sectoral working to identify, mitigate, and address health inequalities. Data derived from interviews, surveys and workshops indicate that while most stakeholders involved saw the value HIA could bring to their work, further efforts are required to realise the benefits of HIA as a decision-support tool. Barriers included lack of familiarity of HIA across sectors, and for those involved in carrying out the HIA, lack of adequate training, time and access to local data.

Conclusions: HIA can contribute to embedding a Health for All Policies approach, however, greater effort from the public health professionals is required to advocate for HIA as a tool to influence policy. Our results suggest that its practical application requires (i) intersectoral training on HIA that supports a broader understanding of the social determinants of health, (ii) knowledge of the purpose and remit of the policy, plan or programme being appraised and (iii) ensuring a broad range of relevant expertise and experience on the steering group tasked with leading the HIA.

Key messages:

- HIA can contribute to embedding a Health for All Policies approach.
- Stakeholders do see the value that HIA can bring to their work, however, further efforts are required to realise the benefits of HIA as a decision-support tool.

Abstract citation ID: ckae144.1561
Developing a community engagement toolkit for health impact assessment in Ireland

Tara Kenny

K Nash[1], T Kenny[1], M O'Mullane[1], B Harris-Roxas[2]
[1]School of Public Health, University College Cork, Cork, Ireland
[2]School of Population Health, Faculty of Medicine, University of South Wales, Sydney, Australia
Contact: tarakenny@ucc.ie

Background: Community involvement is a core principle of Health Impact Assessment (HIA). However, current guidance for HIA published by Ireland's Institute for Public Health does not include guidelines on community engagement in HIA. As part of the project HIA-IM - 'Development of a Health Impact Assessment Implementation Model: Enhancing Intersectoral Approaches in Tackling Health Inequalities,' a Community Engagement Toolkit was created, with the aim of providing guidance for those carrying out HIAs and engaging with community in the process. The project will implement two HIAs, on the Cork City Development Plan (2022-2028) and the national Climate Action Plan (2024). Incorporating the learnings from the first HIA, the Toolkit will be employed in the second HIA of the project.

Methods: To develop the toolkit, a literature review of community engagement in HIA was conducted, with benefits and challenges, key approaches, and case studies of HIA's gathered from grey literature and peer reviewed articles. In line with the participatory nature of HIA, a public consultation event was held, which was presented as a case study within the Toolkit.

Results: Findings from the literature review contend that engaging with community in HIA captures the lived experiences and local circumstances of the community, fostering empowerment and greater health awareness. However, many practitioners find community engagement to be practically challenging, citing factors such as time and resource constraints; with risks of consultation fatigue and raising expectations.

Conclusions: The review identified tools that have been used to mitigate these challenges and risks to facilitate meaningful community participation. These findings, along with learnings from conducting the first HIA, has informed the content of the Toolkit. Therefore, this Toolkit aims to complement national HIA guidance to centre the community voice in future HIA practice.

Key messages:

- Developing a toolkit to strengthen participatory approaches and community engagement in health impact assessment in Ireland.
- Centering the community voice in health impact assessment: the inclusion of lived experiences and local circumstances in health impact assessment practice in Ireland.

Abstract citation ID: ckae144.1562
What are the challenges in the Health Technology Assessment of genetic and genomic applications?

Valentina Baccolini

V Baccolini[1], C Isonne[1], LM Siena[1], A Sciurti[1], G Migliara[2], I Leone[1], C Marzuillo[1], G La Torre[1], P Villari[1]
[1]Sapienza University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy
[2]Link Campus University, Department of Life Sciences, Health, and Health Professions, Rome, Italy
Contact: valentina.baccolini@uniroma1.it

Introduction: Evaluating genetic/genomic applications (GGAs) is crucial for their implementation in clinical practice but hindered by several issues, such as rapid development processes and unclear benefits. Since these challenges lack comprehensive discussion, this study aims to identify and analyze all barriers emerged in the Health Technology Assessment (HTA) of genetic/genomic tests, filling a gap in the current literature.

Methods: PubMed, Scopus and Web of Science were searched to identify studies that specifically discussed any challenge or barrier in the HTA evaluation of GGAs. No restriction was applied on evaluation aspect or study type. Challenges/barriers were then grouped into the domains outlined in the EUnetHTA Core Model. A narrative synthesis of the main findings was performed. This study was supported by the EC and MUR- PNRR-M4C2-I1.3 Project PE_00000019 'HEAL ITALIA'.

Results: 19 articles were included: one third involved experts from different countries, and about 50% were author perspectives. Articles either focused on one aspect only (37%) or were more general (47%). The most challenging domain was economic aspects (69%), followed by clinical effectiveness (47%) and social impact (42%), but issues were found in all domains. The lack of a standardized HTA approach, the paucity of evidence on clinical outcomes, the challenges in capturing all health benefits, and the difficulties in identifying the healthcare pathways triggered by the test were consistently mentioned across the HTA domains.

Conclusions: Our study systematically summarized challenges in the HTA evaluation of GGAS, providing a thorough analysis and categorization of these issues. Various challenges surfaced, notably related to the identification of costs, as well as clinical and nonclinical benefits. There is a need for exhaustive discussion on potential solutions to facilitate the assessment process of these technologies to ultimately foster their implementation in clinical practice.

Key messages:

- There are multiple challenges in the HTA evaluation of genetic and genomic tests in clinical practice that impact every HTA domain.
- There is a need for concrete efforts in generating further evidence in relation to the definition of costs and benefits of the healthcare pathways triggered by genetic/genomic applications.

Abstract citation ID: ckae144.1563
The efficacy of vaccination against respiratory syncytial virus across priority population subgroups

Chiara de Waure

A Domnich[1], C Bertola[2], C Lupi[2], M Vece[2], E Lorenzini[2], C de Waure[2]
[1]Hygiene Unit, San Martino Policlinico Hospital IRCCS for Oncology and Neurosciences, Genoa, Italy
[2]Department of Medicine and Surgery, University of Perugia, Perugia, Italy
Contact: chiara.dewaure@unipg.it

Background: Respiratory syncytial virus (RSV) has recently become a vaccine-preventable disease as two vaccines have been approved for use and a third one is likely to become available by the end of the year. National Immunization Technical Advisory Groups as well as scientific societies across the world have issued recommendations on RSV vaccination that differ in respect to the identification of the target group. The latter has been identified in respect to age or underlying medical conditions mostly according to epidemiological data. In order to strengthen the evidence basis for future decisions, we performed a stratified meta-analysis of efficacy data considering all the three RSV vaccines currently or soon available.

Methods: We searched Randomized Controlled Trials (RCTs) assessing the efficacy of RSV vaccines in terms of reduction of RSV-related Lower Respiratory Tract Infection (LRTI). The research was conducted on PubMed and clinicaltrial.gov. The extraction of relevant data was stratified by pre-defined age groups (60-69, 70-79, 80+) and presence of underlying conditions increasing the risk for RSV.

Results: Three RCTs, one for each of the three vaccines, were considered for the quantitative analysis. Considering the overall 60+ population, the efficacy of RSV vaccines was 78% (95%CI 76-86%) in preventing LRTI. Considering the different age groups (60-69, 70-79, 80+), efficacy was respectively 72% (95%CI 53-84%), 90% (95%CI 66-97%) and 57% (95%CI 0-93%). The efficacy in healthy people and those with at least one underlying condition was similar, namely 77% (95%CI 60-87%) and 78% (95%CI 50-90%).

Conclusions: The available evidence shows the efficacy of RSV vaccines in reducing LRTI with no differences across different priority groups. Further studies may contribute to better understanding if the efficacy may change according to individual characteristics, that could be highly relevant in the decision-making process.

Key messages:

- The available evidence from RCTs shows the efficacy of RSV vaccines in reducing LRTI with no differences across different priority groups.
- National recommendations on RSV vaccination can be further informed for future studies investigating RSV vaccines efficacy across different subgroups.

Abstract citation ID: ckae144.1564
Impact Assessments - existing procedures and potentials for health and health equity

Gabriele Gruber

G Gruber[1], M Weigl[1], S Ecker[1], S Haas[1], D Antony[1]
[1]Health, Society and Equity, Gesundheit Österreich, Vienna, Austria
Contact: gabriele.gruber@goeg.at

Impact assessment tools are used in policy making all over Europe, some have a legal foundation, others were performed voluntarily for certain measures. Usually, impact assessment procedures are dedicated to specific policy areas or political fields. As policies often have impacts in more than one political area, an interlinkage of impact assessments would be appropriate - also to foster co-benefits of policy making. To follow this approach of a more integrated way of impact assessment, it is necessary to gain an overview and understanding of different procedures in place on national level. As policy making is important for designing healthy living environments, a specific task in the EU Joint Action Prevent NCD is focussing on fostering health and well-being through impact assessment procedures. Therefore, an assessment of the existing impact assessments in the participating member states will be performed in 2024. By using a document analysis of guiding material like guidelines, standards or web applications for the specific impact assessment types, it will be investigated how health and health equity aspects are already included. A qualitative comparison of the results can deliver similarities and differences but also promising practices in the member states. The preliminary results of this analysis will be presented. By learning about the different impact assessment procedures in place, potential synergies and entry points for health and health equity could be found. In a next step, a comprehensive checklist for health and health equity should be developed and piloted in the member states. The final version of checklist should be a guiding material that could be included in various Impact Assessment procedures.

Key messages:

- Impact assessment procedures are important for policy making and can foster co-benefits in various political fields.
- By learning about the different impact assessment procedures in place, potential synergies and entry points for health and health equity could be found.

Assessment of controlled assistance from e-bikes as a mitigation strategy for individual PM exposure

Alberto Bonardi

A Bonardi[1,3], *L Borgese*[2], *F Negro*[3]
[1]Information Engineering, University of Brescia, Brescia, Italy
[2]Industrial and Mechanical Engineering, University of Brescia, Brescia, Italy
[3]Clinical and Experimental Sciences, University of Brescia, Brescia, Italy
Contact: alberto.bonardi@unibs.it

Background: While promoting active mobility and outdoor activities can benefit health (HLT), it also increases Exposure (EXP) to air pollutants, such as particulate matter (PM), due to the increased ventilation rate (VR) under physical activity. Traditional assessments of individual (IND) PM EXP involve costly equipment inaccessible to the public, but real-time low-cost sensors (LCS) are now emerging. This study presents a proof of concept to demonstrate the use of LCS for examining the real-time IND respiratory dose deposited (RDD) to PM cycling across the Brescia province.

Methods: An e-bike was ridden 33 times between 2022 and 2023 wearing a LCS for PM concentration [PM] linked to a GPS. Respiratory dose deposited(RDD) was calculated for six different locations within each route based on experimental PM and various VR.

Results: The LCS allows for the study of the spatial and temporal variability of [PM], revealing a significant difference ($p < 0.01$) according to the heating system operation and no significant difference ($p > 0.05$) depending on the location. RDD increases with [PM] and VR. Real-time and integrated RDD is calculated for routes with high (> 50 µg/m3), medium (25 µg/m3), and low (<10 µg/m3) [PM2.5]. The e-bike assistance is activated when the WHO interim target 4 of [PM] is reached to reduce VR, which corresponds to a shift to a lower physical activity intensity. The RDD calculated using the e-bike assistance over the path reduces RDD by about 23% and 11% over the high and medium [PM], while it never activates for the low [PM].

Conclusions: This study demonstrates that the use of LCS allows the estimation of IND RDD, and the implementation of mitigation strategies based on controlled assistance from e-bikes would enable the reduction of PM individual EXP.

Key messages:

- The integration of HLT data from wearable and air quality LCS enables the promotion of active mobility and outdoor activities controlling the EXP to air pollutants.
- Establishing generalized guidelines based on this mitigation strategies for individual exposure reduction may also inform policy recommendations for promoting active and green mobility.

Abstract citation ID: ckae144.1566

Company commitments on nutrition and sustainability: A three-country comparison

Margaret Steele

M Steele[2], *S Campos*[1], *R Nova*[3], *S Dastoum*[4], *S Vandevijvere*[4], *J Harrington*[5], *A Oliveira*[1], *A Rodrigues*[1], *M Vaz-Velho*[2]
[1]Center for Research and Development in Agrifo, Institute Polytechnic of Viana do Castelo, Viana do Castelo, Portugal

[5]School of Public Health Scoil na Sláinte Poib, University College of Cork, Cork, Ireland
Contact: margaret.steele@ucc.ie

Background: The Business Impact Assessment (BIA) tools were developed by INFORMAS to document companies' commitments on population nutrition (BIA-Obesity) and environmental sustainability (BIA-Sustainability). As part of the EU-funded Food Systems that Support Transitions to Healthy and Sustainable Diets (FEAST) project, we used the BIA-Obesity and BIA-Sustainability to map the public commitments of a range of national and international food companies active in Belgium, Ireland, and Portugal.

Methods: We selected companies (Belgium $n = 37$; Ireland $n = 39$; Portugal $n = 36$) across the packaged food, soft drinks, quick service restaurant, grocery retailers, infant formula, and catering industries. Selection was based primarily on the companies' market shares in each country, but minor adaptations were made to enable comparison of findings between the countries. We searched each company's website, annual reports, and other public sources, logging all commitments relevant to the domains of the BIAs. Domains and criteria were adapted to reflect the regulatory and legislative environment in each country.

Results: In all three countries, commitments on sustainability were significantly stronger than those on nutrition, though still falling short of best practice. Within sustainability, commitments found in Belgium and Portugal were significantly stronger than those found in Ireland. Nutrition-related commitments were more consistent across the three countries, with companies in Ireland and Portugal showing the highest-scoring commitments in relation to product formulation.

Conclusions: Companies across all industry sectors and countries fall short of best practices, with a stronger commitments to environmental sustainability than to tackling obesity and non-communicable diseases. These results underscore the critical necessity for more ambitious government regulations at both European and national levels.

Key messages:

- Critical necessity for government regulations at both European and national levels to adress environmental and nutritional challenges.
- Industry need stronger commitments to tackling obesity and non-communicable diseases.

Abstract citation ID: ckae144.1567

Objective and subjective physical activity assessment in obese patients with eating disorders

Hans-Peter Wiesinger

H-P Wiesinger[1,2,3], *B Bannert*[5], *E Kaiser*[5], *F Riffer*[5], *P Kutschar*[1,4]
[1]Institute of Nursing Science and Practice, Paracelsus Medical University, Salzburg, Austria
[2]Institute of General Practice, Family Medicine and Preventive Medicine, Paracelsus Medical University, Salzburg, Austria
[3]Department of Sport and Exercise Science, Paris Lodron University, Salzburg, Austria
[4]Center for Public Health and Healthcare Research, Paracelsus Medical University, Salzburg, Austria
[5]Psychiatric Rehabilitation Clinic Eggenburg, Psychosomatisches Zentrum Waldviertel, Eggenburg, Austria
Contact: hans-peter.wiesinger@pmu.ac.at

Background: Discrepancies between objective and subjective measures of physical activity have been reported in healthy populations but remain unexplored in adults with obesity and psychosomatic disorders. Exercise is key for reducing these disorders, yet physiological and psychosomatic factors may complicate valid activity assessments in this population. Here, we compare self-reporting with actigraph data in a clinical setting.

Methods: Over two years, 27 obese patients (21 female, 6 male; 43± 14 yrs; 41.3±5.7 kg·m−2) with eating disorders (EDE-Q) were recruited from an Austrian Psychosomatic Center. Total physical activity was assessed using the metabolic equivalent (MET min/w) and sitting time (min/d). Objective data were collected using the SenseWear® wristband (SWA) during weeks 3-4 of patients' clinical stay. SWA was worn for ≥18 h/d on ≥ 4 days, including one weekend day. Patients self-administered the International Physical Activity Questionnaire (IPAQ-SF) in alignment with the ∼7 days of SWA wear. Concurrent validity - SWA as a criterion - was assessed using regression analyses, and proportional bias was examined with regression and equality line similarity analyses.

Results: Comparison showed an overestimation of total activity (+45%; p<.001) and underestimation of sitting time (-28%; p<.001) with IPAQ-SF vs SWA. Within-patient correlations were poor for MET (r=.92, p<.001) and impractical for sitting time (r=.27, p=.018), with a proportional bias for both outcomes (p≤.001). Converting objective to subjective measures yielded typical errors of 232 (total activity) and 90 min (sitting time).

Conclusions: The observed disparities emphasize the need to integrate sensor-based assessment of physical activity into clinical practice or tailored public health initiatives for adult obesity and psychosomatic disorders. However, further research is needed to evaluate the long-term impact of incorporating accurate SWA data on intervention efficacy in this vulnerable group.

Key messages:

- There was strong evidence for meaningful differences in objective vs subjective physical activity assessments in obese patients with eating disorders.
- Integrating objective measures into treatment seems crucial to improve exercise-guided interventions and address the global obesity and psychosomatic disorders pandemic.

Abstract citation ID: ckae144.1568
Combating antimicrobial resistance: A framework for educational tool innovation

Avis Anya Nowbuth

AA Nowbuth[1,2], *VS Parmar*[1]
[1]Department of Neuromedicine and Movement Science, Norwegian University of Science and Technology, Trondheim, Norway
[2]Department of Research, Pan-African Organization for Health, Education and Research, Missouri, USA
Contact: anya.a.nowbuth@ntnu.no

Issue: The World Health Organization (WHO) stresses the need for educational and training initiatives to address antimicrobial resistance (AMR) across human, animal, and agricultural sectors. AMR, a growing public health threat, was responsible for approximately 4.95 million deaths in 2019. Traditional educational frameworks tackling AMR are often applied in isolated sectors, failing to incorporate a holistic or collaborative approach.

Description of the Policy: The Holistic Engagement and Adaptive Response Theoretical framework (HEARTf) proposes a comprehensive, innovative approach combining behavioral theories, and persuasive technology, including the Theory of Planned Behavior, Persuasive Technology, and Diffusion of Innovation. The framework is designed to integrate stakeholders in developing and accessing educational tools, specifically a game designed to teach students about AMR. HEARTf emphasizes a multidisciplinary methodology, beginning with Phase 1 (exploratory phase) to gather baseline information from potential prescribers in Norway and Zambia.

Results: Initial application of HEARTf is leading the development of an educational game on AMR. This game uniquely combines behavioral theories and digital design, focusing on high-impact areas of AMR. Preliminary feedback indicates enhanced stakeholder engagement and a heightened willingness to adopt AMR best practices across different sectors.

Lessons: The HEARTf approach demonstrates the potential for enhancing AMR education through innovative, theory-based game design and development. It advocates for the continued integration of comprehensive educational strategies into global health initiatives to combat AMR effectively. These actions, being tailored to diverse sectors, suggest that similar holistic, theory-driven approaches may be beneficial in other public health crises.

Key messages:

- HEARTf fosters innovative, multidisciplinary AMR education, enhancing stakeholder engagement and adoption of best practices.
- Theory-based educational tools in AMR developed using HEARTf can significantly impact global health strategies and should be integrated into broader public health efforts.

Abstract citation ID: ckae144.1569
A cross-country comparison of the organisation and reimbursement of intensive care in Europe

Elke Berger

E Berger[1], *H Rödiger*[1], *R Busse*[1]
[1]Department of Health Care Management, Berlin University of Technology, Berlin, Germany
Contact: elke.berger@tu-berlin.de

Background: During the pandemic, intensive care capacity was a heavily discussed topic in Europe. Many European countries have increased their intensive care capacities to ensure treatment of all COVID-19 patients. A study, however, revealed that organisational characteristics, among other factors, were associated with in-hospital mortality. Our study thus aimed at reviewing international models for the organisation and reimbursement of intensive care.

Methods: Based on a scoping review, a number of European countries (Denmark, England, France, Germany, Italy, the Netherlands, Sweden) was selected for a questionnaire-based expert survey.

Results: In most countries, intensive care is defined by law, while the definition in two countries has a recommendatory character and/or is driven by reimbursement. In line with the European Society of Intensive Care Medicine's recommendations, the majority of countries has organised intensive care around 2-3 different (heterogeneously defined) levels of care for which reimbursement sometimes differs according to the level. For most countries, the number of physical (i.e., number of operable beds) as well as human resources (i.e., nurses) in intensive care is unknown. Many countries have an intensive care register which, in the case of Germany, was only implemented as a response to the pandemic. However, comparability is limited due to differences in indicators used. Although promising telemedical approaches in intensive care do exist, their use is not yet formalized in most countries.

Conclusions: Most countries rely on a level-based organisation of intensive care, even though clear evidence on their effect is missing. Heterogeneity of definitions as well as quality monitoring makes a comparison difficult. Further research is needed to better understand best practices and thus increase resilience as well as pandemic preparedness. Telemedical interventions could elevate (access to) high-quality care, especially in times of crises.

Key messages:

- Further research is needed to better understand best practices and thus increase resilience as well as pandemic preparedness.
- Telemedicine could elevate (access to) high-quality intensive care, especially in times of crises.

Abstract citation ID: ckae144.1570
BEST-COST project: a scoping review on the use of multiple deprivation indices in Europe

Gaëlle Mogin

G Mogin[1], V Gorasso[1], CM Baravelli[2], J Idavain[3], M Lepnurm[3], S Delaunay-Havard[4], A Luyten[5,6], M Corda[7]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Disease Burden, Norwegian Institute of Public Health, Bergen, Norway
[3]Department of Health Statistics, National Institute for Health Development, Tallinn, Estonia
[4]Environmental and Occupational Health Division, French Public Health Agency, Saint-Maurice, France

[6]Department of Epidemiology and Public Health, University of Basel, Basel, Switzerland
[7]Egas Moniz Center for Interdisciplinary Research, Egas Moniz School of Health & Science, Almada, Portugal
Contact: gaelle.mogin@sciensano.be

Background: A Multiple Deprivation Index (MDI) is a composite measure designed to comprehensively evaluate the socio-economic status of individuals within a population. While various countries have employed their own versions of MDI to assess deprivation, none have been developed at the European level thus far. The BEST-COST project (www.best-cost.eu) aims to integrate the dimension of social inequalities in the assessment of the burden of environmental stressors, using a new MDI. Therefore, the objective of this study is to conduct a scoping review to identify and assess current MDIs while extracting details on the methodologies employed in their development.

Methods: We conducted a scoping review on deprivation indices in European countries, encompassing three databases (Medline, Embase and Web of Science). Following screening of all the articles based on inclusion criteria, we specifically examined the methodological choices made across the development of the MDIs, such as the choice of the underlying indicators, geographical scales, data source used, and if and/or how indicator weighting was applied in creating a composite score.

Results: In total, 22 MDIs were identified from 195 articles. 42% of these indices were developed from census data at the municipality level or finer. About half of them (55%) employed weighting of indicators, thereby reflecting their relative importance within the index's score. From these 22 MDIs, a total of 156 individual indicators were extracted. These indicators encompass several domains such as basic amenities, crime, education, employment, family structure or income. The extensive variety of indicators can be attributed to cultural differences within the EU, data availability and the specific time period during which each index was developed.

Conclusions: Several European countries have separately developed their own MDI, showcasing significant variability in both the included individual indicators and the methodologies applied.

Key messages:

- This review highlights the variability of existing indices and which methodologies could be used for the development of a Europe-wide multiple deprivation index.
- It further emphasizes the importance of considering cultural differences and data availability across countries in this process.

Abstract citation ID: ckae144.1571
A Conceptual Model for Health Impact Assessment of Personalized Prevention Policies

Cristina Costa

C Costa[1,2], F Lopes[1], A Costa[1,3,4], ML Cardoso[1,3], AV Gris[5], P Kannan[6], F Garvão[1,2], M Perola[6], S Boccia[5], AM Vicente[1,3]

[5]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[6]THL, Helsinki, Finland
Contact: cristinartcosta@gmail.com

Background: Personalized prevention and pharmacogenomics are emerging fields in global health, promoting tailored approaches to disease prevention and individualized drug therapy, based on the individuals' genetic profile. However, adoption of these technologies in public health is challenged by the possibility of health disparities. Health Impact Assessment (HIA) is a useful tool to address this issue, by examining how policies differentially impact population groups, guiding stakeholders to more equitable and inclusive outcomes. Solid frameworks for assessing health impacts are needed to avoid heterogeneity when accounting for equity outcomes in HIA. This study tested a conceptual model for HIA in personalized medicine, using a case study in pharmacogenetics to map potential impacts and outcomes, with a focus on health equity.

Methods: A conceptual model for a HIA was developed to map expected impacts and outcomes of a health policy, aimed at enforcing DPYD genotype-guided dosing to prevent fluoropyrimidine toxicity in colorectal cancer patients. The conceptual model was developed based on literature reviews and consultation with stakeholders. Identification of relevant impacts guided selection of indicators and quantitative impact assessment using a Markov chain model.

Results: Impact pathways were identified using a three-tiered reference framework encompassing individual and population perspectives, organizational factors, and overarching health system considerations. The final diagram outlined key outcomes in four categories: health, organizational, economic and equity. HIA projections using this model were obtained for the DPYD testing policy.

Conclusions: In the rise of personalized medicine and pharmacogenomics, health inequalities challenges need to be addressed before implementation in healthcare. This study provided a novel HIA conceptual model for personalized prevention policies based on genomic information, with an emphasis on equity.

Key messages:

- HIA is an adequate tool to evaluate potential health inequalities resulting from personalized medicine policies in healthcare.
- This study provides a validated framework for HIA of personalized prevention policies grounded in genomic data.

Abstract citation ID: ckae144.1572
Frailty and quality of life in italian older adults: implications for public health interventions

Giulia Picardo

C Donnoli[1], V De Luca[2], V Formosa[1], G Picardo[1], A Aprile[1], E Carnevale[1], M Bisogno[1], M Chimienti[1], G Liotta[1], M Illario[2]
[1]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy
[2]Department of Public Health, University of Naples Federico II, Naples, Italy
Contact: picardogiulia@gmail.com

Background: The increasing focus on frailty in older adults underscores the significance of a timely multidimensional assessments and early detection to avert adverse outcomes. The primary aim is to integrate digital technologies, specifically online assessment tools, for the identification of frailty and the assessment of Quality of Life (QoL) in elderly individuals.

Methods: A nationwide multicentric study was conducted. Seven Italian centers and regions evaluated frailty in older adults residing in the community, through a prospective observational cohort study. The chosen questionnaires, Sunfrail+ and SF-12, were implemented through an easily accessible online tool, swiftly generating final scores for each test. The cross-sectional analysis included 503 older adults. The cut off to define a person "frail" is 3 positive alerts in Sunfrail baseline items, according to the literature.

Results: In this sample an average of 2.31 positive alerts were generated. Significant associations were established between the number of positive warnings and SF-12 physical and mental indexes, indicated by $X2=53.1$ ($p < 0.001$) and $X2=25.1$ ($p < 0.001$), respectively. The difference between two groups (frail and not frail) in relation to QoL is statistical significantly (U di Mann Whithney $p < 0.001$). Mean QoL mental and physical indexes are 46.3 and 39.3 in frailty group, versus 51.7 and 46.5 in non frailty group, respectively. The correlation is conceptually consistent: as frailty increases, QoL decreases.

Conclusions: The frailty assessment associated with the QoL assessment provides relevant information to monitor the impact of prevention interventions at community level. The assessment of frailty leads the prevention intervention whose impact could be assessed also through QoL tools. This study underlines a meaningful association between assessment tools, substantiated by conceptual correlations.

Key messages:

- Sunfrail and SF-12 are easily accessible online tool useful for identification of frailty and the assessment of Quality of Life (QoL) in elderly individuals.
- The older population in Europe is increasing a timely assessment of frailty must be a public health priority.

Abstract citation ID: ckae144.1573
A year of rapid reviews: evidence-based decision support for Austrian social insurances & hospitals

Reinhard Jeindl

R Jeindl[1], J Mayer-Ferbas[1], C Wild[1]
[1]Austrian Institute for Health Technology Assessment GmbH, Vienna, Austria
Contact: reinhard.jeindl@aihta.at

Background: The Austrian Institute for Health Technology Assessment (AIHTA) has supported the decisions of Austrian social insurance funds and hospital providers with rapid reviews since 2023. This summary of rapid reviews aims to provide insights on findings, as well as experiences and challenges of conducting the rapid reviews after one year.

Methods: We included all rapid reviews that were requested to the AIHTA team in 2023. For research questions that were withdrawn, the reasoning was documented. The completed rapid reviews were grouped into medical specialties, depending on the intervention analysed. The conclusions of the rapid reviews were presented in tabular form, with the strength of the available evidence classified as high, moderate, low or insufficient.

Results: The rapid reviews on interventions ($n = 9$) cover a variety of medical specialties (orthopaedics, gynaecology, neurology, physical medicine, ophthalmology, vascular surgery and dermatology). In three rapid reviews, the analysed evidence on the intervention was insufficient for benefit (compared to standard of care). In four rapid reviews, the evidence indicated a potential benefit with some limitations (e.g. indication-specific results, or minimal clinically important difference not clearly achieved). In two rapid reviews, the evidence indicated a potential benefit. For three topics, no rapid review was conducted (topic scope too broad for rapid review, change in prioritisation). Challenges include time constraints, as well as narrowing the research questions to be suitable for rapid reviews.

Conclusions: The overview of rapid reviews highlights evidence-based findings on medical interventions. Further steps include collecting feedback from inquirers, on the extent to which the evidence from rapid reviews was used to support the decision-making. Rapid reviews are a feasible tool but require continuous evaluation and further adaptation of methods.

Key messages:

- The rapid reviews to inform decision-making processes for Austrian social insurance funds and hospitals spanned multiple specialties and revealed varying levels of evidence.
- To improve the implementation of rapid reviews, and to overcome challenges of time constraints and narrowing down research questions, feedback from stakeholders should be collected.

Abstract citation ID: ckae144.1574
Indicators of the clinical utility of genetic or genomic testing: a scoping review

Angelica Valz Gris

A Valz Gris[1], A Pezzullo[1], T Diego[1], M Porcelli[1], M Di Pumpo[1], N Scarsi[1], WP3 PROPHET Collaboration Group[2,3,4], S Boccia[1]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Estonian Genome Centre, University of Tartu, Tartu, Estonia
[3]Department of Health Promotion, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
[4]THL, Helsinki, Finland
Contact: angelicavalzgris@gmail.com

Background: Genetic or genomic tests are the cornerstones of personalized prevention. Previous reviews primarily focused on theoretical frameworks rather than actual assessments and assessed dimensions rather than specific indicators within these dimensions. Our scoping review aimed to review the dimensions and the specific indicators measured in the published assessment reports of genetic or genomic tests.

Methods: We selected formal assessments of genetic and genomic test used for prevention through PubMed, Web of Science, Scopus, websites of 20 different organizations, Google, and Google Scholar. Also, through a separate analysis we identified ten comprehensive dimensions of clinical utility through an analysis of 30 theoretical frameworks for genetic and genomic tests. From the included assessments, we extracted all the indicators, clustering them based on the comprehensive dimensions.

Results: From 3054 unique references and 12000 grey literature search results, we collected 57 assessments, all from high income-countries (in Europe (53%) and North America (47%)). The assessment methods were HTA (42%), EGAPP (25%), ACCE (21%) and other (12%). 951 disease-specific indicators were extracted from the assessments. Analytic validity (60%), clinical validity (79%) clinical efficacy (79%), economic impact (58%) were the most common dimensions (had at least one indicator). However, only 12 assessments (21%) include indicators that compared health outcomes between tested and untested groups. Equity, acceptability, legitimacy, and personal value were evaluated in less than 15% of the documents.

Conclusions: Our study illustrate that, although dimensions such as equity and acceptability, are significantly emphasized in traditional evaluation frameworks, these are often not considered in the assessments. Additionally, our study has underscored a significant dearth of primary evidence concerning the clinical efficacy of these technologies.

Key messages:

- Our study highlights the prevalence of evaluations lacking indicators for equity, acceptability, and legitimacy dimensions and a lack of direct evidence of clinical efficacy.
- The catalog of indicators was openly provided as a resource for researchers and institutions working in evidence-based evaluations of personalized preventive healthcare.

Rapid health technology assessment to inform policy: a case study with respiratory syncytial virus

David Byrne

D Byrne[1], V Power[1], A Bergin[1], A Panaro[1], K Cardwell[1], C Teljeur[1], KA Walsh[1,2], P Harrington[1], M Ryan[1,3]
[1]Health Technology Assessment Directorate, Health Information and Quality Authority, Dublin, Ireland
[2]School of Pharmacy, University College Cork, Cork, Ireland
[3]Department of Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland
Contact: dabyrne@hiqa.ie

Background: Respiratory syncytial virus (RSV) can cause severe acute respiratory tract infection in infants and older adults. However, until recently, no immunisation interventions were available to reduce the burden of RSV disease in the general population. New health technologies have now been authorised in Europe for infants (a long-acting monoclonal antibody (nirsevimab) and a maternal vaccine (RSVpreF)), and two vaccines for adults aged $\geq$60 years (RSVPreF3 and RSVpreF). A rapid health technology assessment (HTA) was requested by the Irish Department of Health to support an interim decision on RSV immunisation.

Methods: The rapid HTA commenced in January 2024, and comprised description of technology, a summary of international practice, national and international epidemiology and burden of disease, and a costing analysis. The summary of international practice (including underpinning evidence) was undertaken rather than a systematic review of effectiveness and safety due to the rapidly changing evidence base and short timeline within which information was required.

Results: While new recommendations regarding immunisation against RSV are emerging internationally in response to recently authorised technologies, implementation and funding strategies are not currently widespread. Compared with a full HTA, a rapid HTA enabled an efficient and flexible approach to producing a high quality evidence synthesis to inform a temporary policy decision, taking approximately 6 months to complete rather than 12 months or longer. A full HTA is planned to inform long-term decision-making on this topic, but would not have been feasible to inform an interim decision.

Conclusions: This rapid HTA will inform a temporary decision on immunisation policy for a single RSV season in Ireland. Conducting a rapid HTA prior to a full HTA has enabled timely decision-making, with implications for Ireland's national healthcare system and people at risk of severe RSV-related disease.

Key messages:

- Innovations in immunisation against RSV are leading to changes in policy across Europe.
- Rapid HTA can support timely, evidence-based public health decision-making in a fast-evolving field.

Health Impact Assessment in Personalized Prevention: three applications on pharmacogenomic testing

Angelica Valz Gris

A Valz Gris[1], P Kannan[2], A Costa[3], M de Fátima Silva Lopes[3], ML Cardoso[3], A Pezzullo[1], D Tona[1], M Perola[2], AM Vicente[3], S Boccia[1]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]THL, Helsinki, Finland
[3]Department of Health Promotion, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
Contact: angelicavalzgris@gmail.com

Background: In recent years, literature on the efficacy of genetic and genomic tests has expanded, yet the impact of personalized prevention programs that include such tests remains understudied. Our study aims to test the use of the Health Impact Assessment (HIA) framework, traditionally applied in non-health policy evaluation, to assess the impacts of personalized prevention policies.

Methods: We selected a policy mandating dihydropyrimidine dehydrogenase (DPYD) genetic test use before prescribing fluoropyrimidine for colorectal cancer (CRC) patients. Three HIAs are being conducted in Italy, Portugal, and Finland to assess the applicability across different contexts. The assessment involves literature review, comparative risk modeling, and stakeholder interviews. Three national steering committees, comprising representatives from key interest groups and experts, will evaluate evidence to gauge policy impacts and offer recommendations.

Results: The potential impacts identified include CRC patients' outcomes, economic, organizational, patient experience, clinician workload, and equity. Preliminary results show a consensus in literature and national guidelines on the ability of the DPYD test to reduce adverse events and enhance the quality of life of CRC patients. However, the assessment reveals context-specific effects regarding equity, influenced by the prevalence of ethnic groups and variations in access to health services across regions. Differences also emerged on organizational aspects like the availability of resources such as laboratories and personnel. A lack of literature was observed on patient acceptability and clinician attitudes towards the test.

Conclusions: The use of HIA in personalized prevention might assist in identifying policy impacts often overlooked through the involvement of key interest groups in the assessment process. Such effort can further emphasize the significance of evaluating these programs while considering the geographical context.

Key messages:

- Our study innovatively applies the Health Impact Assessment framework to evaluate personalized prevention programs in pharmacogenomic, addressing a critical research gap.
- Preliminary findings underscore the importance of considering geographical factors in public health policy evaluation, highlighting nuanced context-specific effects.

A Personal Health Record for patients with multiple sclerosis: A 2-year evaluation study

Jiska Aardoom

J Aardoom[1], LN Van den Berg[1], LE Kiveron[1], ME van den Akker[2], E Hoitsma[3], NH Chavannes[1]
[1]Department of Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands
[2]Department of Biomedical Data Sciences, Leiden University Medical Center, Leiden, Netherlands
[3]Department of Neurology, Alrijne Hospital Leiden, Leiden, Netherlands
Contact: j.j.aardoom@lumc.nl

Background: Multiple sclerosis (MS) is a chronic disease impacting the central nervous system, affecting 2.8 million people worldwide. Effective self-management is crucial for treating chronic diseases, including MS. Personal health records (PHRs) show promise in supporting self-management, potentially empowering patients and enhancing their engagement in treatment and health. However, implementation challenges persist.

Objectives: This study aimed to) assess the feasibility and usability of the PHR according to patients and healthcare professionals (HCPs), and 2) evaluate implementation determinants, and exploring preliminary effects on a range of outcomes related to the quality, efficiency, and costs of care, as well as health-related outcomes.

Methods: A mixed-methods study was conducted in a Dutch hospital. Quantitative data from 80 patients and 12 HCPs were collected via questionnaires at baseline (T0), after one (T1) and 2 years (T2). Focus group interview were conducted at T2 with 7 patients and 4 HCPs.

Results: Most patients never logged in during the first year and logged in a couple of times during the second year, with 15 minutes per log-in session. The HCPs mainly logged in a couple of times per year, averaging six minutes per session. Patients' and HCPs' usability and satisfaction scores were below average and moderate respectively. Various facilitators and barriers were identified, including knowledge gaps, staff capacity issues, and ICT obstacles. No significant differences were found in preliminary effects. Qualitative data highlighted benefits in terms of gaining insight into health data but revealed challenges with log-in issues and information retrieval.

Conclusions: Implementation challenges hindered PHR adoption. The evolving nature of PHRs requires ongoing evaluation and adaptation to optimize their potential benefits. Utilizing a participatory design approach and a dedicated implementation team could enhance adoption and maximize benefits.

Key messages:

- A personal health record (PHR) for patients with MS was evaluated within the care setting of a Dutch hospital, demonstrating limited usability and moderate satisfaction.
- Diverse obstacles impeded the adoption and uptake of the PHR, but potential solutions lie in continuous development with a participatory design approach and dedicated implementation team.

Abstract citation ID: ckae144.1578

Right-Siting Care and Decongesting Specialist Outpatient Clinics - A Singapore Case Study

Cheryl Chong Zhiya

CZY Chong[1], RJR Chong[2], JJH Chng[2,3]
[1]Primary and Community Care Division, Ministry of Health, Singapore, Singapore
[2]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore
[3]National University Hospital, Pathology Department, Singapore, Singapore
Contact: cherylchongzy@yahoo.com

Issue: Globally, Specialist Outpatient Clinics (SOCs) face a growing burden due to rising chronic diseases. This strain on resources leads to long appointment wait times (LAWTs), delaying diagnoses and treatments. This is particularly of concern in countries with rapidly ageing populations such as Singapore.

Description: The Right-Site Care Program is a healthcare transformation initiative implemented by individual healthcare clusters within Singapore to improve access to timely SOC care by directing patients to the most appropriate care level (right-siting). This transitions stable chronic disease patients to primary care providers (PCPs) for ongoing management. A standardised approach utilises evidence-based guidelines for patient selection, followed by identification and transfer of suitable patients to PCPs. This multi-center program offers a real-world example of healthcare system optimisation for chronic disease management.

Results: A multi-source data analysis, including program reports and peer-reviewed studies from participating healthcare clusters, was conducted to evaluate program impact. The analysis focused on LAWTs, patient outcomes and implementation challenges. Right-siting yielded mixed results across various conditions. Right-sited patients had better survival rates, likely due to closer monitoring and management of chronic conditions with higher total outpatient attendance frequencies. (1) Improvements were particularly significant for diabetes mellitus patients who successfully transitioned to PCPs. (2) However, challenges such as patient scepticism about PCP competence and a preference for specialist care have been identified. (3)

Lessons learned: Right-siting care can improve patient outcomes for certain chronic diseases. The program's impact varied across different chronic diseases, highlighting the need for tailored strategies. Educational interventions addressing patient concerns can facilitate smoother patient transitions and program success.

Key messages:

- Right-siting care shows promise, with improved patient outcomes for conditions like diabetes mellitus.
- Patient education is crucial to overcome patient scepticism and preference for specialists.

Abstract citation ID: ckae144.1579

Impact of COVID-19 on cardiology and neurology services in a peripheral hospital in Northern Israel

Tomer Bernstine

T Bernstine[1], S Spitzer[1], R Pleban[1], A Ron[3], A Armon-Omer[2], I Kains[1], J Hamudi[2], R Shahien[1,2], M Edelstein[1,2]
[1]Bar Ilan University, Safed, Israel
[2]Ziv Medical Center, Safed, Israel
[3]Independent Consultant, Rosh Pinna, Israel
Contact: tomerbernstine@gmail.com

Background: The indirect impact of COVID-19 pandemic on clinical services remains incompletely described in secondary care hospitals outside major urban centers. We compared clinical outcomes before and during the pandemic in a disrupted service (Neurology) and a non-disrupted one (Cardiology) in a peripheral hospital in Israel, using Cerebral Vascular Accident (CVA) and ST-elevation myocardial infarction (STEMI) as clinical indicators, respectively.

Methods: We compared demographics, treatment and outcomes from CVA and STEMI patients who attended Ziv Medical Center, Israel, during the pandemic (15/3/2020-15/4/2022) and before (1/1/2018-14/3/2020), Using chi-square, t-test and Wilcoxon-Mann-Whitney tests.

Results: 1029 CVA and 497 STEMI patients were included. Those who arrived during the pandemic were demographically comparable to those arriving before. Compared to pre-pandemic, intra-pandemic median time for CVA patients from arrival to imaging was longer (23 vs. 19 minutes, $p = 0.001$). However, timing from arrival to tissue Plasminogen Activator administration was similar (49 vs. 45 min, $p = 0.61$). The likelihood of transfer to another hospital was higher (20.3% vs. 14.4% $p = 0.01$) and median length of stay (LOS) was shorter (3 vs. 4 days, $p < 0.05$). Among STEMI patients, median time from arrival to percutaneous coronary intervention during the pandemic was shorter than before (45 vs. 50 minutes $p = 0.02$) and median ejection fraction at discharge was higher (50% vs. 45% $p = 0.02$). Mean LOS was shorter (3.86 vs. 4.48 $p = 0.01$), and unplanned re-admission to the ED was less frequent (7.8% vs. 14.6% $p = 0.01$). No significant changes in mortality were observed.

Conclusions: Our data shows no major negative impact of the COVID-19 pandemic on CVA and STEMI outcomes, and possibly improved care in the less disrupted department. Follow-up qualitative studies with neurology and cardiology staff already in action to comprehend how quality of care was maintained during the crises.

Key messages:

- In peripheral setting, COVID-19 hadn't negatively impact Neurology or Cardiology acute clinical outcomes.
- The consequences of maintaining clinical performance when working under adverse conditions requires further research.

Abstract citation ID: ckae144.1580

Oncofertility in primary health care: the role of the Portuguese family doctor

Gustavo Monteiro

GP Monteiro[1], M Carvalhinho[2], H Amorim[1]
[1]USP, ULS Entre Douro e Vouga, Santa Maria da Feira, Portugal
[2]USF Águeda Mais Saúde, ULS Região de Aveiro, Águeda, Portugal
Contact: gustavonpmonteiro@gmail.com

Background: The increasing number of cancer cases diagnosed at young ages and the impact of the disease and treatments on reproductive function have led to the development of Oncofertility. While oncologists typically lead these discussions, family doctors, as primary care providers, also play a crucial role. This study aims to assess family doctors' knowledge, attitudes, and practices regarding fertility preservation in cancer patients.

Methods: This cross-sectional study, conducted between April 2023 and March 2024, surveyed 351 General and Family Medicine doctors from the Portuguese Northern Regional Health Administration. The questionnaire, consisting of 15 questions, assessed sociodemographic profiles, knowledge, attitudes, and practices. Data were analyzed using descriptive statistics and multivariate logistic regression.

Results: Most participants were female (80.5%) and under 40 years old. The majority (91.5%) had treated fewer than 10 cancer patients under 40 in the past two years. Key barriers included lack of knowledge (63.3%), time constraints (57.0%), and patient age (18.5%). Male physicians were more likely to address specific fertility concerns (OR 2.239) and less likely to view patient age as a barrier (OR 0.459). Physicians aged 31-35 were less likely to discuss fertility preservation (OR 0.553) but more likely to address it in the first consultation (OR 2.969). Urban-based physicians were less likely to discuss fertility preservation (OR 2.099). Only 9.1% always discussed fertility preservation before treatment, 27.6% did so sometimes, and 63.3% never discussed it.

Conclusions: There are significant gaps in the knowledge and practices of family doctors regarding fertility preservation for cancer patients. Targeted training and resources are urgently needed to support family doctors in effectively discussing fertility preservation, crucial for improving the quality of life of young cancer patients wishing to preserve their fertility.

Key messages:

- Empowering Portuguese family doctors to address fertility concerns in cancer patients contributes to comprehensive oncofertility care, improving patient outcomes and quality of life.
- Integrating oncofertility support with Portuguese family doctors strengthens primary care, ensuring discussion of fertility preservation is considered as part of cancer treatment planning.

Abstract citation ID: ckae144.1581

Barriers to young people's use of sexual and reproductive health services in Asia-Pacific

Watcharakorn Riabroi

W Riabroi[1], B Gregory[2], D Mackay[1], E Germeni[2]
[1]Public Health, School of Health and Wellbeing, University of Glasgow, Glasgow, UK
[2]HEHTA, School of Health and Wellbeing, University of Glasgow, Glasgow, UK
Contact: w.riabroi.1@research.gla.ac.uk

Background: Qualitative literature extensively documents young people's barriers to accessing sexual and reproductive health (SRH) services in Asia-Pacific countries. However, efforts to synthesise this research for practical use in healthcare policy and practice are lacking. This systematic review aims to systematically review and synthesise published qualitative literature focusing on young people's utilisation of SRH services and understanding common access barriers.

Methods: We systematically searched five electronic databases from inception until 24 June 2022: MEDLINE, EMBASE, PsycINFO, CINAHL, and Web of Science. Google Scholar and reference lists of all included studies were also searched. We used the Critical Appraisal Skills Programme (CASP) checklist for appraising the quality of included studies and analysed the data using a thematic synthesis approach.

Results: We included 31 papers reporting the experiences of over 1800 young people from 16 Asia-Pacific countries. Thematic synthesis identified several factors affecting adolescents' utilisation of SRH services, which were grouped into six descriptive themes: navigating puberty; lack of SRH knowledge; embarrassment and confidentiality concerns; low decision-making autonomy; traditional practices and religious beliefs; and socio-cultural norms. Our overreaching analytical theme highlighted the role of shame as a key emotion hindering young people's utilisation of SRH services.

Conclusions: Direct communication about SRH issues is crucial for teenagers. Embarrassment, privacy concerns, and stigma significantly affect their service utilisation decisions. Inclusive interventions for both youth and their communities by addressing socio-cultural factors are essential for optimising service accessibility and guiding evidence-based interventions and policies across diverse cultural contexts.

Key messages:

- Understanding young people's SRH service barriers in Asia-Pacific countries: Socio-cultural norms are highlighted as crucial for optimising service utilisation among young individuals in this area.
- Inclusive interventions and policies are needed for enhanced accessibility.

Abstract citation ID: ckae144.1582

Early exposure to (hetero)sexism in medical settings: young patients' experiences with gynaecology

Céline Miani

C Miani[1], M Ouma[1], A Alaze[1]
[1]Bielefeld University, Bielefeld, Germany
Contact: celine.miani@uni-bielefeld.de

Background: Gynaecology is a highly gendered specialty where gender norms are particularly susceptible to shape patient-provider interactions. Consultations about contraceptive practices, reproductive choices, and sexual activity are fertile settings for the potential confrontation of different sets of gender-related expectations, and the expression of gender-based discrimination, i.e. sexism and heterosexism. We therefore investigated young patients' first experiences with gynaecological care in Germany with a focus on their experiences of (hetero)sexism.

Methods: We conducted 15 qualitative interviews with a gender-inclusive sample of patients aged 16-25 who narrated their first consultations and experiences of gynaecological care. We analysed the data thematically.

Results: Cis-gender heterosexual women composed the majority of the sample; a trans man and two persons who reported being at some point in same-sex relationships were also included. The main reasons for a first consultation were painful periods and contraception. Participants narrated examples of gender-based discrimination, with providers making what was perceived as gender-insensitive, demeaning, or plainly homophobic remarks. Those were particularly present in relation to conversations about the contraceptive pill, with either providers refusing to prescribe it on the account that the patient didn't have sex or "real sex" (i.e. heterosexual intercourse) or with providers pushing for use of the pill "just in case", even when patients didn't need nor want it. Additionally, sexist, unrequited arguments about how the pill could enhance a patient's breast or skin occurred in several conversations.

Conclusions: Our study shows clear occurrences of (hetero)sexism on the part of gynaecologists, from demeaning comments to more subtle reminders of sexist gender norms. It highlights the need to implement more patient-centred, gender-sensitive gynaecological practise to support the promotion of respectful care.

Key messages:

- Young patients are exposed to various forms of gender-based discrimination in gynaecological care in Germany, highlighting how entrenched traditional, (hetero)sexist gender norms are among providers.
- Promoting more gender-sensitive, respectful care could start with a reflection on consultations around the contraceptive pill, as they often crystallise the manifestation of damaging gender norms.

Abstract citation ID: ckae144.1583
Hemato-oncology services and COVID-19 Pandemic: The experience of Kazakhstan

Maral Yerdenova

M Yerdenova[1], *A Myrkassymova*[1], *B Iskakova*[1], *A Izekenova*[1], *A Izekenova*[2], *A Bukharbayeva*[1], *G Mergenova*[1,3]
[1]Kazakh National Medical University, Almaty, Kazakhstan
[2]Kenzhegali Sagadiyev University of International Business, Almaty, Kazakhstan
[3]Global Health Research Center of Central Asia, Almaty, Kazakhstan
Contact: maralyerdenova@gmail.com

Objectives: The COVID-19 pandemic in Kazakhstan disrupted numerous healthcare services, including those critical for hemato-oncology patients, due to the strained healthcare system. This study examines how the COVID-19 pandemic has affected access to hemato-oncology healthcare services in Almaty, Kazakhstan.

Methods: We retrospectively analyzed patient data from two tertiary centers, City Clinical Hospital 7 (H7) and Kazakh Institute of Oncology and Radiology (KazIOR), from March 1, 2019, to February 28, 2022. Variables included age, gender, residence, hospitalization rate, treatment outcomes (discharged/deceased/transferred), diagnoses (acute leukemia, lymphoproliferative diseases, myeloproliferative diseases), and referral sources. The Statistical Yearbook of Kazakhstan provided comparative data.

Results: From 2019-2022, 6,763 hemato-oncology hospitalizations were registered: 3,583 in H7 and 3,180 in KazIOR. The mean age was 55.04 (SD = 16.07) for females and 51.2 (SD = 16.7) for males. Urban and rural patient proportions were 6,191 (92%) and 571 (8.4%), respectively (Chi-square 13.8, P = 0.001). Fewer patients were discharged in 2020-2021 (n = 2,047) compared to 2019-2020 (n = 2,387) and 2021-2022 (n = 2,081) (Chi-square 20.09, P = 0.003). The death rate was higher in 2020-2021 (3.5%) than in 2019-2020 (3.2%) and 2021-2022 (2.6%) (Chi-square 20.09, P = 0.003). Emergency admissions were 403 (19%) in 2020-2021, 368 (14.8%) in 2019-2020, and 394 (18.3%) in 2021-2022 (Chi-square 2,231, P < 0.001). Transfers from other hospitals increased by 12.4% in 2020-2021.

Conclusions: The COVID-19 pandemic negatively impacted access to hemato-oncology services, increasing mortality. Further studies are needed to understand the factors affecting hospitalization and mortality trends during healthcare crises. Funding: Grant No. AP09260497.

Key messages:

- Access to healthcare services during COVID-19 pandemic for hemato-oncology patients.
- Impact of the pandemic on access to healthcare.

Abstract citation ID: ckae144.1584
Primary clinics achieving regular follow-up of patients: Teamwork aspects among healthcare staff

Maram Khazen

M Khazen[1], *A Golan Cohen*[2], *AJR Rose*[3]
[1]Public Health Systems, The Max Stern Yezreel Valley College, Emek Yezreel, Israel
[2]Leumit, Leumit Healthcare Services, Tel Aviv, Israel
[3]Braun School of Public Health, Hebrew University, Jerusalem, Israel
Contact: maramk@yvc.ac.il

Backgrounds: Studies have shown that more temporally regular primary care visits, or visits more evenly spaced in time, are associated with improved patient outcomes. However, no study has examined what clinic staff can do to encourage greater temporal regularity (TR). We aimed to understand factors related to healthcare staff dynamics that contribute to higher TR for adults with chronic conditions.

Methods: The study is part of a two-stage mixed methods project. In the first stage, we ranked clinics according to their TR level. In this qualitative stage, we interviewed staff at 6 clinics with extremely high TR (regular follow-up with primary care physician, or PCP), and 6 clinics with extremely low TR. Interviews were conducted with 15 PCPs, 12 nurses, 15 administrative staff, and 4 pharmacists between July 2022- September 2023. Interviews were audiotaped, transcribed, and analyzed using Atlas qualitative analysis software.

Findings: Themes emerged regarding best ways to promote regular follow-up of patients with chronic conditions. Strategies included having a defined system to reach out to no-show patients, having routine staff meetings to discuss no-shows, adapting workflow to meet the needs of challenging patients, dealing with bureaucracy on patients' behalf, informal channels of communication with patients, and consulting social workers more often. Relational aspects among staff members at high TR clinics emphasized flat as opposed to hierarchical relationships, as well as high levels of teamwork.

Conclusions: Teamwork between staff members in primary care settings can contribute to more proactive care delivery, with greater potential to prevent long-term complications. The findings suggest that a high-functioning multidisciplinary care team that focuses on creating the right sorts of interactions and teamwork among staff members, and uses proactive strategies to help engage patients, can contribute to more temporally regular care and thus improved outcomes.

Key messages:

- Stronger teamwork and flat relationships between staff members in primary care settings can result in proactive medicine and developing strategies that improve patients' regular follow-ups.
- Programs focusing on how medical staff utilize their dynamics/relations to improve health outcomes and how doctors' role align with the staff, can facilitate regular follow-ups of challenging patients.

Defining medical deserts—an international consensus-building exercise

Monica Brînzac

MG Brînzac[1,2,3], E Kuhlmann[4,5], G Dussault[6,7], MI Ungureanu[1,3], RM Chereches[1], CO Baba[1]

[6]IHMT, Lisbon, Portugal
[7]WHO-CC for Health Workforce Policy & Planning, Lisbon, Portugal
Contact: monica.brinzac@publichealth.ro

Background: Medical deserts represent a pressing public health and health systems challenge. The COVID-19 pandemic further exacerbated the gap between people and health services, yet a commonly agreed definition of medical deserts was lacking. This study aims to define medical deserts through a consensus-building exercise, explaining the phenomenon to its full extent, in a manner that can apply to countries and health systems across the globe.

Methods: We used a standard Delphi exercise for the consensus-building process. The first phase consisted of one round of individual online meetings with selected key informants; the second phase comprised two rounds of surveys when a consensus was reached in January 2023. The first phase-the in-depth individual meetings-was organized online. The dimensions to include in the definition of medical deserts were identified, ranked and selected based on their recurrence and importance. The second phase-the surveys-was organized online. Finally, external validation was obtained from stakeholders via email.

Results: The agreed definition highlights five major dimensions: 'Medical deserts are areas where population healthcare needs are unmet partially or totally due to lack of adequate access or improper quality of healthcare services caused by (i) insufficient human resources in health or (ii) facilities, (iii) long waiting times, (iv) disproportionate high costs of services or (v) other socio-cultural barriers'.

Conclusions: The five dimensions of access to healthcare: insufficient human resources in health or; facilities; long waiting times; disproportionate high costs of services and; other socio-cultural barriers, ought to be addressed to mitigate medical deserts. The term medical deserts might not be the most appropriate term for defining areas with insufficient access to health services as it excludes essential domains, such as access to public health and preventive services.

Key messages:

- Medical deserts directly and negatively impact the health outcomes of the people living in it.
- Medical deserts might not be the most appropriate term for defining areas with insufficient access to medical services, as it excludes public health and preventive services.

Abstract citation ID: ckae144.1586
GIS and statistics to analyze scale change consequences on medical desert classification in France

Cindy Padilla

C Padilla[1], M Bonal[2], G Chevillard[2], V Lucas-Gabrielli[2]

[1]RSMS, EHESP, Rennes, France
[2]IRDES, IRDES, Paris, France
Contact: cindy.padilla@ehesp.fr

Background: Accessibility is a crucial way to overcome geographical restrictions and provides a path for alleviating the medical desert. Less attention has been paid to the choice of spatial unit in the effect of healthcare multi-accessibility. Inside the OASES European program, the France team proposes to create medical desert classification at the municipality level. The contribution of this study is to highlight the consequences of the choice of spatial scale on spatial distribution and the discrepancies between medical desert classifications.

Methods: Analyses were carried out in metropolitan France and overseas departments, at the commune scale and two other supra-communal scales used by public policies in France. For each spatial unit, a multidimensional and professional classification has been conducted using a three-step method: scores, principal component analysis and clustering. To demonstrate the presence of spatial dependence and to measure homogeneity between classifications joint count autocorrelation indicators and Theil's indexes were applied.

Results: Our results present 7 classes of municipalities, and 5 classes of EPCI or living territories according to their level of healthcare accessibility, the dynamic of supply, and the needs of the population. Spatial representation of the classification demonstrates greater variability at the municipality level than other supra scales. Informative contrasted classes at the municipality level disappeared in favor of the middle class in all accessibility at supra scales. The results demonstrate that spatial dependence between areas at the municipality level reduced the scale effect.

Conclusions: Spatial approaches have become increasingly popular since they enable decision-makers to identify priority areas and allocate resources. Recognizing the instability across various scales is therefore crucial for thinking about the optimal unit of data aggregation when investigating the medical desert.

Key messages:

- Choice of the scale is a mix between public policy decisions and data availability.
- Contiguity constraint is a way to reduce the loss of information after aggregation.

Characteristics of applicants with a first-time recognition of need for long-term care

Susanne Schnitzer

S Schnitzer[1], C Haeger[1], T Baldenius[2], K Jürchott[2], A Kuhlmey[1], A Schwinger[2], S Blueher[1]

[1]Charité, Department of Medical Sociology and Rehabilitation Science, Charité, Berlin, Germany
[2]WidO, Scientific Institute of AOK, Health Insurance, Berlin, Germany
Contact: susanne.schnitzer@charite.de

Background: The increasing number of care-dependent individuals requires approaches to prevent care dependency or reduce loss of independence. Long-term care assessments can provide valuable insights into this. In Germany, the Medical Service is responsible for the long-term care assessment (care level) that focuses on limitations in independent living.

Objectives: The aim of this contribution is to describe initial applicants with identified need for long-term care.

Materials and methods: The nationwide database consists of long-term care assessments conducted by the German Medical Service of health insured people aged 60 and above who received a care level (1=smallest till 5= largest limitations) for the first time in 2021. Long-term care-relevant information is analyzed descriptively.

Results: 339,486 individuals with an average age of 79.6 years (SD: 8.4) were analyzed. The age distribution shows that the 80-89 age group comprises half of the sample (49.9%), whereas those aged 90+ encompass the smallest proportion of the sample (9.3%). More women than men received a care level (59.0% women vs. 41.0% men), with women predominant in care level 1-2 and men in the higher care level 3-5. Overall, approximately half of the sample received care level 2, 32.4 % received care level 1. Care levels 3-5 were assessed less frequently (16.2 % vs. 4.8 % vs. 1.7 %). The most frequent care-relevant diagnoses were senility (R54), polyarthrosis (M15), and dementia (F03).

Conclusions: Over three quarters of initial applicants are classified into the lowest care levels (1 and 2). Accordingly, tertiary prevention measures are recommended, as these may delay the further progression into a higher care level.

Key messages:

- Over three quarters of initial applicants for long-term care are classified into the lowest care levels. Accordingly, tertiary prevention measures may recommended to delay further care progression.
- The most frequent care-relevant diagnoses were senility (R54), polyarthrosis (M15), and dementia (F03).

Rehabilitation delivery models to foster healthy ageing - a scoping review

Roxanne Maritz

R Maritz[1,2], *V Seijas*[1,2,3], *P Fernandes*[4], *RM Bernard*[3], *LH Lugo*[5], *J Bickenbach*[1,2,3], *C Sabariego*[1,2,3]

[1]Center for Rehabilitation in Global Health Systems, University of Lucerne, Luzern, Switzerland

[2]Faculty of Health Sciences and Medicine, University of Lucerne, Luzern, Switzerland

[3]Swiss Paraplegic Research, Nottwil, Switzerland

[4]Department of Clinical Medicine, Federal University of Parana, Parana, Brazil

[5]Rehabilitation in Health Research Group, University of Antioquia, Medellin, Colombia

Contact: roxanne.maritz@unilu.ch

Background: Rehabilitation is crucial for healthy ageing among older adults, who face heightened risks of non-communicable diseases, infections, injuries, and mental health issues. Yet, understanding tailored rehabilitation for this demographic remains limited. To fill this gap, we conducted a scoping review to identify rehabilitation delivery models targeting older adults' functioning and healthy ageing.

Methods: We systematically searched Medline and Embase (January 2015 to May 2022) for English-language studies on rehabilitation approaches for older adults. Three authors independently screened records for eligibility and synthesized findings through quantitative and qualitative analysis.

Results: Among 6,933 records, we assessed 585 articles, identifying 283 studies with 69,257 participants. Six main rehabilitation delivery models emerged, with outpatient (24%) and telerehabilitation (22%) being predominant. Multidisciplinary teams (31.5%) often followed integrated care principles (30.4%). However, most studies adopted a disease-centric approach (59.0%), neglecting prevalent issues like pain, sensory impairments, incontinence, and sexual dysfunctions. Therapeutic exercises (54.1%) and self-management education (40.1%) were common interventions.

Conclusions: Our scoping review outlines diverse rehabilitation delivery models for older adults, highlighting gaps in addressing prevalent issues and emphasizing evidence-based strategies to promote healthy ageing. It underscores the need for systematic functional assessment and expansion of rehabilitation programs to cover prevalent health concerns. While limitations include reliance on published research and not assessing model effectiveness, this review lays groundwork for future research and innovation in rehabilitation and healthy ageing.

Key messages:

- The scoping review identifies six rehabilitation delivery models for older adults.
- The scoping review advocates for evidence-based strategies for enhancing healthy ageing through rehabilitation.

TB Care in Ukraine: Understanding Access Barriers at the Primary Healthcare Level

Mariia Samko

A Boiko[1], *U Snidevych*[1], *V Odrynskyi*[1], *M Duda*[1], *P Pavlenko*[2], *B Hinchey*[1], *N Avaliani*[1], *E Polomoshnova*[1], *M Samko*[1], *A Tokar*[1]

[1]USAID Health Reform Support, Kyiv, Ukraine

[2]Office of Health USAID Regional Mission to Ukraine, Kyiv, Ukraine

Contact: msamko@hrs.net.ua

Background: In the WHO European Region, Ukraine is a high-priority country for TB control, being one of nine globally with high rates of multidrug-resistant TB. The WHO emphasizes patient-centered TB care, prioritizing patients as key figures in the care continuum. Thus, our aim was to explore barriers impacting the accessibility of TB services for patients at the primary healthcare level (PHC) in Ukraine.

Methods: During December 2022-June 2023, a qualitative study was conducted across eight PHC facilities in the Kyiv, Odesa, Mykolayiv, and Volyn regions. The study comprised: 4 focus groups involving 27 family doctors, 16 in-depth interviews with managers and health authorities from regional and national levels, as well as 25 interviews with TB patients. All data was transcribed, manually coded and deductively analyzed.

Results: All participants highlighted the benefits for patients of providing TB care continuum at the PHC level, yet the program lacks clear requirements for training of family doctors and nurses. Overall family doctors perceived positively various TB training they received; but despite this, they expressed doubts and reported a lack of practical skills, affecting the quality of care provided. Patients highlighted several barriers in interacting with healthcare providers, including stigma and cases of dismissive behavior of healthcare workers, communication challenges, and breaches of patientś data confidentiality. Patients also mentioned self-stigma, and perceptions of family doctors as poorly trained in TB. Still, patients who received healthcare services from the same family doctor "during long time" positively described their experience with TB services too.

Conclusions: Establishing robust patient-provider interaction at the PHC level can help overcome persistent barriers to TB care continuum in Ukraine. To achieve this, a comprehensive TB training program tailored for PHC family doctors and nurses should be developed and implemented.

Key messages:

- Expanding TB healthcare services to primary healthcare levels in Ukraine can be beneficial for patients. Training primary healthcare staff can enhance TB care quality.
- Establishing robust patient-provider interaction at the PHC level can help overcome persistent barriers to TB care continuum in Ukraine.

Organisation of medical care in large scale incidents: a practice-oriented research in Belgium

Marie Dauvrin

J Cornelis[1], *M Dauvrin*[1], *A Desomer*[1], *S Gerkens*[1], *C Primus-de Jongh*[1], *W Christiaens*[1]
[1]Belgian Health Care Knowledge Centre, Brussels, Belgium
Contact: marie.dauvrin@kce.fgov.be

Background: CBRNe incidents are emergency situations involving the release of chemical (C) or biological (B) substances or radiological/nuclear (RN) contamination, sometimes through an explosion (e). They can result from intentional malicious acts (e.g. terrorism) or unintentional situations (e.g. accidents). In this context, people (victims, care providers, witnesses), equipment (infrastructure, vehicles), animals, objects and/or the environment (buildings, ambulances) may be contaminated by a substance that could pose a threat to health. CBRNe incidents can quickly overwhelm the response capabilities of the affected region and put the healthcare system under great pressure. This research investigated ways of improving the organisation of medical care in CBRNe incidents in Belgium.

Methods: this study involved a mixed method approach in 2022-2023 with scoping and in-depth interviews with actors at operational and strategic levels (public health, Internal Affairs, army, fire departments), participative workshops with stakeholders, contextual desk search, ad hoc literature review and international comparison completed with interviews with national experts (Norway, The Netherlands, France and United Kingdom, United States of America).

Results: hospitals need to be distinguished in type 1 specialized hospitals for decontamination, major trauma management and advanced care for severely burned patients and in type 2 hospitals managing spontaneous arrivals of victims and non-specialised care. All hospitals need to have a strict lock-down policy. On the incident site, an emergency medical mobile team needs to manage the decontamination with the firefighters before the transfer to the most appropriate facility. Additional conditions were found to improve the efficiency of medical care.

Conclusions: this practice-oriented research contributes to a better organization of medical care in case of CBRNe incidents, with the emergence of practical and feasible solutions.

Key messages:
- Hospitals need to be distinguished according to the need for specialised care in case of CBRNe incidents.
- On site decontamination needs to be performed by health professionals and firefighters.

Abstract citation ID: ckae144.1591
Innovations in residential treatment that promote multi-drug addiction recovery

Cheryl Currie

CL Currie[1], *M Swisterski*[1]
[1]University of Lethbridge, Lethbridge, Canada
Contact: cheryl.currie@uleth.ca

Background: As the drug addiction crisis deepens in many countries across the globe, governments are rapidly expanding publicly funded treatment facilities. At the same time, the illicit drug market has evolved with many substances now containing multiple addictive drugs that complicate recovery. The evidence base for treatment remains primarily focused on single substances. The purpose of this study was to examine the lived experience of adults who attended in-patient treatment centres for multi-drug addiction in Canada.

Methods: This qualitative study was conducted in 2022 with 32 adults who voluntarily attended an in-patient treatment centre for drug addiction (44% female, 23-53 years). All had been addicted to multiple substances including opioids, crack and methamphetamines. Most (70%) were homeless before treatment. In 1-hour semi-structured interviews adults described the structures and programming that helped them recover in these facilities. Many tried multiple facilities and thus had a rich history of lived experience to draw from. Narrative inquiry was used to characterize qualitative themes across interviews using a phenomenological lens.

Results: Seven qualitative themes emerged from the data. Residential treatment centres that were effective at helping adults recover from multi-drug addiction: (1) provided flexible stays up to 100 days; (2) felt like a home not a prison; (3) permitted opioid replacement therapies; (4) provided a variety of recovery tools (e.g., cognitive behavioural therapy, Narcotics Anonymous, cultural supports); (5) helped adults reunite with family, find a safe place to stay, and find work before discharge; (6) provided transitional housing after discharge if needed; and (7) provided free long-term recovery support and check-ins after discharge.

Conclusions: The findings of this study highlight 7 actions that treatment facilities can adopt and test with their own clients in an effort to better support multi-drug addiction recovery.

Key messages:
- A stronger evidence base is needed to inform in-patient multi-drug addiction treatment.
- Findings underline 7 actions treatment facilities can take to promote multi-drug addiction recovery.

Abstract citation ID: ckae144.1592
Trend of body mass index and its impact on glycemic control in Finnish patients with type 2 diabetes

Zhiting Wang

Z Wang[1], *P Lavikainen*[2], *K Wikström*[1,3], *T Laatikainen*[1,3]
[1]Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio, Finland
[2]School of Pharmacy, University of Eastern Finland, Kuopio, Finland
[3]Public Health and Welfare, THL, Helsinki, Finland
Contact: zhiting.wang@uef.fi

Background: Obesity prevalence has increased in Finland and is prevalent in patients with type 2 diabetes (T2D). Understanding the trend in body mass index (BMI) and its impact on glycemic control helps in the assessment of treatment strategies for T2D. We aimed to investigate the current trend in BMI among Finnish patients with T2D and the glycated hemoglobin (HbA1c) control across different BMI categories.

Methods: Regional data on electronic health records (EHRs) covering all public health care in North Karelia, Finland, were used. Patients with T2D (ICD-10 code E11) in 2012-2022 were identified from EHRs. In each study year, patients with ≥ 1 measurement of BMI and HbA1c were included in data analysis. Generalized estimating equations regression analyses were performed to evaluate the trends.

Results: The annual number of patients in the analyses ranged from 5149 to 10216 in 2012-2022. The unadjusted mean BMI remained stable. However, an increasing trend in BMI was observed in the age-adjusted model and remained unchanged with further adjustment for sex, duration of diabetes, and antidiabetic medication use, reflecting the aging of the patient population and lower BMI in aged patients. Patients with higher BMI had higher HbA1c levels in 2012-2022. The increasing trends in HbA1c over time were observed across different BMI categories (except for the obsess class III) accounting for age, sex, and duration of diabetes. However, a decreasing trend in HbA1c was found in the obese class III category with further adjustment for antidiabetic medication use, along with the highest usage rates of the new antidiabetic medications during the follow-up.

Conclusions: Our findings suggest that weight management requires increased attention in Finnish patients with T2D and is also important for better glycemic control. Multimodal treatment, including effective lifestyle counseling, self-care support, and medication management, is needed.

Key messages:

- More attention and resources are needed to achieve optimal weight control.
- Weight management could aid in better glycemic control.

Abstract citation ID: ckae144.1593
Trends in Regional Disparities of Cardiovascular Surgery and Mortality in South Korea

Dal-Lae Jin

D-L Jin[1,2], K-H Kim[3], ES Chung[4], S-J Yoon[5,6]
[1]Department of Health Policy and Health Management, Korea University of Graduate School, Seoul, South Korea
[2]Transdisciplinary Major in Learning Health Systems, Korea University of Graduate School, Seoul, South Korea
[3]Department of Health Administration, College of Nursing and Health, Kongju National University, Gongju, South Korea
[4]Department of Thoracic and Cardiovascular, Gangbuk Samsung Hospital, Seoul, South Korea
[5]Institute for Future Public Health, Department of Preventive Medicine, Seoul, South Korea
[6]Institute for Future Public Health, Graduate School of Public Health, Seoul, South Korea
Contact: jdlvalue@gmail.com

Objectives: Regional disparities in cardiovascular care in South Korea have led to uneven patient outcomes. Although procedure access and needs are increasing, few studies have linked regional service availability to mortality rates. This study analyzed variation in utilization of major cardiovascular procedures by region and association with short-term mortality to provide better evidence on links between healthcare resources distribution and patient survival.

Methods: A cross-sectional study was conducted using nationwide claims data on patients who underwent coronary artery bypass grafting (CABG), percutaneous coronary intervention (PCI), stent insertion, or aortic aneurysm resection in 2022. Regional variation was assessed by a Relevance Index (RI). The associations between regional RI and 30-day mortality were analyzed.

Results: The RI was lowest for aortic aneurysm resection (mean, 26.2; standard deviation, 26.1), indicating the most uneven regional distribution among the surgical procedures. Patients undergoing this procedure in regions with higher RIs showed significantly lower 30-day mortality (adjusted odds ratio [aOR], 0.73; 95% confidence interval, 0.55 to 0.96; $p = 0.026$) versus those with lower RIs. This suggests that cardiovascular surgery regional availability, as measured by RI, has an impact on mortality rates for certain complex surgical procedures. The RI was not associated with significant mortality differences for more widely available procedures like CABG (aOR, 0.96), PCI (aOR, 1.00), or stent insertion (aOR, 0.91).

Conclusions: Significant regional variation and underutilization of cardiovascular surgery were found, with reduced access linked to worse mortality for complex surgeries. Addressing disparities through cooperation among hospitals and policy efforts is warranted to improve outcomes.

Key messages:

- This study analyzed regional variations in major cardiovascular procedures using the Relevance Index and investigated their impact on mortality rates within 30 days of admission.
- Addressing regional disparities requires improved healthcare infrastructure and comprehensive networks of specialists to ensure timely and high-quality cardiovascular care across South Korea.

Abstract citation ID: ckae144.1594
Hospital policies as a tool to reduce gaps between ethnic groups of employees and patients

Amit Gur

A Gur[1], L Inchi[1]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
Contact: amitgu@yvc.ac.il

Background: As diverse organizations, hospitals require an inclusive culture that respects and promotes ethnic diversity. Violence, a threat to this diversity, hampers effective organizational functioning. Our study delves into the positive influence of cultural diversity policies and communication about violence on the perception of the hospital's atmosphere regarding ethnic differences among health employees. It enhances hospital labor relations and mitigates the risk of workplace violence.

Methods: 372 hospital employees with an average tenure of 6.5 and an average age of 38 filled out an online close-ended questionnaire (83% are Israeli Jews, 68% are female). 91% report working closely with people from different ethnic origins. Respondents ranked the atmosphere in the hospital regarding ethnic differences between employees and patients, the hospital's cultural diversity policy, and organizational communication about violence. Data were analyzed by SPSS 28.

Results: Positive correlations were found between variables. A positive atmosphere was significantly related to the hospital's cultural diversity policy ($r=.14$, $p=.002$) and to organizational communication about violence ($r=.22$, $p< .001$). However, the regression analysis (with control variables age, sex, and managerial role) revealed that despite employees acknowledging the hospital's efforts to address diversity and violence, these factors only predict 10% of the variance of the hospital atmosphere [$F(5, 366) = 8.346$, $p < .001$; $R^2=.10$].

Conclusions: The hospital should increase actions that will improve the ethnic atmosphere in the hospital. Understanding how the encounter, where employees and patients from diverse ethnic backgrounds interact, influences the hospital's atmosphere is crucial. These interactions can lead to tensions and offensive behaviors toward employees if not managed well. Hospitals can create an inclusive and harmonious work environment by addressing these tensions.

Key messages:

- A cultural diversity policy and communication are necessary to maintain harmonious working relationships. It is essential, particularly in health organizations characterized by ethnic diversity.
- Reducing the perception of ethnic differences may increase well-being and decrease violence. While hospitals often don't prioritize these issues, this study forefront their influence and importance.

Contact: tania.gaspar.barra@gmail.com

The hospital health care professionals are the frontline fighting COVID-19 considering they are responsible for all the care provided to patients during all the time they spend at the hospital for diagnosis, treatment or recovering of the COVID-19 disease and other diseases. The purpose of this study was to determine the impact of COViD-19 at the hospital management level and, also, to understand how psychosocial environment, and satisfaction of Health Professionals were affected. A case study was performed in a Portuguese Hospital. Data were collected at one hospital under study at two different occasions: the first before the pandemic (November 2019) and the second almost two years after the pandemic started (November 2021). Regarding data collection, 37.0% of participants responded in the occasion 1 (n = 296) and 63.0% responded in the occasion 2 (n = 503). The instrument for the Assessment of Global Management of Health Organizations (AGMHO) Comparing timings pre and during pandemic COVID-19, it was found that the participants in the pre- COVID-19 era showed stronger organizational culture, higher quality of life, better psychosocial environment regarding content/leadership and higher job satisfaction when compared to the participants during pandemic COVID-19. On the other hand, participants in the second occasion were found to have higher psychosocial risks related to mental health when compared to participants in the pre- COVID-19 phase. The results obtained allow us to identify priorities in terms of promoting well-being and satisfaction of professionals and overall well-being of the health organization, namely intervention in leadership relationships and psychosocial risks at work related to the physical and psychological demands of work, stress management and a more active and involved role for the professional.

Key messages:

- This knowledge facilitates labelling and prioritizing the promotion of well-being and satisfaction of professionals and overall well-being of the health organization.
- The product is a comprehensive diagnostic model of the factors influencing the results in health organizations.

Abstract citation ID: ckae144.1596
Using Unsupervised Learning Methods to Explore the Trajectory of Long-Term Care Service in Taiwan

Yu-Hung Chang

YH Chang[1], HH Lu[1], SC Chien[1], CM Yen[2], CY Lai[1], RH Chung[1], HY Chiou[1]
[1]Institute of Population Health Sciences, National Health Research Institutes, Zhunan Township, Miaoli County, Taiwan
[2]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei Township, Yunlin County, Taiwan
Contact: yuhungc@nhri.edu.tw

Background: Understanding the temporal trends in long-term care (LTC) utilization enables more effective planning by government and service providers. This study employed machine learning methods to explore LTC utilization trajectories among care recipients in a southern county of Taiwan.

Methods: Administrative data from the government-funded LTC programme was utilized, with a total of 24,614 participants included after excluding those with less than six months of data. Daily service utilization records, mainly focusing on caregiving services, were aggregated, and the number of days each participant used LTC services within every 30-day period post-application was calculated. Utilization rates during 6 and 12 months post-application were separately analyzed. K-means clustering, an unsupervised machine learning method, was employed to select the optimal classification and identify LTC utilization trajectories using 10-fold cross validation. Temporal frequency variations of each caregiving service within each trajectory group were visualized using heatmaps.

Results: In the analysis of LTC utilization within the first 6 months post-application, trajectories were classified into 7 groups; while within 12 months, trajectories were divided into 4 groups. These trajectories can be categorized into 4 distinct patterns: High-Stable (6 mo: 21.3%; 12 mo: 35.7%), Low-Stable (6 mo: 33.1%; 12 mo: 37.2%), High-Decrease (6 mo: 12.8%; 12 mo: 10.7%), and Low-Increase (6 mo: 32.7%; 12 mo: 16.5%). We further explored differences in socio-demographic characteristics and needs factors among trajectory groups. Heatmaps were used to illustrate temporal variations in the utilization rates of specific service items, which played a significant role in determining the trajectories.

Conclusions: K-means clustering is useful in identifying distinct patterns among LTC users. Tailored service delivery strategies can be designed to meet the diverse needs of these different user groups.

Key messages:

- The unsupervised machine learning method distinguished various temporal dynamic patterns in LTC utilization.
- Tailored service delivery strategies can be designed to meet the diverse needs of these different user groups.

Abstract citation ID: ckae144.1597
Making integration happen: managers' views on multidisciplinary work in Finnish health system

Soila Karreinen

S Karreinen[1], S Paatela[2], M Huhtakangas[3], H Paananen[4], M Satokangas[2,5], LK Tynkkynen[1,2]
[1]Faculty of Social Sciences, Tampere University, Tampere, Finland
[2]Welfare State Research and Reform, THL, Helsinki, Finland
[3]Department of Health and Social Management, University of Eastern Finland, Kuopio, Finland
[4]Faculty of Management and Business, Tampere University, Tampere, Finland
[5]Department of General Practice and PHC, University of Helsinki, Helsinki, Finland
Contact: soila.karreinen@tuni.fi

Background: In Finland, a large-scale health and social service reform was implemented in 2023. The structural reform centralised the organising of health and social services from some 200 organisations to 22 wellbeing services counties (WBSC). One goal of the reform was to promote service integration between and within health and social services. The reform offers a unique opportunity for investigating how such change unfolds. This study addresses the integration aspirations of those who are responsible for implementing the change, that is middle managers in WBSCs. We focus on micro and meso levels and explore how the aim of multidisciplinary collaboration is interpreted as part of advancing service integration by middle managers in one newly formed WBSC.

Methods: The data for this qualitative study were derived from 11 semi-structured interviews with senior and middle managers responsible for various fields of health and social care services in a single WBSC between October 2022 and June 2023. Inductive thematic analysis was applied.

Results: The managers framed multidisciplinary collaboration very positively and easier to achieve in the new organisation with health and social services united under the same management. The managers acknowledged the need to form collaborative structures (e.g. meetings) and processes at all levels of organisation. Leadership plays a crucial role in creating space for the professionals to form an experience of a shared every-day work. However, previous structures and patterns of work still seemed to limit these endeavours. Tensions between, for example, professional groups or units were left essentially untouched. Multidisciplinary collaboration will serve especially persons with complex and multiple needs and was framed key to cost savings.

Conclusions: While the structural reform opens a window of opportunity to new collaborative patterns, competing logics and interests as well as power imbalances may hamper the development if not addressed.

Key messages:

- Middle managers had high hopes for multidisciplinary work after the health system reform, including effects on the difficult issues concerning costs and health workforce availability.
- While the managers were prepared to promote multidisciplinary work, the prior organisational boundaries and logics hindered integration. Different tensions between stakeholders need more attention.

Abstract citation ID: ckae144.1598
Perspectives on collaboration in maternity and child health: Patients and caregivers' views

Anne Hermans

A Hermans[1]*, A Franx*[1]*, J Van der Kooy*[1]
[1]Obstetrics and Gynaecology, Erasmus Medical Center, Rotterdam, Netherlands
Contact: anne.c.m.hermans@gmail.com

Background: The World Health Organization promotes people-centred organization of maternity care and preventive child healthcare (PCHC). However, globally and in the Netherlands, these services often operate separately, causing care discontinuity. We posit that this disproportionately affects vulnerable patients, hindering tailored-care. Our aim is to explore how collaboration between healthcare providers is perceived by mothers and providers, and understanding challenges and needs for integration.

Methods: We conducted 14 semi-structured interviews with mothers ($n = 9$) and healthcare providers (midwives, PCHC caregivers, $n = 5$). Women were categorized as non-vulnerable, potentially vulnerable, or vulnerable based on social situation, enabling comparison of care experiences.

Results: We found that the experienced interprofessional collaboration varied; most non-vulnerable women perceived the interprofessional collaboration as sufficient, whereas women from the potentially vulnerable group were uncertain who to turn to when help was needed. They expressed a need for expectation management to know what to expect from different healthcare providers. Furthermore, they were confused about which healthcare domain (i.e., maternity care or PCHC) 'was in the lead' in the postnatal period. Healthcare providers expressed a need for mutual understanding of expertise to foster trust and ease transitions between maternity care and PCHC. Themes emerged: organizational structures, support levels for collaboration, and trust among providers.

Conclusions: Our findings suggest the necessity for governance and shared ownership in healthcare collaboration in the maternity care and PCHC continuum to meet the needs of potentially vulnerable women effectively.

Key messages:

- Experienced interprofessional collaboration varies among women based on vulnerability.
- Clear governance and shared ownership are crucial for meeting the needs of potentially vulnerable women in maternity and child health services.

Abstract citation ID: ckae144.1599
Healthcare in police custody: a conceptual framework for measuring and improving quality of care

Robert Verheij

ND Zinger[1]*, VN Slev*[2]*, RA Verheij*[1,3]*, I Bos*[1]*, DS Kringos*[4]
[1]NIVEL, Utrecht, Netherlands
[2]Department of Forensic Medicine, Public Health Service, Amsterdam, Netherlands
[3]School of Social and Behavioral Sciences, Tilburg University, Tilburg, Netherlands
[4]Amsterdam Public Health, Amsterdam UMC Location University of Amsterdam, Amsterdam, Netherlands
Contact: r.verheij@nivel.nl

Background: Individuals in police custody are often in poor (mental) health and can be in need of medical attention. The delivery of primary healthcare in police custody differs from other custodial and non-custodial settings, due to its short-term character and the reliance on custody officers and healthcare professionals to access care. Therefore, medical care for detainees in police custody requires its own standards and indicators to measure the quality of care. We aimed to develop a conceptual framework for (actionable) indicators to measure the quality of care for people detained in short-term police custody settings in the Netherlands.

Methods: We conducted a scoping review and consulted with experts. The scoping review involved Embase, Medline, PsycINFO, CINAHL, Criminal Justice Abstracts, PiCarta and Cochrane, and was supplemented with grey literature searches. We consulted twenty-seven stakeholders with a wide variety of expertise in the field of healthcare in police custody to discuss and validate the conceptual framework.

Results: The conceptual framework consists of 14 domains of structures (e.g. staff and facilities), processes (e.g. triage and coordination of care) and outcomes (e.g. effectiveness and satisfaction) that need to be considered when developing quality indicators for the healthcare provision in police custody. The scoping review yielded 68 publications providing information on common health issues and recommendations related to quality assurance or improvement.

Conclusions: The conceptual framework will guide the development of (actionable) quality indicators, which will be evaluated on relevance and measurability. These are crucial for monitoring care quality and enhancing a learning health systems approach. This study fills a gap in the existing scientific literature by shedding light on the factors contributing to the quality of primary healthcare provision for people detained in short-term custody settings.

Key messages:

- The conceptual framework guides the development of (actionable) quality indicators for healthcare in police custody.
- This study contributes to the creation of a learning health system for healthcare in short-term police custody settings.

Abstract citation ID: ckae144.1600
Developing regional Diabetes Registries in Italy: pilot projects implementation within JACARDI

Beatrice Formenti

B Armocida[1]*, G Cappai*[2]*, M Di Martino*[2]*, R Gnavi*[3]*, L Monasta*[4]*, M Pompili*[5]*, D Galeone*[6]*, LM Mariani*[6]*, B Formenti*[7]*, G Onder*[7]

[4]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Trieste, Italy
[5]Regional Health Agency, Marche Region, Ancona, Italy
[6]Directorate-General for Health Prevention, Ministry of Health, Rome, Italy
[7]Fondazione Policlinico Gemelli IRCCS and UCSC, Rome, Italy
Contact: beatriceformenti1992@gmail.com

Issue/Problem: In Italy a National Diabetes registry is planned but not yet set up at the Ministry; JACARDI is contributing to speed up the process so that critical gaps in health data availability can be filled. While some regional registries exist, the lack of cohesion and standardization hinders the tracking of prevalence, incidence, and sequelae, crucial for evidence-based policymaking amidst rising diabetes rates.

Description of the Problem: The JACARDI project, supported by EU funding and running for four years, engages 76 partners from 21 countries and includes 142 national-level projects. Among its focus areas is enhancing data availability, aiming to establish harmonized regional Diabetes registries in Italy to tackle this issue. These efforts aim to create a scalable model enabling data linkage, diabetes type differentiation, and socio-demographic integration. Collaboration with health authorities and societies, drawing insights from existing registries, informs the development process.

Results: A total of 11 regional Diabetes registries are currently in the design phase of implementation. They adhere to a clearly defined methodology, with established essential parameters and data linkage. Consensus on these parameters and linkage was reached through stakeholder discussions, drawing on past registry experiences. The primary goal of the registries is to monitor diabetes prevalence, stratify incidence by demographics, and track sequelae to inform targeted interventions and resource allocation. While scalability beyond Italy may encounter administrative challenges, standardized protocols facilitate transferability. Data Protection stands out as a significant implementation obstacle.

Lessons: Standardized data collection, stakeholder collaboration, and sustainability are vital in registry development. Leveraging data availability for surveillance demonstrates adaptability and scalability, offering valuable insights for enhancing diabetes management.

Key messages:

- Standardized data collection and stakeholder collaboration are pivotal in establishing effective diabetes registries, fostering equity and improving health outcomes.
- Leveraging data availability for surveillance offers a scalable and sustainable approach to diabetes management, facilitating informed policymaking and interventions.

Abstract citation ID: ckae144.1601
Plan for the crisis!

Background: The COVID-19-crisis has posed major challenges for organisations providing care in terms of fulfilling their contracts as well as maintaining their quality standards. This project aimed to analyse the implementation of gender and diversity sensitive crisis preparedness in health and social care organisations in Austria. The innovation of this project lies in the organisational crisis preparation including the interfaces of all organisations and actors involved in the care of a vulnerable person.

Methods: A comprehensive survey and analysis of existing structures and processes was carried out. A participatory approach was used to develop modular guidelines tailored to different crisis scenarios. This was followed by a detailed process analysis, integration of good practices and the creation of assessment tools for practical evaluation. Staff training and technology needs were identified, followed by an assessment of the applicability of the findings to other social sector organisations.

Results: This project created guidelines with modular structures that enable preparation for crises and their consequences. Thereby strategies for risk mitigation and good practice examples, e.g. from the COVID-19 pandemic, were developed. A self-assessment of the status of crisis preparation as well as the continuous monitoring with special consideration of the intersectional diversity of the target groups and their vulnerability was developed and made available on the web.

Conclusions: The project results in guidelines as well as a self-assessment and monitoring tool directly benefiting the participating organisations. Through its transferability to other organisations the project promotes overall crisis resilience and sustainably strengthens the care for vulnerable groups in times of crisis. In addition, solidarity-based help in crisis situations is promoted. The project promotes not only organisational, but also individual as well as macro-social and economic benefits.

Key messages:

- The project developed guidelines for gender and diversity sensitive crisis preparedness for health and social care organisations, including risk mitigation strategies and self-assessment/monitoring.
- Crisis preparation must be systematically implemented in health and social care organisations involved in care of vulnerable persons.

Abstract citation ID: ckae144.1602
The potential of non-clinical guidance alongside e-mental Health to overcome non adherence

Claudia Van Der Heijde

CM Van Der Heijde[1]*, CE De Bruijn-De Goffau*[1]*, P Vonk*[1]
[1]Student Health Services, University of Amsterdam, Amsterdam, Netherlands
Contact: c.m.vanderheijde@uva.nl

Background: Mental health problems account worldwide for over an eighth of the global burden of disease and waiting lists nowadays are commonplace. E-Health has potential to reduce mental illness, whilst waiting for therapy or as a stand alone. A big problem with implementation of E-health in clinical practice is non adherence. Non-clinical guidance could make a difference as compared to the non guidance modus. Our research question is: what factors contribute to the potential of non-clinical guidance in overcoming non adherence for e-mental Health for patients with depressive, anxiety and stress symptoms?

Methods: We did a qualitative study in a Dutch general practice. The treatment consisted of several modules accompanied by non-clinical guidance by a healthcare assistant. Out of 190 invited patients, 31 patients participated. Eight weeks after being invited, 11 semi-structured interviews were conducted until data saturation. Thematic analysis was used with open, axial and selective coding.

Results: Three major themes emerged: 1) The patients were satisfied with the non-clinical guidance in almost all aspects: Negative comments arose from an urge for more contact or tailoring. 2) The form of the guidance (e.g. non-clinical; used interface) was subordinate to the amount and tailoring of it. 3) Adherence could further be improved through a more personal introduction, explaining the benefits of certain exercises and more time management.

Conclusions: The potential of non-clinical guidance in overcoming non adherence for e-mental Health can be improved by further tailoring and increasing the interactivity when needed. Further research is also needed, after the suggested improvements, whether the intervention is effective, compared to a therapist guided and a non guided version. This study needs to be repeated in other clinical settings.

Key messages:

- Non-clinical guidance, alongside e-mental health has potential to help with non adherence, thereby decreasing the burden of waiting lists.
- Non-clinical guidance was positively received by patients who received e-mental health, although further tailoring could make online treatment even a larger success.

Abstract citation ID: ckae144.1603
Identifying gaps in health system governance to eliminate informal patient payments

Marzena Tambor

M Tambor[1], P Koufopoulou[2,3], DA Bygvraa[4], L Eklund Karlsson[5], S Buch Mejsner[6]
[1]Health Economics and Social Security Department, Institute of Public Health, Jagiellonian University, Cracow, Poland

[4]Department of Medicine, Sahlgrenska Academy, School of Public Health and Community Medicine, Gothenburg, Sweden
[5]Unit for Health Promotion Research, Institute of Public Health, University of Southern Denmark, Esbjerg, Denmark
[6]Department of Public Health, Aarhus University, Aarhus, Denmark
Contact: marzena.tambor@uj.edu.pl

Background: Informal patient payments continue to exist in many European countries. These payments might take various forms but can be broadly defined as any payments in addition to formal fees determined by the terms of entitlement. Poor health system governance is considered one of the main factors contributing to their presence, although different aspects of governance might be relevant in each country. The aim of this study was to develop an assessment instrument to help identify gaps in health system governance that contribute to informal patient payments.

Methods: The study has been performed in 2022-2023 in three stages. In the first step, relying on the TAPIC framework and available literature on informal patient payments, we developed a list of questions for each domain of governance: Transparency, Accountability, Participation, Integrity, Capacity. In the second step, the questionnaire was assessed by external experts to ensure it covers the full range of relevant aspects. We then applied the instrument to three European countries, i.e. Denmark, Greece, and Poland, where informal payments differ in scale.

Results: The developed instrument includes 22 questions in the five TAPIC domains. They particularly refer to the role of governance in eliminating underlying reasons for informal patient payments (poor quality of health care) and effective penalization of these payments. The application of the instrument showed that in two countries where informal payments are more common, i.e. Greece and Poland, quality and waiting time guarantees are poorly defined, monitored, and incentivized, while existing mechanisms only penalize payments proven to be bribes.

Conclusions: There is a broad range of health system governance aspects that can be directly or indirectly linked to informal patient payments. The proposed instrument can facilitate the development of long- and short-term policies to eliminate informal payments in European countries.

Key messages:

- Policy makers need to take greater account of the role of governance in ensuring health care quality to eliminate informal patient payments.
- The lack of mechanisms to penalize all types of informal payments may contribute to the commonness of these payments in Europe.

Abstract citation ID: ckae144.1604
Referral and disease patterns of patients treated at the Nicosia General Hospital Breast Centre

Georgios Nikolopoulos

M Papadopoulos[1], M Loizidou[1], C Giannopoulou[1], G Nikolopoulos[1], A Yiallourou[1,2]
[1]Medical School, University of Cyprus, Aglantzia, Nicosia, Cyprus
[2]Breast Center, Nicosia General Hospital, State Health Services Organisation, Nicosia, Cyprus
Contact: nikolopoulos.georgios@ucy.ac.cy

Background: Cyprus has one of the lowest mortality rates from breast cancer in Europe. The reasons behind this have not been investigated but it is speculated that the ease of access to Breast Centers in combination with an increased public awareness play a role. The aim of this study was to investigate referral and disease presentation patterns of patients treated at the Nicosia General Hospital (NGH) Breast Centre and define opportunities for effective public health interventions.

Methods: A retrospective study of all patients (585) with in situ or invasive breast cancer treated at the NGH Breast Centre between February 2017 and November 2023 was conducted. Data on referral sources, symptoms, and cancer stage at the time of diagnosis were analyzed using Stata 18.

Results: Most patients were referrals from the national population screening program (42.2%), followed by self-referrals (40.6%), and General Practitioner (GP)/or other specialist referrals (17.2%). Half of the patients (50.3%) were asymptomatic at diagnosis. In addition, 8% of the patients diagnosed with invasive breast cancer were Stage I, 65% Stage II, and 27% Stage III.

Conclusions: Our study provides important insights forming the basis of public health activities for the early detection of breast cancer based on the fact that 20% of newly diagnosed breast cancer cases in Cyprus receive treatment in NGH Breast Center. Although adherence to the national population screening program does not meet desired expectations, a significant proportion of breast cancers were detected via this program highlighting its effectiveness in early detection of asymptomatic cancers. A large proportion of patients were self-referred underlining the high degree of breast cancer awareness in Cyprus but also the media-induced anxiety which leads to early investigations.

Key messages:

- Screening program and breast cancer awareness campaigns are effective in detecting breast cancers early.
- These activities should be sustained to further reduce breast cancer mortality rate.

Abstract citation ID: ckae144.1605
Leaders' perceptions of integrating health and social services after a structural reform in Finland

Satu Paatela

S Paatela[1], S Karreinen[2], M Huhtakangas[3], LK Tynkkynen[1,2]
[1]The Department of Public Health and Welfare, THL, Helsinki, Finland
[2]Faculty of Social Sciences, Tampere University, Tampere, Finland
[3]Department of Health and Social Management, University of Eastern Finland, Kuopio, Finland
Contact: satu.paatela@thl.fi

Background: Health and social service system was reformed in Finland at the beginning of 2023. The responsibility for organizing health and social services was transferred from c. 300 municipalities to 22 well-being services counties (WBSCs). One aim of the reform was to support integration between and within health and social services. The purpose of this study is to describe strategic leadership approaches to implementing integrated care. The study highlights the issues that should be paid attention to when integrated care practices are implemented.

Methods: The qualitative study utilized semi-structured interviews collected from the upper-level leaders of the WBSCs (n = 25) responsible for the implementation of the reform. The interviewees represented 11 WBSCs. The data were collected in May-August 2023. Inductive content analysis was used for data analysis.

Results: Four strategic leadership approaches to implementing integration were identified: 1) service user-based leadership approach, 2) partnership-based leadership approach, 3) service system-based leadership approach, and 4) knowledge-based leadership approach. Most of the interviewees combined several different leadership approaches in their talk. Each approach emphasized different aspects of implementing integration and the contextual factors that have to be addressed at different levels of the health and social service system.

Conclusions: While the macro level reform toward more integrated health and social service system was implemented, the findings reveal that more efforts are required at the meso and micro levels of the system to fulfill the goal of integrated services. The paper highlights the importance of strategic leadership and its different aspects in implementing integrated care at different levels of the system.

Key messages:

- The paper provides a way of comprehending integration from the perspective of strategic leadership.
- The conceptualization through the different leadership approaches may facilitate forming a shared vision for integration among leaders and managers.

Abstract citation ID: ckae144.1606
Tackling health inequalities by creating new practices of integrated health access

Viola Burau

S Mejsner[1], *M Fehsenfeld*[1], *V Burau*[1]
[1]Department of Public Health, Aarhus University, Aarhus, Denmark
Contact: viola@ph.au.dk

Background: Health inequalities often emerge in-between health and social care sectors, as part of transitions between providers across the two sectors. Integrated health access is important for addressing these inequalities. Therefore, we need to understand processes of organising integrated health access and how these shape pathways of accessing care. We draw on sociological understandings of organising as practice that emerges as part of interactions between professionals and users.

Methods: We did observations of interactions between professionals and users ($n = 18$ days) and semi-structured interviews with users, professionals, and managers ($n = 33$) in the specialised mental health services in Central Denmark Region and FACT-inspired teams in 3 municipalities. We also conducted 3 focus groups with regional and municipal professionals from these teams. Data was analysed through a qualitative thematic analysis.

Results: Each team had distinct cultures of collaboration and different levels of cross-sectoral collaboration. Creating new, more integrated practices seemed to rely on both, supportive organisational structures and committed engagement in inter-sectoral spaces to change professional meaning systems. When teams were able to collaborate closely, it was easier to retain hard-to-reach users in treatment. However, professional differences could easily create division and therefore maintaining and building relationships were highly important. These mechanisms illustrate the importance of ensuring meaningful spaces for cross-sectoral work, where professionals can interact and create the needed changes.

Conclusions: Organising integrated health access is not merely about providing structures but is also highly dependent on interactions between professionals and users. Analysing interactions between professionals from across sectors, is important to understand the sustainability of integrated health access. In turn, this could help to tackle social inequalities in health.

Key messages:

- Introducing integrated health access is highly dependent on interactions among professionals.
- Integration of professional practices across sectors helps retain hard-to-reach users in treatment.

Abstract citation ID: ckae144.1607
Primary care utilization in Bulgaria: some effects of the COVID-19 pandemic

Maria Rohova

M Rohova[1], *S Koeva*[1]
[1]Health Economics and Management Department, Medical University - Varna, Varna, Bulgaria
Contact: maria.rohova@mu-varna.bg

Background: Disruptions to primary care provision during the pandemic set back prior advancements in screening and chronic disease management. Delays in routine vaccination added to preexisting hesitancy and sustained the downward trend in vaccination rates. The study examines the magnitude and duration of primary care disruptions in Bulgaria between 2020 and 2022.

Methods: The impact of the pandemic on primary care is assessed using administrative data from the National Health Insurance Fund covering the annual number of primary care services. To evaluate the effect on healthcare utilization, the average number of check-ups per person during the pandemic is compared to a pre-pandemic period (2017-2019).

Results: After the onset of the pandemic, all visits declined significantly on an annual basis. In 2020, overall prophylactic check-ups dropped by 6-13% and remained lower than the baseline until 2022. Initial figures for 2023 suggest some recovery, while specific services are likely to experience an ongoing decrease. During the pandemic, the average number of prophylactic examinations for children fell between 6.9 and 9.3%. In 2022, there was a modest resumption, although these services did not reach the preceding levels. Adult prophylactic visits declined by approximately 10-12% between 2020 and 2021, but following a U-shaped pattern, they rebounded in 2022. Visits associated with chronic diseases experienced a drop of 7.8% in 2020 and continued to decrease in the next two years. Child vaccination was affected for a shorter period. In 2022, the coverage for most vaccine-preventable diseases was close to the pre-pandemic levels. However, the uptake of MMR and pneumococcal vaccines failed to demonstrate a clear path to recovery.

Conclusions: During the pandemic, a considerable drop in primary care utilization has been recorded. Effective recovery requires sustained service delivery and a rapid post-lockdown rebound to mitigate the negative impact on health outcomes.

Key messages:

- Primary care needs additional recovery measures to prevent long-term harmful impacts on health outcomes.
- Investing in service delivery innovations can boost resilience during disruptive events.

Abstract citation ID: ckae144.1608
Barriers and enablers towards integrated care for sexual violence victims in humanitarian settings

Engy Sawah

E Sawah[1], *K Kielmann*[1], *J Michielsen*[1]
[1]Public Health Department, Institute of Tropical Medicine, Antwerp, Belgium
Contact: esawah@itg.be

Background: Sexual violence (SV) is a complex public health issue that necessitates a coordinated multisectoral response. Ideally, this response should be provided through an integrated care package to strengthen timely access and comprehensive care for victims. However, in humanitarian settings with high levels of SV, care is often offered through fragmented silos, exacerbating the burden on the health workforce and victims.

Methods: Using the Valentijn framework, a qualitative, real-time Delphi study was conducted with 17 SV care experts representing 7 geographical subregions to gain informed opinions on key contextual and health system barriers and enablers for integrated care for SV victims in humanitarian settings.

Results: Challenges and enablers reported across the diversity of the participants' contexts showed consistency. Contextual challenges included volatile contexts, collapsed health systems, and poor infrastructure. Professional challenges included a lack of expertise among healthcare providers (HCPs), high staff attrition, and compassion fatigue among HCPs. Health systems challenges included poor referral and coordination mechanisms, insufficient resources, misaligned donor-programme priorities and low prioritisation of SV comprehensive care. Key enablers reported were effective networking, community engagement, capacity building, co-locating services, participatory management, promoting staff's sense of ownership, digitalised information systems, and joint patient files.

Conclusions: The sustainability of integrated care for SV victims can be strengthened by ensuring HCPs access regular psychological support and training and are incentivised to provide quality care. Regular coordination among actors, including donors, can support integrating care that responds to patients' holistic needs. Further research is needed to assess HCPs' and SV victims' experiences of current service delivery and how to optimise integrated care in humanitarian settings.

Key messages:

- Addressing care providers challenges in humanitarian settings, such as high attrition, lack of training, psychosocial support, and burnout, can ensure proper integration of sexual violence care.
- Integration of sexual violence care demands systemic changes, including aligning donor-programme goals, building accountability mechanisms and the buy-in of political and community leaders.

Abstract citation ID: ckae144.1609
Clinical coordination in cancer diagnosis: healthcare stakeholders' viewpoints in Latin America

Olivia Oturai

O Oturai[1], I Vargas[2], ML Vázquez[2], AS Mogollón-Pérez[3], P Eguiguren[4], AL Torres[5], A Peralta[5], M Rubio-Valera[6], S Dias[7], SS Jervelund[1]

[4]School of Public Health, University of Chile, Santiago, Chile
[5]Public Health Institute, Pontifical Catholic University of Ecuador, Quito, Ecuador
[6]CIBER of Epidemiology and Public Health, Parc Sanitari Sant Joan de DéuSant, Sant Boi de Llobregat, Spain
[7]Public Health Research Centre, NOVA University of Lisbon, Lisbon, Portugal
Contact: olivia.oturai@sund.ku.dk

Background: Delays in diagnosis contribute to increasing cancer mortality rates in Latin American countries due to, among others, highly fragmented healthcare systems. The objective of this study, part of a larger research project (EquityCancer-LA), was to analyze cross-level coordination during cancer diagnosis and factors influencing it from healthcare stakeholders' perspectives in Chile, Colombia, and Ecuador.

Methods: This descriptive-interpretative qualitative study was based on 114 semi-structured individual interviews in 2022-23 using a criterion sample of health professionals from primary care (PC) (n = 40) and secondary care (SC) (n = 44) as well as managers and policy makers (n = 30) from two public healthcare networks in each country. Sample reached saturation. A thematic analysis was conducted first by country and then comparatively, guided by the theoretical framework of clinical coordination.

Results: In all countries, informants highlighted limited cross-level exchange of information and limited coordination of clinical management, delays in referral, and long waiting times after referral, leading to diagnostic delays. Factors hindering coordination differed across countries: structural (insufficient personnel, access to diagnostic tests in PC); organizational (limited/inadequate coordination mechanisms, e.g. shared clinical records; poor working conditions); and health professional characteristics (limited knowledge and skills among PC doctors). Direct feedback was emphasized to facilitate coordination of cancer diagnosis: virtual joint clinical conferences in Chile, co-location of PC and SC in Colombia, and informal networks (based on personal contacts) in Ecuador.

Conclusions: The findings underscore the critical coordination problems contributing to delays in cancer diagnosis. Addressing these challenges requires strategic interventions aimed at strengthening primary care and fostering cross-level coordination.

Key messages:

- Cancer diagnosis in Latin America suffers from coordination deficits due to structural, organizational, and professional factors.
- Strengthening primary care and cross-level coordination is needed.

Abstract citation ID: ckae144.1610
Reducing Emergency Room's overcrowding

Giulio Pedrazzoli

G Pedrazzoli[1], A De Luca[2], G Messina[1,5], EM Guerreschi[1], C Lorenzini[3], M De Marco[3], L Baragatti[4], F Leoncini[6], A D'Urso[7], N Nante[1,5]

[6]Primary Care Unit, LHA South-East Tuscany, Siena, Italy
[7]General Management, LHA South-East Tuscany, Siena, Italy
Contact: g.pedrazzoli@student.unisi.it

Introduction: The ageing of the population and the consequent increase in the epidemiology of chronic diseases pose numerous challenges at both hospital and territorial levels. In this context, one phenomenon that deserves particular attention is the frequent use of emergency services by 'frail' people. The aim of our study was to identify the most frequent users of the University Hospital's Emergency Room (ER) of Siena, based on their care at territorial level.

Materials and methods: A retrospective study was carried out on the data of accesses to the ER of the University Hospital's of Siena from June to September 2023. Patients were stratified according to the number of admissions, excluding those with only one admission during the study period. After identifying those with four or more accesses, the USL-TSE management system 'Astercloud' was used to check whether they were in integrated home care (ADI) or planned home care (ADP). Descriptive analysis was performed using STATA software.

Results: During the study period, 2347 patients were admitted to the ER, 78.95% had two admissions, 14.96% had three, 4.26% had four, 1.24% had five, 0.34% had six, 0.13% had seven, 0.09% had eight and, finally, 0.04% had eleven admissions. 93.1% of the sample had fewer than four admissions (2,204 patients), while 6.1% had four or more admissions (143 patients). Of the 143 patients studied, 16.1% were in home care, 13.3% in ADI and 2.8% in ADP. 36.8% of patients in ADI died within 4 months of the last admission during the period studied.

Conclusions: Our results suggest that the identification of people at risk of frequent use of the ER seems essential. Equally important is the existence of effective coordination and cooperation between hospitals and the community, with special attention to certain categories of patients. All of this is aimed to achieve overall appropriateness and therapeutic effectiveness, thus avoiding inappropriate admissions to the ER.

Key messages:

- Significance of identifying individuals prone to frequent use of emergency services to underscore the need for proactive management strategies to address their healthcare needs.
- Coordination and cooperation between hospital facilities and community-based services to enhance appropriateness of care and reduce inappropriate Emergency Room admissions.

Abstract citation ID: ckae144.1611
A systematic review of cancer overdiagnosis in multimorbid patients

Sarah Wilson

SP Slight[1,2], H Abdalla[1], N Hassan[1], S Wilson[1], R Slight[1,2]
[1]School of Pharmacy, Newcastle University, Newcastle Upon Tyne, UK
[2]Cardio-thoracic Department, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK
Contact: sarah.wilson@newcastle.ac.uk

Background: Cancer screening looks for early signs of cancer in people who do not currently exhibit symptoms. However, screening can also identify abnormalities that do not progress to produce symptoms or death. This could include the identification of tumours, which stop growing or grow very slowly; patients usually die with them rather than from them. We systematically reviewed the literature to investigate the harmful consequences of cancer overdiagnosis in multi-morbid patients.

Methods: We followed the PRISMA reporting guidelines and registered the review with PROSPERO (CRD42024475175). A Population, Intervention, Comparator, Outcome and Study design (PICOS) framework was used as an organising framework. Peer-reviewed studies were included except case series, case report reviews and conference abstracts. Four large databases (Medline, Embase, APA Psych INFO and Scopus) were searched in Nov23 using appropriate keywords grouped into categories: multimorbidity, overdiagnosis, patient harms, cancer screening. Titles were screened according to the eligibility criteria and their quality assessed. Studies needed to have investigated the extent of harm caused by overdiagnosis (e.g., overtreatment).

Results: A total of 200 articles were retrieved, with seven meeting our inclusion criteria. All included studies were based in the US. Breast and prostate cancer overdiagnosis was reported to be 15% higher in multimorbid populations compared to the average-risk population. Multimorbid individuals were more vulnerable to the harms of cancer overdiagnosis, with psychological, physical and financial harms reported.

Conclusions: These findings contribute valuable insights into the intricate interplay between comorbidities, cancer overdiagnosis, and associated harms. Radical treatment interventions in multi-morbid patients can carry greater risk of complications. Current screening guidelines only address average-risk populations; future guidelines need to reflect these findings.

Key messages:

- Cancer overdiagnosis was found to be higher in multimorbid populations compared to the average-risk population.
- Multimorbid individuals are also more vulnerable to the harms of cancer overdiagnosis.

Abstract citation ID: ckae144.1612
Factors influencing an advanced nursing practice service for people with intellectual disabilities

Tessa Schulenkorf

T Schulenkorf[1], K Ilskens[1], S Nadolny[1,2], A Gröndahl[1], M Grunwald[1], S Palmdorf[1,3], N Borchardt[1], C Grebe[1], A Maaß[1], Ä-D Latteck[1]
[1]Department of Health, InBVG, Hochschule Bielefeld - University of Applied Sciences and Arts, Bielefeld, Germany
[2]Interdisciplinary Center for Health Sciences, Martin Luther University Halle-Wittenberg, Halle, Germany
[3]Nursing Science Staff Unit, Niels-Stensen-Kliniken, Franziskus-Hospital Harderberg, Georgsmarienhütte, Germany
Contact: tessa.schulenkorf@hsbi.de

Background: People with intellectual disabilities (PWID) have less access to preventive healthcare services and are therefore more likely to suffer from certain chronic diseases. Advanced Practice Nursing (APN) can be a suitable approach for this group. However, APN is not yet widespread in all European countries. This intervention focuses on PWID in Hamburg, Germany, who receive case management and prevention focusing on stress, nutrition, mobility and addiction through community-based APN to improve their health status. We aimed to explore the facilitators, barriers and experiences of stakeholders in the context of the APN intervention.

Methods: We conducted 90 semi-structured problem-centered interviews with PWID, family members, professional caregivers and prevention service providers in 2023 and 2024. We employed convenience sampling. Data were analyzed by qualitative content analysis with mixed inductive-deductive coding using MAXQDA.

Results: Overall interviewees were satisfied with the intervention. It was reported that the clients exercised more, ate healthier, learned techniques to reduce stress and coped better with addiction. In addition, barriers to preventive services were reduced. We identified factors that positively influenced the success of the intervention: good interprofessional collaboration, successful relationship building with clients, concise goal setting and target group-specific work materials. Barriers were: neglect of the professional care network, difussion of agreements, lack of available prevention services, and communication problems. The results are preliminary.

Conclusions: This is one of the first evaluation studies of an APN intervention for PWID in Germany. The results show that this new form of care can be implemented if the relevant stakeholders work together and good relationships with the clients are established. Specific goals should be defined and the professional carergivers should develop a community network.

Key messages:

- APN is a suitable approach for disease prevention and health promotion for people with intellectual disabilities, given interprofessional collaboration and a well-established relationship with clients.
- Preventive healthcare for the target group is difficult to implement if the stakeholders do not work together and if there are insufficient suitable preventive services available in the community.

Abstract citation ID: ckae144.1613
Advanced nursing practise as a preventive approach for adults with intellectual disabilities

Marie Grunwald

M Grunwald[1], S Nadolny[1,2], A Groendahl[1], C Grebe[1], K Ilskens[1], T Schulenkorf[1], N Borchardt[1], S Palmdorf[1,3], A Maaß[1], Ä-D Latteck[1]
[1]Department of Health, Institute for Education, Hochschule Bielefeld – University of Applied Sciences and Arts, Bielefeld, Germany
[2]Interdisciplinary Center for Health Sciences, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany
[3]Niels-Stensen-Kliniken, Nursing Science Unit, Franziskus-Hospital Harderberg, Georgsmarienhütte, Germany
Contact: marie.grunwald@hsbi.de

Background: Various barriers impede access to preventive health services for people with intellectual disabilities in Germany. As a result, they are more likely to suffer from certain chronic diseases. Internationally, Advanced Nursing Practice (ANP) has proven to be a suitable approach to care for this group. In Germany, ANP is not yet widespread. The aim of this study is to improve healthcare for people with intellectual disabilities through ANP-led case management.

Methods: A randomized controlled trial was conducted in an urban community setting. Inclusion criteria were: ICD-10 diagnosis F70-F79, age ≥ 18 and care level ≤ 3. The intervention group (IG) received four outreach home visits focused on prevention and health promotion. The control group (CG) received usual care. Allocation was done using computer-assisted, permuted block randomization. Researchers were blinded during data collection and analysis. The primary outcome was health status after 12 months (t2) (WHODAS). Secondary outcomes were health status after 6 months (t1), health-related quality of life (HQOL) after 6 and 12 months (EQ5D-VAS), and resilience after 6 and 12 months (RS-11). Analysis was performed via ANCOVA with Bonferroni correction at a significance level of 0.025.

Results: 214 participants were randomized. At t2, 176 participants remained (IG: $n = 85$, CG: $n = 91$). Health status at t2 showed a mean difference (MD) of -4.58 points in favor of the IG ($p = 0.01$). For resilience, a MD of $+1.95$ (t2) points in favor of the IG was obtained ($p = 0.05$). We measured a MD for HQOL of -1.19 ($p = 0.72$) in favor of the CG.

Conclusions: A clinically relevant effect of ANP-led case management was achieved on the health status, but not on resilience and HQOL. ANP for people with intellectual disabilities can contribute to health promotion and thereby improve the community health. Therefore, ANP can be used as an innovative approach in the course of reorganization of healthcare for vulnerable populations in Germany.

Key messages:

- ANP-led case management can have a clinically relevant effect on the heal status of people with intellectual disabilities over the course of one year.
- ANP-led case management can be seen as a new approach to health promotion and disease prevention in Germany.

Abstract citation ID: ckae144.1614

Experiences with paediatric hospital health care: a cross-sectional study among paediatric patients

Eva Murko

E Murko[1], *M Kralj*[1], *M Poldrugovac*[1], *M Zaletel*[1], *N Zupancic Ropret*[1]
[1]NIJZ, Ljubljana, Slovenia
Contact: eva.murko@nijz.si

Background: The measurement of patient experiences is gaining importance in many healthcare systems, including the Slovenian one. The need for a national survey on patient experiences in the paediatric inpatient settings emerged recently.

Methods: The survey took into account various aspects of inpatient healthcare such as admission, hospital staff, safety, food and discharge from hospital. As part of the study, children/parents were able to give praise and suggestions for improvements. We used three different questionnaires adapted to the cognitive abilities of children - a child questionnaire for the age group 9-13 years in paper form, an online adolescent questionnaire for the age group 14-18 years, and an online parent questionnaire for the age group 0 (1 month)-8 years. The questionnaires were cognitively tested and piloted before national rollout.

Results: The national survey was conducted between September 2023 and March 2024 and included paediatric patients who spent at least one night in an acute paediatric hospital ward. The survey included 25 paediatric wards and totally 1965 questionnaires were valid for analysis. The rough response rate was 17,6 %. The first preliminary results of the qualitative analysis suggest that surveyed paediatric patients and their parents rate highly inpatient health care services received, however they point out also to areas that need improvement such as environmental factors (noise, temperature), food, infrastructure (outdated facilities & equipment) and in some cases attitude of hospital staff.

Conclusions: National institute of public health carried out the first national survey on paediatric patient reported experience measures in acute hospitals in Slovenia. The results of this survey will be used to improve the quality of inpatient health care services in paediatric wards, as well renew focus on the requirements of European charter of children rights and United Nations Convention on the Rights of the Child.

Key messages:

- National institute of public health carried out the first national survey on paediatric patient reported experience measures in hospitals in Slovenia.
- The results of this survey will be used to drive hospital quality improvements.

Abstract citation ID: ckae144.1615

Who took care of patients with diabetes during the COVID-19-pandemic? A registry-based study

Corinne Rijpkema

C Rijpkema[1,2], *L Ramerman*[1], *LL Peters*[3,4], *JWM Muris*[5], *T Colde Hartman*[6], *M Homburg*[3], *I Bos*[1], *RA Verheij*[1,2,7]

Background: The rise of people with chronic diseases strains our healthcare system. Chronic disease management programs (CDMP) provide accessible care for patients with a chronic disease, aiming to prevent further development of the disease and avoid the need for (more costly and severe) hospital treatments. During the COVID-19 pandemic, CDMP provided at general practices (GP) for diabetic patients were downscaled. It remains unknown whether this downsizing led to increased care in other healthcare settings. We examined the changes in healthcare utilization by Dutch diabetic patients in 2020 and 2021 compared to 2019 regarding; 1) CDMP consultations, 2) hospital care for diabetes and 3) regular GP care.

Methods: In this retrospective observational study, data from electronic health records of GPs, participating in Nivel Primary Care Database, of 15,247 Dutch diabetic patients who were enrolled in CDMP, were linked to hospital claims data. Differences in healthcare utilization in 2020 and 2021 compared to 2019 were assessed quarterly using regression analyses.

Results: Results show that CDMP care was notably lower in 2020 and 2021, compared to 2019 (-35%). From Q1 2021 onwards, patients received more hospital care for diabetes (+13%) and regular GP care increased from Q3 2020 onwards (+14%). Compared to 2019, reduced CDMP contacts in 2020 were significantly associated (p = 0.001) with increased regular GP care in 2021. In the short-term, decreased CDMP in the first half of 2021 was significantly associated with increased regular GP care (p = 0.033) and hospital care (p = 0.037) in the second half of 2021.

Conclusions: Temporarily downscaling CDMP care during the COVID-19-pandemic was associated with increased hospital and regular GP care for diabetic patients. These findings contribute to making informed decisions regarding measures during future pandemics.

Key messages:

- Chronic disease management programs at GPs appear to be effective in preventing disease exacerbations, and may help prevent (expensive) utilization of hospital care.
- This research prompts further investigation into the desirability of CDMPs among patients, GPs, hospitals and policymakers, crucial for assessing undesirable healthcare shifts in diabetic patients.

Substitution of care through the eyes of Dutch health insurers: a qualitative study

Jesper Dros

JT Dros[1], *I Bos*[1], *CE van Dijk*[2], *BR Meijboom*[3], *RA Verheij*[1,2,3]
[1]DLZ, NIVEL, Utrecht, Netherlands
[2]FAZ, National Health Care Institute, Diemen, Netherlands
[3]Tranzo, Tilburg University, Tilburg, Netherlands
Contact: j.dros@nivel.nl

Objectives: The objective of health policy measures in the Netherlands is to promote the substitution of care from hospitals to general practitioners (GPs), with reimbursement facilitating this shift. Given that health insurers are tasked with healthcare reimbursement in the Netherlands, understanding their experiences regarding care substitution is crucial.

Methods: First, informal interviews were held with employees from the Dutch Ministry of Health, Welfare and Sports, the National Health Care Institute and the Netherlands Institute of Health Services Research to construct the topic list. Then, we conducted semi-structured interviews with 15 employees from 7 health insurers, including healthcare purchasers, strategists, client relations executives, and business analysts, between February and April 2024. Transcripts were analyzed in MAXQDA by two researchers, after member checking.

Results: Insurers navigating substitution face a complex interplay of competition and collaboration, lacking a comprehensive framework. Long-term agreements with hospitals and GPs are seen as potential solutions, contingent on building trust. Diverse views on insurers' roles emerge, from passive reimbursement to active infrastructure support. Budgetary constraints vary, with some insurers feeling constrained by national budgets for GPs and hospitals while others perceive more flexibility. Risks equalization and deductibles are identified as hindrances to substitution efforts, necessitating changes in financial incentives.

Conclusions: Overall, addressing these complexities requires aligning incentives and balancing collaboration and competition to optimize resource allocation to effectively meet evolving healthcare needs. A comprehensive framework to balance collaboration and competition might be helpful.

Key messages:

- Understanding insurers' views on care substitution is vital for healthcare policy in the Netherlands.
- A comprehensive framework is needed to balance collaboration and competition, aligning incentives effectively.

Abstract citation ID: ckae144.1617
Effectiveness of a policy to reduce non-urgent night-time consultations in out-of-hours services

Corinne Rijpkema

L Ramerman[1], *C Rijpkema*[1,2], *R Verheij*[1,2]
[1]NIVEL, Utrecht, Netherlands
[2]Tilburg University, Tilburg, Netherlands
Contact: c.rijpkema@nivel.nl

Background: The utilization of Out-of-Hours General Practice (OOH-GP) services in the Netherlands has been increasing steadily. This has placed significant pressure on triagists and GPs to provide accessible and high-quality care, particularly because of patients with low-urgency health problems, who can wait to visit their GP during regular working hours. To alleviate the strain on OOH services during the night, the "spoed=spoed" policy has been implemented. This policy stipulates that only patients with urgent health problems can consult with a GP during the night (11 p.m. to 8 a.m.). However, it remains unclear whether this policy has effectively reduced consultations during the night.

Methods: For this study, we used pseudonymised data from electronic health records of 2/3 of Dutch OOH services (catchment area of 12.3 million), from Nivel Primary Care Database, from 2020-2023. We analysed the effects of the policy on contact rates and proportion of high-urgency health problems, by comparing OOH services that did and did not implement the policy, by comparing 6 months before and after implementation and by analysing variances across OOH services.

Results: Overall, there were no differences in the number or proportion of high-urgency consultations across OOH services that did and did not implement spoed=spoed. In those that did, there were no differences before and after implementation. However, certain OOH services exhibited a decrease in consultation, while also showing a higher proportion high-urgency health problems.

Conclusions: There is currently no definitive evidence regarding the effectiveness of "spoed=spoed". However we should learn from the varied effects and experiences in different OOH-services, to facilitate further implementation or adaptation of the policy.

Key messages:

- OOH services can and should learn from each other on what solutions are implemented to lower the care-burden during the night.
- Policies aimed at reducing the utilization of OOH serviced should consider the conaxt from the patient, health care provider and organization.

Introduction: The importance of timely reperfusion therapy in Cardiovascular diseases is crucial, leading to the creation of time-dependent networks for Acute Coronary Syndrome treatment. The ACS-STEMI treatment network in Tuscany operates across three health authorities (LHAs),including South-East Tuscany. The network ensures ACS-STEMI treatment in 12 hospitals integrating new territories such as Piombino and Elba into the network. Aim of the study is to assess the impact of an analytical monitoring system of the times to reperfusion treatment and the actions to improve the performance of the network.

Methods: In this retrospective study an analytical evaluation of the network's performance was conducted. We utilized data on patient transport, symptom onset to medical contact times, and outcomes from the National Outcomes Program (PNE).Analytical evaluations in 2021 measured the network's performance, identifying main delay causes. The treatment process is divided into periods from symptom onset to coronary reperfusion, and interventions like public campaigns, ECG transmission and fast-track transfers have been implemented.

Results: South East Tuscany LHU had the lowest 30-day mortality rate for ACS patients in Italian hospitals with 300 cases annually in 2020 and 2021.Improvements continued into 2022 and 2023, further reducing mortality rates in patients initially admitted to SPOKE hospitals. For Piombino and Island of Elba residents,30-day mortality decreased from 8.8% (2017-2020) to 5.7% in 2022. The Grosseto hub treated 80% of STEMI patients within 90 minutes in 2022.

Conclusions: The establishment of a well-organized time-dependent network for ACS-STEMI treatment in Tuscany has significantly improved patient outcomes, demonstrating the critical role of timely and efficient care pathways. The network's success is attributed to several factors, including improved accessibility, enhanced coordination among healthcare facilities, and effective use of technology and resources.

Key messages:

- Treatment networks for ACS/STEMI can improve health outcomes in peripheral areas.
- Structured clinical-care pathways in delivering high-quality care for ACS patients reduces ACS mortality.

Contact: mak0320@belle.shiga-med.ac.jp

Background: Prompt action at stroke onset is required to improve prognosis. Some previous studies indicated that visiting local clinics may initially delay access to specialized care. We examined the relationship between the presence of chronic diseases known as risk factors for stroke and visiting a local clinic before admission to the hospital for acute stroke care.

Methods: This study utilized data from stroke patients aged 18 and older who were registered in the Shiga Stroke and Heart Attack Registry (SSHR) from January 2011 to December 2015. We excluded cases with onset during hospitalization or those with impaired consciousness assessed by the Japan Coma Scale (JCS $>=$10). The presence of comorbid chronic diseases was determined based on the past history and medications presented at admission. Local clinics are defined as clinics or hospitals that are not equipped to provide acute stroke treatment. Multivariate logistic regression analyses, adjusting for sex, age, modified Rankin Scale score before onset, and stroke subtypes, were performed to calculate odds ratios and 95% confidence intervals for visiting a clinic before hospitalization according to the presence of chronic diseases such as hypertension, diabetes, dyslipidemia, and atrial fibrillation, respectively.

Results: Data from 11,111 out of 14,620 registered cases were analyzed. Among these participants, 5,774 had hypertension, 1,951 had diabetes, 2,111 had dyslipidemia, and 882 had atrial fibrillation. A total of 2,405 (21.6%) cases visited a local clinic at stroke on set. The adjusted odds ratios for visiting clinics by the presence of hypertension were (1.22, 95% CI: 1.11 -1.34), diabetes (1.14, 1.01-1.28), dyslipidemia (1.07, 0.95 -1.20), and atrial fibrillation (0.80, 0.67 -0.95).

Conclusions: The present study indicated that individuals with hypertension and/or diabetes are more likely to initially visit a local clinic at stroke onset, whereas those with atrial fibrillation were not.

Key messages:

- Approximately 20% of mild stroke patients first consult local or primary care doctors at stroke onset. This trend was particularly observed in individuals with hypertension and diabetes.
- Emphasizing the need for direct access to specialized emergency care for individuals with chronic diseases is important to avoid delays in acute stroke care.

Abstract citation ID: ckae144.1620
How to improve informal caregiver's quality of life and health literacy? – a NGT approach

Ana Rita Pedro

AR Pedro[1,2], *D Brandão*[1,2], *B Raposo*[2], *AS Cunha*[2], *A Escoval*[1]

[1]NOVA National School of Public Health, Public, Comprehensive Health Research Center, NOVA University Lisbon, Lisbon, Portugal

[2]NOVA National School of Public Health, Public Health Research Center, CISP, NOVA University Lisbon, Lisbon, Portugal

Contact: rita.pedro@ensp.unl.pt

Background: Previous studies revealed that informal caregivers have a large number of unmet needs, reinforcing the necessity of national policies that ensure an adequate sustainability of the provision of informal care and takes into account the needs of caregiving dyads in the planning process. This study aimed to identify and consensualize initiatives and action strategies to improve the Portuguese Informal Caregiver's reality and health literacy levels.

Methods: A Nominal Group Technique (NGT) was conducted with 10 experts. The NGT panel was asked about feasible action strategies to improve informal caregiver's reality, consensualized and voted them according to perceived relevance in a semantic differential (1 pts to nothing relevant and 6 pts to very relevant), allowing a score calculation.

Results: Thirty-two initiatives emerged from the NGT. The five most relevant initiatives were identified based on an average score namely: 1) Pressure political decision-makers on the need for an effective implementation of the Informal Caregiver status, which is not being done (score=56); 2) Creation of a specific emergency social line for informal caregivers, as a measure of greater equity (score=52); 3) Raise employers awareness about caregiving demands (score=52); 4) Creation of a proximity social manager, linked to primary care services, that facilitates caregiver connection to health and social care services (score=51); 5) Decentralization of respite care services support, with multidisciplinary teams (score=49).

Conclusions: The informal caregiver's role needs to be recognised and understood by healthcare and social care providers. (Re)design political, economic and social policies that address both caregiver and care recipients' needs is critical to enable the continuity of informal care provision.

Key messages:

- Informal caregivers play a fundamental social role but still have many needs to be addressed, particularly at the level of the official definition of their role.
- (Re)design political, economic and social policies targeted to informal carers is imperative to enable the continuity of informal care provision.

The WHO health system performance assessment applied to child healthcare in Luxembourg, 2011-2022

Tanja Ducomble

T Ducomble[1], *T Seuring*[1], *F Berthet*[1]
[1]National Health Observatory, Strassen, Luxembourg
Contact: tanja.ducomble@obs.etat.lu

Background: Health System Performance Assessments (HSPAs) evaluate health systems in terms of their objectives and their overall goals, such as access to quality services and health improvement. Beyond the overall health system assessment, HSPA can evaluate performance in providing care to specific populations. We assessed the response of the Luxembourg health system to children's particular health needs, by populating the WHO HSPA framework for universal healthcare with child-specific indicators.

Methods: We searched international databases, guidelines, policy documents, and the scientific literature to identify child-specific indicators suitable for assessing the health system objectives as defined by the WHO HSPA framework. To select the most relevant indicators, we conducted expert appraisal regarding feasibility, validity and actionability. Those indicators were calculated based on available national data. To explore inequities within the system, we performed socioeconomic stratifications.

Results: Twenty-nine indicators were used to populate the framework, sourced from social security databases ($n = 15$), monitoring and surveillance ($n = 11$), and surveys ($n = 2$). For effectiveness assessment, we used 11 indicators and found that preventive services performed best for children under two years. Five indicators showed good accessibility to primary and secondary care. Another five indicators assessed safety indicating a recent increase in the relative use of broad-spectrum antimicrobials and an overuse of caesarean sections. Additional disaggregation of three indicators didn't expose socioeconomic inequities in service delivery. Data gaps exist to assess children's user-experience and financing of child health services.

Conclusions: The WHO HSPA framework proved valuable for evaluating the Luxembourg health system's performance for children. We identified good performance in accessibility and effectiveness for young children, alongside data gaps to assess user-experience.

Key messages:

- The application of national child-specific indicators to the WHO health system performance assessment, highlighted strengths in accessibility and effectiveness while also pointing to key data gaps.
- We used the WHO health system performance assessment (HSPA) to evaluate the health system for children in Luxembourg. This exercise enhances the development of a tailored national HSPA framework.

Abstract citation ID: ckae144.1622
Managing no-shows in healthcare: insights from an urban Health District in Northern Italy

Paolo Ragusa

P Ragusa[1,2], *A Russotto*[1,2], *D Catozzi*[2], *A De Angelis*[1,2], *A Durbano*[1,2], *S Orecchia*[2], *R Siliquini*[1]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Local Health Authority of Turin, Turin, Italy
Contact: paolo.ragusa@unito.it

Background: Non-attendance at healthcare appointments, known as no-show, poses significant challenges to healthcare systems, disrupting patient care continuity, exacerbating waiting times, and straining resources. Addressing this issue is crucial for optimizing health care delivery and containing costs. This study explores the phenomenon of patient no-shows and aims to identify factors associated in a densely populated healthcare district in Turin, Northern Italy.

Methods: Data were extracted from the healthcare management system covering outpatient care appointments in the health district in 2022 and 2023. The analysis included various patient and service-related variables. Missing information on key variables were managed with listwise deletion. Descriptive statistics provided an overview of missed appointment rates, while multivariate analysis explored various patient and service-related variables.

Results: A 5.1% ($n = 6198$) no-show rate was observed out of 120,405 records. The total cost incurred due to missed appointment fees amounted to €127,244. Several factors were associated with a significantly increased likelihood of no-show ($p < 0.05$), including initial visit ($OR = 1.11$), deferred priority ($OR = 1.22$), non-exempt status from healthcare co-payments ($OR = 1.36$), exemption based on income ($OR = 1.82$), age under 18 ($OR = 2.46$) and under 65 ($OR = 2.32$), male gender ($OR = 1.17$), residency outside the Piedmont Region ($OR = 1.31$) and outside Italy ($OR = 2.46$), and longer waiting time ($OR = 1.01$).

Conclusions: This study sheds light on the widespread issue of patient no-shows and its economic implications. It provides clear direction for implementing tailored interventions in healthcare settings. As a response to these findings, a telephone recall project was launched. Its efficacy will be evaluated in subsequent assessments to determine if it can effectively alleviate the burden of no-shows, thus enhancing healthcare efficiency and ensuring continuity of care for patients.

Key messages:

- The no-show phenomenon has important implications both organizationally and economically.
- The magnitude and major determinants of patient no-shows must be recognized to guide the deployment of tailored interventions in a real-world setting.

Abstract citation ID: ckae144.1623
Cost-effectiveness analysis of Chagas disease screening in pregnant women and their infants in Italy

Mario Cesare Nurchis

MC Nurchis[1], *A Heidar Alizadeh*[1], *GM Raspolini*[1], *P Marraffa*[2], *M Dentato*[2], *L Olivo*[1], *MM Gianino*[2], *G Damiani*[1,3]
[1]Università Cattolica del Sacro Cuore, Rome, Italy
[2]Università di Torino, Turin, Italy
[3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: nurchismario@gmail.com

Background: Currently, Chagas disease (CD) is widespread in European nations that host notable populations from Latin America. Vertical transmission is a pathway for the spread of the disease in countries where it is not endemic. Due to socio-economic disparities, CD is a public health concern in non-endemic regions, raised by migration phenomena in vulnerable population groups who face similar hindrances as those most at risk in endemic areas. The aim is to evaluate the cost-effectiveness of CD screening versus no screening in pregnant women and their infants in Italy.

Methods: A Bayesian Markov model was employed to compare the CD screening versus the no screening alternative. Model parameters were sourced from pertinent scientific literature. A lifetime perspective was adopted, aligning with the perspective of the Italian National Health Service. The Eurozone threshold was applied. Costs and benefits were discounted at a rate of 3%. Gibbs sampling served as the algorithm for Bayesian inference. Uncertainty was addressed through a probabilistic sensitivity analysis (PSA) and a value of information analysis (VOI), depicted via the Cost-Effectiveness Acceptability Curve (CEAC) and Expected Value of Perfect Information (EVPI). Results were presented as the Incremental Cost-Effectiveness Ratio (ICER).

Results: The base case results showed that CD screening was cost-effective, with an ICER of €5,112 [€1,850 - €10,043]. Furthermore, according to the CEAC, the screening option exhibited the greatest probability of being cost-effective across all thresholds. Additionally, the EVPI per mother was €818 based on a threshold of €50,000/diagnosis.

Conclusions: Implementing a structured CD screening program also in non-endemic countries has the potential for early detection and treatment. This contributes to SDG 3 by improving access to healthcare, preventing transmission, and reducing the disease burden as well as informing public health policies for marginalised populations.

Key messages:

- This study proves that screening for CD in pregnant women and their infants in a non-endemic area is a cost-effective strategy and possibly cost-saving in the long term.
- Study findings could support a wider implementation of CD screening in Italy by informing health policy-makers in their decision-making process.

The meaning of organizational culture and structure for interprofessional collaboration

Liliane Redzewsky

L Redzewsky[1,5], *U Thielhorn*[2], *C Wallesch*[3,5], *M Körner*[4]
[1]University of Freiburg, Freiburg, Germany
[2]Catholic University of Applied Sciences Freiburg, Freiburg, Germany
[3]BDH Klinik Elzach, Elzach, Germany
[4]Bern University of Applied Science, Bern, Switzerland
[5]BDH Bundesverband Rehabilitation, Bonn, Germany
Contact: liliane.redzewsky@mail.medizin.uni-freiburg.de

In Germany, early neurological rehabilitation (ENR) acts as a link between acute inpatient care and rehabilitation, aiming to restore patients' ability to rehabilitate amid their complex clinical conditions. Interprofessional cooperation (IPC) is crucial for harmonized treatment due to patients' vulnerability. An interprofessional team comprising medical, nursing, and various therapy professionals is essential for this purpose. To explore the meaning of organizational culture and structure to IPC, 15 group discussions in 5 clinics were conducted with $n = 76$ participants.

1. Weekly team meetings are used to coordinate treatment goals and outcomes, but their implementation varies from clinic to clinic. Two types of meetings were identified: those that focus primarily on billing compliance and others that address patients' long-term perspectives. However, both require additional social service involvement and are not sufficient to adequately address daily tasks, requiring additional IPC coordination. Some clinics have therefore introduced daily meetings to improve the coordination of IPC tasks.

2. Therapy planning and therapist assignment shape IPC and task fulfillment. Three therapy planning methods were observed: centralized, block-based, and flexible, each with different therapist allocation strategies. Centralized planning with flexible allocation leads to appointment pressure and interprofessional communication challenges. Block therapy reduces therapist turnover and promotes better interprofessional coordination in patient care. Flexible therapy planning is conducted through daily interprofessional meetings with shared task allocation and planning leads to a shared understanding.

Initial analysis underscores the meaning of organizational structure on interprofessional task fulfillment in ENR, emphasizing the importance of enhancing different cooperation formats which can balance stability and flexibility and integrate social services effectively in patientcare.

Key messages:

- Morning interprofessional meetings on the ward facilitate flexible responses to daily changes in patients' health conditions and promote interprofessional collaboration.
- The consideration of occupational group-specific processes in ward organization is a necessary structural prerequisite for successful interprofessional collaboration.

Abstract citation ID: ckae144.1625
Overcoming non-usage of e-mental health: A qualitative study in a Dutch general practice

Claudia Van Der Heijde

CM Van Der Heijde[1], *JD Van Winkoop*[1], *P Vonk*[1]
[1]Student Health Services, University of Amsterdam, Amsterdam, Netherlands
Contact: c.m.vanderheijde@uva.nl

Background: Worldwide percentages of people with mental health problems are substantial and increased during the COVID pandemic (to about 25 % in the general population). E-mental health has potential to help with waiting lists, rising health care costs and work pressure. To reach the desired effects, participants need to use the technology as intended. Non-usage though is a common problem. Research question is: what elements obstruct the intention to use e-mental Health interventions, plus what are barriers to bridging the intention-behaviour gap?

Methods: In a qualitative study, semi-structured interviews were conducted (interview guide). We recruited patients who were invited for an e-mental health intervention in a Dutch general practice but did not start the intervention. Data saturation occurred with 11 patients. Open, axial and selective coding was done on the transcribed interviews using the software ATLAS.ti.

Results: Five main themes were associated with non-use: 1) 'Expectations about the eHealth in general' were neutral to positive. 2) 'thresholds to start e-mental health' were: negative expectations about the content, lacking mental capacity due to mental problems, missing personal contact, the therapy with the mental health professional in general did not fit their needs or aversion towards more screen time. 3) 'lack of planning'. 4) lacking encouragement from mental health professional 5) 'Expectations from therapy in general'. (a.o. face-to-face contact and tailoring)

Conclusions: Embedding the e-mental health more into regular therapy has potential to overcome non-usage. The mental health care professional has social influence to increase usage, by a clear and convincing introduction plus joint review of the exercises during consultations. This study needs to be repeated in other clinical settings. Future research should also include age (computer use) and disease prognosis to define when e-mental health is a suitable solution for patients.

Key messages:

- E-mental health interventions have potential to help with waiting lists, rising health care costs and workload, but non usage is a problem.
- Embedding the e-mental health more into regular therapy has potential to overcome non-usage.

Abstract citation ID: ckae144.1626
Health care provider payment schemes in Central and Eastern European countries

Marzena Tambor

C Ndayishimiye[1,2], *M Tambor*[1], *K Dubas-Jakóbczyk*[1]
[1]Health Economics and Social Security Department, Institute of Public Health, Jagiellonian University, Cracow, Poland
[2]Doctoral School of Medical and Health Science, Jagiellonian University Medical College, Cracow, Poland
Contact: marzena.tambor@uj.edu.pl

Background: Health care provider payment schemes are key elements of the health care system that influence providers behavior, quality of care, and efficient use of resources. In recent decades, Central and Eastern European (CEE) counties have implemented various reforms that have changed payments methods and other elements of the purchasing process. The aim of the study was to provide an overview of the current provider payment schemes within the public health system in selected CEE countries and identify the main directions of their reforming.

Methods: Based on existing literature, a theoretical framework and data collection form were first developed. Next, desk research was conducted to collect data on provider payment methods and other elements of the purchasing process in primary care, outpatient specialized care, hospital care, and long-term care. The collected information was verified and supplemented though consultations with national experts. Nine countries were included: Bulgaria, Croatia, Czechia, Estonia, Latvia, Lithuania, Hungary, Poland, and Romania. The study was conducted in 2023.

Results: Capitation, fee-for-service, and case-based payments are the most commonly used methods in the analyzed countries. The countries are increasingly using blended payment methods. Primary and hospital care have the most diverse payment method mix and have experienced the most substantial changes in their payment schemes since 2010. The most common changes focused on modifying existing methods (detailing payment categories, changing the principles of tariff valuation), and introducing additional methods to pay for specific services or performance (fee-for-service, bonus payments).

Conclusions: CEE countries are following similar directions in reforming provider payment systems, with the goal of strengthening primary health care, shifting emphasis from inpatient to outpatient care and improving cooperation between health care providers.

Key messages:

- CEE countries largely use output-based methods to pay for health care services.
- Provider payment systems are becoming more blended as countries look for the most effective payment method mix to meet policy objectives.

Abstract citation ID: ckae144.1627
Documenting the availability and accessibility of reproductive health services for youth in Albania

Florida Doci

F Doci[1], *AM Foster*[1]
[1]Interdisciplinary Health Sciences, University of Ottawa, Ottawa, Canada
Contact: florida.doci@uottawa.ca

Youth in Albania are initiating sexual activity at an earlier age. However, use of all forms of contraception has declined in the last decade and uptake now stands at 4%. The self-reported prevalence of sexually transmitted infections (STIs) and STI symptoms has risen dramatically, as has reliance on abortion as a predominant method of family planning. In 2020-2022, we conducted a multimethod qualitative study in Albania to document the availability and accessibility of sexual and reproductive health (SRH) services and examine challenges that youth face when seeking SRH care. This study comprised a document review, a curriculum review, a community-based survey with 273 youth, semi-structured interviews with 15 youth, semi-structured interviews with 15 key informants, and a service mapping exercise in Tirana. Lack of adequate infrastructure and bureaucratic hurdles make it difficult for youth to navigate and access SRH services in Albania. A third of survey participants (n = 90, 33%) expressed discomfort inquiring about SRH matters, while nearly two-thirds rarely or never sought SRH services from a doctor or clinic. Furthermore, Albania's school-based sexuality education curriculum lacks in topics, content, and responsiveness, resulting in inconsistent learning experiences and limited knowledge of SRH. Sexuality education is primarily focused on the anatomy and physiology of reproduction, leading to significant knowledge gaps in other aspects of SRH. Only half of survey participants (n = 150, 55%) had received any education on birth control, contraception, or family planning; and only few had knowledge about gender identity (n = 103, 38%), or consent (n = 77; 28%). Widespread lack of awareness and fear of judgment contribute to the underutilization of SRH services among youth in Albania. Improving knowledge and awareness, alongside investing in infrastructure and capacities, are essential to enhancing accessibility and quality of SRH services for Albanian youth.

Key messages:

- Lack of knowledge and awareness prevent youth from accessing SRH services.
- Establishing youth-friendly services and training health providers and educators are crucial to delivering confidential and non-judgmental youth-friendly SRH care.

Evaluation of the Beneficial Parenting Partnership Model Assimilation in Parent-Infant Centers

Shiran Bord

S Bord[1], *Y Paldi*[2], *R Baruch*[3], *E Stolerman*[3], *M Yeudai-Yadid*[4], *D Zimmerman*[3], *I Gens*[3], *I Schuman Adatto*[5], *M Yaari*[6]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel valley, Israel
[2]Tovanot, Gedera, Israel
[3]Public Health Department, Israeli Ministry of Health, Jerusalem, Israel
[4]Nursing Department, Israeli Ministry of Health, Jerusalem, Israel
[5]Lotem, Kfar Malal, Israel
[6]Goshen, Jerusalem, Israel
Contact: Shiranb@yvc.ac.il

Background: The Beneficial Parenting Partnership (BPP) model is being implemented in Parent-Infant Centers (PIC) across Israel to improve the partnership skills of PIC nurses when working with parents, promote child development, and enhance parental well-being. This initiative is being led by the Israeli Ministry of Health, Goshen NGO, and Lotem company and is supported by the Yad Hanadiv and Bernard van Lear foundations.

Methods: The first data collection (T1) was held from December 2022 to January 2023 among 706 parents of children aged two weeks to 36 months (M = 8.17 months, SD = 7.48) who visited one of 18 PICs. Research assistants approached the parents and asked for their agreement to fill in the study questionnaire. Of these, 328 parents agreed to participate in the follow-up study (T2) held in January-February 2024 using a telephone survey. Differences in the parent's satisfaction, visit experience, and parental well-being were assessed using parried sample T-tests. A linear regression model was calculated to assess the factors predicting the increase in the parent's visit satisfaction.

Results: Significant differences were measured between T1 and T2 in parental satisfaction (M = 4.51 and 4.71 retrospectively,

$P < 0.001$), parental positive visit experience ($M = 4.58$ and 4.68 retrospectively, $P = 0.019$), and parental well-being ($M = 3.81$ and 3.97 retrospectively, $P < 0.001$). Findings suggest a marked improvement in satisfaction, visit experience, and reported well-being after a year of BPP model assimilation among PIC nurses. The regression model, explaining 42% of the variance in increased parental satisfaction, indicated that a higher increase could be predicted by a higher increase in positive visit experience and a higher trust level in the PIC nurse at T1.

Conclusions: The BPP model's assimilation among Israeli PIC nurses was successful, resulting in improved parent experience, satisfaction, and well-being.

Key messages:

- The Beneficial Parenting Partnership model is well-suited for implementation among nurses working with parents of babies and toddlers to promote collaborative nurse-parent communication.
- During routine meetings at Parent-Infant Centers, nurses can act as a catalyst for promoting parental well-being.

Abstract citation ID: ckae144.1629

Productivity and consultation times in Portuguese primary care: trends and payment model variations

Francisco Madeira

F Madeira[1,2], *J Pestana*[3], *J Perelman*[1,2]
[1]NOVA National School of Public Health, Lisbon, Portugal
[2]Comprehensive Health Research Center, Lisbon, Portugal
[3]Nova School of Business and Economics, Lisbon, Portugal
Contact: fmc.madeira@ensp.unl.pt

Background: Portugal faces a shortage of primary care workforce resulting in an increase in patients without Family Physician (FP). While expanding the patient list per FP may help, it could also result in excessive workloads, compromising Consultation Times (CT) and quality of care. Furthermore, it is important to study the role of the primary healthcare (PHC) financing model in incentivizing their productivity. This study aims to analyse the productivity and CT in PHC units in Portugal, variation over time, and differences across PHC unit payment models.

Methods: 6,563 PHC units with different payment models (salary at UCSP, salary and group pay-for-performance at USF-A, and salary, capitation, and individual pay-for-performance at USF-B) from 2015 to 2022 were analysed, including the annual numbers of medical and nursing consultations and full-time equivalents (FTE) of physicians and nurses. Weekly productivity (WP) was calculated using the consultations per FTE physician and nurse. CT were determined by dividing each FTE's weekly workload by WP. Multivariate analysis explored differences in CT between PHC units, temporal variations, and the influence of the patient population characteristics.

Results: FTE physicians had a mean WP of 117 consultations (SD 39) lasting 22.4 minutes (SD 7.0). FTE nurses had a mean WP of 56 consultations (SD 18) lasting 41.0 minutes (SD 14.3). Compared to UCSPs, USF-A and USF-B had shorter CT ($p < 0.05$) by 2.48 to 4.05 minutes for medical consultations and by 5.51 to 8.04 minutes for nursing consultations. CT increased over time, decreased with higher PHC age and favorable socio-demographic context, and increased with higher population density and elderly patients' proportion ($p < 0.05$).

Conclusions: USF-B professionals showed higher productivity and shorter CT, suggesting that financial incentives are effective in enhancing productivity but that gains may be obtained with losses in visit duration.

Key messages:

- Effective workforce management is crucial given the current primary care professionals shortages.
- Physicians and nurses in PHC units pay-for-performance exhibit higher productivity and shorter consultation time.

Abstract citation ID: ckae144.1630

Mapping patient pathways for NCDs from a policy perspective: a novel multinational initiative

Katrien Danhieux

K Danhieux[1], *F Monnet*[1,2], *H Safadi*[3], *C Surján*[3], *G Varga*[3], *J Lám*[3], *J Van Olmen*[1], *E Wouters*[2]
[1]Family Medicine and Population Health, University of Antwerp, Wilrijk, Belgium
[2]Center for Population, Family and Health, University of Antwerp, Antwerp, Belgium
[3]Gottsegen National Cardiovascular Center, Budapest, Hungary
Contact: katrien.danhieux@uantwerpen.be

Background: Chronic diseases like CVD and DM pose global health challenges. Understanding patient pathways is vital for effective disease management and reducing morbidity and mortality. However, until now, comprehensive multinational mapping of patient pathways from a policy or regulatory perspective in the context of chronic disease has not been undertaken. Previous investigations into patient pathways mainly focused on the perspective of individual patients, assembling trajectories of those patients, but did not delve into how these pathways were designed.

Methods: Patient pathways for CVD and DM will be mapped across 11 countries: Belgium, Finland, France, Hungary, Iceland, Italy, Latvia, Poland, Romania, Slovenia, and Spain. Using a survey tool, detailed descriptions and diagrams of healthcare pathways will be collected, stratified by Kaiser Permanente health pyramid strata. Stakeholder interviews on policy and practice level will refine mappings and identify gaps in the policies.

Results: Preliminary findings reveal diverse healthcare trajectories and identified multiple gaps in disease management across countries. For many countries, a complete well-developed patient pathway was not found; instead, the pathways were rather fragmented and lacking for some strata of the health pyramid. These insights underscore the need for tailored interventions and enhanced care coordination to optimize continuity of care and patient outcomes.

Conclusions: Comprehensive patient pathway mapping offers a strategic framework to address gaps in chronic disease management. Our study emphasizes the importance of collaborative efforts in developing context-specific interventions and strengthening healthcare systems to improve public health outcomes.

Key messages:

- Comprehensive patient pathway mapping reveals numerous gaps in global chronic disease management, prompting the need for enhanced strategies.
- Collaborative efforts are key to addressing gaps in chronic disease care.

Abstract citation ID: ckae144.1631

Inequalities in access to early child services in Bulgaria

Sonya Nedelcheva

S Nedelcheva[1], *K Dokova*[1]
[1]Social Medicine and Health Care Organization, MU-Varna, Faculty of Public Health, Varna, Bulgaria
Contact: sonya.koleva@mu-varna.bg

Background: Children's health has been a major focus of European health policy since 2000, with particular emphasis on early childhood and integrated services for children with chronic diseases. However, research on early child care in Bulgaria is sparse, mainly focusing on the role of nurseries, kindergartens and nursing care. Our aim is to investigate whether there are disparities in access to early childhood health services in Bulgaria.

Methods: A survey was conducted among mothers of children up to 7 years old between April and June 2022. The questionnaire, containing 49 questions, was based on the theoretical framework from the EU project 'Models of child health appraise', covering topics as: geographical and financial access to services, equity, quality, responsiveness to children and family needs, considered key features of outpatient child medical care. Statistical analysis utilized Chi-square, Fisher's exact and ANOVA tests.

Results: A total of 413 Bulgarian women, with a mean age of 34.3 (± 5.1), participated in the study. Almost all women (91.3%) reported that their children had a primary care provider. The mean time to reach the GP/pediatrician's office was 16 minutes (95% CI 14.6 - 16.7), longest for residents of small towns and villages (21 minutes), $p = 0.004$. Parents from small towns (including villages) were six times more likely to experience financial difficulties related to their children's healthcare services compared to those from the capital city ($p = 0.047$), as well as parents with low-income ($p = 0.031$). Emergency healthcare was the most demanded service by families with children under 7 years old, possibly due to its free availability. Parents with secondary education and from small towns lack access to non-medical health-promoting or preventive services such as breastfeeding consultations, speech therapy and others.

Conclusions: Significant financial and geographic disparities in access to early child health services exist in Bulgaria.

Key messages:

- There are serious social health inequalities related to the access to outpatient child health services in Bulgaria.
- There is an urgent need for specific child and family health strategy based on the principles of proportionate universalism.

Abstract citation ID: ckae144.1632
Changes in TB contact tracing during the COVID-19 pandemic. An Irish single centre experience

Kira Casey

K Casey[1], *S Fennessy*[1], *C Wallace*[1], *P Lyng*[1], *S O'Beirne*[1]
[1]St Vincent's University Hospital, Dublin, Ireland
Contact: caseyki@tcd.ie

Contact tracing following the diagnosis of tuberculosis (TB) is a crucial process in the identification and treatment of both secondary TB cases and also infected contacts who may require treatment for latent TB infection. During the COVID-19 pandemic, Public Health and Respiratory teams in the St Vincent's University Hospital (SVUH) TB clinic in Dublin, Ireland, noted anecdotally that there appeared to be fewer contacts screened by public health services per index active TB case identified. To investigate this, we performed a retrospective review of the TB contact tracing service in SVUH, examining and comparing contact tracing of active TB cases in the 3 years prior to the pandemic (2017-2019) and four years thereafter (2020-2023). Results from 2017-2019 calendar years, prior to the COVID-19 pandemic noted an average of 4.77 contacts per index TB case (total 107 index cases and 510 contacts). In comparison, our data from 2020-2022 noted an average of 3.03 contacts per index TB case (total 59 index cases and 179 contacts). As pandemic restrictions were lifted again, we found our 2023 data to be more comparable to that of pre-pandemic times, noting 4.54 contacts per index case (total 22 index cases and 100 contacts). The reduction in TB contacts per index cases noted during the COVID-19 pandemic may reflect work and lifestyle changes over that time, particularly an increase in remote work but also social distancing. It is interesting that as the population emerged from the isolation measures of the pandemic, contact numbers returned quickly to pre-pandemic levels. In line with global concerns, our data highlights the ongoing workload of TB contact tracing locally and the importance of resource allocation for these services.

Key messages:

- Our Irish centre experienced a notable but temporary reduction in contacts requiring screening by public health services, per index active TB case, during the COVID-19 pandemic.
- In line with global concerns, our data highlights the ongoing workload of TB contact tracing locally and the importance of resource allocation for these services.

[3]Research Chair on Mistreatment of Older Adult, University of Sherbrooke, Sherbrooke, Canada
[4]Faculté des Sciences et École de Gestion, University of Sherbrooke, Sherbrooke, Canada
[5]Research Chair in Digital Health, HEC Montreal, Montreal, Canada
[6]Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada
Contact: aline.aboujaoude@umontreal.ca

Context: Assessing older adults' abilities to carry out their activities of daily living (ADLs) is a key determinant in the provision of homecare services for aging in place. Amidst a growing aging population and lack of human resources, continuous remote monitoring technology appears promising to support health and social care professionals (HSCPs) in identifying service needs. However, implementation studies conducted in real-life settings are lacking. This study is part of an on-going action design research project aimed at developing an ambient telemonitoring system monitoring ADLs to support clinical decision making. It focused on the initial step of implementation and aimed to understand 1) which HSCPs would want to use the system, 2) for which care recipient they requested it, and 3) for which reasons.

Methods: A multiple embedded case study utilizing mixed methods was conducted across 3 healthcare establishments in Quebec, Canada. Descriptive statistics from surveys and medical records was conducted to describe the profile of HSCPs and their care recipients. An inductive qualitative analysis was carried out through interviews with 23 HSCPs, in charge of 31 care recipients, to deepen our understanding of the reasons why they requested the system.

Results: HSCPs were primarily women (89%) occupational therapists (43%). Home care recipients were also primarily women (74%), with documented refusal of homecare services (65%), diagnosed with cognitive decline (94%), and living in a single-family home or apartment (68%). Overall, interviews revealed HSCPs challenges in getting the necessary information to assess their care recipients needs, despite the presence of in-home services and other strategies in place (e.g. informal carer support). Moreover, the telemonitoring system was perceived as promising for risk management.

Conclusions: There is an interest for the use of ADL telemonitoring technology in the delivery of home healthcare services for aging in place.

Key messages:

- To facilitate its integration in practice, we explored the need for, and value of, ADLs telemonitoring technology by health and social care professionals (HSCPs) in real-life contexts.
- By studying the integration of innovative technologies in home healthcare practices, such as ADLs telemonitoring, we aim to support HSCPs practice in fulfilling older adults desire to age in place.

Abstract citation ID: ckae144.1634
A Framework for Bariatric Surgery Patient Care: Patient and Professional Perceptions

João Gregório

C Mendes[1,2,3], *M Carvalho*[1], *J Gregório*[2]
[1]Hospital Espírito Santo de Évora, ULSAC, Évora, Portugal
[2]CBIOS, Universidade Lusófona's, Lisbon, Portugal
[3]Comprehensive Health Research Center, Universidade de Évora, Lisbon, Portugal
Contact: joao.gregorio@ulusofona.pt

Introduction: A multidisciplinary health team for perioperative care of the bariatric patient, sustained in a viable framework to support a long-term follow-up service, may decrease rates of complications, help the recognition of the complexity of this chronic disease, and provide a comprehensive bariatric surgery process analysis. This study aimed to analyze patients' and professionals' experiences with the perioperative care process and identify their perceptions of the bariatric surgery process to support the long-term management of obesity surgical treatment.

Methods: This qualitative study was conducted in a bariatric surgery center in south Portugal. Seven health professionals participated in one focus group, and sixteen patients participated in one of the three focus groups. Patients' focus group script had eleven open main questions with follow-up questions to probe for more information, addressing motivations, experiences with the pre-surgery and post-surgery process, and perceptions of lifestyle changes.

Results: Participants reported the need for a reference professional in the hospital to contact, the importance of psychological support to help patients deal with the 'ups and downs' of post-surgery life, and the financial support for physical activity programs.

Conclusions: This research helped identify a need for a framework for long-term follow-up and showed priorities to tailor health services for managing bariatric surgery patients. New bariatric surgery programs should incorporate a diverse health team, focusing on patient support in the long-term follow-up. This team should be led by a dedicated case manager and include physical activity specialists.

Key messages:

- The positive effects of bariatric surgery go beyond weight loss, reinforcing the importance of developing a new conceptual framework based on a patient-centered care model.
- A case manager specialist on the bariatric surgery process may be the key to improving the long-term benefits of bariatric surgery.

Abstract citation ID: ckae144.1635
Hospital satisfaction among older adults by European Union health system clusters

Courtney Queen

R Pasupathy[1], *R Hossein*[1], *C Queen*[1]
[1]Public Health, Texas Tech University Health Sciences Center, Abilene, USA
Contact: Courtney.M.Queen@ttuhsc.edu

Background: Health systems are influenced by political, historical, cultural and socio-economic factors and differ across countries. Classification of EU health systems into 5 clusters has allowed for international comparison and policy recommendations. This study is based on the Andersen's Behavior Model, that predicts that a sequence of predisposing, enabling and need factors influence satisfaction and utilization of healthcare services.

Aim: Examine the nature and relationship of predisposing, enabling and need factors associated with hospital satisfaction of older adults across EU nations by health system classification clusters.

Methods: Data from Wave 9, of the Survey of Health, Ageing and Retirement in Europe (SHARE) were examined using a sample of older adults from 10 EU countries. Analysis: Non-parametric one-way ANOVA (Kruskal- Wallis test) and Multinominal Logistics regression were performed to test the null hypothesis that (1) hospital satisfaction is equal across all clusters, and (2) predisposing, enabling, and need factors, are not predictors of hospital satisfaction.

Findings: There was a statistically significant difference in hospital satisfaction by cluster [Chi Square= 231.44, df = 21; p< .001]. Age, mental health, technology and chronic disease are predictors of health-care facilities satisfaction. [Chi Square 50.94, df = 3, p< .001], Among those that reported to be highly unsatisfied with healthcare facilities, [chronic disease (Beta = -2.64) and mental health (Beta = -4.41) df = 1 p< .001] significantly predicted hospital satisfaction. Implications for Policy and Practice: Initiatives for the care of older adults should not only aim to increase access to care but also provide targeted services for sub populations such as older adults with mental health and chronic diseases. Further, significant investment is required in technology infrastructure within hospitals and technological assistance or training should be provided to older adults.

Key messages:

- Older adults satisfaction with hospitals varies by health system clusters and is predicted by age, mental health, use of technology and chronic disease.
- Chronic disease and mental health are strong predictors of hospital dissatisfaction among older adults.

Abstract citation ID: ckae144.1636
Data ecosystem using smart home technology to support healthy aging

Kang Wang

K Wang[1], *S Cao*[2], *P Morita*[1]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada
[2]Systems Design Engineering, University of Waterloo, Waterloo, Canada
Contact: k386wang@uwaterloo.ca

Background: Smart home technology has been widely used to mitigate the challenges that population aging brings. However, the lack of a centralized data ecosystem has prevented these technologies from realizing their full potential. This project aimed to construct a data ecosystem compatible with smart home sensors to monitor healthcare for seniors, improving their quality of life.

Methods: The infrastructure was constructed using a user-centered design approach, allowing smart devices such as motion, temperature sensors to operate independently and communicate through a Wi-Fi mesh network. API technology provides a reliable channel for real-time data collection. To ensure data privacy and security, extracted data is hosted in a cloud environment that provides comprehensive data protection, and cloud computing is utilized for high-performance computation tasks. Analytical models such as Machine Learning can be implemented to recognize indoor activities, achieving the goal of remote monitoring.

Results: This data ecosystem advances in privacy and security, interoperability, accessibility, and data-sharing. Unified authentication mechanism ensures data is transmitted among heterogeneous devices with minimal vulnerability. Additionally, the common communication protocol provides the foundation of interoperability between devices. With unobtrusive devices, inhabitants are not burdened with operation, ensuring their accessibility and improving their user experience. Lastly, the data is exchanged in a standardized JSON data format, enabling efficient data-sharing board data integration.

Conclusions: This project developed a data ecosystem based on existing smart home environments. The ecosystem is compatible with smart devices that families already have, effectively reducing additional healthcare costs. Implications of this study include helping health policy and decision makers to adopt more smart home ecosystems to keep older people healthy at home.

Key messages:

- Study constructed a data ecosystem compatible with smart home sensors, achieving remote monitoring of indoor activities and improving the quality of life for seniors.
- The developed ecosystem offers promotion in privacy and security, interoperability, accessibility, and efficient data-sharing, reducing healthcare costs.

Abstract citation ID: ckae144.1637
Youth mental health care use during COVID-19: Evidence from administrative data in Alberta, Canada

Carla Hilario

C Hilario[1,3], M Russell[2], L Urichuk[2], V Agyapong[3], K Rittenbach[4], M Dyson[5], N Parker[6], R Babins-Wagner[7]
[1]School of Nursing, University of British Columbia, Kelowna, Canada
[2]PolicyWise for Children and Families, Edmonton, Canada
[3]Department of Psychiatry, University of Alberta, Edmonton, Canada
[4]Cumming School of Medicine, University of Calgary, Calgary, Canada
[5]Provincial Addiction & Mental Health, Alberta Health Services, Edmonton, Canada
[6]Luna Child and Youth Advocacy Centre, Calgary, Canada
[7]Calgary Counselling Centre, Calgary, Canada
Contact: carla.hilario@ubc.ca

Background: The COVID-19 pandemic affected health care service delivery and accessibility. Our study examined how Canadian youth used mental health services before and during the COVID-19 pandemic, and whether youth access and use patterns differed for subgroups based on social determinants previously associated with health care access.

Methods: Cross-sectional population-based administrative health care data from the province of Alberta in Canada was used to examine youth (ages 15-24) mental health care use from 2018/19 to 2021/22. Data was analyzed using an interrupted time series design and segmented regression modeling on type of mental health care use. Outcome measures were mental health care use for: general physician visits, psychiatrist visits, emergency department, hospitalization, and different mental health diagnoses. We stratified by factors related to social determinants, including gender and socioeconomic status.

Results: The analysis indicates an overall increase in the proportion of youth that used mental health care from 2018/19 to 2021/22 (14.4% vs 17.5%, respectively). There was an immediate drop in use with the onset of the COVID-19 pandemic in Canada, followed by a steady rise during the pandemic years, which was largely due to an increase in general physician visits. This rise was seen for most mental health diagnoses of study (i.e., anxiety, adjustment, attention-deficit/hyperactivity disorder, schizophrenia, and self-harm disorders). Service use increased for young women/girls compared to young men/boys and for youth from wealthier neighborhoods.

Conclusions: This study provides evidence to support health services planning and delivery to respond to the mental health needs of youth and to prepare for future public health emergencies.

Key messages:

- Our study findings indicate changes in health care use for mental health among Canadian youth (ages 15-24) during the COVID-19 pandemic, with use patterns differing for youth subgroups.
- Administrative health data can provide evidence to support health services planning and delivery to respond to the mental health needs of youth and to prepare for future public health emergencies.

[8]Department of Health Promotion Sciences, University of Oklahoma Health Sciences Center, Oklahoma, USA
Contact: pongor.vince@semmelweis.hu

Issue/problem: Europe's aging population presents substantial hurdles for healthcare sustainability. To alleviate the social and economic impacts of age-related diseases, promoting healthy aging is imperative. However, motivating individuals to adopt a healthier lifestyle proves challenging.

Description of the problem: Semmelweis University, a leading institution in medicine, health sciences, and health care in Hungary and Central Eastern Europe, has addressed this challenge by establishing the Center of Preventive Services (CPS), serving 12,500 Semmelweis University employees. The CPS conducts comprehensive health risk assessments and offers consultations with specialists in preventive medicine, public health, dietetics, physiotherapy, and health psychology. Motivational interviewing is used to enhance patient engagement and commitment to healthy lifestyle changes.

Results: The CPS has effectively integrated preventive services into the university's healthcare system, reaching a significant number of employees. Early results show improvements in participants' lifestyle and health behaviors due to the effective use of motivational interviewing. According to the first preliminary result, a study on step count conducted within the CPS found that those taking part in motivational interviewing session were able to increase their average daily step count by 1074 (95% Confidence Interval: 116-2033) steps more than controls.

Lessons: The Semmelweis University's CPS provides valuable lessons for integrating healthy aging-focused preventive care into healthcare systems: 1. Effective preventive care requires targeted interventions based on detailed risk assessment and motivational interviewing; 2. Embedding preventive services within existing health infrastructure improves accessibility and utilization; 3. Collaborative and multidisciplinary approaches are essential to comprehensively address the needs of ageing populations.

Key messages:

- Motivational interviewing boosts the effectiveness and engagement of preventive health services, which is essential to meet the challenges of ageing populations.
- The Semmelweis University's model program shows that embedding preventive services into the infrastructure of existing institutions like universities is scalable for better public health.

Assesing health needs of women with breast cancer in a Regula Hospital Dispensary in Crete, Greece

Giorgos Markakis

G Markakis[1], M Maniou[1], K Neofitos[1], N Ioannou[1], M Papadakaki[1]
[1]Social Work, Hellenic Mediterranean University, Iraklion, Greece
Contact: gmark@hmu.gr

Background: Understanding the health needs of women with breast cancer is essential for tailor-made care. Socio-economic factors impact care access and outcomes. Previous research has indicated variations in healthcare experiences based on factors such as education level, employment status, and income. However, specific insights into the health needs of women with breast cancer in Crete, Greece, remain limited.

Purpose: The current study aimed at assessing the health needs of women with breast cancer.

Methods: A total of 161 women were surveyed between June 2023 and December 2023 in a regular Hospital Dispensary at a General Hospital in Heraklion, Greece.

Results: The majority were married (46%) and had an average of 2 children. 16% were graduates of secondary education and 42 % graduates of higher education, 33% retired and 19% full-time employees. Most participants (45%) reported a family income between 10,001 to 20,000 €, 29% under 10000 € and 26 % between 20001 to 30000 €. The majority had received additional medical treatment (75%), with surgery being the most common (30.6%). Other treatment included radiation therapy (28%), chemotherapy (23%), and hormone therapy (18%). Prevalence of comorbidities was high, with hypertension (97%), coronary heart disease (92%), cholesterol issues (43.5%), arrhythmias (82%), thyroid disease (81%), diabetes mellitus (79.5%), and bleeding disorders (43.5%) being reported. Smoking was also prevalent among participants (79.5%).

Conclusions: This study highlights the complex health needs of women with breast cancer in Crete region, Greece and emphasizes the prevalence of comorbidities and the importance of tailored support services and comprehensive care approaches for this population.

Key messages:

- Considering socio-economic factors is critical in healthcare planning and intervention strategies.
- Emphasizing the importance of tailored support services and comprehensive care approaches for this population.

A socially interactive communication skills training for competent health educators

Nicos Middleton

N Middleton[1,2], *M Papapetrou*[1], *M Moore*[2], *C Nicolaou*[1], *M Karanikola*[1], *M Kyranou*[1], *A Kassianos*[1], *E Hadjigeorgiou*[1], *I Orpahnides-Eteokleous*[2], *O Kolokotroni*[1,2]
[1]School of Health Sciences, Department Nursing, Cyprus University of Technology, Limassol, Cyprus
[2]Birth Forward, NGO, Nicosia, Cyprus
Contact: nicos.middleton@cut.ac.cy

Background: Every contact with expectant and new parents can be a “teachable moment” for promoting the health of mother-baby-family; yet, healthcare providers may not effectively perform their educational role. Previous studies have described various setting-specific challenges. Procedural knowledge, resulting in lack of confidence and avoidance, is a universal theme, challenging current communications skills training. Given the evolving role of midwives under the new Cyprus National Healthcare System, there is need for innovative practices.

Objectives: “Baby Buddy Communicators” designed, implemented and piloted tested a socially interactive digital environment on the Edubreak platform, where practicing ($N = 8$) and in-training ($N = 7$) Midwives completed an 8-week iterative hybrid communication skills course along with service-users.

Results: Four situational-based scenarios were co-created with ‘holders of the experience’ tapping on key priorities (elective caesarean, breastfeeding challenges, baby in NICU, postnatal depression). Participants produced video artefacts of role-play consultations and engaged in peer-to-peer and service-user feedback via the in-built video annotations and blog writing tools. Deductive content analysis of the rich material using the 18-item Health Professionals Communications Skills (HPCS) scale identified recurrent patterns tapping on both informational aspects (e.g. incomplete information gathering, overload without assessing comprehension) as well as social skills (e.g. agenda setting, early reassurance, assertiveness).

Conclusions: This cross-sectoral transfer of social video from sports training to healthcare is a “proof of concept”. Inverted (i.e. making current practices visible) and experiential learning (e.g. feedforward) with cross-sectoral (service-user involvement) and cross-module dimensions (i.e. communication skills and evidence-based practice) provided the basis for evaluation and a source of shared learning and reflection.

Key messages:

- Several areas of improvement in communication skills of maternal healthcare providers were identified while peer-to-peer and service-user feedback was a source of reflection.
- The use of digital technology and social video allowed immersive role-playing, observation and constructive feedback loops providing a new paradigm in health communication skills training.

Background: In Feb 2023, the EU’s Joint Action on the transfer of best praCtices In pRimary CarE (CIRCE-JA) was launched with the objective of effectively transferring and implementing six best practices (BPs) among Member States (MS). Transferability from one primary care (PC) setting to another can be challenging given organizational, legal, cultural, social, economic, and environmental factors, requiring robust a methodological framework to guide the transfer process. A scoping review was conducted to identify conceptual models and methodological frameworks for context-relevant and evidence-informed BP transfer in PC settings.

Methods: The study aimed to identify models or frameworks to guide BP transfer in PC settings, whilst maximizing transferability. The JBI methodology was used, and an extensive search was conducted in PubMed (time limit: Jan ‘13-May ‘23). All publications of original research, systematic reviews, and text and opinion papers in English were eligible for inclusion. Key exclusion criteria were set, i. e., intervention type, level of care and reporting quality. The search was supplemented by gray literature review.

Results: From a total of 369 publications, 9 met eligibility criteria, reporting on 10 conceptual and methodological models/framework largely varying. These included transfer models applicable to all BPs as well as elements specific to some BPs, i.e., addressing integration, patient-centered care, care coordination, and health promotion. Strengths and weaknesses were identified for all.

Conclusions: Transferability of health interventions is complex, requiring systematic consideration of setting and intervention characteristics to inform and support local adaptation, implementation, and decision-making. Key elements identified can support the CIRCE-JA BP transfer and are largely relevant for further BP transfer across PC settings in EU MS, incl. for local adaptation, stakeholder engagement and effective implementation monitoring.

Key messages:

- Innovative BPs are successfully deployed in many EU MS. To best support transformation for strong EU primary care and resilient health systems, it is important to ensure evidence-informed BP transfer.
- This review reports on the selection of appropriate frameworks and models, and key elements thereof, to allow successful transfer of CIRCE-JA BPs and other BP transfer across PC settings in Europe.

Improving the healthcare response to migrants landing in Lampedusa through a multimodal strategy.

Alessandra Diodati

LG Sisti[1], G Canzone[2], F Scorsino[1], C Napoli[1], C Camponi[1]
[1]National Institute for Health, Migration and Poverty, Rome, Italy
[2]Local Health Authority, Palermo, Italy
Contact: alessandra.diodati@inmp.it

Issue: Lampedusa island is a crucial Italian entry point for migrants and the only health facility is the outpatient clinic that relies on the helicopter transfer to the mainland for urgencies. When the influx of migrants -and of tourists- increases, the health demand burden rises. Moreover, the plurality of the actors involved in migrants' reception and assistance makes healthcare organization complex. In 2023, 115.000 arrivals were recorded with an increase of pregnant migrants transferred by helicopter; moreover, the lack of an EMTs-equipped ambulance and coordination gaps between actors were raised.

Description of the practice: Also paving on law 50/2023, in 2023 INMP and other institutions promoted a multimodal strategy to support healthcare in Lampedusa. A needs assessment grounded on settings and processes field observation and key stakeholders' structured interviews was designed. Hence, an equipped ambulance service was set in September 2023 and an obstetric triage (ObT) procedure for pregnant migrants was tested. Further, operational protocols for migrants' health have been drafted and enclosed in a MoU signed between key institutions, and a dedicated Committee monitoring protocol implementation was also set.

Results: Until now the ambulance has carried out 242 operations, mostly in response to community requests and ObT has led to using helicopter solely for real Ob urgencies. Also, the MoU has improved the coordination between actors, and the monitoring Committee-just settled-has already identified new priorities such as of defining a procedure for pregnant migrants requesting pregnancy termination.

Lessons: A multimodal strategy based on field assessment, enhancing coordination between actors and rolling-out of shared procedures has improved the effectiveness, efficiency and appropriateness of healthcare in Lampedusa, requiring a slight increase in resources. Remarkably, the healthcare reinforcing results in beneficial also for the general population.

Key messages:

- Massive influx of migrants in Lampedusa has required strengthening health services on the island.
- Evidence-based interventions based on needs assessment have improved healthcare for both migrants and the general population.

[6]Ukrainian Foundation for Public Health, Kyiv, Ukraine
Contact: halyna.skipalska@gmail.com

Issue/problem: Survivors of gender-based violence (GBV) and conflict-related sexual violence (CRSV) in Ukraine face significant challenges in accessing appropriate healthcare services. Despite governmental commitment, acknowledgment and regulatory frameworks, including the ratification of the Istanbul Convention, gaps persist in integrating comprehensive GBV/CRSV services into primary healthcare (PHC) settings, exacerbated by the ongoing conflict with Russia.

Description of the problem: An analysis of healthcare providers' knowledge has revealed deficiencies in effectively supporting GBV/CRSV survivors. Barriers include workload pressures, lack of intersectoral cooperation and case-management protocols, and insufficient training opportunities on survivor support. In collaboration with the World Health Organization, the global Clinical Management of Rape (CMR) guidelines was adapted for Ukrainian context. Among findings from CMR trainings attended by 443 PHC providers in 2022-2023 (213 participants in 2022 and 230 participants in 2023), the results underscore gaps in PHC workers' basic knowledge and readiness to effectively support survivors during the war.

Results: Data from WHO training sessions underscored significant gaps in knowledge among healthcare professionals regarding legal protocols, available resources, and best practices in PHC service delivery. Identified barriers emphasized the urgent need for targeted interventions to enhance PHC workers' capacity in GBV/CRSV response.

Lessons: Recommendations focus on systemic enhancements including revising regulatory frameworks, developing standardized protocols, and institutionalizing and providing comprehensive training programs. Innovative approaches like online courses, mentoring programs, and integrated service models are crucial for addressing multifaceted challenges.

Key messages:

- A holistic GBV/CRSV response is an essential component in PHC.
- This intersectoral survivor-centered approach provides safe spaces that can be adapted to other contexts in Europe.

Abstract citation ID: ckae144.1644
Behavioral incentives on pay-for-performance schemes in primary health care: a scoping review

Joana Alves

J Alves[1], CV Dias[2], J Perelman[1], I Gonçalves[3], I Moiane[3], V Morgado[3]
[1]NOVA National School of Public Health, Public Health Research Centre, CHRC, NOVA University Lisbon, Lisbon, Portugal
[2]CHRC, NOVA Medical School, Faculdade de Ciências Médicas, NMS|FCM, Universidade Nova de Lisboa, Lisbon, Portugal
[3]NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
Contact: joana.alves@ensp.unl.pt

Background: Incentivizing healthcare professionals through pay-for-performance (P4P) schemes has become an essential strategy to enhance healthcare quality and efficiency. In Portugal, a P4P framework was put in place in Primary Health Care (PHC). Understanding how these incentives influence healthcare delivery is crucial for optimizing P4P effectiveness.

Objectives: This scoping review aims to compare the impacts of intrinsic and extrinsic incentives of P4P schemes within PHC teams.

Methods: We are conducting a comprehensive scoping review following the PRISMA-ScR guidelines. The databases PubMed/MEDLINE, Scopus, Web of Science, and PsycINFO are being searched to identify experimental and quasi-experimental studies. Eligible studies focused on PHC providers organized in teams, examining the role of intrinsic and extrinsic incentives under both public and private healthcare settings.

Results: Preliminary findings include a Dutch study demonstrating significant improvements in adherence to prescribing guidelines through electronic health records based P4P indicator. In Ethiopia, performance-based non-financial incentives led to enhanced data quality and evidence utilization among health workers. Conversely, a study from Burkina Faso highlighted mixed results in antenatal care quality improvement despite incentive implementation. In Scotland, studies on the removal of financial incentives indicated potential declines in certain quality care metrics, suggesting the complexities involved in the direct and indirect effects of incentive withdrawal.

Conclusions: The preliminary evidence indicates that both intrinsic and extrinsic incentives can significantly impact the effectiveness of P4P schemes, though the nature and magnitude of these impacts vary considerably. The findings underscore the necessity of a nuanced approach to designing and implementing incentive mechanisms in PHC to foster sustainable improvements in healthcare quality.

Key messages:

- Intrinsic and extrinsic incentives significantly influence P4P scheme effectiveness in PHC.
- Designing P4P incentives requires nuanced consideration of varying impacts on healthcare quality.

Reorganisation of the emergency network in the province of Verona

Lorenzo Dragoni

L Dragoni[1], F Palladini[2], D Signorelli[3], A Valerio[4], G Messina[1,5], N Nante[1,5]
[1]Hygiene and Preventive Medicine, University of Siena, Siena, Italy
[2]Medical Direction, University Hospital of Verona, Verona, Italy
[3]Health Management, LHA Verona, Verona, Italy
[4]Emergency Unit, University Hospital of Verona, Verona, Italy
[5]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: dragoni11@student.unisi.it

Background: In recent years, in the provincial context of Verona, has been perceived an increasing pressure on the Emergency Room (ER). There was therefore a need to identify possible actions to optimize the emergency network. The aim of the study was to evaluate the impact of the first corrective measure implemented: the redistribution of the municipalities' afferences.

Methods: Data on the actual number of beds in each facility and on the emergency equipment were obtained from the various medical directions. Once the population/bed index had been calculated, it was adjusted according to the characteristics of the various facilities. Based on these data, the redistribution of afferences was carried out. The period monitored in the study covers the first three months after the reorganisation (January 2024) in comparison with the same period in 2023. The data collected were used to calculate both activity indicators for the PS and the Urgent Emergency Medical Service (UEMS).

Results: With a stable number of calls recorded in the two periods examined (20,366 in 2023 and 20,255 in 2024), with regard to the locations affected by the redistribution of municipalities, there is a decrease in the number of ambulance calls in San Bonifacio (-7.5%) and Villafranca (-16.2%) and an increase in Peschiera (+13.6%) and Negrar (+16.5%) compared to the quarter of the year 2023. There is no significant increase in Borgo Roma.

Conclusions: The organizational structure of the emergency services in the province of Verona is part of a highly complex framework. In any case, this first change has proved to be effective in addressing some of the factors influencing the contribution of the ER, but the overall impact and extent of the change will have to be studied in depth in order to optimize the network as much as possible.

Key messages:

- The reorganisation of such a complex area is a very difficult challenge, but the path we are taking seems to be the right one.
- It will also be necessary to act at the level of the internal processes of each ER in order to successfully complete the reorganization.

Abstract citation ID: ckae144.1646

A national job profile for infection control nurses in public health: the development and content

Sofie Noorland

SA Noorland[1], K De Groot[1], AL Francke[1,2], RS Batenburg[1,3]
[1]NIVEL, Utrecht, Netherlands
[2]Department of Public and Occupational Health, Amsterdam University Medical Centre and Vrije Universiteit Amsterdam, Amsterdam, Netherlands
[3]Department of Sociology, Radboud University Nijmegen, Nijmegen, Netherlands
Contact: s.noorland@nivel.nl

Background: The COVID-19 pandemic emphasized the crucial role of infection control nurses (ICNs) in public health. ICNs working in multidisciplinary infection control teams face challenges, such as new infectious disease outbreaks and vaccination hesitancy. Recognizing the complexity in this domain, Dutch ICNs in municipal public health services expressed the need for a national job profile describing their tasks and responsibilities.

Methods: A mixed methods approach was used to develop a job profile. National and international documents on infection control professionals were studied by desk research. Insights from Dutch infection control professionals and experts were collected through a survey ($n = 171$), two interactive discussion meetings (18-22 participants) and meetings with an advisory group of stakeholders, including representatives of the Dutch nurses' association. Descriptive statistics and deductive content analysis were used to analyze the data.

Results: The diverse methods facilitated the development of a job profile for Dutch ICNs. The profile describes that, within infection control teams, ICNs play a key role in coordinating and monitoring infection control measures. They facilitate collaboration among (at-risk) individuals, the infection control team, and the collaborating partners. Additionally, ICNs identify emerging risks for infection control and coordinate infection prevention activities in collaboration with the infection control team. During large-scale outbreaks, ICNs take a leading role and, where appropriate, delegate tasks such as contact tracing to crisis workers.

Conclusions: We developed the first job profile that outlines the tasks and responsibilities of ICNs in Dutch public health services. It contributes to strengthening infectious control services to face future challenges. Findings emphasize the ICNs' pivotal role in coordinating and monitoring infection control efforts, while enhancing collaboration, even during large outbreaks.

Key messages:

- In close collaboration with infection control professionals a robust job profile was developed, describing the tasks and responsibilities of infection control nurses in the Netherlands.
- The new job profile contributes to strengthening the position of infection control nurses working in municipal public health services and infection control teams.

Abstract citation ID: ckae144.1647

Life course prevention - challenges for public health lying ahead

Tit Albreht

T Albreht[1,2]
[1]Centre for Health Care, NIJZ, Ljubljana, Slovenia
[2]Department of Public Health, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia
Contact: tit.albreht@nijz.si

Issue/problem: Demographic and epidemiological transitions have now shifted the focus from vulnerable population groups onto the active population, in particular young adults. At the same time lessons from the covid-19 pandemic taught us about missing actions on the elderly. While the latter have shown compliance and have followed most preventative activities, we observe scepticism and reluctance in the young adults.

Description of the problem: The covid-19 pandemic showed that young to middle-aged adults were the most reluctant group to adhere to preventative measures but in complying to the recommendations concerning vaccination. Since European activities are now focusing on addressing determinants of NCDs and are hoping to mobilise all population strata, including young and middle-aged adults, it would be important to explore how this mindset might affect the overall attitude to prevention.

Results: Health policy should explore specifically the needs of young to middle-aged adults (e.g. ages 30 to 44) to list their specific needs, expectations from preventative activities. On the other hand, it would be necessary to find out about the concerns, reluctance, and objections. The interplay of these will play a significant role in acceptance of present and future preventative activities. Exploration on these topics presents the following challenges: 1. Multiple sources of information on given health problems; 2. Lack of structured accessible and well-understandable explanations of advantages and benefits; 3. Inappropriate communication by health professionals or agencies on their behalf; 4. Complexity of the problem, which is then translated into complex and not easily understood messages.

Lessons: Learning about the specific needs of young adults, their expectations from the health systems in terms of prevention and health care as these will shape their overall attitude to prevention and have an impact on their families, particularly children.

Key messages:

- Knowledge about expectations, needs, concerns, and reserves with respect to prevention is essential for the future activities on prevention.
- Involving young and middle-aged adults in the preparation of the future preventative activities for their population groups is essential.

Abstract citation ID: ckae144.1649

Utilization patterns and preferences of telemedicine services in the post-Covid-19 era in Israel

Hadar Samuel

H Samuel[1], *T Norman*[1], *V Myers*[2,3], *A Ziv*[2], *R Wilf-Miron*[2,3]
[1]Health Policy Research Team, Myers-JDC-Brookdale Institute, Jerusalem, Israel
[2]Gertner Institute of Epidemiology, Sheba Medical Center, Tel HaShomer, Israel
[3]School of Public Health, Tel Aviv University, Tel Aviv, Israel
Contact: hadars@jdc.org

Background: While telemedicine can streamline healthcare delivery, suboptimal use may compromise care quality and access. Given the increased adoption of these services during and after the Covid-19 pandemic, understanding best practices through examination of utilization patterns and patient preferences is crucial. This study estimated utilization rates, patient preferences and perceptions of response received for different physician-encounter channels for common clinical and administrative scenarios.

Methods: Cross-sectional telephone survey in Hebrew or Arabic of 519 Israelis who contacted a doctor in the past year for clinical or administrative needs. Data collected during April-June 2023, focused on chosen contact channel, reasons for choice, perceived response adequacy, and hypothetical future preferences.

Findings: 78% of encounters with family physician for clinical need were in-person, with lower rates for phone (16%) or messaging (6%); in-person dominated with encounters with specialists (94%). Conversely, for administrative needs, more used phone (15%) or messaging (48%), though 37% still preferred in-person encounter. Video usage was negligible (<1%). Main reasons for in-person choice were perceived need for physical exam, habit, or negative perception of remote service quality. Convenience/exam-free needs drove phone/messaging use. While most patients were satisfied with their chosen channels, phone consultations had lower future preference rates.

Conclusions: Matching channel to need is crucial. Physical exams require in-person visits, though they are not always required and many stick with in-person out of habit; remote options like messaging can streamline administrative tasks. Patient education could address habits and help familiarize patients with new options. Optimizing phone visits and promoting video options could enhance adoption due to their benefits.

Key messages:

- In-person visits are preferred for clinical needs, while messaging/phone are underutilized for administrative tasks, highlighting missed opportunities for convenient telemedicine options.
- Addressing patient habits and perceptions around remote healthcare channels is crucial for optimizing telemedicine adoption and streamlining care delivery.

Abstract citation ID: ckae144.1650
Workplace health promotion measures and use of medical services in the German Federal Armed Forces

Ute Seeland

U Seeland[1,2], M Hauck[1], R Roehle[3,4,5], C Dickob[6], J Ucar[1], L Arnold[1], SN Willich[1], T Reinhold[1], S Ludwig[1,7], R Roy[8]

Contact: gendermed@ute-seeland.de

Introduction: Workplace health promotion measures (WHPM) are among recommended options for maintaining employees health, important for the German Federal Armed Forces as an employer. In order to detect associations between WHPM and health care utilization, we recorded the number of outpatient visits and hospital stays, differentiated according to gender, military or civilian activity.

Methods: Prospective longitudinal observational substudy with cross sectional analysis of items regarding use of medical services at T0 (6-9/2022). Analysis for T1 (2023) and T2 (2024) follow. Data were obtained with a web-based employee survey to record self-reported endpoints. A total of about 224.000 employees by the German Armed Forces were addressed.

Results: Survey participation rate was 10.5% (n = 23.568) of all employees in T0, 29.1% were women and 0.3% reported being diverse, 43.2% of the participants were <40 years of age. Independently of taking part in WHPM, we did not detect differences in the proportion of male soldiers receiving treatment in hospitals of the German Federal Armed Forces. Among female soldiers without WHPM, 37.5% stayed in hospitals and with WHPM 30.5%. Higher % of women (84%) than men (78%) presented to the military - or family physician (w: 81%, m: 73%), independent of participation in WHPM and assignment for civil or military. In last 4 weeks, more women (81.3%) than men (65.6%) were prescribed medication. Female employees in civilian w.p.(84.8%) took more medications than those in military w.p (77.7%). Oral contraception was used by 20% of women in both civilian and military w.p.

Conclusions: There are no gender differences nor difference for civilian or military employees concerning the number of days staying in hospital. More women than men recieved regular outpatient medical care and more women than men take medication regularly.
*Ludwig S and Roy R share last authorship

Key messages:

- There are no gender differences nor difference for civilian or military employees concerning the number of days staying in hospital.
- More women than men recieved regular outpatient medical care and more women than men take medication regularly.

Abstract citation ID: ckae144.1651
The determinants of oral health in Turkish elderly: an analysis of Turkey Health Survey (THS) 2022

Irem Şevik

I Şevik[1], A Davas[1]
[1]Public Health, Ege University, İzmir, Türkiye
Contact: iremsevik@gmail.com

Background: Oral health is an integral part of health and wellbeing; however, the use of dental care by the elderly is lower compared to other services. Considering the relationship between oral health and chronic diseases, along with healthcare use patterns, evaluating oral health in the elderly is crucial. This study aims to assess the oral health status and individual, socioeconomic and healthcare related factors in people aged 65 and over in Turkey.

Methods: This cross-sectional study was based on THS 2022 micro dataset. Participants aged 65 and over constituted the population of this study, with 3144 participants included. Data analysis was performed using SPSS 28.0 and included descriptive statistics, Pearson's chi-square and logistic regression.

Results: The mean age of participants was 72.57 with 54% being women.Self-reported poor oral health was noted in 25.8%, and 75.2% did not receive dental care in the past year. Individual factors such as older age, obesity, and multimorbidity, as well as social factors like female gender, being single, and language barrier, were associated with worse oral health. Education and social support were also associated with oral health. Among economic factors, employment showed a significant association. Concerning healthcare-related factors, not using oral care in the past year, unmet dental care needs due to financial constraints, appointments, and transportation were associated with worse oral health. Logistic regression revealed significant associations between oral health and age, multimorbidity, gender, language, education, social support, employment, dental care use, unmet dental care needs due to financial constraints and transportation.

Conclusions: Addressing barriers and risk factors is needed to improve oral health among Turkey's elderly. Efforts should focus on enhancing access to dental care and addressing socioeconomic determinants of oral health.

Key messages:

- Identifying and addressing barriers and individual, socioeconomic and health-care related risk factors associated with poor oral health among the elderly in Turkey is important.
- It is needed to prioritize efforts aimed at enhancing access to oral care for the elderly in Turkey by both improving physical access and addressing social determinants to ensure better oral health.

Abstract citation ID: ckae144.1652
Organization of Vaccination Sites in Quebec: Perception of Users, Employees and managers

Mathieu Lanthier-Veilleux

M Lanthier-Veilleux[1,2], *EM Pépin*[2,3], *LND Ezin Aloffan*[2], *J Loslier*[1,2], *K Nour*[2,3], *M Guay*[1,2]
[1]Sciences de la Santé Communautaire, Université de Sherbrooke, Longueuil, Canada
[2]Direction de Santé Publique, CISSS de la Montérégie-Centre, Longueuil, Canada
[3]Université de Montréal, Montréal, Canada
Contact: mathieu.lanthier-veilleux@usherbrooke.ca

Since late 2020, vaccination sites have emerged rapidly in order to protect the population against COVID-19. Health services in Montérégie (Québec) are provided by three organizations. Each adopted a different approach to immunization. The Regional Public Health Department took this opportunity to describe, compare, and explain these three approaches. A mixed methods design through a multiple case study was conducted. Users, employees and managers were interviewed at the end of 2021 on several performance-related topics. Individual interviews with employees and managers in mid-2022 further explored these topics. 38 managers, 360 employees, and 946 users participated in the survey. 9 managers and 10 employees were interviewed. Most participants were satisfied with vaccination organization regardless of the model used, mainly because of high geographic and temporal accessibility of the sites. Further signage to indicate directions could optimize accessibility. High adaptability was essential for managers and employees. Training strategies such as people to refer to and pairing allowed to better deal with frequent changes and staff rotation. The addition of ongoing training could be beneficial. Rapid changes in employee schedules were identified as a challenge. The use of technology-based scheduling tools, accessible to all, brought added flexibility, which was appreciated. Several ideas were used to communicate updates on a daily basis. However, timely implementation of new recommendations remained an ongoing challenge. Dedicated clinics for specific clienteles were successful. Community partnerships were generally beneficial, although establishing more of them could potentially reach other vulnerable communities. To improve accessibility and minimize health social inequities, a greater investment in local partnerships might reach more vulnerable clienteles. Regular communication and innovative employee support are key elements to improve fluidity of operations.

Key messages:

- Reaching out for vulnerable clienteles is essential to minimize health social inequities.
- Rapid changes in services needs underlign fluidity communication importance.

Abstract citation ID: ckae144.1653
The trajectory of frailty index among spousal caregivers: longitudinal evidence from China

Mingming Liu

H Pikhart[1], *A Peasey*[1]
[1]Epidemiology and Public Health, Epidemiology & Health, University College of London, London, UK
Contact: mingming.liu.21@ucl.ac.uk

Background: Very few studies have investigated the association between providing unpaid caregiving to a spouse and the frailty of caregivers. This study aims to examine the impact of providing spousal care on frailty among the middle aged and older Chinese population.

Methods: Data were derived from the 2011, 2013, 2015, and 2018 waves of China Health and Retirement Longitudinal Study (CHARLS) including 4,008 participants aged 50 and above. Frailty was assessed using a composite mean score based on 41 indicators according to Rockwood frailty criteria, including self-reported health, medically diagnosed conditions, medical symptoms, functional activities assessment, Activities of Daily Living (ADLs), and Instrumental Activities of Daily Living (IADLs). A growth curve model was employed to investigate the differences in frailty among caregivers and non-caregivers.

Results: Compared to non-caregivers, spousal caregivers were more likely to have a higher frailty when adjusted for all covariates (Beta=0.010, SE = 0.003, $p < 0.001$). Furthermore, female caregivers exhibited a higher rate of change of frailty index over time (Beta=0.002, SE = 0.001, $p < 0.05$) compared to female non-caregivers, while no such effect was found in males.

Conclusions: The findings of this study reveal that providing unpaid care to a spouse is associated with an increase in the frailty index over time particularly among female caregivers. These insights underline the necessity for Chinese policymakers to develop and implement targeted interventions aimed at reducing burden on spousal caregiving, thereby preventing an increase in frailty among these caregivers. Such measures would also align with the broader objective of promoting healthy ageing.

Key messages:

- Chinese policymakers need to develop and implement targeted interventions to reduce the burden on female spousal caregivers and prevent increased frailty.
- Focusing on the frailty of female spousal caregivers is crucial for promoting healthy aging.

Abstract citation ID: ckae144.1654
Long-term Survival After Cancer: A Scoping Review of the Health Care Landscape in Germany

Sarah Messer

S Messer[1], *N Cryns*[1], *M Ernst*[1], *U Dirksen*[2], *V Gruenwald*[3], *N Skoetz*[1]
[1]Institute of Public Health, University of Cologne, Cologne, Germany
[2]Department of Pediatrics III, West German Tumor Center, Essen, Germany
[3]Interdisciplinary Uro-oncology, West German Tumor Center, Essen, Germany
Contact: sarah.messer@uk-koeln.de

Background: Cancer remains a global health concern, with a significant increase in new cases projected in the coming years. Although cancer treatment and diagnosis have advanced, leading to improved survival, survivors often face complex physical, emotional, and cognitive challenges. The objective of this scoping review is to provide an overview of the current landscape of specialized long-term survivorship care services in North Rhine-Westphalia (NRW) with a focus on vulnerable groups.

Methods: The scoping review involves two search approaches: a manual search performed by two review authors and a systematic search performed by an information specialist following Scoping Review guidance. The protocol was published on the OSF platform. The systematic search was conducted in databases such as LIVIVIO, MEDLINE and Scopus. The manual search involves identifying key categories of survivorship services and conducting online searches based on these categories in duplicate. Data extraction and synthesis is conducted using EPPI-Reviewer software, and focuses on services characteristics, patient demographics, program format, and accessibility.

Results: The study has identified more than 300 survivorship care services across North Rhine-Westphalia. According to preliminary results some services offer comprehensive care, while others have significant gaps, particularly in addressing the needs of vulnerable groups. One example of these gaps is the lack of tailored services specifically designed for people with a migration background. Most of the services are not available in multiple languages or gender-specific oriented. The results will be presented on the congress in detail.

Conclusions: This scoping review underscores the importance of tailored survivorship care, especially for vulnerable groups. Public health actions should focus on addressing disparities in access to survivorship services, enhancing existing programs, and developing new policies to support cancer survivors.

Key messages:

- Effective survivorship care requires attention to vulnerable groups.
- The care of long-term cancer survivors should receive more attention in research.

Preventive Resilience: The Role of Long-Term Care Organizations' Collective Agency Capacity

Holger Pfaff

H Pfaff[1], *T Pförtner*[2], *K Hower*[1]
[1]Institute, IMVR - Universität zu Köln, Cologne, Germany
[2]Department Special Pedagogy, University of Cologne, Cologne, Germany
Contact: holger.pfaff@uk-koeln.de

Background: The COVID-19 pandemic has intensified pressure on healthcare organizations (HCOs), particularly long-term care organizations (LTCOs. An HCO's resilience is closely linked to its proactive ability to address and manage both novel and persistent stressors. This proactive approach, termed 'preventive resilience,' involves preemptively averting stressors to safeguard the organization's resilience mechanisms.

Objectives: The aim of this presentation is to examine the hypothesis asserting that preventive resilience is, to a significant extent, nurtured by the collective capacity of a Long-Term Care Organization (LTCO) to act and react as a cohesive social system. This collective agency capacity of an LTCO is posited to play a pivotal role in fortifying preventive resilience of HCOs.

Methods: We conducted a pooled cross-sectional study on long-term care organizations in Germany during the initial (April 2020) and subsequent waves of the pandemic (December 2020-January 2021). Our sample comprised 503 leaders during the first wave and 294 leaders during the second wave from various long-term care organizations. The study involved top managers of these facilities reporting their perceptions of the collective agency capacity of the LTCO, assessed using the AGIL short scale. Additionally, they were asked to gauge the facility's exposure to both general non-pandemic demands and pandemic-specific demands.

Results: We discovered a notable inverse relationship between leaders' perceptions of the collective agency capacity within their Long-Term Care Organizations (LTCO) and their assessments of general demands. However, no significant association was observed between the agency capacity and the magnitude of pandemic-specific demands.

Conclusions: The findings tentatively endorse the notion that cultivating the collective agency capacity of nursing facilities enhances their resilience to familiar general demands, particularly during periods of exceptional stress.

Key messages:

- Cultivating the collective agency capacity of nursing facilities enhances their resilience to familiar general demands.
- The collective capacity to act and react in a cohesive way is a general resistance resource of healthcare organizations.

Abstract citation ID: ckae144.1656
Rethinking electronic health records implementation in Germany: a value-based health system approach

Tugce Schmitt

T Schmitt[1,2]
[1]International Health, Maastricht University, Maastricht, Netherlands
[2]Epidemiology and Public Health, Sciensano, Brussels, Belgium
Contact: tugce.schmitt@sciensano.be

Problem: The Digital Act (Digital-Gesetz) in Germany stipulates that electronic health records (elektronische Patientenakte; ePA) will be set up for all persons under the statutory health insurance (SHI) in 2025; those who do not wish to use ePA can object. This opt-out approach aims to increase the coverage of ePA among the SHI population to 80%, which has been ca. 1.5% since its launch in 2021. According to law, ePA is managed solely by the patient and does not replace the conventional patient file stored in the medical practice management system. Without appropriate measures, it is likely that multiple parallel patient files are created, with the risk of ePA being side-lined over time.

Description: The Ministry of Health aims to make ePA the central platform for patients' healthcare provision throughout their life. With ePA, patients should receive useful information about their healthcare as well as reminders and tailor-made medical advice. For healthcare providers, ePA should become an essential part of the healthcare process with containing reliable information and supporting the treatment. However, understanding ePA as more than a digital health solution, factors beyond technical interoperability must be considered for its successful implementation.

Results: The full potential of ePA and its positive impact on healthcare to tackle the fragmentation issue can only be realised when it is viewed as a helpful tool of collaboration for all involved parties. The existing regulatory frameworks in Germany create disincentives for greater integration, coordination, and interconnection, with each sector following its own reimbursement system and reinforcing the division between them. This contradicts with the idea of ePA fostering patient-centredness and inter-sectoral collaboration.

Lessons: How a health system functions and how health services are governed and remunerated have a substantial impact on the healthcare providers' acceptance of digital services.

Key messages:

- Changes in the governance of health systems may be necessary when implementing electronic health records to bring person-centred care and overcome the separation of in-patient and out-patient sectors.
- Rather than a paternalistic approach, the relationship between the patient and healthcare provider should move towards a partnership model, based on the motivation of keeping individuals healthy.

Contact: gloriaspatari@gmail.com

Background: Escalating violence against healthcare workers is a significant public health issue that undermines care quality and workers' health. This descriptive study aims to examine trends in aggression across different pandemic phases.

Methods: The study analysed reported violence among healthcare workers from 2018 to 2023 within a Local Health Authority in Genoa, Italy. Variables of interest included the severity of aggression, the professionals affected, and the locations of incidents. Data was analysed using appropriate statistical methods, including multinomial logistic regression, to assess relationships across pandemic phases.

Results: Reported aggressions rose from 48 incidents in 2018 to 103 in 2023, totaling 463. Pre-pandemic physical violence was at 39%, dropping to 27% during and after the pandemic (χ^2=7.4, df = 2,

$p < 0.025$). Nurses experienced the highest violence rates, with an average of 72% pre-pandemic and 74% post-pandemic, reducing to 51% during the pandemic if compared with doctors (Coef -0.80; 95%CI -1.45|-0.15). Over half of incidents occurred in Emergency and Psychiatric Services, from 77% before to 51% after pandemic. Conversely, violence in Local Services rose from 7% before to 24% during and 28% after pandemic (χ^2=56.9, df = 6, $p < 0.000$). If compared to Hospitals, violence in Local Services increased during (Coef 1.44; 95%CI 0.40|2.48) and post-pandemic (Coef 1.001; 95%CI 0.13|1.87), and in Psychiatric Services decreased post-pandemic (Coef -0.98; 95%CI -1.67|-0.29).

Conclusions: Violence against healthcare workers shifted during and post-pandemic, mirroring the decentralisation of healthcare due to pandemic. The urgent development and implementation of effective violence prevention strategies are imperative. These should include training, psychological support, security enhancements, and a strong organisational culture that prioritises safety and respect. Protecting healthcare workers is crucial for their well-being and to ensure high healthcare quality.

Key messages:

- Escalating violence undermines care quality and healthcare worker well-being. Effective prevention strategies are essential, including training, support, and an organisation that prioritises safety.
- Nurses are the main victims of violence. Violence is higher in Emergency Departments, but incidents are increasing in Local Health Services, due to organisational changes during and post-pandemic.

Abstract citation ID: ckae144.1658

The impact of diabetes pay-for-performance program on hyperglycemic hyperosmolar state (HHS)

Tsung-Tai Chen

T-T Chen[1]
[1]Department of Public Health, Fu Jen Catholic University, New Taipei, Taiwan
Contact: 084907@mail.fju.edu.tw

Background: To examine the effects of a diabetes pay-for-performance (P4P) program on the negative metabolic outcome: hyperglycemic hyperosmolar state (HHS) of patients in Taiwan.

Methods: Four years (2008~2011) of data from the National Health Insurance Administration (NHIA) databases were examined. P4P patients included those who were newly enrolled in the P4P group in 2010, and consecutively included in 2011. Patients were never enrolled are defined as non-P4P group in these two years. The caliper matching method and a generalized estimating equation were used to estimate difference-in-differences models (baseline year 2009) and examine the effects of the P4P program on the count of the adverse outcome.

Results: The P4P program was associated with decreases in the incident of HHS (IRR 0.53, $P = 0.02$).

Conclusions: The disease management component of the diabetes P4P program can be beneficial for reducing the incidences of HHS.

Key messages:

- The disease management component of the diabetes P4P program can be beneficial for reducing the incidences of HHS.
- The disease management component of the diabetes P4P program is important.

Abstract citation ID: ckae144.1659

Increased feelings of nervousness among older Europeans post-pandemic

Courtney Queen

C Queen[1,2], *R Sabzevari*[3], *R Pasupathy*[1]
[1]Public Health, Texas Tech University Health Sciences Center, Abilene, USA
[2]Statistics Unit, Riga Stradins University, Riga, Latvia
[3]Research Methods, Evaluation, Measurement and Statistics, Texas Tech University, Lubbock, USA
Contact: courtney.m.queen@ttuhsc.edu

Background: Feelings of nervousness are typically associated with situational factors and are temporary, less intense, and manageable with self-care. Study

Aim: This study examines which situational conditions are significant for feeling nervous among European older adults during the second wave of COVID-19.

Methods: Using data from Wave 9, COVID-19 Survey 2 (Summer, 2021) of the cross-national panel dataset the Survey of Health, Aging, and Retirement in Europe (SHARE), this study utilizes a sample of 49,253 adults over 50 years old from 27 countries in Europe. Analysis: Binary logistic regression indicates all variables are significant predictors of feeling nervous: Gender [Wald= 498.7, $p = 0.001$ (<0.05)]; chronic disease [Wald= 1635.002 $p = 0.001$ (<0.05)], employment [Wald= 164.544, $p = 0.001$ (<0.05)]; home care [Wald= 138.4, $p = 0.001$ (<0.05)], technology [Wald= 20.66, $p = 0.001$ (<0.05)]; social support [Wald= 106.66, $p = 0.001$ (<0.05)], and financial support [Wald=35.5, $p = 0.001$ (<0.05)] [Chi-Square=3216.401, df = 6 and $p = 0.001$ ($p < 0.05$)].

Findings: The odds ratio (OR) for gender is .627 (95% CI .601-.653), for chronic disease, is 2.659 (95% CI: 1.716 - 4.119) and employment is .675 (95% CI: .635-.717) and homecare is (OR)3.47(95% CI: 2.83-4.28); OR for social support is 855(95% CI:.830-.881), financial support 1.779 (95% CI: 1.47-2.15), and technology (OR).956 (95% CI: 938-.975). The model correctly predicted 94% of cases without feeling nervous and 16% of cases where people did feel nervous, giving an overall percentage correct prediction rate of 68%. Implications for Policy and Practice: Knowledge from this study can inform the introduction of public health interventions for older adults targeted toward specific situational circumstances that reduce nervousness.

Key messages:

- While feelings of nervousness can be situational, the impact on mental health can go beyond the contextual environment.
- Public health policies can support targeted interventions aimed at developing the coping skills necessary to better respond in times of crisis.

Abstract citation ID: ckae144.1660

Core set of indicators to evaluate healthcare workers support programmes: a consensus-based approach

Paulo Sousa

S Guerra-Paiva[1], *I Carrillo*[2], *JJ Mira*[2,3], *J Fernandes*[4], *R Strametz*[5], *E Gil-Hernández*[3], *P Sousa*[1]
[1]Public Health Research Centre, CHRC, NOVA National School of Public Health, Lisbon, Portugal
[2]Health Psychology Department, Miguel Hernandez University, Elche, Spain
[3]FISABIO, Alicante-Sant Joan Health District, Alicante, Spain
[4]NOVA National School of Public Health, Lisbon, Portugal
[5]Wiesbaden Institute for Healthcare Economics and Patient Safety, Wiesbaden, Germany
Contact: Paulo.Sousa@ensp.unl.pt

Objectives: Considering the widespread implementation of support programmes for healthcare workers (HCWs), there is an urgent need to establish a standardised set of indicators for their ongoing assessment. This study seeks to develop a consensus framework for evaluating interventions aimed at supporting HCWs affected by patient safety incidents (PSIs) or other distressing situations, commonly referred to as second victims (SVs). Having a core set of indicators it is crucial for facilitating comparative analyses across different organisations and time periods.

Methods: A qualitative study was conducted from June 2023 to March 2024. The study involved a multidisciplinary group of members part of the European Researchers Network Working on Second Victims. The consensus-building process utilised insights from a scoping review (phase 0) and a nominal group technique (phase 1) to develop a questionnaire for Delphi Rounds (phase 2). Indicators were rated on a scale of 1-5, with consensus reached if over 70% of participants rated an indicator as both feasible and sensitive scoring above 4. A consensus conference was subsequently organised.

Results: From an initial pool of 91 indicators, 55 were rated online, with 35 progressing to the Delphi rounds. A total of two Delphi rounds were performed and achieved response rates exceeding 60% and 80% respectively, resulting in consensus on 11 indicators for evaluating SV' support programmes. These indicators encompass various aspects such as awareness and activation of the programmes, organisational processes and structures, institutional training provisions and assessment of the impact of the programme in the SVs.

Conclusions: This study endeavors to provide guidance for future SVs' programs namely in the critical areas of programme's awareness and activation, structural and process enhancements, and programme's impact on SVs. Moreover, these indicators are suitable for multiple healthcare contexts and levels of implementation.

Key messages:

- The priorities for evaluation of second victim programmes' include their impact on healthcare workers, awareness and activation, organisational processes and structures and institutional training.
- Utilizing a multidisciplinary consensus approach, we defined a set of indicators that are adaptable to diverse contexts that provide care and varying levels of second victim support implementation.

Abstract citation ID: ckae144.1661

The evaluation of an eHealth tool to prevent and alleviate migraine complaints in adults

Claudia Van Der Heijde

CM Van Der Heijde[1], F Jurgens[1], D Tempelman[1], WMM Altink-van den Berg[2], P Vonk[1]
[1]Student Health Services, University of Amsterdam, Amsterdam, Netherlands
[2]Social and Behavioural Sciences, University of Utrecht, Utrecht, Netherlands
Contact: c.m.vanderheijde@uva.nl

Background: Migraines attacks cause great suffering in individual patients. There is great unfulfilled potential to increase patients' knowledge about various personal triggers and subsequent treatments. The objective of this study is to pilot test an e-Health tool that aims to increase migraine patients' knowledge. It takes into account personal preferences and contributes to informed decision-making in choosing the appropriate method. Considering the shortage of primary care physicians and other health care providers, such an e-Health tool could be of great value.

Methods: lessmigraine.nl consists of a website with information plus an electronic decision aid. It was evaluated on its content, development process and effectiveness, and its contribution to the patients' empowerment process. A first round of usability testing was done using semi-structured interviews and thematic analysis with 12 patients from a Dutch General Practice until data saturation. After minor improvements to the e-tool, in a first implementation step subsequently 85 patients used the e-tool.

Results: Patients' expectations were exceeded in terms of the content of the e-Health tool, as all patients discovered new potential migraine triggers. Most patients found the tool effective in the sense that it provided enough information to decide on an appropriate treatment. The implementation was successful in the sense that all 85 participants completed the e-tool. Most important triggers were stress, sleeping problems, changes in weather and flickering or bright light.

Conclusions: The majority of the migraine patients were satisfied with the e-Health tool. It enlarged their knowledge of prevention and treatment options and therefore empowered them in their decision-making process and communication with their GP. Other aspects of implementation need to be studied. This study needs to be repeated in other clinical settings.

Key messages:

- Migraines cause great suffering in individual patients: Considering the shortage of primary care physicians and other health care providers, an e-Health tool could be of great value.
- The e-Health tool increases patients' knowledge about migraine, including personal triggers and subsequent treatments.

Abstract citation ID: ckae144.1662

Racism in inpatient settings in Germany: professionals' perspectives

Hürrem Tezcan-Güntekin

H Tezcan-Güntekin[1], E Stüwe[1], S Papadopoulou[1], K Meshkova[2], S Merz[1]
[1]Alice Salomon University of Applied Science, Faculty of Health and Education, Berlin, Germany
[2]Fulda University of Applied Science, Fulda, Germany
Contact: tezcan@ash-berlin.eu

Background: Experiences of racial discrimination during healthcare encounters have increasingly been recognised as a source of health inequity. Narrative accounts by racialised healthcare users have dominated research in the field but it is equally important to capture the perceptions and practices of professionals to understand how racism operates in healthcare provisioning. This presentation asks: how does racism manifest in the German inpatient healthcare system (hospitals, rehabilitation facilities), and are there areas or phases of healthcare provisioning where racism is observed more frequently?

Methods: Problem-centred expert interviews (Döringer 2021) with 20 healthcare professionals from medicine, nursing, and therapeutic professions working in hospitals or rehabilitation facilities across three German federal states. Data were analysed using documentary method (Bohnsack 2002).

Results: Racism occurs widely in German inpatient settings. It manifests both structurally, e.g. in the absence of professional translators for healthcare users with limited German skills, and interpersonally, e.g. in the form of microaggressions and stereotyping but also the witholding of treatment and verbal abuse. Targets of racism are both patients and staff, especially internationally recruited healthcare workers. Respondents thereby identify night shifts, psychiatric settings and the emergency ward as contexts where racism is more likely to occur. The hierarchical nature of and pervasive power asymmetries in hospitals thereby prevent effective interventions against racial discrimination.

Conclusions: Racism in German healthcare institutions requires multiscalar public health interventions, particularly at the level of the institutions themselves. These include the establishment of a robust and low-threshold complaints structure, spaces for self-reflection for professionals, and mandatory anti-racism training rather than a focus on diversity-sensitive competence.

Key messages:

- In future research approaches, structurally determined reproductions of racism should be investigated using a multi-method approach.
- Experiences of powerlessness are reported by both those affected by racism and those professionals who observe racism and should be addressed by the institutions.

Abstract citation ID: ckae144.1663
Factors that influence the need for mental health services for older adults in Europe

Courtney Queen

R Pasupathy[1], *R Hossein*[1], *C Queen*[1]
[1]Public Health, Texas Tech University Health Sciences Center, Austin, USA
Contact: Courtney.M.Queen@ttuhsc.edu

Background: Mental health is an integral component of health, and affects close to a 100 million Europeans. Little is known about the predictors of older adult's mental health demand among health systems in European countries. This study is based on the Andersen's Behavior Model, that predicts that predisposing characteristics, enabling factors, and behavioral factors, influence need or demand factors of healthcare services.

Aim: This study has two overall objectives: (i) to investigate the determinants of older adults' mental health services demand; and (ii) examine the relationship between predisposing characteristics, and enabling resources, with services demand.

Methods: Data from Wave 9, of the of the cross-national panel dataset of the Survey of Health, Ageing and Retirement in Europe (SHARE) were examined using a sample of 47, 345 older adults.

Analysis: The Omnibus test was used to evaluate the fit model and Multinomial Logistics Regression were performed to test the null hypothesis that predisposing characteristics, enabling resources, and behavioral factors are not predictors of need or demand.

Findings: Predisposing characteristics such as gender (b=-.43, s.e.=.017, p<.001) and age (b=-1.96, s.e.=2.2, p<.001), and enabling factors such as homecare (b = 2.40, s.e.=0.1, p<.001), social support (b=-.26, s.e.=0.012, p<.001), financial support receiving (b=.51, s.e.=.086, p<.001), income (b=.09, s.e.=.009, p<.001), and behavioral factors such as use of technology are predictors of mental health services need or demand [Chi-Square= 3319.58, df = 15 and p <.001].

Implications for Policy and Practice: Initiatives for the care of older adults should not only aim to increase access to care services for sub populations such as older adults with mental health but also consider enabling resources such as financial and social support and behavioral factors such as use of technology.

Key messages:

- Demand for mental health services for older adults are influenced by predisposing, enabling and behavioral factors.
- Investing in financial services, social support and technology may reduce the demand for mental health services among older adults.

Abstract citation ID: ckae144.1664
Social Infrastructure and Organizational Resilience - A Theoretical Model

Holger Pfaff

H Pfaff[1]
[1]IMVR, University of Cologne, Cologne, Germany
Contact: holger.pfaff@uk-koeln.de

Background: Considering resilience as a necessity for health care organisations (HCOs), many researchers argue that fluidity is a must and that organisational structures (formal and informal) hinder the adaptability and resilience of health care organisations. Contrary to this statement, my thesis posits that fundamental adaptive processes leading to new equilibria depend on a stable core that persists amidst change, enabling and catalysing these transformations.

Methods: The phenomenon of resilience within healthcare organisations is examined through the lens of sociological systems theory. Rooted in Talcott Parsons' assertion that social systems, including healthcare organisations, must perform four basic functions (Adaptation, Goal Achievement, Integration, Latency: AGIL) to survive and function, our research uses the deductive method to derive the necessary structural social components required to cope with external demands.

Results: The application of the methods yields four complex basic structures rooted in the social structure of healthcare organisations: adaptive structures (flexible structures & resource generating structures), goal achievement structures (governance enabling collective goal setting, decision making and persistence), integrative structures (social capital and social networks) and sustainability structures (socialisation structure, knowledge base, organisational culture).

Conclusions: As the core of stability, this 'four-component social infrastructure' is essential for facilitating higher-order forms of resilience, such as new equilibria. In its absence, healthcare organisations would flounder during change, posing risks to the resilience of these HCOs. Thus, structure is indeed inherent in the chaos of resilience activities. In other words, there is order in the chaos of resilience, and it is essential.

Key messages:

- Fundamental adaptive processes leading to new equilibria depend on a stable core that persists amidst change, enabling and catalysing these transformations.
- There is order and structure in the chaos of resilience.

Abstract citation ID: ckae144.1665
Living alone and care levels' distribution in first-time recipients of long-term care in Germany

Christine Haeger

C Haeger[1], *S Schnitzer*[1], *T Baldenius*[2], *K Jürchott*[2], *A Kuhlmey*[1], *A Schwinger*[2], *S Blüher*[1]
[1]Institute of Medical Sociology and Rehabilitation Science, Charité - Universitätsmedizin Berlin, Berlin, Germany
[2]WIdO, Scientific Institute of AOK, Berlin, Germany
Contact: christine.haeger@charite.de

Background: As demographic shifts occur, along with longer life expectancies and advancements in medical care, there is a noticeable rise in the population requiring long-term care. In Germany, the Medical Service oversees the assessment for long-term care needs, which specifically evaluates the extent of limitations in maintaining independent living. These limitations are categorized into care levels ranging from 1 (indicating minor limitations) to 5 (denoting the most severe limitations).

Methods: Data from the long-term care assessment conducted nationwide in Germany are utilized for the analysis presented. The study focuses on individuals aged 60 and above with a first-time recognition of need of long-term care. Descriptive analysis is conducted on the distribution of care levels and living arrangements.

Results: The analysis encompassed 339,486 individuals, with an average age of 79.6 years (standard deviation: 8.4), of whom 59.0% were female. Approximately half of the sample were categorized under care level 2, while 32.4% fell into care level 1. Higher care levels (3-5) were less frequent (16.2%, 4.8%, 1.7% respectively). Individuals living alone were predominantly found in the lower care levels, whereas those not living alone were more commonly represented in care levels 3-5. Additionally, older individuals were more frequently assigned higher care levels.

Conclusions: Over 75% of initial applicants are classified within the lowest care levels (1 and 2) with a higher proportion of those living alone. One possible explanation is that within partnerships, the presence of a partner may serve as a form of support during the early phases of long-term care, with external assistance becoming necessary only as care needs escalate to higher levels. Further research should focus on examining the role of living alone in the need for long-term care.

Key messages:

- Initial applicants of long-term care in Germany living alone are more often classified in lower care levels (indicating minor limitations) than in higher care levels (indicating severe limitation).
- Partnerships may delay higher long-term care needs; research should explore living alone's impact on long-term care.

Abstract citation ID: ckae144.1666
Pertussis on the territory of Serbia in 2024 - challenges and opportunities for the future

Verica Jovanovic

V Jovanovic[1], E Grego[2], LJ Pavlovic[2], S Jovanovic[3], H Gospodinovic[2], J Ivanovic[2], M Ivanovic[2], M Veljkovic[1], M Cabrilo[2]
[1]Centre for Disease Control, Institute of Public Health, Belgrade, Serbia
[2]Centre for Microbiology, Institute of Public Health of Serbia, Belgrade, Serbia
[3]University Clinical Centre of Serbia, Belgrade, Serbia
Contact: verica_jovanovic@batut.org.rs

Introduction: Surveillance of pertussis in Serbia is passive surveillance and every 3 to 4 years an increased number of positive cases are registered in the population. The last quarter of 2023 and the first quarter of 2024 are characterized by an increased number of pertussis cases.

Methods: Descriptive study of cases with confirmed pertussis in the territory of the Republic of Serbia based on the evidence by the Public Health Service System of the Institute of Public Health of Serbia

Results: According to data from the Public Health Service System in the Republic of Serbia, a total of 1348 confirmed cases of pertussis were registered by the end of April 2024 (incidence rate 20.2 per 100,000 inhabitants).

Conclusions: The largest number of cases was registered in the age groups of people older than 20 years, that is, aged 10 to 14 years, while the highest age-specific incidence rate was recorded in the age group of infants younger than 12 months and in children aged 10 to 14 years. Of the total number of reported cases, 120 (8.9%) were hospitalized, with the largest number of those hospitalized being in the age group younger than 12 months (85, ie 70.8% of hospitalized cases). As for the territorial distribution, the largest number of pertussis cases in relation to the place of residence was reported from the territory of two districts, Južnobački District and the City of Belgrade, where the highest incidence rates were also registered. The postponement of timely vaccination against pertussis and the impossibility of vaccinating newborns up to 2 months of age have influenced the increase in the number of infected persons. Also, advanced PCR diagnostics during Covid and the possibility of applying PCR diagnostics in pertussis helped the timely diagnosis of pertussis. The introduction of vaccination with another dose of acellular pertussis vaccine and vaccination of pregnant women would be a desirable public health intervention to prevent pertussis infection.

Key messages:

- Protection of the target population before starting school and at the age of 14 will contribute to stopping the occurrence of new cases of pertussis. These are public health challenges.
- PCR diagnosis of pertussis influenced the timely diagnosis of this infection and the possibility of its adequate and timely treatment.

Abstract citation ID: ckae144.1667
Optimizing vaccination to reduce waste and boost coverage in Primary Health Care Units

Ilana Eshriqui

D Ribeiro[1], D Schimdt[1], M Rangel[1]
[1]Public Health, Hospital Israelita Albert Einstein, São Paulo, Brazil
Contact: ilana.eoliveira@einstein.br

Background: In immunization, vaccine consumption typically exceeds the number of recipients. The number of doses per vial influences wastage and vaccination coverage goals. In Brazil, 48% of the National Immunization Program's vaccines are multidose, with 4 having limited shelf-life post-opening. Strategies to reduce wastage aim to optimize dose utilization, enhance process quality, and broaden coverage effectiveness. The objective was to outline strategies for reducing wastage and expanding coverage for children under 5 in 14 São Paulo city Primary Health Care Units (PHCUs).

Methods: The Lean Six Sigma approach guided the stages. A group conducted contextual analysis to identify PHCU barriers. Data on wasted doses and vaccination were gathered. Weekly meetings for data analysis began in May 2023, following DMAIC phases: Define, Measure, Analyze, Improve, Control. An action plan stemmed from these phases for PHCU implementation.

Results: Data analysis, from January 2022 to June 2023, revealed a significant vaccine wastage trend, reaching 59% from January to December 2022 and increasing to 63% from January to June 2023. This wastage incurs an average annual cost of R$614,416.26, due to lost doses from expiration after vial opening and expiration of shelf life. The vaccines analyzed were BCG, Oral Polio Vaccine (OPV), Measles, Mumps, and Rubella (MMR), and Yellow Fever. At the project start in May 2023, vaccination coverage was 90%, increasing to 93% afterward. This rise resulted from actions taken and improved data monitoring. Post-project, vaccine wastage reduced by 7 percentage points (from 62% to 56%).

Conclusions: Addressing vaccine wastage and expanding vaccination coverage for children under 5 are critical in healthcare. Utilizing Lean Six Sigma, key issues in PHCUs were identified, leading to an action plan that reduced wastage, increased coverage, and standardized processes.

Key messages:

- Vaccines are valuable resources and wasting them means reducing financial resources in health.
- Vaccination coverage is crucial to protect the population's health, prevent disease outbreaks, and maintain the country's economic health, reducing costs for treating preventable diseases.

DM. Poster display: Health literacy

Abstract citation ID: ckae144.1668
Generating qualitative evidence of the validity of the Health Literacy Questionnaire Parent

Samantha Belfrage

S Belfrage[1], J Faulkner[1], M Husted[1], S Fraser[2], S Patel[3]
[1]Health & Wellbeing, University of Winchester, Winchester, UK
[2]Faculty of Medicine, University of Southampton, Southampton, UK
[3]University Hospital Southampton, Southampton, UK
Contact: s.belfrage.20@unimail.winchester.ac.uk

Background: Health literacy refers to the skills needed to access, understand, and navigate health information and services. The Health Literacy Questionnaire (HLQ) is a widely used validated measure of health literacy capturing nine distinct domains. The HLQ-Parent is a recent adaption of the HLQ which has been designed to capture the nuanced health literacy skills required by primary care givers of children. Generating qualitative evidence of validity of such tools is an important element of the validation process as it captures understanding and interpretation of items which is not achievable by quantitative methods alone. Therefore, the purpose of this study was to generate qualitative evidence of the validity of the HLQ-Parent.

Methods: A qualitative study implementing the HLQ-Parent during face-to-face cognitive interviews with concurrent probing was conducted. Primary carers of children aged 16 or under living in England were recruited via voluntary organisations supporting families. Qualitative data analysis was conducted on the audio recordings in the form of text summaries. Parents' chosen HLQ-Parent responses were compared to their narrative responses and coded by the researcher as match, no match or unclear. Parents' narrative responses were also compared to the HLQ-Parent item intent descriptions and coded as concordant, discordant, or unclear.

Results: Overall, participants (n = 9, mean age 40 years, 88.9% female) narrative responses matched to their chosen HLQ-Parent response, while their narrative responses were concordant with the HLQ-Parent item intent descriptions. Two participants narratives did not match their responses for the item:' I have enough information to help me deal with my child's health'.

Conclusions: The qualitative data provided evidence that participants understood and answered the HLQ-Parent items as intended. Study results contribute validity evidence for the use of HLQ-Parent to measure parental health literacy.

Key messages:

- This study contributes evidence to the validity of the HLQ-Parent.
- Qualitative methods provide valuable insights that enhance the overall understanding of health literacy measurement tools.

How can we support the development of health literacy in young people?

Craig Smith

C Smith[1], S Belton[1], S Meegan[1], S Behan[1], HR Goss[1]
[1]School of Health and Human Performance, Dublin City University, Dublin, Ireland
Contact: craig.smith57@mail.dcu.ie

Over the past two decades, there has been an increased interest in Health literacy (HL) to improve health behaviours and health outcomes. Due to its potential impact, HL is considered one of the major issues in public health and is increasingly being recognised in recent policies and initiatives. Although, the research justifying the importance of HL continues to grow, there is a lack of research focusing on strategies to improve HL and challenges that are faced when supporting HL, particularly in young people. Thus, this study aimed to explore, from the point of view of international academics and community-based practitioners, (i) key considerations when supporting young people's HL; (ii) major challenges to supporting young people's HL; and (iii) possible solutions to overcome such challenges. A stakeholder mapping exercise was used to recruit academic and community-based practitioners to take part of in a one-to-one interview (n = 29). Reflexive thematic analysis was used to analyse the data. The preliminary findings suggest that: the participants feel the use of participatory approaches is essential when designing a HL-focused program; the importance of embedding HL education and awareness into schools; the value in using interactive style learning; and the importance of targeting those 'hardly reached' populations. The participants highlighted that accessibility to schools; difficulty in engaging young people; and ensuring programs are sustainable as major challenges. Solutions to overcome which challenges were posited, including professional development for teachers; the development of engaging and context specific programs that target the young person's physical and social environment; and importance of influencing national policies to value HL. These findings can be used to inform interventions and policies to target the HL of young people.

Key messages:

- The importance of adopting participatory approaches when developing health literacy interventions.
- The importance of developing feasible, context specific and engaging health literacy curricula within schools.

Abstract citation ID: ckae144.1670
A lifestyle program for socially vulnerable community-dwelling elderly

Julie Vanderlinden

S Lambers[1], P Verschelden[1], E Es[1], J Vanderlinden[1,2]
[1]Department of Health Care, Odisee University of Applied Sciences, Brussel, Belgium
[2]Medical Sciences, University of Brussels, Brussel, Belgium
Contact: julie.vanderlinden@odisee.be

Problem: Socially vulnerable older adults often face lower health literacy and limited access to health care.

Description of the problem: Current lifestyle programs are often insufficiently adapted to this socially vulnerable target group. As a result, these older adults are underrepresented in lifestyle programs. From a public health perspective, lifestyle programs that improve the poorer physical and mental health of these older adults, should be made more accessible by involving the expertise, participation and needs of this group. The aim of this study was to develop and implement a lifestyle program adapted to the expectations and needs of socially vulnerable older adults.

Results: Both the target group and the local community (health) centers were involved during the co-creative phase of development. A neighborhood analysis was used to identify and reach out to the target group. Motivators and barriers for a healthy lifestyle were identified through focus groups. The developed program consisted of 10 weekly group sessions. Various health aspects were integrated, including exercise, nutrition, stress, sleep, positive psychology, meaningful living, and motivation. Nine centers for community dwelling older adults in Flanders and Brussels were included. In total, 93 older adults were recruited out of which 76 completed the full program. In the final phase, the program was evaluated by means of objective and subjective measuring methods. Finally, the local community (health) centers are currently involved in the program's sustainability through a trainers' program.

Lessons: The belongingness, the catering, the empowering attitude of the trainer and the 'fun' factor turned out to be success factors for the adherence to the program. The participating centres experienced an increase in numbers of older adults that were attracted to their activities that are focused on healthy lifestyle behaviors. The continuity of the program is currently being examined.

Key messages:

- A neighbourhood analysis in collaboration with local partners helped to reach the target group.
- The program was made attractive by the involvement of the older adults, the fun-factor and the small groups.

Abstract citation ID: ckae144.1671
Factors associated with over-the-counter drug misuse among young people: a narrative review

Md Ismail Tushar

MI Tushar[1], I Kersbergen[1]
[1]SCHARR, The University of Sheffield, Sheffield, UK
Contact: tushar_9167@hotmail.com

Background: Over-the-counter (OTC) medications are sold directly to customers without requiring a doctor's prescription. Misuse of OTC drugs is higher in adolescents and young adults than in the general population. This review is the first to narratively synthesize the factors associated with OTC drug misuse among adolescents and young adults (14-25 years old).

Aim: To identify the factors that are associated with OTC drug misuse among adolescents and young adults (14-25 years).

Methods: A comprehensive search of three electronic databases, including MEDLINE, PsycINFO and Web of Science, was conducted to retrieve publications between 1 January 1997 and 31 July 2023. The AXIS tool was used to aid critical appraisal. Papers were analysed using thematic analysis.

Results: Eight studies were eligible for inclusion in this narrative review We identified four key themes: motivational factors; health literacy; illicit drug use and socioeconomic status. Sensation-seeking and using OTC drugs for recreational purposes were associated with OTC misuse. Limited health literacy and lack of understanding of OTC drugs were significant factors for misusing OTC drugs. Greater use of OTC drugs at the same time as alcohol and other illicit drugs represented that they were at increased risk for misusing OTC drugs. Finally, adolescents and young adults with low income, from rural areas and with lower educational attainment were most likely to misuse OTC drugs.

Conclusions: Although over-the-counter medications (OTCs) encourage self-medication, their rising misuse has led to a public health problem to which nations worldwide are responding. Therefore, education and awareness among OTC drug users policy will be helpful further on strategies to prevent the misuse of OTC drugs.

Key messages:

- This review identifies some of the factors for misusing OTC drugs, and education and awareness among OTC drug users policy may be helpful further in strategies to prevent the misuse of OTC drugs.
- This review also identifies that changing the user habits and availability of OTC drugs policy may also be helpful in further strategies to prevent the misuse of OTC drugs.

Abstract citation ID: ckae144.1672
Professional health literacy of health professions in Austria - results of the HLS-PROF-AT study

Denise Schuetze

D Schuetze[1], *C Strassmayr*[1], *T Link*[1], *R Griebler*[1]
[1]Austrian National Public Health Institute, Vienna, Austria
Contact: denise.schuetze@goeg.at

Background: Health professions play a crucial role in strengthening the health literacy (HL) of the population - provided that they themselves have the necessary professional HL. This encompasses competencies related to information and knowledge management, conveying information and knowledge, patient involvement and shared decision-making, and professional digital HL. In 2022 and 2023, data on professional HL were collected in Austria.

Methods: Nearly 4,400 healthcare professionals (doctors, nurses, physiotherapists, pharmacists, midwives, dieticians) were asked about their challenges across the four domains of professional HL. A score was calculated for each domain, with five additional subscores for the domain conveying information and knowledge. The relationship between socio-demographic, job-related and organisational characteristics and professional HL were investigated using T-tests, variance analyses and multivariate regression models.

Results: The greatest challenge for all healthcare professions is supporting patients in dealing with digital information, followed by conveying information and knowledge. Apart from pharmacists, the least difficulties were found in the domain patient involvement and shared decision-making. Furthermore, the results demonstrate that a high level of professional HL is associated with more favourable organisational conditions for HL-promoting patient communication and (very) good preparation in training for the tasks of professional HL. There is no systematic correlation between professional HL and years of professional experience.

Conclusions: Overall, healthcare professionals rated their professional HL positively. However, the results also highlight areas for improvement. Alongside promoting professional HL in the context of (further) training, it is important to enhance organisational framework conditions for promoting patients' HL - ideally supported by initiatives to promote the organisational HL in healthcare organisations.

Key messages:

- The greatest challenge for the health professions surveyed is to support patients in dealing with digital information and to convey information and knowledge to their patients.
- Good preparation in training for the tasks of professional HL and favourable organisational conditions for HL-promoting patient communication are associated with a higher professional HL.

Abstract citation ID: ckae144.1673
Development of the health literacy responsiveness (HLR) evaluation framework for HLR interventions

Maiken Meldgaard

M Meldgaard[1,2], *A Aaby*[1], *LS Østergaard*[3], *IR Heuck*[1]
[1]Department of Public Health, Aarhus University, Aarhus C, Denmark
[2]Health Transformation Unit, Deakin University, Melbourne, Australia
[3]Steno Diabetes Center Sjælland, Copenhagen, Denmark
Contact: mme@ph.au.dk

Background: Health literacy responsiveness (HLR) interventions include actions at different levels of an organization to provoke change and improve environments ensuring equitable access to and use of information and services (1). However, generic instruments measuring the effect of HLR at intervention level are inconsistent, making evidence on HLR intervention effects difficult to compare (2). The objective of this study was to develop an evaluation framework based on core outcome domains of HLR to facilitate higher consistency in future evaluations of HLR interventions.

Methods: HLR outcomes were identified through a narrative literature review and categorized into domains through a content mapping process. Expert consensus on core outcome domains was reached through a Delphi process. Experts within the field of HLR were invited to participate and answer three questionnaires designed to rank and clarify potential core outcome domains. Quantitative and qualitative analysis was performed to select and complete the final core outcome domains in the HLR evaluation framework (HLR-EF).

Results: The literature search resulted in identification of nine reviews. A total of 383 outcomes were identified from these reviews and included in the content mapping process, which resulted in a total of 26 core outcome domains. Experts ($n = 15$) participated in the three-round Delphi process, which resulted in consensus on 15 core outcome domains in HLR-EF allocated under five headings.

Conclusions: The study has successfully managed to identify a set of core outcome domains applicable in future evaluations of HLR interventions based on systematic methodologies and expert consensus. Context-sensitive manuals for the use of the HLR-EF is under development and the instrument is ready to be applied in future evaluation of HLR interventions, potentially making future measuring, reporting and comparison of results significantly easier.

Key messages:

- Instruments facilitating evaluation of HLR interventions are non-generic and inconsistent.

- HLR-EF has been developed using a narrative literature review, content mapping, and a Delphi process, and defines 15 core outcome domains for evaluation of HLR interventions.

Abstract citation ID: ckae144.1674
Predictors of infectious disease-related behaviors among adolescents in Armenia

Varduhi Hayrumyan

V Hayrumyan[1], Z Sargsyan[1], A Agopian[1], L Musheghyan[1], T Harutyunyan[1]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
Contact: vhayrumyan@aua.am

Background: We explored the behaviors related to infectious diseases (ID) and its predictors among 15-17 years old adolescents in Armenia.

Methods: We surveyed adolescents from public and private high schools in Yerevan and one province in 2023. The instrument explored ID-related behaviors, health literacy (HL), interest in health, and socio-demographics. ID-related behaviors were measured with five Yes/No questions about sharing a toothbrush, covering their mouth when coughing or sneezing, and washing hands with soap and water - before eating, after using the bathroom, and when coming home. HL was assessed with ten questions on a scale from 'Strongly disagree' to 'Strongly agree'. Summative scores were calculated for ID-related behaviors and HL. Multivariable regression analysis explored factors associated with ID-related behaviors.

Results: Overall, 366 students completed the survey, most of them being females (64.4%). The majority were interested in health issues (80.7%). Almost all respondents reported not sharing a toothbrush with other persons (97.9%) and usually covering their mouth when coughing or sneezing in public places (94.1%). Somewhat lower percentages reported washing hands with soap and water before eating (82.0%), after using the bathroom (89.2%), and when coming home (86.6%). The mean behavior score was 4.52 out of 5 (SD = 0.92) and the percent score was 90.4%. The average HL score was 17.41 out of 30 (SD = 4.47). In the regression analysis, being female vs. male, being interested in health vs. not, studying in private vs. public schools, and having higher HL were independent significant predictors for higher score of ID-related behaviors.

Conclusions: Armenian adolescents reported high levels of compliance with ID-related behaviors. Improving health literacy and fostering interest in health can help further enhance the performance of preventive behaviors. Interventions targeting public schools and male adolescents are particularly pertinent.

Key messages:

- Being female, studying in private schools, having higher interest in health issues, and better health literacy independently positively influence infectious disease-related behaviors.
- Promoting health literacy and fostering interest in health in high schools have the potential to further enhance infectious disease prevention behaviors among adolescents.

Abstract citation ID: ckae144.1675
Cross-sectional survey of health literacy among high school students in Armenia

Zhanna Sargsyan

Z Sargsyan[1], V Hayrumyan[1], A Agopian[1], L Musheghyan[1], T Harutyunyan[1]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
Contact: zhsargsyan@aua.am

Background: We assessed the level of health literacy (HL) and explored its predictors among 15-17 years old adolescents in Armenia.

Methods: We conducted a survey among adolescents in public and private schools in the capital Yerevan and an adjacent province in 2023. The instrument included items on HL, general interest in health and socio-demographics. Ten questions measuring HL with four answer options were summed into the HL score (0-30). Multivariable regression model explored the independent associations of socio-demographic factors and interest in health issues with the HL.

Results: Overall, 366 students completed the survey. About 64% were females. The majority were interested in health issues (80.7%). Most participants felt they, in general, received sufficient health information (75.1%), could follow physician's instructions (80.1%), were confident in advising family or friends on health improvements (70.5%), could easily give examples of health-promoting actions (76.8%), and explain their choices for health (77.6%). Additionally, 82.2% could judge the environmental impact of their actions, 82.0% could find understandable health information when needed, and 85.3% could assess how their behavior affects their health. Fewer respondents were confident in figuring out if the health information is correct (68.2%) or identifying correct health information when faced with conflicting data (67.1%). The average HL score was 17.41 (SD = 4.47), with a 58.0% percent score. In the regression analysis, being from private school vs. public and being interested in health vs. not were significant predictors of higher HL.

Conclusions: Despite having moderate HL level, a significant portion of Armenian adolescents lacked confidence in discerning correct health information. Interventions should prioritize enhancing HL, emphasizing critical evaluation skills and providing accessible and reliable health information resources tailored to adolescents, particularly in public schools.

Key messages:

- The health literacy among Armenian adolescents was moderate with many lacking confidence in identifying correct health information and differentiating when faced with conflicting data.
- Attending a private school and having an interest in health were significant predictors for higher health literacy, emphasizing the need for targeted health and policy interventions.

Abstract citation ID: ckae144.1676
Health literacy and access to health services: insights from a national survey in Italy

Luigi Palmieri

B Marcozzi[1], B Unim[1], A Rosano[2], C Lorini[3], G Bonaccorsi[3], C Donfrancesco[1], P Zanobini[3], C Lo Noce[1], D Galeone[4], L Palmieri[1]
[1]Cardiovascular, Endocrine-Metabolic Diseases, ISS, Rome, Italy
[2]National Institute for the Analysis of Public Policy, Rome, Italy
[3]Health Sciences, University of Florence, Florence, Italy
[4]Ministry of Health, Rome, Italy
Contact: luigi.palmieri@iss.it

Background: Health Literacy (HL) entails accessing, understanding, evaluating, and applying healthcare (HC) information. Aim of this study is to assess HL association with HC services use in the Italian adult population.

Methods: A national survey was conducted in Italy in 2021, in the framework of the WHO network Measuring Population and Organizational Health Literacy (M-POHL). A validated questionnaire was administered to a representative sample of the Italian resident population aged 18+ years (N = 3,500). A 4-point Likert scale was used for answers: very easy, easy, difficult, very difficult. The HL index, as the percentage of very easy/easy responses, was categorized as Inadequate (0-50%), Problematic (51-66%), Sufficient (67-80%), Excellent (81-100%). Inadequate/Problematic were combined in

'Limiting' and Sufficient/Excellent in 'Not limiting' categories. A multivariate logistic regression analysis, adjusted by sex, age, geographical area, education, and financial deprivation, was used to explore the associations between HL and the frequency, of utilization of general practitioners-GPs (never, once/twice, three/more times), medical or surgical specialist services-MSS (never, once, twice/more), inpatient hospital services-IHS (never, once/more), day-patient hospital services-DPS (never, once/more), taking sick days at work-SD (never, once/twice, three/more) in the last 12 months, and emergency services-ES (never, once/more) in the last 24 months.

Results: In Limiting HL (64.6%), the prevalence of never using ES is significantly lower compared to Not limiting HL (81.83% vs 83.80%); likewise for never using MSS (45.84% vs 51.24%) and never using DPS (90.87% vs 93.80%). Significant association with Limiting HL was found for using MSS once (Odds Ratio-OR=1.55), twice/more (OR = 1.76) and taking SD once/twice (OR = 1.58).

Conclusions: Results demonstrate that people using HC services more frequently, in particular MSS and taking SD, require dedicated support to improve HL.

Key messages:

- This study aims to evaluate the association of the individual Health literacy level with the use of several healthcare services in the Italian adult population.
- 'Limiting' Health Literacy is associated with using medical or surgical specialist services twice or more times and taking sick days at work once or twice.

Abstract citation ID: ckae144.1677
A process evaluation of a LifeLab Dublin; an interactive health literacy intervention

Craig Smith

C Smith[1]*, S Belton*[1]*, J Issartel*[1]*, S Meegan*[1]*, HR Goss*[1]
[1]School of Health and Human Performance, Dublin City University, Dublin, Ireland
Contact: craig.smith57@mail.dcu.ie

The argument for targeting adolescent health has been made strongly, with poor lifestyle behaviours often emerging during this life stage. Furthermore, there is consistent evidence of a widening socioeconomic gap in health indicators. Developing health literacy (HL) in youth populations to improve lifelong health behaviours has garnered increased interest in recent years. This process evaluation examines the acceptability, fidelity and dose delivered of the pilot of LifeLab Dublin: a nine-week, school-based HL intervention for low socioeconomic adolescents. The intervention, which comprised of two out-of-school, interactive HL experiences in conjunction with seven school-based lessons, took place between September and December in 2021 and involved students aged 11 - 13. The health issues targeted were previously identified by the teachers and students of the target population, and the learning activities within the out-of-school experiences were co-designed by adolescents of a similar demographic. Overall, the intervention was perceived positively by the students and teachers, particularly the two interactive out-of-school experiences. The teachers, however, highlighted issues with the volume and content of the school-based lessons, resulting in a reduced number of lessons being delivered. The fidelity of the two LifeLab experiences was high, demonstrating that the students engaged well with the learning activities and that the experience aligned with LifeLab's core principles and underpinning theoretical constructs. The findings from this study highlight the value in implementing experiential style learning in school-based HL education and the benefit of involving participants in the design of intervention. The evaluation provided valuable insight into the refinements required to enhance the efficacy of the intervention, as well as providing an evidence-base to inform future school-based HL interventions for low socioeconomic adolescents.

Key messages:

- The benefit of adopting experiential style health literacy education with young people.
- The benefit of including young people in the design of a health literacy intervention.

Abstract citation ID: ckae144.1678
An update on the concept and importance of health literacy in young people

Craig Smith

C Smith[1]*, S Belton*[1]*, S Meegan*[1]*, S Behan*[1]*, HR Goss*[1]
[1]School of Health and Human Performance, Dublin City University, Dublin, Ireland
Contact: craig.smith57@mail.dcu.ie

The burden of non-communicable diseases is a growing public health crisis that requires immediate action. As health literacy (HL) has been strongly linked with health behaviours and health outcomes, it has many potential implications for health care and health education. Although recent research has emphasised the importance of developing HL early in life, much of the research has focused on understanding and improving HL in adult populations. As young people socialise in different contexts and are exposed to different health-related situations, they require different HL competencies. As part of a wider project, this study aims to gather the perceptions of international academics and community-based practitioners on the concept and importance of HL in and for young people. Specifically, the study aims to (i) explore current understandings of the concept of HL in young people; (ii) examine the importance of HL for young people; (iii) identify those at risk of having low levels of HL; and (iv) determine the specific health behaviours that young people are currently struggling with. A stakeholder mapping exercise was used to recruit academic and community-based practitioners to take part in a one-to-one interview (n = 29). Reflexive thematic analysis was used to analyse the data. The preliminary findings suggest that HL is a very broad yet individualised concept that is critical to develop at an early age given the difficulty young people face in adopting healthy behaviours in their social and physical environment. Furthermore, the participants highlighted that minority groups, such as members of the travelling community and refugees, and those from low socioeconomic populations, are at greatest risk of low HL. Finally, the health issues that appeared to be of most concern in young people were vaping, social media use and poor mental health. These findings can be used to inform appropriate interventions and policies to target the HL of young people.

Key messages:

- Health literacy is a very, yet individualised, concept that is critical to develop given the difficulty young people face in adopting healthy behaviours in their social and physical environment.
- Minority groups, such as members of the travelling community, refugees, and those from low socioeconomic populations are at greatest risk of low levels of health literacy.

Abstract citation ID: ckae144.1679
The association between health literacy and colorectal cancer screening uptake in Taiwan

Yi-Jing Lin

CW Hsu[1]*, YJ Lin*[1]*, YC Shen*[1]*, YR Wang*[1]
[1]Taiwan Health Promotion Administration, Taipei, Taiwan
Contact: yijing@hpa.gov.tw

Background: Population-based cancer screening programs have been confirmed as a cost-effective strategy for early detection of colorectal cancer, leading to reduced mortality and morbidity. In Taiwan, the government has provided an immunochemical fecal occult blood test (iFOBT) every two years to all citizens aged 50 to 74 years since 2013. The study aims to determine the association between iFOBT uptake and health literacy (HL).

Methods: Data from the National Health Interview Survey (NHIS), a population-based cross-sectional survey conducted in 2021-22 in Taiwan, were applied. The European Health Literacy Survey Short Form (HLS-EU-Q16), self-reported iFOBT participation within the past 2 years, and covariates assessed by face-to-face interview. The present analysis included those age-eligible for screening (n = 3,871) and applied the survey-weighted multivariable logistic regression to estimate odds of iFOBT uptake between HL skill levels, controlling for age, education attainment, socioeconomic status, health status, and household urbanicity level.

Results: In general, 44.6% of participants had utilized the iFOBT, and 79.9% had adequate HL skills which reported higher iFOBT uptake rates (45.9%) than their counterparts (39.4%). Multivariable analysis showed that having adequate HL was associated with greater odds of iFOBT utilization (adjusted odds ratio [aOR] = 1.79; 95% CI: 1.29-2.49). Additionally, compared to those households registered in the township, participants in higher urbanicity levels had lower iFOBT uptake: city (aOR = 0.62; 95% CI: 0.47-0.82). Other predictors that contributed significantly were participants' gender and having 2 or more chronic diseases.

Conclusions: Inadequate HL skills and urban residency may reduce participation in the CRC screening program, despite its free availability. More efforts should include literacy-friendly designed materials and the provision of tailored support in urban settings.

Key messages:

- HL skills are significantly associated with the CRC screening uptake in Taiwan. Improving HL could have positive effects on people's participation.
- Urbanicity levels are also predictors associated with screening utilization. Disseminating health service information in localized ways should be a potential option.

Abstract citation ID: ckae144.1680
The association between cancer literacy and cancer screening behaviours: a systematic review

Valentina Baccolini

C Isonne[1], A Pistollato[1], A Sinopoli[2], J Iera[1], A Sciurti[1], C Marzuillo[1], P Villari[1], V Baccolini[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Department of Prevention, Local Health Authority Roma 1, Rome, Italy
Contact: valentina.baccolini@uniroma1.it

Background: This study aimed at investigating the association between cancer literacy (CL) and adherence to cancer screening programs.

Methods: PubMed, Scopus and Web of Science were searched. Any study, published until March 2024, that investigated the associations between CL and cancer screening intention or uptake in any target population were eligible. For CL measurement, both validated and ad hoc tools were considered. For each outcome, articles were grouped according to the type of cancer investigated and results were narratively synthesized.

Results: A total of 3426 records were retrieved. After deduplication and screening process, six studies were included. Population enrolled was heterogeneous as well as the tool used to measure CL. Four studies explored the relationship between CL and screening uptake, one focused solely on screening intention and another investigated both intention and uptake. Significant association was found between CL and screening intention in the two studies included, with higher literacy levels correlating to increased intent for screening. A significant association between higher CL and skin cancer screening uptake was reported, while the uptake of prostate cancer screening was not significantly associated with CL levels. By contrast, mixed results were obtained investigating breast, cervix and colorectal screening uptake.

Conclusions: Higher levels of cancer literacy appeared to be associated with screening intention, while its association with screening uptake was found barely significant for any screening type, suggesting that other factors influence the actual screening uptake. However, the scarce number of studies, along with the absence of validated tools and the heterogeneity of target populations, limits the generalizability of the results. Further research, differentiating screening types and timelines and using multivariate models, is needed to clarify the role of CL in screening behaviours.

Key messages:

- Higher levels of cancer literacy appear to be associated with screening intention, suggesting its importance in promoting motivation for early cancer detection.
- Association between cancer literacy and screening uptake was found barely significant for any screening type, suggesting that other factors influence actual screening uptake, urging further research.

Abstract citation ID: ckae144.1681
Beyond the like button: how european public health institutions use social media in 2024?

Duarte Vital Brito

D Vital Brito[1], A Garcia[2,3]
[1]Public Health Unit, Western Lisbon Local Health Unit, Lisbon, Portugal
[2]School of Communication and Media Studies, Lisbon Polytechnic, Lisbon, Portugal
[3]Higher Institute of Education and Sciences, ISEC Lisbon, Lisbon, Portugal
Contact: duartebrito6@gmail.com

Background: In 2024, 62% of world's population actively use social media (SM), with people aged 16 to 64 spending an average of 2 hours and 23 minutes daily across 6,7 SM platforms - most people use Facebook but spend more time on TikTok. While these platforms are essential for disseminating public health information, this study aims to explore their use by public health institutions in European countries.

Methods: We analysed the SM engagement of 32 health institutions recognized by ECDC across 29 European countries. Data collected focused on Facebook, Instagram, X, LinkedIn, TikTok, and YouTube, including SM presence on official websites, number of followers, and posts from January to March 2024. Additional data included followers per 100.000 residents, with population statistics from Worldometer and SM usage from DataReportal.

Results: Most institutions (30) are active on SM, particularly on Facebook (28), X (23), Instagram (22), YouTube (22), and LinkedIn (21). Spain and Slovenia's institutions are active on all analysed platforms, while only four institutions are on TikTok. The most used platforms were Facebook and X, with averages of 59,7 and 58,1 publications, respectively. There are disparities in engagement across platforms, with Facebook having the highest average followers (177.241) and TikTok the lowest (1.961) among all platforms. Notably, the most followed platform within ten institutions did not match country's most popular platform, indicating a misalignment in SM platforms' strategy. There was an average of 2.756 followers per 100.000 residents among analysed countries.

Conclusions: Public health institutions in Europe are actively using SM platforms to disseminate health information, mainly Facebook, X, LinkedIn, and Instagram. Despite high engagement on Facebook and X, there is a need for strategic alignment with audience's preferences, particularly in underutilized platforms like TikTok, to optimize the effectiveness of public health communication.

Key messages:

- The majority of European public health institutions actively use social media, with Facebook leading; however, newer platforms like TikTok are underutilized.
- There is a need for public health institutions to realign their social media strategies to better match the platforms preferred by their audiences to maximize the effectiveness of their communication.

Contact: ehernandez@uoc.edu

Background: According to different reports, Spain is among the European countries that use digital health technologies the most. However, to develop inclusive and fair digital health services, there is the need to feature digital health knowledge, skills, confidence, and a positive attitude about their significance. This work aims to draw a picture of digital health literacy levels in Spain.

Methods: A stratified sample of the Spanish population regarding gender, age group and area of residence was used. Participants were recruited from an online panel and by direct approach to balance quotas. Between May 2021- May 2022, participants filled a self-administered online survey, including the Spanish version of the eHealth Literacy Questionnaire (eHLQ) and the eHealth Literacy Scale (eHEALS).

Results: Digital health literacy showed similar mean scores, between 2.6-2.7 out of 5 with similar SD on each of the 7 dimensions of the eHLQ. The highest scores were related to knowledge about filling data in digital health services and knowledge about health and how the body works, and feelings about the usefulness of digital technology for health. In contrast, lower scores were related to sharing health information by technology, thinking that using technology gives access to better health services, and the possibility to contact usual health professionals with technology. Latent profile analysis identified 5 user profiles. Significant differences were found according to age, inhabitants per municipality, technology use, self-perceived health status, educational level, socioeconomic index and eHEALS scores; not by gender.

Conclusions: As the scores are similar in the different subscales, competencies, attitudes and confidence in digital health that they measure are balanced. However, the main challenge appears in granting users access to digital services that work, which involves the definition and monitoring of strategies until the final implementation.

Key messages:

- Digital Health literacy in Spain differs according to different aspects, not only age, educational or socioeconomic level.
- Confidence in usefulness is a common denominator among the five digital health service user profiles identified.

Abstract citation ID: ckae144.1683

Low health literacy is associated with health-related institutional mistrust beyond education

Alexandros Heraclides

A Heraclides[1], A Hadjikou[1], K Kouvari[1], E Karanika[1], I Heraclidou[2]
[1]Health Sciences, European University Cyprus, Nicosia, Cyprus
[2]Psychology, University of Cyprus, Nicosia, Cyprus
Contact: a.heraclides@euc.ac.cy

Background: Institutional mistrust, the lack of confidence and overall suspicion towards authorities or systems, usually governmental, but also extending to the health sector, poses a major obstacle towards public health policies and actions. Lower educational attainment has been linked to higher mistrust, but the role of health literacy in particular remains unclear.

Methods: Cross-sectional study in the general adult population of Greece and Cyprus following proportional quota sampling (January 2022 to May 2023). The current analysis is based on a sub-sample of 292 participants, with complete information on health literacy (main exposure, assessed via the validated HLS-EU-Q16) and health-related institutional mistrust (main outcome, assessed via a new culturally adopted questionnaire comprising 11 items). Multiple linear regression was used to determine associations between the aforementioned factors, adjusting for educational attainment and other potential confounders.

Results: Exploratory factor analysis revealed 3 health-related institutional mistrust dimensions, towards: (a) governmental authorities and the media (i.e., the system), (b) doctors and other health professionals, and (c) the scientific community. Health literacy was negatively associated with all mistrust dimensions, with associations being particularly strong with mistrust towards the system (B, 95% CI per unit increase in the HL scale: -0.87, -1.58; -0.15) and the scientific community (-0.71, -1.11; -0.32). These association remained robust to adjustment for educational attainment and other sociodemographic factors.

Conclusions: Mistrust towards a perceived system, comprising the government and media, as well as towards the scientific community on health-related matters, is higher among individuals with low health literacy, irrespective of educational attainment. Enhancing health literacy could act as a novel target for public health approaches aiming to tackle health-related institutional mistrust.

Key messages:

- Health-related institutional mistrust is a complex phenomenon, which appears to have different dimensions, relevant to the perceived system, health professionals, and the scientific community.
- Low health literacy is an independent predictor of health-related institutional mistrust, rendering it a novel target for attempts towards reversing this phenomenon and its adverse health consequences.

Abstract citation ID: ckae144.1684

How to measure the general Environmental Health Literacy

Hannah-Lea Schmid

S Lopez Lumbi[1], L Masciangelo[1], M Liebig-Gonglach[1], A Duda[2], J Rodenkirchen[3], A Hoyer[3], C Hornberg[1], T Mc Call[1,2]
[1]Sustainable Environmental Health Sciences, Medical School OWL, Bielefeld University, Bielefeld, Germany
[2]Environment and Health, School of Public Health, Bielefeld University, Bielefeld, Germany
[3]Biostatistics and Medical Biometry, Medical School OWL, Bielefeld University, Bielefeld, Germany
Contact: hannah-lea.schmid@uni-bielefeld.de

Background: Many environmental factors, both natural or man-made, are associated with health risks. To make informed decisions about these potential risks, certain skills and competencies are necessary. The concept of Environmental Health Literacy (EHL) which integrates aspects of Science Literacy, Health Literacy and Environmental Literacy encompasse these competencies. To assess to what extent individuals or groups are environmental health literate, a general Environmental Health Literacy Scale is necessary. To the best of our knowledge, there is no validated instrument to measure general EHL.

Methods: Two phases of scale construction were conducted: 1) Item development with deductive methods which includes a literature review and assessment of existing scales resulting in two suitable studies for scale construction. Included items were translated to German language. 2) Scale development with pre-testing of items followed by applying potential items (n = 38) to a sample of of 454 students. Internal consistency (Cronbach's alpha), Kaiser-Meyer-Olkin Criterion (KMO), Bartlett's test, Velicer's minimum average partial (MAP) test for number of underlying factors and Exploratory Factor Analysis using Principal Component Analysis with oblimin rotation and stepwise item reduction were assessed.

Results: Velicer's MAP identified 3 factors, Cronbach's alpha = .92, KMO = .92, Bartlett's Test revealed significant correlation. Seven items were removed from the scale due to low factor loadings (< .3). Factor 1 (access) explains 18% of variance, factor 2 (knowledge) 12% and factor 3 (reflection) 10%, respectively. Overall, the model explains 40% of variance. Model fit represented by RMSEA index = .05.

Conclusions: A new general EHL scale has been developed and proven to be suitable for a students sample. This marks the first step towards a validated tool for multiple purposes. Cultural adaptation as well as multiple language validations are in process.

Key messages:

- The process towards a general Environmental Health Scale has started.
- The development of a validated EHL scale will improve understanding on whether the general population or subgroups are able to gain, understand and act upon information regarding environmental health.

Abstract citation ID: ckae144.1685
Psychometric evaluation of a COVID-19 health literacy scale applying Rasch analysis

Marlene Meyer

M Meyer[1], *K Dadaczynski*[2,3], *M Messer*[4], *O Okan*[1]
[1]TUM School of Medicine and Health, Technical University Munich, Munich, Germany
[2]Public Health Centre Fulda, Fulda University of Applied Sciences, Fulda, Germany
[3]Centre for Applied Health Science, Leuphana University Lueneburg, Lueneburg, Germany
[4]Department of Nursing Science II, Trier University, Trier, Germany
Contact: marlene.meyer@tum.de

Background: Assessing health literacy in times of the COVID-19 pandemic is vital, since health literacy has been highlighted as a personal resource for managing health information. The HLS-Covid-Q22 questionnaire was developed to measure self-reported COVID-19 health literacy in adults. It has been used and validated, mainly using confirmatory factor analysis, in some studies with different target groups. However, several comprehensive validation studies are needed to ensure the feasibility of a novel measurement tool. In the current study, Rasch analysis has been chosen, as this analysis transforms the categorical responses of the items of the HLS-Covid-Q22 into linear measures.

Methods: The psychometric properties of the HLS-Covid-Q22 were evaluated in a sample of 2187 German adults applying Rasch analysis. The data is from the German COVID-HL school survey that was generated by employing an online survey in school principals during the third infection wave from March to April 2021 in four federal states. Applying the Partial Credit Model for polytomous data, the responses to the HLS-Covid-Q22 items were transformed into linear measures, unidimensionality was tested and several indices to assess the quality of the measurement tool were computed.

Results: Unidimensionality of the questionnaire could be confirmed. The rating scale steps worked as intended. Participants used every rating category. Item fit could be verified. High reliability indices were found with a person separation index of 3.41, person reliability of .92, item separation of 20.08 as well as item reliability of 1.0.

Conclusions: The HLS-Covid-Q22 appeared to be a reliable and valid questionnaire which has not been validated by applying Rasch analysis before. Even though Rasch analysis is already a well-established validation method in other disciplines, it should be used to evaluate other health literacy questionnaires more often to gain comprehensive insights into the intended functioning of measurement tools.

Key messages:

- The HLS-Covid-Q22 questionnaire appears to be a valid and reliable measurement tool.
- Rasch analysis is an appropriate method to evaluate the psychometric properties of likert-type rating-scale questionnaires.

Abstract citation ID: ckae144.1686
The effect of health literacy course on the level of health literacy in medical students

Hilal Ozdemir Oztel

V Topcu[1], *H Ozdemir Oztel*[1], *S Ozkan*[1]
[1]Public Health, Gazi University Faculty of Medicine, Ankara, Türkiye
Contact: hilallozzdemirr@gmail.com

Health literacy (HL) concerns not only individuals but also health systems and health professionals. Most of the literature on HL has focused on patient factors, with little emphasis on the communication skills and practices of health professionals. Training is needed at all levels to understand the concept of HL and its impact on health inequalities. This study is an intervention study. Data were collected from 29 students taking the third year elective course at the Faculty of Medicine through an online survey. The survey consists of 40 questions aimed at assessing the demographic characteristics of the participants, the TSOY-32 Scale and some factors affecting HL. During the training period, role-play scenarios were played to teach the importance of HL, sample videos were watched to evaluate physician-patient communication, and case studies were conducted. The mean pre-test TSOY-32 scale score of the participants was 32.8±5.8. The mean post-test TSOY-32 scale score was 36.4±7.1. There was a significant difference between pretest and posttest groups in terms of TSOY-32 scale score (p = 0.033). Health professionals often overestimate patients' HL levels and do not have sufficient competence to effectively manage limited HL. These gaps need to be addressed through the curricula of medical schools and specialties.

Key messages:

- Training on health literacy improves medical students' communication skills, bridging gaps in patient care.
- Addressing health literacy in medical training enhances patient-doctor communication, vital for quality care.

Abstract citation ID: ckae144.1687
Health literacy and health-related outcomes among preschool educators: a cross-sectional survey

Sophie Rauschmayr

S Rauschmayr[1,2], *C Krudewig*[1,2], *O Okan*[1,2]
[1]School of Medicine and Health, Technical University of Munich, Munich, Germany

[2]WHO Collaborating Centre for Health Literacy, Technical University of Munich, Munich, Germany
Contact: sophie.rauschmayr@tum.de

Background: Given the increasing use of childcare services and the shortage of skilled workers, preschool educators are under particular pressure. Health literacy has previously been shown to be an asset for stress and well-being in school principals. Within the organizational health literacy in preschools project, the Health-Literate Preschools Survey aims to assess educators' health literacy levels and investigate differences in health-related outcomes based on these levels.

Methods: Preschool educators from a Bavarian county participated in a cross-sectional online survey in February 2024. Sociodemographic information, health literacy, and health-related outcomes (well-being, exhaustion, psychosomatic complaints) were assessed using established self-report tools. Descriptive statistics and variance analyses were carried out using SPSS.

Results: The sample consists of $N = 114$ preschool educators from a Bavarian region (94.6% female, Ø 41.5 years). Of the educators, 23.7% showed adequate, 50.0% problematic, and 26.3% inadequate health literacy levels. Kruskal-Wallis H analyses indicated statistically significant differences in well-being ($H(2, n = 113) = 14.200$, $p < 0.001$), exhaustion ($H(2, n = 114) = 6.098$, $p = 0.047$), and psychosomatic complaints ($H(2, n = 114) = 8.910$, $p = 0.012$) across health literacy levels.

Conclusions: The survey provides first-time insights into preschool educators' health literacy and health-related outcomes in Germany. Only one-quarter of preschool educators demonstrated adequate health literacy levels. Further, the findings confirm the link between health literacy and well-being and stress already shown for other samples. Health promotion initiatives for preschool staff should focus on strengthening educators' health literacy, especially given their role model function for children.

Key messages:

- This survey is the first assessment of health literacy among preschool educators, which is an important target group given their role model for young children.
- Preschool educators demonstrated overall low levels of health literacy, which is associated with well-being, exhaustion, and psychosomatic complaints.

Abstract citation ID: ckae144.1688
Food and nutrition literacy in Austria - results of a representative study

Denise Schuetze

D Schuetze[1], R Griebler[1], T Link[1], K Schindler[2]
[1]Austrian National Public Health Institute, Vienna, Austria
[2]Department of Internal Medicine III, Medical University Vienna, Vienna, Austria
Contact: denise.schuetze@goeg.at

Background: A healthy diet is a key factor in people's long-term health. The nutritional health literacy and food literacy of the population play a crucial role in this. In 2021, comprehensive data on these competences were collected for the first time in Austria.

Methods: Almost 3,000 people were surveyed online. Nutrition health literacy was assessed with the newly developed Nutrition Health Literacy Scale (NHLS) and food literacy with the Self-Perceived Food Literacy Scale Short-Form (SPFL-SF). Scores and subscores were calculated. Associations between socio-demographic and socio-economic factors and the competences surveyed were assessed using t-tests, variance analysis, correlations, and multivariate regression models.

Results: In terms of nutritional health literacy, respondents score an average of 60 out of 100 points, with judging (51 points) and applying (60 points) nutritional information being the most difficult. In the area of food literacy, respondents score an average of 62 out of 100 points. The most challenging areas are 'healthier choices' (44 points), 'healthy snacking' (52 points) and 'healthy eating in exceptional circumstances' (54 points). In both areas, men and people with less formal education score lower. In the case of nutritional health literacy, people aged 65 and over have greater difficulties. Conversely, this group performs better in the area of food literacy. Differences by income can only be seen for nutritional health literacy, to the detriment of low-income groups.

Conclusions: Possible options for action include the provision of quality-assured and target-group-specific information, the implementation of appropriate tools to facilitate the assessment of foods, and measures to strengthen assessment skills, digital health literacy, food and nutrition skills.

Key messages:

- The survey showed that there is potential for improvement in both nutritional health literacy and food literacy.
- The biggest challenge is to evaluate and use nutritional information and to stick to a healthy diet without making exceptions.

Abstract citation ID: ckae144.1689
Measuring Vaccine Literacy in Switzerland: How is the situation after COVID-19?

Rebecca Jaks

R Jaks[1], SM De Gani[1,2]
[1]Careum Center for Health Literacy, Careum Foundation, Zurich, Switzerland
[2]Careum School of Health, Kalaidos University of Applied Sciences, Zurich, Switzerland
Contact: rebecca.jaks@careum.ch

Background: Vaccinations are one of the most effective medical health interventions and one of the most important preventive measures. However, the population is often unsure about vaccination, and the roles and responsibilities of the key actors seem often unclear. To adequately protect the population against vaccine-preventable diseases, the Swiss Confederation, the Cantons and other stakeholders have developed the National Vaccination Strategy and an associated action plan. For its implementation, studies on the population's knowledge, attitudes, skills, and vaccination behavior are crucial. Thus, the Swiss Federal Office of Public Health launched a study to assess vaccine literacy and its relation to vaccination readiness and behavior in the adult population in Switzerland.

Methods: A representative sample of 2,500 people living in Switzerland will be surveyed in summer 2024. The online questionnaire will include validated instruments, e.g. the HLS19-VAC Instrument to measure vaccine literacy or the 7C Vaccination Readiness Scale, as well as questions on correlates of vaccine literacy, vaccination readiness and behavior.

Results: The results of the survey will be presented, with a focus on vaccine literacy, vaccination readiness and behavior and their correlates. Specifically, differences among the three main language regions and between specific population groups will be shown. Further, a comparison with data from previous studies will be presented.

Conclusions: Despite having an advanced healthcare system, to date Switzerland has only partially reached its objectives in terms of vaccination, both for individual protection and collective immunity. New data on vaccine literacy, vaccination readiness and behavior as well as on the influencing factors are needed, especially after the pandemic, to guide effective future actions and measures to improve the vaccine coverage and public health in Switzerland.

Key messages:

- Due to the COVID-19 pandemic the topic of vaccination in general has received increasing attention and may has changed people's knowledge and attitudes towards vaccination.

- Newest data on vaccine literacy, vaccination readiness and behavior are necessary to inform future, targeted actions and increase vaccine uptake.

Abstract citation ID: ckae144.1690
Systematic review of reviews: occupational exposures and work disability

Elli Hartikainen

L Salonen[1], *E Hartikainen*[1], *K Undem*[2], *S Solovieva*[1]
[1]Finnish Institution of Occupational Health, Helsinki, Finland
[2]The National Institute of Occupational Health in Norway, Oslo, Norway
Contact: elli.hartikainen@ttl.fi

Background: Occupational exposures significantly impact workers' health and may lead to temporary or permanent work absence. Although the effect of occupational exposures on work participation has been studied extensively, research remains fragmented in covering different exposures and outcomes. This review investigates the evidence on the associations between occupational exposures and work disability.

Methods: Following PRISMA guidelines, a systematic review of reviews was conducted using PubMed, Scopus, and Web of Science. Reviews and meta-analyses of observational studies examining associations between occupational exposures and self- or physician-assessed sickness absence or disability retirement, published until 2023, were included. The review findings were supplemented with an additional search for original studies published after 2012 focusing on exposures less covered by the reviews. Quality assessment was performed using AMSTAR and the NH quality assessment tools.

Results: A total of 21 reviews and meta-analyses and 35 complementing original studies were included. While 10 reviews covered psychosocial exposures and 19 reviews focused on temporary work disability, fewer examined other exposures like chemicals (3 reviews, 7 original studies) or permanent work disability (8 reviews, 17 original studies). Next, we'll further synthesize these studies to evaluate the levels of the evidence.

Conclusions: Our review found that published studies primarily focused on work-related psychosocial exposures and temporary work disability, revealing gaps in research on other occupational exposures like chemicals and permanent work disability.

Key messages:

- There's a need to explore a wider range of occupational exposures and their impact on work disability beyond psychosocial exposures.
- The focus of prior reviews on occupational exposures and temporary work disability underscores the importance of studying the impact of these exposures on permanent work disability in future research.

Abstract citation ID: ckae144.1691
Mental health literacy in German teachers – What do they know? What do they need?

Jennifer Piloth

J Piloth[1], *A Edelmann*[1], *L Eppelmann*[1], *M Wessa*[1,2]
[1]Leibniz-Institut für Resilienzforschung gGmbH, Mainz, Germany
[2]Johannes Gutenberg-Universität Mainz, Mainz, Germany
Contact: jennifer.piloth@lir-mainz.de

Background: Preventing mental health problems and promoting mental wellbeing is the aim of school-based mental health literacy (MHL) programs. Previous research suggests that good MHL (knowledge and skills regarding mental health, resilience, and help-seeking) helps people to take good care of their own and others' mental health and use support-services. In this context the MHL of teachers is highly relevant, as they act as role models and interact with affected pupils on a regular basis, for which certain knowledge and skills are necessary. In this study, we therefore seek to investigate the level of MHL in German high-school teachers as well as their exposure to impaired students and their desire for further education on pupils' mental health.

Methods: The data are collected as part of an effectiveness study of a school-based intervention to strengthen MHL (BEWARE), which was developed by our working group. We collect data from teachers who are involved in BEWARE as coaches as well as from those not directly involved ($n \approx 300$). Data collection takes place online at three measurement timepoints (6 months apart each). For the analysis presented here, data of the first measurement timepoint with respect to MHL, skills in handling affected students and wishes for additional education on pupils' mental health are included.

Results: As the data collection is still ongoing, statistical analyses are not yet completed. We will present data on the current state of knowledge on MHL in German teachers as well as their abilities to deal with affected pupils and their wish for further education. In addition, we will relate the number of affected pupils they teach to depict the relevance in their daily life at school to the above-mentioned measures.

Conclusions: The acquired data and respective analyses will give us important insights about the objective and subjective need of MHL training in schoolteachers (based on assessed knowledge and their reported wish of additional education).

Key messages:

- Our study will give us important insights about the objective need of MHL training in high-school teachers based on assessed knowledge.
- Our results will depict which formats of training teachers would prefer for additional education on pupils' mental health, which will be a valuable basis for the development of future programs.

Assessing cancer prevention literacy among European population: a cross-sectional study

Paula Romeo-Cervera

P Romeo-Cervera[1], *M Pinto-Carbó*[1], *A Blanco-Cabañes*[2], *MA Torres-Mariner*[1], *J Fons-Martínez*[3], *M Vanaclocha-Espí*[1], *S Castán-Cameo*[1,4], *T de Pablo-Pardo*[1], *A Molina-Barceló*[1], *BUMPER Consortium*
[1]Cancer and Public Health Research Unit, FISABIO-Public Health, Valencia, Spain
[2]Communication and Documentation Department, FISABIO-Public Health, Valencia, Spain
[3]Vaccine Research Area, FISABIO-Public Health, Valencia, Spain
[4]General Directorate of Public Health, Regional Ministry of Health, Valencia, Spain
Contact: paula.romeo@fisabio.es

Background: Cancer prevention literacy (CPL) is essential for empowering individuals to make health-informed decisions and adopt preventive measures to reduce their cancer risk. This study aims to measure CPL among the European population.

Methods: A cross-sectional population-based study was conducted from February to March 2024 among European residents over 18 years old ($N = 2312$) in the context of BUMPER Project (https://bumper.cancer.eu/). An online self-administered questionnaire was developed including: sociodemographic characteristics (age, gender, country of residence, educational level), and CPL (general and by European Code Against Cancer -ECAC- topics). A descriptive analysis was performed and the chi-square and Kruskal-Wallis test were calculated to examine the relationship between CPL and sociodemographic variables.

Results: 44.2% showed a high level of CPL, followed by 39.5% with medium, and 16.3% with low level. 61.1% of participants are not aware of ECAC. ECAC topics with higher levels of knowledge are:

UV exposure (88.3%), pollution (81.6%), tobacco (78.7%), second-hand smoking (60.9%). ECAC topics with lower levels are: hormone replacement therapy (47.9%), breastfeeding (41.6%), and vaccination (32.9%). Statistically significant differences ($p < 0.05$) are observed in CPL level by gender, country of residence, and educational level. Those with a higher % of low CPL levels are men (22.8%), people from West and South Europe (20.8% and 18.1%), and primary education level (34.7%).

Conclusions: CPL level is medium-high among the European population, with social and gender inequalities. Further studies are needed to delve into these inequalities.

Key messages:

- The cancer prevention literacy level is medium-high among the European population, with social and gender inequalities.
- There is a need of tailored interventions to address social inequalities in cancer prevention literacy among European population.

Abstract citation ID: ckae144.1693
Implementation of organizational health literacy depending on school characteristics in Germany

Cara Krudewig

C Krudewig[1,2], *S Kirchhoff*[1,2], *O Okan*[1,2]
[1]School of Medicine and Health, Technical University of Munich, Munich, Germany
[2]WHO Collaborating Centre for Health Literacy, Technical University of Munich, Munich, Germany
Contact: cara.krudewig@tum.de

Background: Children and adolescents are important target groups for health promotion measures to sustain a healthy upbringing. Organizational health literacy in schools is a promising environmental intervention to strengthen health literacy in school children. This study examines the relationship between school characteristics and the implementation of organizational health literacy.

Methods: School principals in Germany were invited to complete a 20-minute online survey between November 2022 and July 2023. An 8-item self-report tool was used to measure organizational health literacy in schools (OHLS-Q-SF) that comprehends eight different areas within schools to become health literate. A hierarchical cluster analysis was carried out to identify groups according to the composition of the socioeconomic status of the student body. Descriptive statistics, Mann-Whitney-U tests, and Kruskal-Wallis tests were performed.

Results: 598 school principals (73.6% female, Ø 52.3 years old) who worked at primary schools (49.1%), secondary schools (37%), and special education schools (13.9%) completed the survey. Cluster analysis revealed two groups. The first one (36.8%) contains schools with mainly students with lower socioeconomic status, and the second group (63.2%) contains schools with more students from middle or higher socioeconomic status. The socioeconomic status of students within the schools showed no significant results for any area of organizational health literacy, whereas all eight areas are more likely implemented if the schools already participate in a school health promotion program or network ($p < 0.001$).

Conclusions: Participating in a school health promotion program was associated with higher levels of implementation in all areas of organizational health literacy in schools. This finding highlights the importance of those programs. Integrating organizational health literacy into those interventions can be a beneficial approach to sustaining health literate schools.

Key messages:

- Participating in a school health promotion program or network might facilitate schools to become health literate organizations.
- In Germany, the socioeconomic status of the students within the schools is not associated with the implementation of organizational health literacy.

Abstract citation ID: ckae144.1694
Making health information understandable: the COVID-19 patient guideline

Annika Oeser

A Oeser[1], *S Messer*[1], *S Schneider*[1], *N Lund*[2], *R Haase*[3], *U Janssens*[4], *N Kreuzberger*[1], *N Skoetz*[1]
[1]Institute of Public Health, University of Cologne, Cologne, Germany
[2]Department of Intensive Care Medicine, University Hospital Hamburg-Eppendorf, Hamburg, Germany
[3]Patient representative, Germany
[4]Medical Clinic & Medical Intensive Care Medicine, St.-Antonius-Hospital, Eschweiler, Germany
Contact: annika.oeser@uk-koeln.de

Issue: Evidence-based practice guidelines offer a reliable source of information, providing recommendations based on the most recent evidence. However, these guidelines are complex and difficult to understand for laypersons. This creates a knowledge gap, affecting shared-decision making, treatment acceptance, understanding of a disease and recommendations of disease prevention.

Description of the problem: Patient guidelines (PatG) aim to bridge this knowledge-gap by providing simplified versions of practice guidelines in lay language. This is a common practice internationally. An example is the German evidence-based COVID-19 practice guideline, published in 01/2024. In March, a multidisciplinary team, including a patient representative, created and reviewed a PatG outline, prioritising topics based on patient relevance, and discussed relevant information. The authors translated guideline recommendations into lay language, researched additional information, and created supporting graphics. A methodology chapter explaining both guidelines and a short medical term dictionary were also included.

Results: In 05/2024, the COVID-19 PatG, around 70 pages long, was finalized including information on treatment, diagnostics, intensive care, and support resources. A feedback round was initiated. Comments will be incorporated for the final version to be published in the national guideline registry by end of 05/2024. Updates of the PatG and practice guidelines will occur frequently.

Lessons: We faced challenges in simplifying medical concepts and interventions and accurately translating recommendations without losing key information. The length of the PatG may discourage readers. Despite these challenges, we are committed to enhancing accessibility, using simpler language, and adding supporting graphics to improve the PatG in the future.

Key messages:

- Despite some challenges, patient guidelines pose as a reliable form of patient information.
- The COVID-19 patient guideline is a reliable and evidence-based source of information.

Abstract citation ID: ckae144.1695
Development of a tool for generating comprehensible, individualized and digitalized outpatient letter

Rebecca Jaks

R Jaks[1], *D Nicca*[2], *P Künzler-Heule*[3], *B Brülke*[4], *A Jonietz*[4], *R Post*[4], *SM De Gani*[1,5]
[1]Careum Center for Health Literacy, Careum Foundation, Zurich, Switzerland

[4]«Was hab' ich?» gGmbH, Dresden, Germany
[5]Careum School of Health, Kalaidos University of Applied Sciences, Zurich, Switzerland
Contact: rebecca.jaks@careum.ch

Background: Patients often remember little from a medical consultation or a conversation with a doctor. A comprehensible, individual patient letter summarizing the consultation can support, as a German project which successfully implemented a digital tool to generate such a letter in inpatient care showed. Based on this, our aim is to develop a tool for letters in outpatient care in Switzerland, to support understanding of the consultation and increase patient's health literacy (HL).

Methods: The development of the tool was conducted participatively with targeted health professionals (HP) and patients with a chronic disease to 1) identify specific patient groups and situations, 2) confirm eligibility and receive concrete input regarding structure and content, and 3) to ensure the technical practicality and usability by the target groups. Concretely, several expert and patient interviews, a focus group and consultation observations were performed. Further workshops and usability tests are planned.

Results: We first defined 8 criteria to identify situations suitable for the development of the letter (e.g. high information need) and interviewed 5 experts on selected topics. Based on this, chronic back pain was chosen for a deeper feasibility analysis: A focus group interview ($n = 4$ HP) and 5 telephone interviews with patients confirmed the eligibility and provided information on the structure and content of the letter. Observations of 5 consultations provided further insights. Then, a first concept for the letter's content was developed and is currently being finalized. It consists of: 1) summary; 2) background; 3) diagnosis; 4) treatment; and 5) next steps and includes infoboxes and a glossary.

Conclusions: The tool for patient letters can be adapted to other diseases (e.g. chronic back pain) and settings (outpatient care). In a next phase, the letter will be piloted in an outpatient clinic and evaluated with HP and patients. The effect on HL will also be assessed.

Key messages:

- Comprehensible, individualized, and digitalized patient letters can help patients to deal with health information and take better decisions for their health and well-being.
- The developed patient letter and the corresponding tool should be easily adaptable for other diseases and settings.

Abstract citation ID: ckae144.1696
The empowering role of health literacy in combatting fake news, misinformation and infodemics

Saskia De Gani

A-S Beese[1], *E Guggiari*[1,2], *R Jaks*[1], *SM De Gani*[1,2]
[1]Careum Center for Health Literacy, Careum Foundation, Zurich, Switzerland
[2]Careum School of Health, Kalaidos University of Applied Sciences, Zurich, Switzerland
Contact: saskia.degani@careum.ch

Background: In times of the rapid digital transformation, people need to acquire specific knowledge, skills and attitudes to deal with data, digital information and technology. Such skills are particularly important in times of crisis, as the COVID-19 pandemic has shown. Alongside the pandemic, a so called "infodemic" has emerged, i.e., an overabundance of information, accompanied by misinformation, which impedes sound decision-making processes, affects health literacy (HL) and impacts public health. However, while misinformation poses a well-known threat to our health and well-being, we still lack viable concepts and approaches to satisfactorily solving this issue. Thus, we aimed at reviewing the concept of HL in view of the infodemic and health-related challenges.

Methods: In a 12-month participatory process in Switzerland in 2023, we investigated the empowering role of HL in light of the polycrisis. On behalf of the Swiss Federal Office of Public Health, we conducted a literature review on existing HL definitions. Then, we conducted 6 expert interviews and 2 focus group interviews with other 10 experts in HL and associated domains, which guided and informed the review process.

Results: As a result, HL can be understood as a bundle of competencies to proactively deal with health-related information, services, and challenges and thereby empowers people to manage their and other's health and well-being. Thus, HL empowers people to better manage digital information and services and promotes critical thinking. This in turn is necessary to assess information quality, uncover misinformation and to adequately manage health data and information.

Conclusions: HL represents a crucial prerequisite for individuals, professionals, and decision-makers to find trustworthy health information, to reflect upon the quality and credibility of sources and content, and to understand the complex interrelations of the determinants of health and is therefore crucial for public health.

Key messages:

- Health literacy empowers people to adequately deal with fake news, misinformation and infodemics.
- Strengthening health literacy offers great potential for public health to promote critical thinking and to rebuild trust.

Abstract citation ID: ckae144.1697
Development and validation of a tool for assessing breast cancer health literacy among Chinese women

Pei Chenyang

P Chenyang[1], *L Yuanli*[1]
[1]School of Health Policy and Management, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China
Contact: chenyang3061@163.com

Background: Breast cancer (BC) is a major malignancy that seriously threatens women's health. No unified, evidence-based, standardized assessment tools for BC literacy are available in China yet.

Objectives: We sought to develop an assessment tool to measure BC health literacy among Chinese women and to test the tool's reliability, validity, and feasibility.

Methods: Group discussion, expert consultation, and small-sample pilot investigation were conducted to develop an initial assessment tool. A multi-stage stratified random-sampling process was used to select women aged 18-64 years in Yichang City, Hubei Province, China, for an onsite survey. Project analysis and exploratory factor analysis were used to screen the questions to create a formal assessment tool, which was further evaluated by feasibility analysis and the measurement of reliability and validity.

Results: The official version of the assessment tool for Chinese female BC health literacy includes 32 items. Nine common factors (policy knowledge, uncorrectable risk factors, modifiable risk factors, identification of early warning signs #1 and #2, screening methods, breast self-awareness and examination behaviors, timely seeking of medical help and standardized treatment, and rehabilitation) were extracted through exploratory factor analysis with factor loadings of 0.511-0.873 and a cumulative explained variance of 65.989%. Confirmatory factor analysis revealed $\chi 2/df = 1.61$, $CFI = 0.91$, $TLI = 0.90$, $RMSEA = 0.04$, and $SRMR = 0.06$. The overall Cronbach's α coefficient was 0.875, and the split-half reliability was 0.770 (both >0.700).

Conclusions: An assessment tool for Chinese female BC health literacy was developed with acceptable feasibility, reliability, and validity. The application of this tool can help to promote BC prevention and control in China and may also benefit other countries.

Key messages:

- An assessment tool for Chinese female BC health literacy was developed with acceptable feasibility, reliability, and validity.

- The application of this tool can help to promote BC prevention and control in China and may also benefit other countries.

Abstract citation ID: ckae144.1698
Assessing cyberchondria and eHealth literacy differences in urban and rural China

Yulu Lin

Y Lin[1], *R Xu*[1]
[1]Rehabilitation Science, The Hong Kong Polytechnic University PolyU, Hung Hom, Hong Kong
Contact: linyulu98@gmail.com

Background and Objectives: This study aimed to explore the association between cyberchondria and eHealth literacy in the general Chinese population, and to assess how this relationship changes between urban and rural residents.

Methods: Data obtained from a web-based, cross-sectional survey that evaluate cyberchondria and its impact on health in February 2024. The Cyberchondria Severity Scale - 12 item was used to measure the cyberchondria, while the eHealth Literacy Scale was used to evaluate eHealth literacy. Descriptive analysis was used to describe the background characteristics of the participants. Then, a multivariable linear regression model was then performed for urban and rural subsample to examine the relationship between cyberchondria and eHealth literacy, respectively, providing a comparative analysis between the urban and rural populations.

Results: A total of 634 individuals completed the questionnaire. The average age was 33.2 years ($SD = 7.4$), with approximately 50.3% ($n = 319$) being female. Urban residents made up 71.4% ($n = 451$) of the participants. The mean eHEALS scores for urban and rural residents were 31.9 ($SD = 4.3$) and 30.4 ($SD = 4.2$), respectively. The CSS-12 scores for urban residents were 40.3 ($SD = 7.58$) and for rural residents were 39.1 ($SD = 7.2$). Linear regression analyses showed a significant association between eHealth literacy and cyberchondria for urban residents (Beta = 0.30, $p < 0.001$), but age and education level had no significant impact. For rural residents, a statistically significant association between eHealth literacy and cyberchondria was also observed (Beta = 0.40, $p = 0.002$).

Conclusions: Overall, eHealth literacy consistently predicts cyberchondria severity in both urban and rural samples. Higher eHealth literacy is linked to greater cyberchondria, especially in rural areas. Future research should explore other potential mediators, including psychological factors, internet usage patterns, and access to healthcare services.

Key messages:
- eHealth literacy strongly predicts cyberchondria severity in both urban and rural populations, with a notably stronger impact observed in rural settings.
- Urban and rural differences highlight the need for customized digital health literacy programs to effectively address region-specific challenges and behaviors.

Abstract citation ID: ckae144.1699
Factors Influencing Health Literacy among South Korean Adults: A Nationwide Study

Ji Eun Kim

JE Kim[2], *Y Bae*[4], *IH Song*[1,3]
[1]School of Social Welfare, Yonsei University, Seoul, South Korea
[2]Department of Family Environment & Welfare, Chonnam National University, Gwangju, South Korea
[3]ICONS Convergence Academy, Yonsei University, Seoul, South Korea
[4]Grad School of Family Environment & Welfare, Chonnam National University, Gwangju, South Korea
Contact: junekim@jnu.ac.kr

Background: Health literacy is crucial for health knowledge, behaviors, and outcomes, but research on health literacy has been limited to specific populations and settings in South Korea. This study aimed to identify factors influencing health literacy in a nationally representative sample of South Korean adults to inform public policies.

Methods: This cross-sectional study utilized data from the 2020 Korea Health Panel survey (10,262 adults aged 18-84 years). Sociodemographic factors (age, gender, education level, monthly household income, employment status, marital status, household characteristics, and region) and health (subjective health status, presence of chronic diseases, depression, and health insurance status) factors were examined. Health literacy was assessed using the 16-item European Health Literacy Survey Questionnaire (HLS-EU-Q16). Linear regression analysis was performed to identify factors associated with health literacy.

Results: The mean health literacy score was 9.1 (SD 1.60), with significant differences across age groups ($p < 0.001$). Linear regression analysis (adjusted $R2=0.287$, $F = 322.83$, $P < 0.001$) revealed that higher age, female gender, lower education, lower household income, being single, living outside a metropolitan area, having chronic diseases, lower subjective health, depression, and being uninsured or receiving medical aid were significantly associated with lower health literacy (all $p < 0.001$).

Conclusions: This study identified several socio-economic and health-related factors significantly associated with health literacy among South Korean adults. The findings suggest that older individuals, who may require more time to understand and use health information, are particularly vulnerable to low health literacy. These results provide valuable insights for developing targeted interventions and public health policies aimed at promoting health literacy and successful aging in the context of a rapidly aging society.

Key messages:
- Various socio-economic and health-related factors significantly influence health literacy among South Korean adults.
- Older individuals are particularly vulnerable to low health literacy, which has implications for successful aging in a rapidly aging society.

Abstract citation ID: ckae144.1700
How to measure Organizational Vaccine Literacy: an exploratory cross-country survey

Arianna Bellini

A Bellini[1,3], *ML Russo*[1,2], *I Aloise*[1], *G Marchetti*[2,3], *S Scarso*[1,2,3], *C De Marchi*[1,2], *C Bartolucci*[1], *ME Tosti*[2,3], *S Declich*[2,3], *M Marceca*[1,2]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Italian Society of Migration Medicine, Rome, Italy
[3]National Center for Global Health, ISS, Rome, Italy
Contact: arianna.bellini@uniroma1.it

Background: The project AcToVax4NAM (Grant No. 101018349-3° EU Health Programme) aims to ensure equal and guaranteed access to vaccination services for Newly Arrived Migrants (NAMs). The working group developed a tool that measured the level of Organizational Vaccine Literacy (OVL), defined as an organizational effort to make the Health System easier to access and navigate, thereby facilitating informed decision-making regarding vaccinations for individuals, families and communities.

Methods: A systematic literature review was undertaken to identify validated tools for measuring OVL, but none was found. Consequently, the review was broadened to include tools for assessing Organizational Health Literacy, which were then adapted to define OVL. A questionnaire consisting of 22 questions divided into 7 sections was developed, utilizing a scale of 1 to 5 to gauge

OVL. The survey was then distributed among healthcare services in 8 countries of the AcToVax4NAM consortium.

Results: We received 88 responses, mainly from Italy (26%), Spain (23%) and Greece (12%), encompassing 17 facilities, primarily vaccination centers and health prevention departments. Questions about the clarity and easy access to vaccination information provided by organizations had high mean scores, except the questions on the navigability of websites for foreign patients (mean scores $<$ 3). Notably, responses related to the issue of cross-sectoral collaboration between health services and other partners (e.g., patient associations, NGOs), had a mean score of 2.56. Low scores were observed in the area related to the perception of possible individual contribution to systemic organizational efforts.

Conclusions: Shifting to an approach in which organizations prioritize equity and address complex needs, rather than leaving it to individuals to navigate the complex world of healthcare providers, could bring benefits to population groups, particularly those at risk of not accessing prevention services, such as NAMs.

Key messages:

- After conducting a systematic review to identify validated instruments for the measure of Organizational Vaccine Literacy (OVL), a tool consisting of 22 questions was developed to measure OVL.
- Shifting to an approach where organizations prioritize equity and address complex needs, rather than leaving it to individual responsibility, could significantly benefit vulnerable population.

Abstract citation ID: ckae144.1701
Project Health Resilience: a health literacy programme for 16–19-year-olds delivered by doctors

Leonora Weil

A Grindlay[1,2], D Marks[8], A Zuriaga Alvaro[6], C Rau[3], C Lewis[4], G Landy[5], A Cross[1], C Dillon[7], M Mortlock[7], L Weil[2,6]
[1]Public Health, NHS, London, UK

[3]Emergency Medicine, NHS, London, UK
[4]General Practice, NHS, London, UK
[5]Psychiatry, NHS, London, UK
[6]Legacy and Health Equity Partnership, NHS England, London, UK
[7]Health Improvement, London Borough of Camden, London, UK
[8]Department of Public Health, LSHTM, London, UK
Contact: leonora.weil@ukhsa.gov.uk

Background: Project Health Resilience is an education-setting based health literacy pilot for Londoners aged 16-19. This is a transitional age when young people independently engage with health services. Greater health literacy levels improve use of preventive services, successful management of long-term health conditions and reduce emergency service use. Research during the COVID pandemic also demonstrated the importance of building trust with health professionals to reduce health inequalities. The impact of poor health literacy is observed universally. This intervention was developed to empower young people at a critical time.

Methods: 3 bespoke modules (healthcare access; medical emergencies; mental health resilience) were co-produced with young people and delivered by doctors. During 2023, 46 sessions were carried out with 712 attendances across 8 London settings. A mixed-methods approach, including questionnaires and interviews, was used for the evaluation. The study explored whether taking part resulted in increased awareness of services, knowledge, confidence and trust in health professionals.

Results: Participants reported that topics filled a crucial gap in their learning. Awareness and confidence increased for: awareness of different health services (increase of 18%) and mental health services (38%), confidence calling emergency services (13%), confidence dealing with medical (34%) or mental health emergencies (40%). Knowledge questions answered correctly increased across the 3 modules (46% pre vs 60% post). Trust levels increased and findings suggest that doctors delivering sessions was a key component.

Conclusions: Findings add to the evidence base around education-setting based health interventions improving health literacy. Providing a unique opportunity for adolescents to engage with health professionals can increase trust levels. Doctors delivering health education at this critical age is a pioneering model which can be replicated in other settings.

Key messages:

- Health literacy education is particularly impactful at this critical age of transition; this can contribute to reducing health inequities across the life course.
- Trust, collaboration, and co-production were core principles upon which this pilot thrived. Without input from young people, it is difficult to design appropriate and impactful interventions.

Abstract citation ID: ckae144.1702
Health literacy and individuals’ perception regarding Heart Failure management: patient perspective

Ana Rita Pedro

AR Pedro[1,2], B Raposo[2], D Brandão[1,2], H Martinho[3], M Almeida[3], M Pardal[4], F Bernardo[4], AS Cunha[2]

[3]Medical Affairs, AstraZeneca Portugal, Barcarena, Portugal
[4]Evidence Generation, AstraZeneca Portugal, Barcarena, Portugal
Contact: rita.pedro@ensp.unl.pt

Background: Heart failure (HF) is a multidimensional disease that has a significant impact on the quality of life of people with this condition and the person’s level of health literacy is a key element in disease management. Therefore, this analysis aims to assess the correlation between the level of health literacy of people with HF and their level of concern about managing the disease, their perception about quality of life, and access to healthcare.

Methods: Cross-sectional study conducted through a survey among adults with HF, residents, and healthcare consumers in Portugal. The survey comprised 6 questions on health literacy (HLS-EU-Q6); 9 dimensions of concerns in HF management (4-level scale ranging from “not concerned” to “very concerned”); quality of life and access to healthcare perceptions (5-level scale ranging from “very bad” to “very good”). Concerns global score was calculated based on 9 dimensions of concerns about HF management. The statistical analysis included Spearman’s and Pearson’s correlations.

Results: A total of 428 responses were analysed. Respondents had a mean age of 70 years, 52.1% were men and 67.9% have secondary education. 47.0% of respondents perceived their access to healthcare as “good”, 63.3 % perceived their quality of life as “reasonable” and 61% have low levels of health literacy. Individuals with a higher health literacy level tended to have lower levels of concerns regarding HF management ($r=-0.133$; $p=0.006$); individuals with a higher level of health literacy tended to have a better perception of their access to healthcare ($\rho=0.145$; $p=0.003$) and quality of life ($\rho=0.220$; $p<0.001$).

Conclusions: The findings reinforce that overcoming health literacy obstacles must continue to be a focus of healthcare systems and institutions to enhance healthcare access, quality of life, and chronic disease management. These efforts may result in better health outcomes, promote health equity and general well-being in this population.

Key messages:

- Individuals with Heart Failure with higher levels of health literacy report less concerns about the management of their condition.

- Individuals with Heart Failure and lower levels of health literacy have a worst perception of their access to healthcare and quality of life. Health literacy promotion must continue to be a priority.

Contact: wieke.vanboxtel@hu.nl

Early exposure to health literacy (HL) and fostering children's HL development for health promotion purposes is believed to positively influence their ability to lead healthier lives during adulthood (WHO, 2021). Our qualitative study on children's perspectives on health and HL showed that children perceive health in a broader context emphasizing aspects of everyday life. When engaging with health information, they often encounter irrelevant information and struggle to discern its trustworthiness (van Boxtel et al., in preparation). In this study, we aim to co-design HL activities with children in primary school for the context of health promotion. Children, aged 9-12 years, formed co-design teams and participated in six 1-hour sessions. Initially, they discussed what HL is and selected the most relevant HL skills to address. Through activities like body mapping, they explored ways to learn these skills. Subsequent sessions involved brainstorming ideas for the designing, and prototyping activities. A larger group of children tested these prototypes, followed by evaluations and improvements by the design team. Preliminary results indicate that children prefer designing HL activities that resonate with their everyday experiences. However, they often relied on familiar ideas unless aided to think creatively, therefore we used AI tools for ideation. The final designs, such as life-sized board game about healthy food, show potential to learn HL in schools. Results of the learning outcomes from these activities are pending and will be presented at the conference. Co-designing with children leads to meaningful HL activities that encourage active engagement with health information. This study inspired us to build a toolbox for learning HL skills for children aged 9-12-years-old in primary schools or childcare settings. We also aim to co-design other identified HL skills and competencies from our Delphi study (Van Boxtel et al., in preparation).

Key messages:

- HL activities co-designed by children reflect daily life relevance, fostering deeper engagement and learning.
- Using co-design, we enable children to actively engage with health information and learn specific HL skills.

Abstract citation ID: ckae144.1704
Youth voices: A participatory approach to promoting mental health literacy through digital means

Michaela Wright

M Wright[1], *F Reitegger*[2], *B Gasteiger-Klicpera*[1,2], *M Vidmar*[3], *M Veldin*[3], *K Borzucka-Sitkiewicz*[4]
[1]Research Center for Inclusive Education, University of Graz, Graz, Austria

[3]Educational Research Institute, Ljubljana, Slovenia
[4]Faculty of Social Sciences, University of Silesia, Katowice, Poland
Contact: michaela.wright@uni-graz.at

A concerning number of young people worldwide experience mental health challenges, often compounded by limited mental health literacy, such as a lack of knowledge about how to recognize mental disorders and strategies for seeking help (Cairns & Rossetto, 2019). Therefore, it is crucial to promote mental health literacy among youth. Due to the scarcity and often high cost of readily available mental health services, as well as concerns about anonymity, digital programs have become an alternative means of reaching youth. To this end, a digital prevention program was developed. The pivotal question now is how to effectively promote young people's mental health literacy through digital means, more specifically: How to develop (1) evidence-based and (2) target group-specific content? To investigate these questions, two systematic reviews were conducted that analyzed a total of 65 digital evidence-based mental health programs. Since the active use of programs also depends on how suitable and appealing the content is for the target group, a participatory approach was chosen to actively involve the target group in the process of developing the program's design and content. Therefore, four participatory workshops were conducted in Slovenia, Poland, and Austria, with 12-15-year-old students (N = 182). Selected results from the systematic reviews and cross-national results from the workshops will be presented. It was found that psychoeducation is an important and effective method for promoting mental health literacy among youth and that young people prefer this content to be delivered as briefly and concisely as possible, and in a multimodal format. The discussion will highlight key takeaways regarding the benefits and challenges of this approach, emphasizing the necessity of including student voices in the creation of psychoeducational content for a digital mental health program in order to highlight and recognize young people's right to participate.

Key messages:

- The value of youth participation - Involving young people in the development of content for a digital mental health literacy program is a means to increase its relevance and appeal to them.
- The intricacies of youth participation - Involving young people in the development of a digital mental health literacy program presents challenges that require careful consideration.

Abstract citation ID: ckae144.1705
Efficacy of digital interventions for smoking prevention among children: a systematic review

Vincenza Gianfredi

V Gianfredi[1], *L Traverso*[2], *AC Sgueglia*[3], *C Barbati*[3], *P Bertuccio*[3], *A Odone*[3]
[1]Department of Biomedical Sciences for Health, Università di Milano-Statale, Milan, Italy
[2]Department of Education Sciences, University of Genoa, Genoa, Italy
[3]Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy
Contact: vincenza.gianfredi@unimi.it

Background: Smoking remains a leading preventable cause of morbidity and mortality globally, with initiation often occurring in childhood. Early smoking onset is linked to increased difficulty in quitting and higher risk of long-term health complications. Traditional prevention strategies have not fully succeeded in curbing youth smoking rates, highlighting the need for innovative approaches. Digital interventions (DI), such as gamified education, social media campaigns, and virtual reality, offer a novel avenue for engagement and education. This systematic review aims to assess the efficacy of DI in preventing smoking, and improving knowledge and awareness about smoking damages, among children. This review is part of the PRIN project, whose goal is to evaluate the effectiveness of a DI aimed at school-aged children, intended to increase knowledge about the negative effects of smoking and prevent its use.

Methods: On the 18th of March 2024, PubMed, Scopus, and PsycINFO were surfed for trials and observational studies evaluating DI for smoking prevention among children aged 6-12 years. Study quality will be evaluated using the Cochrane Risk of Bias Tool and New Castle-Ottawa scale. The protocol has been registered in PROSPERO.

Results: From 3,081 initially identified articles, 328 papers were removed because duplicate. The screening process is ongoing.

Conclusions: DI are a promising tool for engaging young populations through platforms they are familiar with and receptive to. By leveraging the high penetration of digital technology in the daily lives of children, these interventions have the potential to deliver smoking prevention messages in a compelling and interactive manner. Understanding the effectiveness of DI in smoking prevention can significantly contribute to public health by providing viable alternatives to traditional methods and potentially reducing future smoking-related health burdens.

Key messages:

- Evaluating digital strategies for smoking prevention among children could offer vital alternatives to traditional methods, potentially reducing long-term health risks.
- Digital interventions (DI) offer promising new ways to engage young audiences on smoking prevention using familiar platforms, potentially reshaping public health approaches.

Abstract citation ID: ckae144.1706

Systematic review of the Health Literacy Questionnaire (HLQ) for global health literacy development

Richard Osborne

M Hawkins[1], S Cartner[1], C Cheng[1], RH Osborne[1]
[1]Centre for Global Health and Equity, Swinburne University of Technology, Melbourne, Australia
Contact: rosborne@swin.edu.au

Background: The Health Literacy Questionnaire (HLQ) is used to inform programs and policies in more than 80 countries. It is a key needs assessment in the Ophelia (Optimising Health Literacy and Access) process, a codesign process to build effective interventions. Ophelia is applied in the European Commission Joint Action on Cardiovascular Diseases and Diabetes initiative (25 projects/13 countries). Given growing demand, an Ophelia digital platform is being developed, and confirmation of robust HLQ psychometric evidence is needed for user confidence in the interpretation and use of HLQ scores in their contexts. This study is a review of the HLQ.

Methods: Developed in Australia in 2013, the HLQ measures nine health literacy domains and is translated to 40 languages. A March 2024 PRISMA systematic search (PROSPERO CRD42022361966) identified 257 articles, which were screened for evidence about internal structure and reliability.

Results: Across 15 countries/languages, 22 articles were included. Study samples included diverse groups, settings and contexts. Out of the 18 studies that used factor analysis, three used the Bayesian approach. All 15 classical factor analysis studies reported satisfactory fit indices in restricted 9-factor models (range CFI=0.841 to 0.995, TLI=0.826 to 0.969, RMSEA=0.048 to 0.084), except two required correlated residuals for acceptable fit indices. Factor loadings were significant except for five items across five studies (range .20 to .99). Three studies used Rasch modelling and found all domains had unidimensionality except for Domain 9 in one study. Most studies reported Cronbach's alpha (range .57 to .95) across all domains, with only three studies reporting $\alpha<.7$.

Conclusions: The HLQ has exceptional robust psychometric properties across cultures and languages, paving the way for users to have confidence in HLQ psychometric validity evidence on the upcoming Digital Ophelia platform to support scaling up of health literacy development.

Key messages:

- The HLQ has robust psychometric properties across countries and languages.
- The HLQ 9-domain profiles can inform intervention development for equitable health outcomes.

Contact: cecilia.guzman@uabc.edu.mx

Background: It has been evidenced that gamification has scope in the change of people behavior and in the acquisition of knowledge, therefore this methodology contributes to the promotion of health and adapts to the needs of children from the language of play, which increases their motivation in health literacy processes, so it is necessary to encourage the acquisition of new methodologies for community mothers and women caregivers, who are configured as promoters of healthy habits with their children.

Objectives: To train 150 women in the methodology of Gamification for the promotion of healthy habits in children; for which 20 sessions were developed addressing the following modules: a) Empowerment of women b) Gamification methodology c) Healthy habits and lifestyles d) Healthy eating e) Physical activity.

Results: The training of women evidenced a) the empowerment and recognition as health promoters for their life and that of their community b) the identification of the methodology of gamification and its application in processes of promotion of healthy habits c) a high adherence in the participation and learning through gamification methodology, training 150 women through sessions mediated by Information and Communication Technologies (ICTs), Learning and Knowledge Technologies (TACs) and Technologies of Empowerment and Participation (TEP) enabling the participation of women from urban and rural territories, which accounts for an inclusive process and democratization of health knowledge, impacting both women and their families, communities and children under their care, an average of 5 members per woman, benefiting 750 people in health promotion actions.

Conclusions: 150 women were certified, who from the application of the gamification methodology promote healthy habits in children, in their families and their communities, starting from the recognition of the experience of these in themselves to be health promoters in their territories.

Key messages:

- Training women in gamification methodologies to promote healthy habits in children strengthens the health system by empowering them in their role as health literacy teachers in their territories.
- ICT, TAC and TEP enable access to health education from an inclusive process that democratizes knowledge so that communities are active agents in health promotion activities.

Public Health Literacy: a concept to develop – Qualitative study among public health professionals

Rana Noureddine

R Noureddine[1,2], *J Arsandaux*[1], *JB Hardouin*[2,3]
[1]LPPL UR4638, Nantes Université, Nantes, France
[2]INSERM U1246 - SPHERE, Nantes Université, Nantes, France
[3]Public and Environmental Health Unit, CHU de Nantes, Nantes, France
Contact: rana.noureddine@etu.univ-amu.fr

Background: Health literacy can be defined as individuals' motivation and skills to access, understand, evaluate, and utilize information to make decisions about their health. Despite Sorensen's widely used definition encompassing both individual and population levels, also known as Public Health Literacy, it remains poorly detailed and is rarely taken into account by measurement tools. As evidenced by the Covid-19 health crisis, limited public health literacy impacts reluctance to accept government recommendations, vaccine hesitancy, and fosters mistrust of science and conspiracy theories in the health field. The main objective of this study was to derive specific public health knowledge and skills from public health professionals for the general population constituted the first step of the development of a public health literacy measurement tools.

Methods: A qualitative study, based on ten semi-structured interviews with public health professionals from various settings (academic, hospital, health prevention, and promotion), working across various public health fields (nutrition, sexual health, mental health), has been conducted since March 2024.

Results: Preliminary analysis identified three main themes: (1) fundamental concepts including identification of health determinants, epidemiology and the purpose of public health interventions, (2) critical skills including the assessment of the level of evidence and reliability of public health information, and (3) civic orientation including environmental impact on health and community approach to interventions.

Conclusions: These detailed insights will guide the creation of a valid measurement tool for public health literacy. This will facilitate the investigation of specific impacts on people's adherence to public health interventions or messages and the development of actions targeting literacy in a more holistic manner.

Key messages:
- Specific public health dimensions have been identified to enrich the existed definition of health literacy.
- Public health concepts, reliability of public health information and community approach constitute the core of public health literacy.

Abstract citation ID: ckae144.1709
Can ChatGPT affect health literacy?

Ivana Marasovic Šušnjara

I Marasovic Šušnjara[1,2], *M Ćulav Šolto*[1]
[1]Department of Public Health, Teaching Public Health Institute of Split-Dalmatia County, Split, Croatia
[2]University Department of Health Studies, University of Split, Split, Croatia
Contact: ivana.marasovic.susnjara@nzjz-split.hr

Background: ChatGPT is a large language model based on artificial intelligence, which nowadays finds application in various fields, including medicine.

Objectives: To investigate the usefulness of ChatGPT related to health literacy and to highlight its potential limitations.

Methods: We searched PubMed/MEDLINE for published research and articles that reviewed ChatGPT in the context of health literacy, written in English over the past five years with free full text access. All original articles were screened.

Results: A total of 53 publications were found. Twenty-five publications met the inclusion criteria and were included in the review. Most of the works presented a positive opinion towards the use of ChatGPT. The authors of six articles believe that ChatGPT generates more readable papers, while four of them believe the opposite. In four articles authors found out possibility to simplify text. The negative sides relate to the possibly insufficient education of users, the accuracy of the information, potential bias, dependence on the outdated data, and the ethical problem of the real authors not being cited, and therefore not recognized for their work.

Conclusions: According to the conducted research, ChatGPT represents an opportunity to improve health literacy by generating accessible and comprehensible information about health. It has also been shown to improve the readability and accessibility of public education materials on selected health topics. Furthermore, while AI models like ChatGPT can serve as a reliable source of health information, they should be used as an addition to professional medical consultation, and not as a standalone advice service.

Key messages:
- ChatGPT represents an opportunity to improve health literacy.
- AI models like ChatGPT can serve as a reliable source of health information, but they should be used as an addition to professional medical consultation, and not as a standalone advice service.

Abstract citation ID: ckae144.1710
Educational and communication strategies to promote HPV vaccination: A Systematic Review

Giovanna Elisa Calabrò

F D'Ambrosio[1], *R Sezzatini*[1], *A Nisticò*[1], *A Maida*[1], *R Bucciardini*[2], *GE Calabrò*[1]
[1]Department of Health Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]National Center for Global Health, ISS, Rome, Italy
Contact: alisacalabro@icloud.com

Background: Despite the evidence supporting the value of vaccination, Cervical Cancer (CC) and HPV-related diseases still represents a public health challenge, requiring international efforts to address all barriers that can reduce vaccine acceptance and equitable uptake. In this context, implementing interventions aimed at enhancing knowledge levels within target populations emerges as a crucial approach to improve vaccination coverage. Thus, this study conducted within the PERCH project (PartnERship to Contrast HPV), aimed to explore all educational interventions/communication strategies adopted at the international level to improve HPV vaccine uptake.

Methods: A systematic literature review was conducted by querying three databases from July 1, 2006 (the time of the first HPV vaccine licensure) to January 30, 2024. It included studies focused on educational interventions/communication strategies adopted by healthcare providers (HCPs) targeting the World Health Organization (WHO)-recommended population for HPV vaccination, as well as parents, caregivers, teachers, and other influential individuals involved in vaccination decision-making.

Results: Overall, 16 studies were considered, with 68.7% (11/16) focusing on educational initiatives and 50% (8/16) on communication strategies. Regarding the target population, 19% (3/16) involved parents/caregivers, 25% (4/16) included both parents and adolescents, and the remaining 56% (9/16) targeted adolescents/young adults. Videos were the most commonly used channel for both types of interventions (54%), followed by informative materials (31%), person-to-person solicitation (17%), social media (15%) and slide presentations (23%).

Conclusions: Understanding the strengths and weaknesses in HPV knowledge and communication is crucial for developing effective, tailored strategies to disseminate reliable information and promote evidence-based knowledge, thereby implementing high-value healthcare.

Key messages:

- Effective communication of vaccination's value to stakeholders is essential for informing health policies, guiding best practices, and countering misinformation.
- Further research is needed to develop interventions that effectively increase HPV vaccine acceptance, aligning with the WHO's goals to eliminate CC and HPV-related diseases.

Exploring the Relationship Between Health Literacy and Alcohol Consumption Patterns in Tuscany

Patrizio Zanobini

P Zanobini[1], N Parsa[1], G Bonaccorsi[1], V Minardi[2], V Possenti[2], M Masocco[2], G Garofalo[3], G Mereu[3], R Cecconi[3], C Lorini[1]
[1]Department of Health Sciences, University of Florence, Florence, Italy
[2]Centro Nazionale per la Prevenzione delle Mal, ISS, Rome, Italy
[3]Department of Prevention, Azienda Unità Sanitaria Locale Toscana Centro, Florence, Italy
Contact: patrizio.zanobini@unifi.it

Introduction: Alcohol consumption is a prevalent aspect of social and cultural life worldwide. However, high and binge consumption has become a significant public health concern. Inadequate health literacy (HL) may contribute to poor awareness and/or knowledge regarding the risks of alcohol-related behaviors. However, to date, only a few studies have examined the relationship between HL and different types of alcohol consumption. This study aimed to investigate the relationship between HL, other sociodemographic determinants, and their influence on high and binge consumption among the general population aged 18-69 in Tuscany.

Methods: The study analyzed data from 2017 to 2022 from a Tuscan population subsample in the Italian Behavioral Risk Factor Surveillance System PASSI. HL was assessed using the Italian version of the six-item European Health Literacy Survey Questionnaire (HLS-EU-Q6).

Results: Among the 12,953 interviewees, binge drinking was reported by 8.3%, while high consumption by 3.6% of the entire sample. In the multivariate logistic regression, participants aged between 50 and 69 years with problematic or inadequate HL levels had an increased adjusted odds ratio for high alcohol consumption. Instead, females, individuals older than 34 years, and those of foreign nationality had a reduced odds ratio for binge drinking. Low HL was a predictor of high alcohol consumption but not of binge drinking.

Discussion: As expected, young males are more likely to engage in binge drinking, while older individuals are more likely to have high consumption. In a challenging period for healthcare system sustainability, it is mandatory to use economic resources efficiently and target the right population with tailored interventions: given that HL impacts on high consumption, research and policy should focus HL interventions specifically on high alcohol consumers. Conversely, educational campaigns aimed at increasing HL in binge drinkers risk to have a lesser impact.

Key messages:

- Health literacy does not influence binge drinking.
- Inadequate levels of health literacy predict high alcohol consumption.

Abstract citation ID: ckae144.1712
Uptake and effectiveness of an Instagram intervention on AMR for undergraduate students

Nathaly Garzon-Orjuela

S Parveen[1], P McHugh[2], A Vellinga[1]
[1]School of Public Health, Physiotherapy and Sports Science, University College Dublin, Dublin, Ireland
[2]J.E. Cairnes School of Business & Economics, University of Galway, Galway, Ireland
Contact: nathaly.garzonorjuela@ucdconnect.ie

Background: With the large volume, diversity and amount of information shared on social media, this offers opportunities to deliver and disseminate health interventions through these platforms. Social media campaigns have been found to be effective in raising public awareness of health issues during the COVID-19 pandemic. Social media is however not widely used to raise awareness on antimicrobial prescribing and resistance.

Aim: To study the potential of Instagram as a tool for promoting awareness and understanding of critical health issues such as AMR among undergraduate students.

Methods: A 3-month Instagram-based educational intervention with Instagram posts with messages on AMR was implemented from January to April 2024. The planning phase involved two co-design sessions and two key-informant interviews, which provided valuable insights and guidance for structuring the intervention. The messages on AMR were developed based on the planning phase to ensure relevance and effectiveness. To evaluate the impact of the intervention, pre and post-intervention surveys were conducted to measure the knowledge levels of the participants.

Results: 126 students signed up for the intervention by following the instagram account and filling the pre-intervention survey. A total of 36 messages were posted during the intervention with an engagement of 2.5% and a daily engagement of 4.6%. The average likes per post was 14.

Conclusions: Type of message and change in knowledge on AMR will be explored to inform future Instagram AMR awareness campaigns.

Key messages:

- Social media interventions can be effective in raising awareness when co-designed with the target audience.
- A good content mix with engaging short format content is key in capturing the attention of the target audience on social media.

Abstract citation ID: ckae144.1713
The Effect of Parents Health Literacy Level on Attitudes Towards Childhood Vaccinations

Sümeyye Şimşek

S Şimşek[1], MM Ören Çelik[2]
[1]Medical School, T.C Istanbul Yeni Yüzyil Üniversitesi, Istanbul, Türkiye
[2]Medical School, Istanbul University, Istanbul, Türkiye
Contact: sumeyye.simsek@yeniyuzyil.edu.tr

While the importance of vaccination services increases day by day, WHO declared vaccine hesitancy as one of the 10 threats to global health in 2019 due to the decrease in vaccination numbers in recent years. Raising parents awareness about childhood vaccines with adequate and accurate information is likely to positively affect vaccination decisions.Although the level of knowledge on this subject depends on parents being able to obtain information using the right sources, this situation can also be associated with a sufficient level of health literacy.This study aimed to evaluate how parents health literacy level affects their attitudes towards vaccines. This cross-sectional study was conducted through a facetoface survey with 400 parents of children under the age of 18 who applied to the Istanbul Faculty of Medicine, ChildHealthDiseasesPolyclinic. Asdata collection tools, a survey form including general approaches to preventive health services and knowledge level about vaccines, as well as the TSOY-32 and PACV were used. As a result of our study, the average of the correct answers given by the participants to the questions regarding their vaccination knowledge levels was determined as

12.1±4.3. The average health literacy general index score was found to be 33.6±4.5. It was determined that 2.5% of the parents had insufficient health literacy levels, and 67.8% had problematic or limited health literacy levels. Parents received a total score of 30.2±23.7 (13 (1-83)) from the PACV scale. It was determined that 13.5% of parents were hesitant about childhood vaccines. It was determined that individuals with vaccine hesitancy had lower general health literacy and vaccine knowledge levels, and they used the media and neighbors as sources of information at a higher rate. Additionally, it was determined that low level of knowledge about the vaccine(OR 1.4 95%CI 1.3-1.6). and using the media(OR 2.3 95%CI 1.0- 4.9) as a source of information poses a risk for vaccine hesitancy.

Key messages:

- Providing community-based training to increase the health literacy level of parents will also create positive changes in vaccine hesitancy.
- Community-based studies should be carried out regarding misconceptions about vaccines, especially those acquired from the media, and individuals should be made aware.

Mental health literacy in Austria - results of the first representative population survey

Robert Griebler

R Griebler[1]*, D Schuetze*[1]*, I Vana*[1]
[1]Austrian National Public Health Institute, Vienna, Austria
Contact: robert.griebler@goeg.at

Background: Mental health has been a pressing public health issue long before COVID-19 and is even more so now. In this context, strengthening mental health literacy (MHL) is seen as a key lever for improving the mental health of the population. qAs there are no nationwide data available, the aim of our study was to collect data on MHL in Austria.

Methods: Data on population MHL were collected in 2023 as part of the second wave of the 'Health Promotion Panel', a representative survey of the Austrian resident population aged 16 and over. Data were collected online and by mail from approximately 1,000 individuals. As part of the M-POHL Health Literacy Survey 2024-2026, we developed and tested a new survey instrument to measure MHL. The MHL instrument comprises 26 MHL tasks distributed across four domains (mental well-being, mental stress, mental health problems, mental illness). The respondents were asked to rate the tasks according to their perceived ease and difficulty. Associations with sociodemographic factors and mental well-being were examined using bivariate and multivariate methods.

Results: In all four domains of MHL, respondents rated tasks related to finding and understanding information and services as easier. Tasks related to judging and applying information and services were rated as more difficult. The results indicate that MHL differs according to age and educational level. Across all tasks and domains of MHL, people aged 60+ and those with lower education exhibited greater difficulties with the MHL tasks. While people aged 60+ had the greatest difficulty in judging information and services, people with lower education had greater difficulty in almost all domains.

Conclusions: This study was the first representative study on MHL and showed major deficits in MHL among the Austrian population, also in prevention and health promotion. Targeted interventions are urgently needed to strengthen MHL in Austria, targeting the most vulnerable population groups.

Key messages:

- A large proportion of the Austrian population has difficulty dealing with information and services to promote, maintain and restore mental health.
- The difficulties also affect the areas of prevention and health promotion that are crucial for coping with mental stress and enhancing well-being in everyday life.

Abstract citation ID: ckae144.1715

Impact of digital health literacy on public health: an umbrella review

Elisabetta Corvo

E Corvo[2]*, M Di Carlo*[1,3]*, W De Caro*[1]
[1]CNAI Italian Nursing Association, Rome, Italy
[2]Canterbury Christ Church, Canterbury, UK
[3]Biomedicine Department - Uniroma2, Rome, Italy
Contact: sii@cnai.pro

Background: Digital health literacy (DHL) is increasingly important for public health initiatives in the digital era. However, its impact on public health outcomes remains unclear. This umbrella review synthesizes evidence on relationships between DHL and public health.

Methods: Electronic databases were searched from 2010 to January 2024 for reviews evaluating associations between DHL and public health outcomes. Two independent reviewers screened records and extracted data. Results were narratively synthesized and screened respect quality using Amstrar 2 check list.

Results: 12 reviews met the inclusion criteria. Higher population DHL was consistently linked to positive health behaviors like preventive screening uptake, medical adherence, chronic disease management, and vaccination. However, lower DHL correlated with health disparities and exacerbated risk of mis/disinformation. DHL interventions improved eHealth skills and health status.

Conclusions: Digital Health Ltieracy shapes engagement with digital public health tools and programs. Integrating DHL assessments into planning can help identify at-risk groups and optimize interventions. Developing population DHL through education represents an avenue to advance health equity and resilience against digital health threats. However, more evidence and more digital maturity of tools appear to be necessary.

Key messages:

- Digital Health Literacy as milestone of next health generation.
- Health outcomes are clearly linked to digital and digital health literacy.

Abstract citation ID: ckae144.1716

Associations between maternal health literacy and prenatal micronutrient intake in Hungarian women

Anita Sisák

A Sisák[1]*, A Szabó*[1]*, ZS Máté*[1]*, R Molnár*[1]*, G Németh*[2]*, H Orvos*[2]*, E Paulik*[1]
[1]Department of Public Health, University of Szeged, Albert Szent-Györgyi Medical School, Szeged, Hungary
[2]Department of Obstetrics and Gynecology, University of Szeged, Albert Szent-Györgyi Medical School, Szeged, Hungary
Contact: sisanirg@gmail.com

Background: Adequate level of health literacy (HL) is an important factor in pregnancy. Low HL may increase the risk of maternal and fetal complications (e.g., gestational diabetes mellitus, low birth weight). This study aimed to measure the levels of maternal HL and its associations with the consumption of folic acid (FoA), vitamin D (VD), and omega-3 fatty acids (FAs) during pregnancy in Hungarian women.

Methods: The questionnaire-based study was conducted at the Department of Obstetrics and Gynecology, University of Szeged among women who gave birth between June and September 2023 (N = 294). Sociodemographic, lifestyle, conception and pregnancy related questions were asked. HL was measured by the Maternal Health Literacy Inventory in Pregnancy (MHELIP) questionnaire (after the Hungarian adaptation); it contains 48 items representing four subscales (maternal health knowledge, search for maternal health information, assessment of maternal health information, and maternal health decision making and behavior). Data analysis was performed by SPSS 29.0. (Ethical permission: 5351)

Results: The mean age of women was 31.53 +-4.75 years. During pregnancy 84.5% of women consumed FoA, 61.8% VD and 41.8% omega-3 FAs. The total mean score of MHELIP on a scale 0-100 was 78.93 (95%CI: 77.77-80.08); the score of “search for maternal health information” subscale was the lowest [57.68 (95%CI: 56.20-59.16)], and the score of “maternal health decision making and behavior” was the highest [86.75 (95%CI: 85.62-87.87)]. Omega-3 FAs and VD consumption was significantly higher in women with higher total and subscales mean scores (except “search for maternal health information”), while FoA consumption was significant in case of “assessment of maternal health information”. (The results are preliminary.)

Conclusions: The association between micronutrient consumption and HL supports that using this tool during pregnancy the mothers who needs more support and health information can be identified.

Key messages:

- The Maternal Health Literacy Inventory in Pregnancy questionnaire is a reliable tool for measuring health literacy in Hungarian pregnant women.
- Maternal health literacy plays an important role in the healthier lifestyle, including prenatal vitamin/micronutrient consumption.

Abstract citation ID: ckae144.1717
Enhancing literacy among the elderly on sexually transmitted infections: an educational intervention

Daniela Lima

D Lima[1], *C Cunha*[2], *A Magalhães*[3], *V Barreira*[4], *R Teixeira*[1], *M Mendes*[1], *R Vasconcelos*[5]
[1]Public Health Unit, Local Health Unit São João, Maia, Portugal
[2]USF Lagoa, Local Health Unit Matosinhos, Matosinhos, Portugal
[3]USF Pirâmides, Local Health Unit São João, Maia, Portugal
[4]USF Horizonte, Local Health Unit Matosinhos, Matosinhos, Portugal
[5]USF Faria Guimarães, Local Health Unit São João, Porto, Portugal
Contact: dani.dslima@gmail.com

Issue: Sexually transmitted infections (STIs) pose significant public health concerns across different settings and countries, especially in elderly populations, in which recent increases have been noted. This project aimed to target STIs literacy among the elderly, addressing a crucial gap in public health education.

Description of the problem: This project focused on improving STIs literacy among elderly residents in a municipality in Northern Portugal. Using innovative methods such as tailored materials and interactive sessions, the intervention aimed to evaluate their effectiveness through pre-, post-, and one-month follow-up STD-KQ questionnaire assessments (composite score of total correct calculated as average, ranged from 0 to 27). Statistical analysis used SPSS IBM for Mac OS® v29. Descriptive statistics: mean ± standard deviation for continuous, proportions (%) for categorical variables. Analysis included only individuals with complete data. ANOVA with Bonferroni post hoc tested intervention impact on STD-KQ scores.

Results: Fifty-one individuals participated in this study, with an average age of 70,89 ± 5,10 years old, and 64,7% female. The average STD-KQ score increased by 151.54% immediately after, 11.39 ± 5.66 ($p < 0,01$), and by 122.54% after one month, 10.08 ± 5.35 ($p < 0,01$), compared to pre-intervention, 4.53 ± 3.96 ($p < 0.01$). The score at one month follow-up remained similar to post-intervention ($p = 0.39$), presenting a significant improvement in STIs knowledge.

Lessons: This pioneering project, to the best of our knowledge the first of its kind, demonstrates the effectiveness of tailored educational interventions in improving STIs literacy among the elderly, with sustained effects after one month. This innovative approach can be adapted and scaled up for broader use in different settings and countries.

Key messages:

- Tailored educational interventions can be a powerful public health strategy to effectively enhance long-term STI literacy among elderly populations.
- Assessing knowledge about STIs can be a crucial initial step for physicians to provide or refer for comprehensive education on safe sexual practices in this age group.

Abstract citation ID: ckae144.1718
Assessment of the level of health literacy in students with specific learning disorders

Caterina Liudmila Graziani

CL Graziani[1], *D Brunelli*[1,2], *D Lorini*[3], *D Bonaccorsi*[3], *D Palese*[1], *D Fedeli*[4], *D Arnoldo*[1,2]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Accreditation, Quality, and Clinical Risk, Friuli Centrale Healthcare University Trust, Udine, Italy
[3]Department of Health Sciences, University of Florence, Florence, Italy
[4]Department of Languages and Literatures, University of Udine, Udine, Italy
Contact: caterinaliudmilagraziani@gmail.com

Background: Specific Learning Disorders (SLDs) include dyslexia, dysorthography, dysgraphia, and dyscalculia and are referred to as specific educational learning disabilities. For students with SLDs, the issue of health literacy (HL) arises because understanding, evaluating and utilising health information are critical to making informed decisions about one’s health. This study aims to determine the level of HL in students with a certified SLD.

Methods: From November 2023 to April 2024, students with an SLD studying at the University of Udine (Italy) who agreed to participate, were surveyed using an online questionnaire on the EUSurvey platform. This consisted of the HLS-EU-Q47 to measure HL, followed by a socio-demographic section. The HLS-EU-Q47 classified HL into 4 levels: inadequate, problematic, sufficient and excellent; descriptive analysis was performed and the correlation with the sociodemographic data was examined using χ^2 test.

Results: 38 students participated (mean age 24 years, 60.5% female), 60% of whom are in an undergraduate degree program. 42% of the sample had a single SLD (26% dyslexia, 13% dysgraphia), while 58% of them have multiple SLDs. Overall, 42% of students were found to have a problematic HL level, 24% inadequate, only 24% sufficient and 11% excellent. No statistically significant association was found between) HL level and gender, number of SLDs, school attended at the time of SLD certification, and use of supports (all p-values>0.05).

Conclusions: The level of HL in students with SLDs appears to be consistent with data from the Italian population (58% inadequate or problematic) from the 2019-HLS19 Health Literacy Survey. This suggests that the presence of an SLD does not affect the level of HL and that it is likely that the university degree is able compensate for HL difficulties that could be related to the presence of an SLD. A larger sample is needed to see if it is confirmed that there is no association between the investigated variables.

Key messages:

- Despite the presence of SLDs, the HL of academic students follows the same trend compared to the general Italian population.
- The structural use of supportive measures by these students probably bridges the gap in access to and correct use of health information.

Abstract citation ID: ckae144.1719
Association between family empowerment and health literacy among parents with preschool children

Natsuyo Yanagi

N Yanagi[1], *H Satoh*[1], *Y Sawada*[1]
[1]Laboratory of Drug Lifetime Management, Graduate School of Pharmaceutical Sciences, The University of Tokyo, Tokyo, Japan
Contact: ntyanagi@gmail.com

Background: For parents raising children, obtaining information and working together to solve problems in a family, including those related to the child's health, is vital (family empowerment). Communicative and critical health literacy is the ability to acquire and utilize information through communication and to critically analyze and use it to manage one's life. This may enhance family empowerment. We aimed to examine the association between family empowerment and health literacy among Japanese parents.

Methods: Data from parents of preschool children aged 3-6 years were collected through an online survey in September 2023. Family empowerment was measured using the Family Empowerment Scale for Parents (FES-P) with five sub-factors (26 items in total) using a 7-point Likert scale. Communicative and critical health literacy was measured using the Communicative and Critical Health Literacy (CCHL) scale, which includes five items on a 5-point Likert scale. Multivariable regression analysis was used to examine this association. Age, sex, education, income, employment status, number and age of children, and family members were used as covariates.

Results: Participants included 600 fathers and 600 mothers. The mean FES-P score was 116.5 (SD 23.0) and the mean CCHL score was 3.50 (SD 0.69). In the crude model, CCHL was statistically significantly associated with FES-P and all five sub-factors, such as 'relationship within the family'. After adjustment for all covariates, the association remained significant for FES-P (beta=0.28, $p < 0.001$) and sub-factors such as 'relationship with the community'. However, 'recognition and combined use of services' was not statistically significant (beta=0.05, $p = 0.078$). The income level showed a significant association with family empowerment and all sub-factors, independent of health literacy.

Conclusions: Health literacy was associated with family empowerment. Improving health literacy could contribute to strengthening family empowerment.

Key messages:

- Improving health literacy could contribute to strengthening family empowerment.
- Financial support may be needed to strengthen family empowerment since income level was associated with it.

Abstract citation ID: ckae144.1720
The Impact of Health Literacy on Diabetes Control

Dulce O

DN do Ó[1,2], *AR Goes*[1], *JF Raposo*[2,3,4], *R Osborn*[5], *I Loureiro*[1]
[1]NOVA National School of Public Health, Comprehensive Health Research, Lisbon, Portugal

[3]NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[4]CEDOC-Center for the Study of Chronic Disease, NOVA Medical School, Lisbon, Portugal
[5]Centre for Global Health and Equity, School of Health Sciences, Swinburne University of Technology, Australia
Contact: dulce.nascimento.o@gmail.com

Introdution: People with diabetes have a significant impact on treatment outcomes through their daily decisions. Therefore, health literacy (HL) is crucial for effectively managing the disease and maintaining overall health. This study aimed to explore the relationships between different dimensions of health literacy, self-care behaviors, and Diabetes Control (HbA1c).

Methods: HLwas assessed using the Health Literacy Questionnaire. 706 individuals with diabetes participated in the study, the majority of whom were male (60.2%), had more than 9 years of schooling (84.7%), and over half were employed (52.4%). To examine the relationship between dimensions of HLand HbA1c, multiple linear regression analysis was conducted.

Results: The study revealed a significant association between higher levels of HLand lower HbA1c levels. There is a statistically significant positive linear correlation between adherence to general nutrition and HLdimensions. In terms of physical activity, a positive correlation was also found with HLdimensions, and blood glucose monitoring showed a positive correlation with health literacy. Greater adherence to nutrition was linked to a decrease in HbA1c levels, while higher adherence to self-monitoring and medication was associated with an increase in HbA1c levels

Conclusions: This study emphasizes the importance of HLin managing diabetes. It underscores the impact of HLin diabetes compensation. The results reveal that higher levels of feeling understood and supported by healthcare professionals, having sufficient information to manage health, actively managing health, and appraising health information among people with diabetes lead to better adherence to blood glucose self-monitoring. Based on these findings, a crucial aspect of effectively managing diabetes will involve empowering individuals with the necessary skills for self-management of their condition, overall health, and treatment regimen.

Key messages:

- The present research reinforces the importance of health literacy for diabetes compensation and self care activies.
- One critical success factor in dealing with diabetes will be investing of health literacy of people with diabetes and health care providers responsiveness.

The relationship between health literacy level and quality of life in bariatric surgery patients

Saygın Altıner

S Altıner[1], *A Çağrı Büyükkasap*[2], *Ö Tonbuloğlu Altıner*[3], *C Özbaş*[3]
[1]General Surgery, Ankara Training and Research Hospital, Ankara, Türkiye
[2]General Surgery, Gazi University, Ankara, Türkiye
[3]Public Health, Gazi University, Ankara, Türkiye
Contact: sygn0607@gmail.com

Background: Today, obesity is an important public health problem. In addition to the intervention programmes developed to prevent obesity, the necessity of medical and surgical treatment is increasing with the growing population. This study was conducted to determine the relationship between health literacy and quality of life in patients undergoing bariatric surgery.

Methods: This cross-sectional study was conducted with the participation of 136 patients aged 18 years and older who underwent bariatric surgery in a general surgery service between January 2021 and December 2023 and whose contact information was available. The survey participation rate was 75.1%. The questionnaire used for data collection consisted of questions about the sociodemographic information of the participants, The European Health Literacy Survey Questionnaire (HLS-EU-Q16) and the Postbariatric Surgery Quality of Life Scale items. Descriptive statistics, Mann Whitney U, Kruskal Wallis H test and Spearman correlation analysis were used to analyze the data. A value of $p < 0.05$ was considered statistically significant.

Results: The mean age of the patients who participated in the study was 38.2 ± 10.8 years; mean BMI was 42.3 ± 6.4 before surgery and 29.0 ± 6.2 after surgery. In the study, 44.1% of the patients who underwent bariatric surgery were found to have inadequate/

problematic health literacy level. Participants who had less than a bachelor's degree ($p = 0.009$) and low income ($p < 0.001$) had significantly lower health literacy levels. In addition, a moderate positive correlation was found between overall health literacy score and quality of life score ($r = 0.252$; $p = 0.003$).

Conclusions: In conclusion, this study shows that improved health literacy positively affects quality of life in patients undergoing bariatric surgery and that health literacy education should be emphasized in this context.

Key messages:

- The level of health literacy of bariatric surgery patients is a determining factor on quality of life, and therefore health literacy education is important, especially in identified risk groups.
- Increased health literacy can have positive results in terms of psychosocial and physical health and improve quality of life after bariatric surgery.

Abstract citation ID: ckae144.1722
Vaccination health literacy: cultural validation and pilot testing of the HLS19-VAC instrument

Jelena Branković

J Brankovic[1], *I Stevic*[1], *D Krajnovic*[1]
[1]Department of Social Pharmacy and Pharmaceutical Legislation, University of Belgrade - Faculty of Pharmacy, Belgrade, Serbia
Contact: jelenabrankovic21@gmail.com

Introduction: VaccinÐ°tion health literacy (VHL) is considered an extremely important aspect of health literacy. HLS19-VAC questionnaire is a 14-item 'subjective' perception-based instrument used for measuring VHL in the M-POHL Health Literacy Survey 2019-2021, which Serbia was not part of.

Aim: Translation and cultural validation of the HLS19-VAC questionnaire and using the validated Serbian version (HLS19-VAC_RS) for pilot study research.

Materials and methods: The English version of HLS19-VAC was translated using a systematic approach; three forward and one back-translations were synthesized and compared by an expert committee. Thereafter, cognitive interviews with 11 participants produced a version that was culturally validated by an expert panel. We conducted a cross-sectional pilot study using a HLS19-VAC_RS, on a convenient sample of the general population in Serbia. VHL was assessed by calculating the score for 4 out of 14 questions. Additional data were collected through a general questionnaire with 30 questions. Descriptive and inferential statistics were used.

Results: Cognitive interviews showed some problems in wording, and cultural adaptation resulted in minor refinements to eight out of 14 items. The instrument was pretested by 11 experts who adjusted it accordingly to produce culturally validated HLS19 -VAC_RS. Of 439 respondents in a pilot study, 15% had problematic VHL, while the levels of sufficient and excellent VHL were nearly the same (38.5% and 35.1%, respectively). There was difficulty in deciding whether to receive the flu vaccine (15.0%) and to find information about recommended vaccines (12.3%). There was a significant statistical difference in responses to VHL and monthly income and alcohol consumption. Most of the respondents contacted pharmacists as primary sources of information about medication (42.7%).

Conclusions: HLS19 -VAC_RS could be implemented in a local context as culturally appropriate. Further testing on a population level is needed.

Key messages:

- HLS19-VAC_RS Questionnaire is culturally appropriate for assessing vaccination health literacy in Serbia.
- Majority of respodents had sufficient or excellent vaccination health literacy.

Abstract citation ID: ckae144.1723
The use of digital technologies to promote sexual health in young adults: a narrative review

Aliete Cunha-Oliveira

A Cunha-Oliveira[1,2,3], *D Santos*[2], *B Marinho*[1], *C Ribeiro*[1], *F Rodrigues*[1], *S Gómez Cantarino*[2,4], *RK Reis*[5]

Contact: alietecunha@esenfc.pt

Background: New technologies have the potential to play an important role in promoting sexual health, especially among young people, who are the biggest users and those at greatest risk of contracting Sexually Transmitted Infections (STI). The risk behavior assumed by young people today highlights this vulnerability in several contexts, such as individual, social, economic, and family. In this sense, it becomes relevant to approach sex education in schools using digital technologies.

Objectives: To identify the evidence in the literature on the use of digital technologies to promote the sexual health of young adults.

Methods: Narrative literature review. Three independent reviewers extracted, analyzed and synthesized the articles and results.

Results: Through the selection process, four studies were included. The articles show that the use of digital technologies (mobile phones/applications) leads to increased knowledge, improved attitudes and sexual behavior among young adults. The interventions studied in the studies were based on Short Message Service, electronic mail interventions and the MyPEEPS mobile application, with the following main focuses: Increased knowledge, attitudes, and behaviors of young adults. Considering the results of the studies, all interventions proved to be effective as facilitators of sexual health promotion.

Conclusions: The use of digital technologies allowed an increase in the promotion of the sexual health of the participants, since there was an increase in the level of knowledge with the use of digital technologies such as SMS, emails and mobile applications when comparing the experimental and control groups. The use of these digital technologies also allowed for a change in attitudes and behaviors, such as a significant increase in serological testing for STIs and an increase in health care seeking.

Key messages:

- The use of digital technology promotes the sexual health of young adults, so these strategies should be implemented by health professionals.
- The dissemination of these digital strategies will have an impact on Public Health, specifically regarding the sexual health of young adults.

DN. Poster display: Health promotion

Abstract citation ID: ckae144.1724
The need for health-promoting school attendance efforts in a Norwegian context

May Olaug Horverak

MO Horverak[1], *GM Langeland*[2], *Ø Hellang*[3], *M Helmersen*[4]
[1]Birkenes Learning Centre, Birkenes Municipality, Birkeland, Norway
[2]Lillesand Upper Secondary School, Agder County, Lillesand, Norway
[3]Department of Health and Social Science, NORCE Norwegian Research Centre, Kristiansand, Norway
[4]Department of Nutrition and Public Health, Agder University, Kristiansand, Norway
Contact: may.olaug.horverak@birkenes.kommune.no

Issue/problem: There has been an increase in mental health issues among young people in Norway in recent years, as in other European countries. This seems to result in more school anxiety and school absence across different school contexts. To meet this challenge, health promotion theory has been applied to develop practices facilitating mastering and empowerment in school.

Description of the problem: The objective of the project has been to develop health promoting principles and practices that support students to thrive and learn in school. Six primary schools, two lower secondary schools, one upper secondary school and five adult learning centres have participated in workshops and discussions for a period of a year. The questions that this project aims to answer are: 1) How can teachers facilitate health promotion in school? 2) How can health promoting practices support school attendance?

Results: The following principles for health promotion in schools were developed: 1) acknowledging by seeing the whole person, 2) trusting each individual, 3) respecting by creating tolerance for differences, 4) facilitating mastery and achievement, 5) facilitating participation by letting students develop ownership to solutions, 6) creating safety through clear and predictable frameworks, 7) facilitating motivation through engagement, 8) building relations by meeting students where they are, 9) promoting significant values.

Lessons: Based on the operationalisation of health promotion in this project, it is recommended that school employees promote and facilitate acknowledgement, trust, respect, mastery, participation, safety, motivation, relations, and values. The health promoting principles developed may easily be transferred to other educational contexts with similar challenges.

Key messages:

- It is important to create an acknowledging and respectful learning environment to facilitate health promotion in schools.
- To support school attendance, the environment needs to be supportive of student participation and empowerment.

Abstract citation ID: ckae144.1725
JOBS Program Germany for health promotion among the unemployed

Alfons Hollederer

A Hollederer[1]
[1]The Faculty of Human Sciences FB 01, University Kassel, Kassel, Germany
Contact: alfons.hollederer@uni-kassel.de

Aim: The unemployed suffer from poorer health than the employed, especially in terms of mental health. At the same time, health promotion reaches unemployed less than employed. The “JOBS Program” is an intervention for the unemployed to promote health. It has shown positive effects in the USA and Finland. The aim of this confirmatory study (Hollederer & Jahn, 2023; Jahn & Hollederer, 2024) was to investigate whether the JOBS Program produces similar effects in Germany.

Methods: A multicenter randomized controlled trial was applied to compare an intervention group (IVG) with a waiting control group (WCG) before (T0; $n = 94$), shortly after (T1; $n = 65$) the intervention and about 6 months after the intervention (T2; $n = 43$). Fourteen JOBS Program trainings have been conducted. Additionally, JOBS Program trainers were interviewed via voluntary computer-assisted web interviews (resulting in 28 interviews).

Results: JOBS Program Germany was beneficial. Following changes in the primary outcomes were identified from T0 to T1: Compared to the WCG, a multivariate regression estimated that the IVG had (1) a 0.34 scale point higher level of self-rated general health ($p = 0.025$; scale range: 1-5 points), (2) a 14.52 scale point higher level of mental well-being ($p = 0.004$), and (3) a 2.74 scale point higher level of life satisfaction ($p = 0.049$). About 6 months after the training had been conducted (T2), participants in the JOBS training showed better general health status (0.41-point; $p = 0.016$) compared to the WCG. Furthermore, 78.5% of the JOBS Program trainers were rather or very satisfied with the theoretical contents and 85.7% with the practical implementation. A central obstacle to the implementation was the COVID-19 pandemic.

Conclusions: This study provides evidence for the effectiveness of the JOBS Program with respect to the above outcomes, and for older and long-term unemployed, suggesting the benefit of regular implementation for different groups of unemployed in Germany.

Key messages:

- The results of the confirmatory study show positive effects of the JOBS Program on the general health status and unemployment-related mental burden among unemployed people in Germany.
- The introduction of the JOBS Program as a nationwide intervention in Germany could be an intervention approach for the unemployed to achieve better health.

Abstract citation ID: ckae144.1726
Promotion included in prevention (PIP)

Nicola Magnavita

N Magnavita[1], *I Meraglia*[1], *G Viti*[1]
[1]Occupational Health, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: nicolamagnavita@gmail.com

Issue/problem: Every year in Europe more than 20 million visits are carried out on workers. The opportunity to integrate health promotion into prevention is now under the attention of large companies, according to the American model known as Total Worker Health©.

Description of the problem: The main critical points of this strategy are the correct balance between promotion and prevention efforts and the extension of the projects to small companies. Furthermore, coordination is necessary between all the figures who promote health, particularly in the national health service.

Results: Occupational risk prevention activities, mandatory in all European countries, have been integrated with health promotion campaigns, addressing health topics chosen in a participatory way. The costs of designing the campaign, information material for employees and data processing are borne by the university, which covers the costs with research funds. No costs are borne by workers or companies. During their medical check-up in the workplace, workers are invited to fill in a questionnaire regarding the project topic, its outcome, and some related factors. Workers receive advice on how to improve their lifestyles and are referred to the National Health Service for any necessary tests or treatments. In the last 15 years, as many annual campaigns have been conducted. Projects have dealt with: Eating behavior disorders; Post-COVID syndrome;

Syncope and presyncope; Headache; Musculoskeletal disorders; Work engagement; Sleep health promotion; Aging; Violence at work; Work organization; Indoor air quality; Mediterranean Diet; Hand skin disorders; Teleworking; Work Ability. More than 30,000 workers from 38 companies participated.

Lessons: The participatory character of the projects, their simplicity and cost-effectiveness, the integration between occupational medicine and basic medicine demonstrate that PIP projects are economical, sustainable, and effective.

Key messages:

- Health promotion can be integrated into the prevention of occupational risks, without additional costs.
- The creation of a network of occupational physicians who are involved in PIP projects respects corporate and professional independence and improves the work culture, health, and safety of workers.

Abstract citation ID: ckae144.1727
Leveraging Social Marketing to Increase Vaccination Rates: A Systematic Review

Cheryl Chong Zhiya

CZY Chong[1], RJR Chong[2], JJH Chng[2,3]
[1]Primary and Community Care Division, Ministry of Health, Singapore, Singapore
[2]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore
[3]National University Hospital, Pathology Department, Singapore, Singapore
Contact: cherylchongzy@yahoo.com

Introduction: Vaccinations are crucial for protecting individuals from preventable diseases, serving as a cornerstone of public health, safeguarding entire populations. Low vaccination rates can have devastating consequences, leading to outbreaks of preventable diseases. Social marketing has had an increasing role to play in public health. This systematic review seeks to investigate social marketing effectiveness in boosting vaccination adherence.

Methods: A literature search was conducted in PubMed, Scopus and Cochrane Library, using keywords "social marketing", 'campaigns", "vaccination", "vaccination uptake". The search was limited to English-language studies, including studies discussing social marketing campaigns and its impact on vaccination uptake. Prior to inclusion, the studies were evaluated for relevance and applicability to the research question. Included studies were analysed for methodology, sample size, data collection methods, and key findings.

Results: Of 198 articles identified, 26 studies met inclusion criteria. All studies reported demonstrable improvement in vaccination adherence and hence higher vaccination rates with the use of social marketing campaigns. Targeted messaging on social media allows communication to be tailored to specific demographics and address their unique concerns. Community engagement combats vaccine hesitancy by dismantling misinformation and rebuilding trust. Additionally, these campaigns leverage social influence and mobilise communities to cultivate pro-vaccine attitudes. By addressing personal choice, knowledge gaps, and hesitancy, social marketing paves the way for greater vaccination uptake.

Conclusions: Social marketing has been proven to be an effective tool in promoting vaccination adherence in public health. As vaccination remains a critical aspect of public health, the continued use of social marketing interventions is essential for improving vaccination rates and ultimately enhancing overall population health.

Key messages:

- Social marketing campaigns lead to higher vaccination rates across various populations.
- By addressing vaccine hesitancy, social marketing paves the way for increased vaccination uptake.

Abstract citation ID: ckae144.1728
Asking to thrive: structures supporting young men's behavioural health in Belfast, Northern Ireland

Amanda Dylina Morse

A Morse[1], K Higgins[1]
[1]Queen's Communities and Place, Queen's University of Belfast, Belfast, UK
Contact: amorse01@qub.ac.uk

Background: Men in Northern Ireland are three times more likely to die by suicide and psychiatric morbidity is significantly higher than for the United Kingdom overall, in part due to the Troubles, a 30-year conflict during which there were 34,000 shootings, 14,000 bombings, and 3,500 deaths. Prior studies suggest strong friendships and high collective efficacy in communities are protective against suicide and self-harm in adolescents and that inquiring about supportive people and structures directly-rather than through parental intermediaries-yields more accurate responses.

Methods: Semi-structured interviews were conducted with 30 adolescent males aged 16-19 from working-class communities across Belfast. Participants were recruited via trusted community partners and often had experiences with sectarianism and restorative justice. A deductive thematic analysis was conducted of interview transcripts, supplemented by responses to the Self-Harm Inventory and a modified Collective Efficacy Scale. Analyses were completed in NVivo and RStudio.

Results: In addition to male peer friendships in which they could share confidences, participants strongly endorsed the value of youth work organisations as keystones in supporting not only their own behavioural health through positive modelling but also the reduction of antisocial and sectarian behaviours in their communities. Participants named specific aspects of these structures they found most useful, including demonstrating "masculine success" though community engagement and family life, providing a safe venue for socialising, and delivering restorative justice programming.

Conclusions: Findings from this study suggest that youth work programming is an important component of both adolescent behavioural health promotion and community safety through the reduction of sectarian and other antisocial behaviours. Participants expressed dismay at the reduction of these services and endorsed both their personal and wider community importance.

Key messages:

- Youth workers may provide valuable positive modelling and behavioural health support to the young men.
- Youth work programmes may function both for behavioural health promotion and community violence reduction in Belfast, Northern Ireland.

Abstract citation ID: ckae144.1729
Knowledge and perspectives about medicinal cannabis in nurses and nursing students in Portugal

Aliete Cunha-Oliveira

A Cunha-Oliveira[1,2], C Paiva[2,3], T Santos[4], I Rosendo[5], J Rui Pita[2,3]

[2]Centre for Interdisciplinary Studies, University of Coimbra, Coimbra, Portugal
[3]Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal
[4]Primary Health Care, ULS de Trás-os-Montes e Alto Douro, Porto, Portugal
[5]Faculty of Medicine, University of Coimbra, Coimbra, Portugal
Contact: alietecunha@esenfc.pt

Background: The opening up of legislation on medicinal cannabis in recent years has been a determining factor in the growth of this therapy. In Europe, regulation of medicinal use is a reality in several countries. Nurses can play a leading role in its administration, helping to ensure that it is carried out more effectively and assuming a fundamental role in the success of the therapy. It is therefore pertinent to analyze the knowledge of nurses and nursing students in Portugal about medicinal cannabis.

Methods: Quantitative descriptive study. A self-completion questionnaire was drawn up and made available on the google forms platform. It was face-validated, content-validated and approved by the Ethics Committee. The instrument included sociodemographic data, questions about cannabis knowledge and perspectives. Descriptive statistics were analyzed.

Results: Out of a total of 610 responses, 318 were nurses and 292 nursing students. Medical cannabis is considered legitimate by 79.6% of nurses and 84.3% of students. When asked about the functions of the endocannabinoid system, 71.7% of nurses and 79.5% of students said they had no knowledge. 88.7% of nurses and 79.5% of students disagreed that they had sufficient knowledge to advise users on the use of medicinal cannabis. Also, 38.4% believe that their patients use cannabis illegally to manage the symptoms of illnesses.

Conclusions: There is a need for continuing training for nurses and for the undergraduate and postgraduate nursing curricula to include this emerging area.

Key messages:

- The results show that this issue is a public health problem. It reinforces the need to formulate public policies in this area and to implement training for nurses and nursing students.
- These measures will be fundamental in preventing the use of illegal cannabis and promoting the safe use of medicinal cannabis.

Abstract citation ID: ckae144.1730
The relationship between sleep quality and emotional eating during the pandemic in Croatian adults

Ivan Miskulin

I Miskulin[1], *S Candrlic*[2], *J Dumic*[1], *I Fotez*[2], *P Puz Britvic*[1], *L Dumic*[1], *M Candrlic*[2], *J Kovacevic*[1], *I Kotromanovic Simic*[1], *M Miskulin*[1]

[2]Department of Interdisciplinary Sciences, Faculty of Dental Medicine and Health Osijek, University of Osijek, Osijek, Croatia
Contact: ivan.miskulin@mefos.hr

Background: Social isolation during pandemics has adverse effects on sleep quality which in connection with COVID-19 distress facilitates the development of emotional eating patterns in various populations. This study aimed to evaluate the interconnection between sleep quality and emotional eating in the Croatian adult population during the COVID-19 pandemic.

Methods: This cross-sectional questionnaire study was conducted from February to June 2021 period. A validated, anonymous questionnaire that contained questions regarding demographic data, data on eating habits, and the Pittsburgh Sleep Quality Index (PSQI), was self-administered to a convenient sample of Croatian adults from central and northwestern Croatia.

Results: The study sample included 939 subjects with, a median age of 42 years (interquartile range 35-48), 35.4% males, and 64.6% females. At the PSQI 22.6% of subjects presented sleep disturbances. Sleep disturbances were more frequent among females ($p < 0.001$), and inhabitants of the Croatian capital Zagreb ($p = 0.001$). Subjects with sleep disturbances detected by PSQI during pandemics consumed a larger amount of food than usual ($p < 0.001$), consumed snacks more frequently ($p < 0.001$), and cooked more in their households ($p = 0.006$).

Conclusions: Poor sleep quality caused by the COVID-19 pandemic led to emotional eating patterns in the Croatian adult population. Health promotion programs directed toward healthy lifestyle choices need to be implemented to successfully tackle observed poor health indicators in the studied population.

Key messages:

- Following the COVID-19 pandemic the obvious deterioration of sleep quality and eating habits is seen in the Croatian general population.
- Comprehensive health promotion programs directed toward healthy lifestyle choices adoption are needed.

Abstract citation ID: ckae144.1731
Prevalence of Tooth Decay and Related Factors Among Primary School Children

Hela Ghali

H Ghali[1,2,3], *S Bhiri*[1,2], *S Souai*[4], *F Khouya*[1], *A Maatoug*[1], *H Selmi*[4], *K Youssef*[4], *M Ben Rejeb*[1,2,3], *H Latiri*[1,2,3], *A Ben Cheikh*[1,2,3]
[1]Department of Prevention and Security of Care, Sahloul University Hospital, Sousse, Tunisia
[2]Faculty of Medicine of Sousse, University of Sousse, Sousse, Tunisia
[3]LR20SP06, Sahloul University Hospital, Sousse, Tunisia
[4]Higher School of Health Sciences & Techniques, University of Sousse, Sousse, Tunisia
Contact: hela.ghali@outlook.com

Introduction: Tooth decay is considered the fourth most important public health problem in the world. According to the latest studies, the prevalence of this disease is also important in school children. The interest of this work is to study the prevalence of dental caries and its influencing factors in primary school children in the city of Sousse (Tunisia) and to formulate recommendations for the prevention of this phenomenon.

Methods: It is a cross-sectional study conducted among pupils enrolled from 1st and 3rd grade of 3 primary schools in the city of Sousse in April 2022 through a questionnaire filled out by the pupils.

Results: A total of 376 participated in the study. Among them, 52,4% were male. The mean age was 7.4 ± 1.2 years. The prevalence of dental caries in our population was 43.9%. Many factors were associated with dental caries including pupils from public schools ($p = 0.000$), poor oral hygiene: [lack of tooth brushing ($p = 0.000$), tooth brushing only 1 time per day ($p = 0.000$), eating in the evening after brushing the teeth ($p = 0.000$), lack of changing the toothbrush ($p = 0.000$)] and unhealthy eating habits ($p \leq 0.05$). Consequently, dental caries was significantly higher among children with overweight body mass index (BMI) (90.9%; $p = 0.016$).

Conclusions: The organization of awareness and information days in schools, the integration of an education program on preventive measures against this phenomenon and the generalization of screening campaigns to detect this disease are necessary measures that should be carried out according to a well determined strategy.

Key messages:

- Dental caries prevalence among primary school children in Sousse is significant, highlighting the urgent need for preventive measures.
- Factors such as poor oral hygiene, unhealthy eating habits, and attending public schools contribute to the prevalence of dental caries.

Abstract citation ID: ckae144.1732
Development and preliminary psychometric properties of the Scale of Health Belief Model for Sleep

Hasibe Kadioglu

H Dikici[1], *H Kadioğlu*[2]
[1]Public Health Nursing, Institute of Health Sciences Marmara University, Istanbul, Türkiye
[2]Public Health Nursing, Health Sciences Faculty Marmara University, Istanbul, Türkiye
Contact: hasibek@gmail.com

Background: Sleep-related problems are a serious risk to physical and emotional health, academic success, and safety in adolescents. A measurement tool is needed to comprehensively evaluate adolescents' sleep and plan the steps necessary for behavioral change. This study aimed to develop a scale based on the Health Belief Model that can reliably and validly evaluate adolescent individuals' beliefs towards sleep.

Methods: This methodological study was conducted with 494 adolescents between September and October 2022 in Antalya, Turkey. Initially, 81 items about sleep were created according to the Health Belief Model. Validity was assessed as content and construct validity and reliability was assessed as internal consistency. Content validity was evaluated with ten expert views The scale was tested for construct validity with Exploratory Factor Analysis (EFA), after which the scale's reliability was evaluated for item-total correlations using Pearson's correlation analysis and for internal consistency with Cronbach's Alpha.

Results: In the first EFA, sixteen factors with eigenvalues greater than 1 explained 63.80% of the total variance. Items with factor loadings of less than .30 and those that appeared in more than one factor with differences of less than %10 were removed from the scale one by one and the analysis was repeated. In the last EFA of the 46-item scale, six factors were found with an eigenvalue greater than 1 that explained 57.7 % of the total variance. The scale's item-total correlations ranged between .26 - .79. Cronbach's coefficient alpha of subscales was found .92 for perceived susceptibility, .90 for perceived severity, .90 for perceived benefits, .81 for self-efficacy, .79 for motivation and .69 for perceived barriers.

Conclusions: The validity and reliability properties of the scale of Health Belief Model for sleep have been found good levels in Adolescents. Its intercultural adaptation for use with adolescents in other countries is recommended.

Key messages:

- The newly developed the scale of Health Belief Model for sleep was found to be valid and reliable.
- It can be used to assess adolescents' beliefs about sleep.

Abstract citation ID: ckae144.1733
Does mindfulness program reduce stress and enhance self-kindness in schools? Healthy Learning Mind

Salla-Maarit Volanen

S-M Volanen[1,2], *M Holopainen*[1,3], *J Lahti*[1,3], *T Vahlberg*[4], *M Hintsanen*[5]
[1]Public Health, Folkhälsan Research Center, Helsinki, Finland
[2]Department of Public Health, University of Helsinki, Helsinki, Finland
[3]Department of Psychology, University of Helsinki, Helsinki, Finland
[4]Department of Biostatistics, University of Turku, Turku, Finland
[5]Department of Psychology, University of Oulu, Oulu, Finland
Contact: salla-maarit.volanen@helsinki.fi

Introduction: There is a scarcity of research with high quality methods on the effectiveness of mindfulness-based interventions (MBIs) on adolescents' mental well-being. This study investigates the MBI effects on adolescents' stress and self-kindness with an extensive cluster RCT design, and a role of self-kindness as a mediator for the association between the MBI and stress. Additionally, the study explores how age, gender, and an independent mindfulness practice moderate the effects on the outcomes.

Methods: Participants (Finnish students, aged 12-15 years) were randomized to a MBI group ($N = 1646$), an active relaxation control group ($N = 1488$), and an inactive control group ($N = 385$). The outcomes were measured at the baseline (T0), at 9-week post-intervention (T9), and at 26-weeks follow-up (T26).

Results: Overall, the MBI was more effective in stress reduction when compared to the active control at T9 ($\beta = -0.04$, $p < 0.01$, $d = -0.11$) and T26 ($\beta = -0.04$, $p = 0.02$, $d = -0.11$). Furthermore, students in the MBI group who carried out their regular mindfulness home practice showed greater decrease of stress. There were no MBI effects on self-kindness, nor did a change of self-kindness mediate the effects of MBI on stress.

Discussion: These findings demonstrate that the 9-week MBI is slightly more effective to reduce stress relative to relaxation training.

Key messages:

- The result highlight the potential of MBI in increasing the stress management among students in school context.
- To ensure the effectiveness of MBIs in school context we need to teach these skills to teacher students already during their basic education in educational institutions and universities.

Abstract citation ID: ckae144.1734
The French experiential knowledge resource center: strengthening and extending its scope of action

Alexis Krache

A Krache[1], *T Delescluse*[1], *M Villeval*[1], *B Georgelin*[1], *C Ferron*[1,2], *F Berdougo*[1], *A Vuillemin*[1,3]
[1]French Society for Public Health, Paris, France
[2]Fédération Promotion Santé, Aubervilliers, France
[3]Université Côte d'Azur, Nice, France
Contact: alexis.krache@sfsp.fr

Issue: The national committee for experiential knowledge in health promotion (EKHP) aims to promote EKHP and improve professional practices. Since 2017, the committee has created methods and toolkits formalizing the capitalization of EKHP. The levers to put the method into practice are in place, now comes the time to find the best means to foster promotion and appropriation of EKHP works.

Description of the problem: The national EKHP resource center has been launched in May 2022, online: www.capitalisationsante.fr. It acts as a database where HP practitioners can read, download and upload EKHP capitalization works (~12-page documents detailing one HP intervention each) and cross-analyses reports. It is driven by three main objectives: 1/ promoting and disseminating HP practitioners' experiential knowledge, 2/ building a community of practice to improve capitalization practices and 3/ making a useful and transferable data available to practitioners.

Results: The now two-year-old website has been visited by 32 000+ individuals. More than 120 works, 12 cross-analyses are published. They were submitted by trained HP practitioners and reviewed by an editorial board before publication. The national EKHP resource center offers insight on how HP interventions work from practitioners themselves who share knowledge on their implementation. Compared to best-practices portals, it offers an innovative bottom-up approach to knowledge transfer. The community of practice (CoP) now supports a network of 200+ trained practitioners. This CoP aims to improve knowledge management and ensure the quality of the works produced. Surveys and feedback show that both building up and accessing EKHP meet a high level of interest.

Lessons: The innovative bottom-up approach and the focus on knowledge management can serve as a model for other settings/ countries. In 2024, levers of appropriation will be investigated and collaboration with other HP resource centers will be better identified.

Key messages:

- The now two-year-old national NEKHPRC enhances EK's part in the HP field by making otherwise unknown data available to the French-speaking HP community.
- Building of a strong community of practice ensures the high quality of the bottom-up approach to the uploading of the works.

Living with Dementia: exploring the challenges and needs of informal Dementia caregivers in Portugal

Henrique Lopes

H Lopes[1], *C Hermenegildo*[1]
[1]Center for Global Health, NOVA-IMS, NOVA University, Lisbon, Portugal
Contact: hlopes@novaims.unl.pt

Background: Dementia profoundly impacts not only those diagnosed but also their informal caregivers. The Nova Center for Global Health at NOVA-IMS, in collaboration with the Alzheimer Portugal Association, embarked on a comprehensive study to explore the various aspects of daily life that affect informal caregivers of people with dementia in Portugal. Understanding these impacts is important for developing targeted interventions that address the caregivers' needs effectively, particularly given the current lack of research on informal dementia caregivers.

Methods: The study utilized a crafted survey developed through initial scripting on key topics identified by informal caregivers and validated by experts on dementia. This phase was followed by a series of in-depth interviews with professionals in neurology, psychology, and social work, as well as with the caregivers themselves. The final survey was distributed among members of the Alzheimer Portugal Association and other volunteers, resulting in 305 valid responses.

Results: Preliminary findings reveal significant emotional, physical, and financial challenges faced by caregivers, underlining the diverse needs across 14 key areas of their lives. The study highlights specific areas where support is lacking, providing a grounded basis for developing more effective support mechanisms.

Conclusions: The 'Living with Dementia' project underscores the complex reality faced by informal caregivers. It calls for innovative, practical solutions that can alleviate the burden on these caregivers and improve their quality of life. By addressing the specific needs identified through this research, policy-makers and support organizations can better tailor their interventions to help those at the front lines of caregiving in dementia.

Key messages:

- Informal caregivers of people with dementia face challenges that necessitate a comprehensive understanding to tailor effective support systems.
- Interventions are needed that address the emotional, physical, and financial hardships caregivers face, improving their overall well-being and capacity to care.

Abstract citation ID: ckae144.1736
Predictors for psychosocial consequences of screening for liver diseases in Germany: a LASSO approach

Urs Fichtner

U Fichtner[1], *A Maun*[2], *E Farin-Glattacker*[1]
[1]Institute of Medical Biometry and Statistics, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg im Breisgau, Germany
[2]Institute of General Practice, Family Medicine, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg im Breisgau
Contact: Urs.Fichtner@uniklinik-freiburg.de

Background: Medical screening is extensively used across various disciplines for early disease detection and prevention of severe progression aiming to reduce disease-specific burden, improve quality of life and promote health. However, screening is debated due to unclear evidence of its overall benefits from a public health perspective. Screening is associated with improved health behavior and cost-effectiveness. However, studies identified adverse effects of screening like psychosocial burden. Most results originate from cancer screening and it is unclear whether they are transferable to other contexts. Within a research program, a systematic screening procedure to detect patients with liver cirrhosis at early stage in an asymptomatic general population was evaluated. In this study, we aimed to identify patient characteristics that predict and explain variance in psychosocial outcomes of screened patients.

Methods: This study analyzed data from 523 participants who underwent a systematic liver disease screening in Germany from Jan 2018 to Feb 2021. We used bootstrapped LASSO regression with 10-fold validation to evaluate the influence of various predictors on the outcomes measured by the Psychological Consequences of Screening Questionnaire (PCQ). The constructs measured by the PCQ are social, physical and emotional dysfunction associated with screening.

Results: We identified lower severity of comorbidities, higher subjective social status, stronger social support, older age, better critical health communication skills and higher health literacy as relevant predictors of lower psychosocial dysfunction, indicating their protective role in preventing psychosocial burden of screening.

Conclusions: From a public health perspective, medical screening offers should take into account patients' individual context regarding their subjective social status, health impairments, personal social networks and health literacy skills to reduce post-screening psychosocial burden.

Key messages:

- Social support, age, health literacy and higher subjective social status were positively associated with lower psychosocial consequences of liver screening.
- The findings indicate that liver screening should be carried out, taking into account the individual's situation and resources available.

How can healthcare professionals assist in improving mothers' health?

Shiran Bord

S Bord[1], *L Inchi*[1], *Y Paldi*[2], *R Baruch*[3], *E Stolerman*[3], *M Schwartz Shpiro*[4], *S Ronen*[4], *L Eisenberg*[5], *M Yaari*[4]

[4]Goshen, Jerusalem, Israel
[5]Nursing Department, Israeli Ministry of Health, Jerusalem, Israel
Contact: Shiranb@yvc.ac.il

Background: Mothers' health is crucial as it significantly impacts the overall health of their children and families. The first year of motherhood can be especially difficult and can lead to a considerable decline in mental health and well-being. However, studies have shown that these challenges persist throughout early childhood. This study examined the association between mothers' self-compassion, social support, and self-care behaviors and their physical and mental well-being.

Methods: In August 2023, a survey was conducted among 521 Israeli mothers (437 Jewish and 84 Arab mothers) of children aged three and under. Linear regression models were used to assess the factors that predict the mothers' physical and mental health. These models explained 11% of the variance in the mothers' physical health and 39% of the variance in their mental health.

Results: Respondents' ages ranged from 19 to 48, with a mean age of 31.5 years. Reported physical health was relatively high (n = 442, M = 78.36, SD = 21 on a scale of 0-100). However, the reported mental health was lower (n = 401, M = 65.88, SD = 20.28 on a scale of 0-100). Reported Physical health was found to be higher for Jewish mothers, younger mothers, and mothers with higher income levels. Further, higher social support and higher self-compassion levels were associated with better perceived physical health (Adj R2=0.11, $P < 0.001$). Mental health was higher for Jewish mothers, younger mothers, and full-time employed mothers. Further, higher social support, self-compassion, and reported self-care were associated with better perceived mental health (Adj R2=0.39, $P < 0.001$).

Conclusions: Health practitioners who work with mothers of young children should take a proactive approach to helping them establish a nurturing environment, practice self-compassion, and engage in self-care activities.

Key messages:

- Encouraging self-compassion and self-care in postpartum mothers is crucial, as it is essential to prioritize the mother's health alongside her baby.
- Low socioeconomic background and Ethnicity are risk factors for lower physical and mental health after childbirth. Reducing health disparities and targeting these vulnerable populations is crucial.

Abstract citation ID: ckae144.1738

Barriers and facilitators to remote healthcare services use: perspectives of women and providers

Maram Khazen

M Khazen[1], *GY Yakov*[1]
[1]Public Health Systems, The Max Stern Yezreel Valley College, Emek Yezreel, Israel
Contact: maramk@yvc.ac.il

Background: The remote health services (RHS) proliferation raises concerns regarding relatively low use among minorities. Arab women in Israel belong to a minority that experiences health disparities, stigmatization, social and economic marginalization. This study aimed to identify barriers and facilitating means to RHS use relevant to Arab women in Israel from the perspective of women, primary care physicians (PCPs), and nurses.

Methods: Semi-structured interviews were conducted with 25 Arab women, 18 PCPs, and 4 nurses from different parts in Israel between December 2023-March 2024. We used a positive deviance approach by interviewing 14 women who succeeded in using RHS and 11 who did not. Interviews were audiotaped, transcribed, and thematically analyzed using Atlas qualitative analysis software.

Findings: The data distilled three main barriers to RHS use: sociocultural- importance of close relations with PCPs, privacy concerns of revealing the body or conversing with unfamiliar physicians, strict supervision by the family (Bedouin society); logistical-limited internet access and infrastructure, personal- unawareness to RHS, digital literacy, normative conceptions of limited quality of care and believing that only some health conditions are suitable for RHS. Facilitating means to RHS use: gender roles-women's role as family health caretakers, mothers maintaining work-family balance and younger women generation feeling responsible for the older generation RHS adoption, accessibility- wider access to care due to limited transportation.

Conclusions: It is important to identify facilitating conditions (e.g., training opportunities, social, technological support), cultured elements (gender roles, limited mobility), and trust to adopting RHS by minority populations. The study provide data for developing requirements to ensure more equitable access to RHS to Arab women including addressing privacy concerns, guidelines for RHS-related information dissemination, and for RHS providers.

Key messages:

- The findings help develop approaches and means to improve RHS use for Arab women from diverse backgrounds by identifying barriers associated with access, culture, and normative conceptions.
- Developing RHS systems into routine care must ensure equitable use across social groups and address economic, logistical, and sociocultural barriers and guidelines for RHS information dissemination.

[4]Executive, Monash University, Jakarta, Indonesia
[5]School of Psychology and Public Health, La Trobe University, Bundoora, Australia
Contact: a.donaldson@latrobe.edu.au

Background: Gambling-related harm is a global challenge. Sports betting is a rapidly growing form of gambling, facilitated by access to online wagering platforms and increased advertising. Most public health initiatives target 'problem' gamblers, ignoring socio-cultural influences. Within this context, we examine what parents think about sports betting, the potential impacts on their children, and whether they participate in sports betting around their children.

Methods: Using a survey of 3,481 Australian adult sports fans with dependent children, we analyse parental attitudes to sports betting and their concerns about possible effects on children. ANOVA and regression methods are used to test for differences in attitudes to sports betting between parents who are gamblers (sports and non-sports) and non-gamblers.

Results: Compared to non-gambling parents, sports-betting parents are much more permissive (by up to 0.9 standard deviations) of sports betting around and by children, and less concerned (by up to 0.6 standard deviations) about any harmful effects of sports betting on children. Sports betting parents place less importance on discussing the risks of sports betting with their children, and the more often a parent bets on sports, the less confident they are about having these discussions. Parents who bet on sports are 5.8 percentage points less likely than non-gambling parents to have had such conversations.

Conclusions: The strong influence of parent modelling and normalisation, combined with policy initiatives that recommend parents discuss potential sports betting risks with their children, implies that having a better understanding of attitudes will facilitate improved educational and harm minimisation policy initiatives. The findings of our study are important for public health policy and should inform interventions aimed at gambling harm reduction. Targeting sports betting parents with better tailored educational campaigns is warranted.

Key messages:

- Children of parents who bet on sports are less likely to receive messages about the risks of sports betting, in addition to being exposed to role modelling that reinforces sports betting.
- Compared to non-gambling parents, those who bet on sports have more permissive attitudes towards sports betting, suggesting targeted messaging and interventions are warranted.

Abstract citation ID: ckae144.1740

Light Physical Activity Throughout the Day and Physical Function in Older Adults

Jong-Hwan Park

D Kim[1], *T Lai*[1,2], *Y Liao*[2], *J Park*[1], *M Sung*[1], *M Jang*[1], *Y Shin*[1], *H Park*[3]
[1]Health Convergence Medicine Laboratory, Biome, Pusan National University Hospital, Busan, South Korea
[2]Graduate Institute of Sport, Leisure and Hospitality, National Taiwan Normal University, Taipei, Taiwan

[3]Department of Healthcare and Science, Dong-A University, Busan, South Korea
Contact: parkj@pusan.ac.kr

Background: Light physical activity (LPA) plays a crucial role in preventing muscle loss and disability in older adults. Since LPA makes up a significant portion of daily activity, understanding how the timing of LPA influences physical function is important for designing effective health interventions.

Methods: This cross-sectional study investigated the association between the timing of LPA and physical function among 200 older adults (mean age 76.3, 55.5% female) attending the geriatric outpatient clinic at National Taiwan University Hospital. LPA was objectively measured using wrist-worn accelerometers for seven consecutive days. Principal component analysis (PCA) was used to identify distinct patterns of LPA timing. Participants underwent assessments of grip strength, basic mobility, walking speed, and lower limb muscle strength. Multivariable linear regression models were adjusted for potential confounders, including gender, age, moderate-to-vigorous physical activity (MVPA), and accelerometer wear time.

Results: Our findings revealed that higher levels of LPA during the morning to noon period were positively associated with better performance across all four physical function tests. Moreover, after controlling for relevant confounders, increased LPA in the late afternoon and evening was positively associated with enhanced basic mobility, walking speed, and lower limb muscle strength.

Conclusions: This study highlights the importance of considering LPA timing when promoting physical function in older adults, independent of MVPA participation. Encouraging LPA, particularly during the morning to noon period, could be a valuable strategy for maintaining and improving physical capabilities in this population. These findings provide actionable insights for clinicians and health professionals when tailoring physical activity recommendations for older adults within geriatric care settings.

Key messages:

- Morning LPA boosts physical function in seniors, enhancing grip, mobility, walking speed, and muscle strength.
- Timing of light activity crucial for older adults' physical health, with morning to noon activity showing most benefits.

Abstract citation ID: ckae144.1741
Lesson from the Covid-19 pandemic: do fear and anxiety lower vaccination hesitancy?

Nuša Crnkovič

N Crnkovič[1], Š Selak[1]
[1]Mental Health Department, NIJZ, Ljubljana, Slovenia
Contact: nusa.crnkovic@nijz.si

Background: The prevalence of vaccination hesitancy has become one of the top ten global health problems. During the Covid-19 pandemic several studies reported negative correlation of vaccination hesitancy with fear of Covid-19 and anxiety. Therefore, the study aimed to explore how fear and anxiety can impact one's intent to get vaccinated.

Methods: In 2021, data from 5999 post-secondary Slovenian students was gathered using a cross-sectional online survey. Binary logistic regression and the Sprearman correlation coefficient was used to explore the relation between Fear of Covid-19 Scale (FCOV), Generalized Anxiety Disorder Questionnaire (ANX) and a question regarding participants' intentions to get vaccinated.

Results: Results showed that only 39.7% of students expressed intention to get vaccinated as soon as possible and 29.2% exhibited no intentions to do so. Logistic regression indicated that only FCOV had a mild and significant ($p < 0.001$) impact on students' intentions to get vaccinated, whereas ANX was found to have only a weak significant ($p < 0.01$) effect on students' intentions to do so. Similarly, ANOVA test showed significant differences with small to medium effect of FCOV on intentions to get vaccinated, but no significant differences were found for ANX.

Conclusions: A low percentage of Slovenian tertiary students expressed intentions to get vaccinated as soon as possible for Covid-19, with only fear having been found to have a small to mild effect on students' intentions to do so. Anxiety, on the other hand, was found to have a small positively predictive effect on vaccination hesitancy, which could reflect affective forecasting error (i. e. believing that the negative consequences of getting vaccinated would be greater than they really are). Therefore, when considering strategies to address the increasing problem of vaccination hesitancy, one must keep in mind that the loss-framed messages might not be sufficient to prompt people to get vaccinated.

Key messages:

- Fear of Covid-19 had only a small to medium significant positive effect on students' expressed intentions to get vaccinated as soon as possible.
- The loss-framed messages might not be sufficient to prompt people to get vaccinated.

Abstract citation ID: ckae144.1742
A repositioning nudge to encourage healthier snack purchases at a supermarket in a deprived area

Loes van den Bekerom

L van den Bekerom[1], L van Gestel[2], J Bussemaker[1,3], M Adriaanse[1,2]
[1]Health Campus The Hague, Leiden University Medical Center, The Hague, Netherlands
[2]Health, Medical and Neuropsychology Unit, Leiden University, Leiden, Netherlands
[3]The Institute of Public Administration, Leiden University, Leiden, Netherlands
Contact: l.van_den_bekerom@lumc.nl

Background: Diet quality positively correlates with socio-economic position (SEP). While nudges are often proposed as promising policy tools for promoting health behavior among lower SEP groups, research addressing their impact within lower SEP groups is limited. This study aimed to 1) examine the efficacy of a checkout repositioning nudge in a supermarket in a deprived area in encouraging purchases of healthier snacks, and 2) describe customers' preferences and needs regarding grocery shopping and healthy eating.

Methods: Daily sales data were collected over four-week control and intervention periods. During the intervention, unhealthy snacks at the checkout were replaced by healthier snacks. Additionally, questionnaires were administered among customers ($N = 90$).

Results: The intervention led to a significant increase in daily sales of healthier snacks ($M = 3.14$, $SD = 2.45$) compared to the control period ($M = 0.54$, $SD = 0.96$), $t(27) = 5.62$, $p < .001$. Despite a statistically significant nudge-effect, the absolute daily sales of healthier snacks remains extremely low. No difference in daily sales of unhealthy snacks was observed between both periods. Questionnaire data showed that customers report to seldomly purchase snacks at the checkout, find it important to eat healthily, think well about what they buy in a supermarket, and long for a healthier and more affordable food offer within the supermarket.

Conclusions: Interventions that are effective among higher SEP groups, such as repositioning nudges, may not be suitable for the circumstances and needs of lower SEP groups. To combat existing health inequalities, interventions must be tailored to lower SEP groups. More system-level interventions that target the healthiness and affordability of the offer may be needed.

Key messages:

- Although nudging is often proposed as a promising policy approach for improving health behavior among lower SEP groups, repositioning nudges may not suit their circumstances and needs.

- To combat health inequalities, interventions must be tailored to lower SEP groups and integrated with system-level policies (e.g., targeting the healthiness and price of the offer in supermarkets).

Abstract citation ID: ckae144.1743
Validating weight optimization's Impact on participants via Social Impact Bonds

Chiyori Haga

C Haga[1], E Bang[2], S Jeong[3], Y Inoue[3], K Kondo[2,4]
[1]Faculty of Medicine, Kagawa University, Miki-cho, Kita-gun, Japan
[2]Japan Agency for Gerontological Evaluation Study, Kashiwa, Chiba, Japan
[3]Faculty of Health Sciences, Niimi University, Niimi, Okayama, Japan
[4]Social Preventive Medical Sciences, Chiba University, Chiba, Japan
Contact: haga.chiyori@kagawa-u.ac.jp

Background: To promote health for everyone, even the health-unconcerned, Okayama City has established the Social Impact Bond (SIB), which funds and executes social programs for defined outcomes, with third-party assessment. This study examined the normalization of participants' physiques three years later to verify the effectiveness of SIB.

Methods: We conducted a study of a quasi-experimental design, non-randomized controlled trial. A total of 8,251 eligible people applied for the program. Of these, 1,599 were enrolled in the National Health Insurance System (NIH), and 731 of them were included in the intervention group in 2018. Among 705 non-participating matched members and randomly selected, 170 were used as the control group. Whether or not the standard physique in the endpoint (EP) FY2021, was used as the dependent variable, and the participation as the independent variable. Age, gender, and physique at baseline (BL) were used as covariates for logistic regression analysis.

Results: A total of 532 patients underwent health checkups for both BL and EP, and the follow-up rate was 60.5% in the intervention group and 52.9% in the control group. Examination of between-group differences in BL revealed that the mean age was 66.7 years significantly higher in the males' intervention group and 60.6 years in the control group ($p < 0.01$). The crude odds ratio (OR) of maintaining or achieving standard BMI in the participating group was 0.90, and the adjusted OR was 1.23 and 1.31 after propensity score matching, both were not significant. On the other hand, when restricted to people with thinness, the pre-adjusted OR was 5.00 and the adjusted OR was 12.43.

Conclusions: Participation in the project contributed about 20% to 30% to weight optimization, and it could not be denied that it was brought about by chance. However, when limited to thin physiques, project participation was about twelve times higher, and the probability of having an appropriate physique was increased.

Key messages:

- SIB might affect the BMI optimization for older people in improving thinness.
- Efforts will be needed to encourage participation among younger age groups.

Abstract citation ID: ckae144.1744
Restoring trust in vaccination through collective engagement with key populations in Eastern Europe

Stefan Mandić-Rajčević

S Mandić-Rajčević[1,2,3], S Cvjetković[3,2], L Oot[4], D Tasevski[5], D Popović[6], A Meghani[7], H Wallace[4], T Cullen-Balogun[4], T Cotelnic[8], L Cogswell[4]

[6]Serbian Public Health Association, Belgrade, Serbia
[7]PATH, Seattle, USA
[8]Center for Health Policies and Studies, Chișinău, Moldova
Contact: stefan.mandicrajcevic@gmail.com

Issue/problem: COVID-19 vaccination rates remained below 50% in Moldova, North Macedonia, and Serbia, especially among vulnerable populations like pregnant women and those with chronic diseases. This was strengthened by a lack of targeted communication and training for healthcare workers, and COVID-19 fatigue. Strategies to increase vaccine demand and confidence are a global priority, especially among vulnerable populations.

Description of the solution: From May 2022 to April 2024, the USAID MOMENTUM Routine Immunization Transformation and Equity project employed behavior integration to design a social and behavior change strategy, centering on vaccination as a part of a healthy lifestyle. It was implemented through continuing medical education (CME) and community engagement (CE) workshops with vulnerable populations, supplemented by cross-country learning exchanges. The outcomes provide a framework for public health initiatives aimed at boosting vaccine uptake through innovative, behavior-based methods.

Results: 1,618 healthcare professionals, able to reach 2.5 to 4.8 million patients, received training in immunization, COVID-19 vaccines, and quality health service, and 99% indicated confidence in applying the knowledge. 265 CE workshops, engaging 4,079 patients, increased awareness and addressed concerns related to vaccination. Of 3,223 patients who were followed up, 47% reported setting an appointment with their doctor regarding vaccination, 27% discussed vaccination with their partners, and 7% proceeded to receive the COVID-19 vaccine.

Lessons: Behavior Integration helped address key barriers to vaccination and informed the design of strategies (i.e. situating COVID-19 vaccination as part of a healthy lifestyle). Establishing trust with healthcare providers and patients through collective engagement improved health behaviors. Focusing on health as a wider priority helped re-establish the significance of vaccination as part of a healthy lifestyle.

Key messages:

- Behavior science and behavior integration helped identify and address barriers, as well as design tailored interventions to improve vaccination demand and confidence.
- Collective engagement, focused on integration of COVID-19 vaccination as part of a healthy lifestyle, achieved results through addressing vaccine hesitance from both sides of the equation.

Contact: d.besselink@pl.hanze.nl

Background: Physical and social distancing measures during the COVID-19 pandemic had the potential to jeopardize health and well-being of older adults. Especially older adults who lived alone faced challenges due to restrictive COVID-19 measures. In this study, we explored views and support needs to maintain health and well-being of older adults living in a single household during the COVID-19 pandemic.

Methods: We employed an interpretative phenomenological analysis, including twenty semi-structured interviews with older adults ($\geq$65 years old) living in single households during the pandemic. Interviews were conducted between June and September 2021, audio-recorded and lasted approximately one hour. Data analysis was guided by the heuristic framework of Smith et al. Trustworthiness of the study was enhanced through bracketing and multiple interdisciplinary moments of revision of the data analysis.

Results: The views and support needs of participants to maintain health and well-being during the pandemic were captured in three overarching themes: 'A lingering search for connectedness', 'Dealing with a discouraging situation to stay well', and 'Leaning on lessons learned during life'. Important resources that enabled participants to maintain health and well-being were: experiences of social connectedness, acceptance of the situation, and (re)gaining a sense of control. Participants described how they leaned on lessons learned from life-experiences when facing situations that challenged their health and well-being.

Conclusions: Our study points out that views and support needs of older adults to maintain health and well-being during the pandemic were diverse and rooted in various coping mechanisms. During future situations similar to the pandemic, public health policies should include strategies to promote social connectedness among older adults who live alone, to prevent adverse health outcomes.

Key messages:

- Experiences of social connectedness, acceptance, and (re)gaining a sense of control were coping mechanisms that enabled older adults to maintain health and well-being during the COVID-19 pandemic.
- Public health policies should include strategies to promote social connectedness among older adults who live alone, to prevent adverse health outcomes during future pandemics.

Issue/problem: Unhealthy diets, along with factors like tobacco, alcohol, and inactivity, contribute significantly to non-communicable diseases (NCDs). Prevention strategies should prioritize reducing exposure to these risk factors. It's also crucial to consider environmental well-being alongside promoting health.

Description of the problem: During 2023/2024, university cafeterias (UC) were evaluated for healthy eating standards compliance, resulting in a noticeable presence of unhealthy foods together with plastic use, alcohol and tobacco consumption. This led to the development of an accreditation program to boost UC as healthy spaces.

Results: The developed program includes 5 mandatory standards and 42 recommendations. Priority objectives are offering healthy food options like fruit, avoiding alcohol and sugary drink ads, banning tobacco, promoting physical activity, and reducing waste for example by encouraging unpackaged water consumption. Our policy emphasizes evaluation and monitoring, so accreditation is valid only for two years. Our goal is to establish UC as sustainable, healthy spaces. To encourage compliance, we offer institutional financial support and accreditation seals to UC, showcasing their commitment to community health. Implementation begins in the 2024/2025 academic year, with an initial evaluation scheduled at that time.

Lessons: Monitoring UC food offerings is crucial for ensuring healthier options. Cafeterias play a key role in promoting healthy habits. Creating environments with healthier options can mitigate non-communicable disease risk factors presence.

Key messages:

- University cafeterias are pivotal in fostering a healthy lifestyle.
- Prioritizing policies to address non-communicable diseases is crucial. Clear programs are essential for sustained effectiveness.

Abstract citation ID: ckae144.1747
Health promotion at local level in Portugal: is childhood obesity a concern in municipal programs?

Margarida Pereira

M Pereira[1]
[1]GOVCOPP, DCSPT, University of Aveiro, Aveiro, Portugal
Contact: mmiguel06@gmail.com

Health promotion programs targeted at distinct health outcomes such as childhood obesity, at local level are increasingly used worldwide. There is a need to better understand the role of local governments (municipalities) as key public health promoters namely in the prevention of obesity in children. This study aims to provide some input regarding this issue in Portugal. In order to achieve this goal, health enhancing programs promoted by Portuguese municipalities in which children could participate were identified. The search of such programs was limited to the municipalities that were part of the Portuguese Network of Healthy Municipalities in 2021 ($N = 57$). A subsequent document analysis was conducted to describe how municipalities conceptualized children's health by retrieving information on which topics the programs were focused on, or acted upon, and identify which socio-ecological model levels of health determinants were addressed (or not) by each program. The 77 identified programs were promoted by 30 municipalities and only 11 programs addressed childhood obesity. Most programs focused on the individual health determinants ($N = 27$) and provided limited information overall, which hindered a more in-depth analysis. The findings suggest that Portuguese municipalities seem to disregard their potential as public health promoters. Childhood obesity is a major public health concern at national level, as reflected in the National Health Plans, but not perceived as such locally. Municipalities are the closest government entities to the population, and it is their responsibility to ensure the population's quality of life, by addressing the social and environmental determinants of health. Hence, municipalities should instill health concerns in all their actions/interventions, taking in consideration the most recent evidence, specifically in the case of childhood obesity.

Key messages:

- This study findings suggest that, despite childhood obesity being a major public health concern at national level, as reflected in the National Health Plans, it is not perceived as such locally.

- There is a need to better understand the role of municipalities as key public health promoters considering they are responsible to intervene on the social and environmental determinants of health.

Identity in the context of physical activity and smoking: A scoping review among adults aged 45+

Kristell Penfornis

KM Penfornis[1], MHM van Vliet[2,3], EF von Haeseler[1], WA Gebhardt[1], E Meijer[2,3]
[1]Health-, Medical and Neuropsychology, Leiden University, Leiden, Netherlands

[3]National eHealth Living Lab, Leiden University Medical Center, Leiden, Netherlands
Contact: k.m.penfornis@fsw.leidenuniv.nl

Background: Identity (i.e., self-perceptions of oneself) plays an important role in health behaviors such as physical activity (PA) and smoking. This review offers a comprehensive synthesis and comparison of how PA- and smoking-related identity is associated with PA and smoking behavior in adults aged 45+. It further synthesizes and compares identity terminology and measurement tools used to capture identity concerning smoking cessation and PA among adults aged 45+. Where applicable, the role of personal, PA-, and smoking-related characteristics were considered.

Methods: A thorough search across 11 databases, updated in May 2023, yielded 5801 unique publications. Ensuing careful screening procedures, 45 peer-reviewed empirical studies were systematically reviewed. Experts in the field contributed to validate and structure the narrative.

Results: The review reveals a complex, enduring connection between identity and behavior in both PA and smoking domains, encompassing processes like identity formation, maintenance, change, and loss. In essence, identities linked to PA and abstaining from smoking emerged as pivotal for promoting active lifestyles and successful smoking cessation. Many parallels but also distinctions emerged within this association, alongside variations in the terminology and measurement tools pertaining to identity. Factors such as gender, age, and behavioral history emerged as influential in shaping identities related to smoking and PA.

Conclusions: Despite variances, findings suggest that the relationship between identity and behavior, including associated processes, may not fundamentally differ between health-promoting and health-compromising behaviors. There is however need for more unified identity definitions and measurement tools. We propose avenues for future research, including exploring causality between identity and behavior to facilitate the development of identity-related smoking cessation and PA-promotion interventions.

Key messages:
- Identities associated with physical activity and refraining from smoking are associated with a physically active lifestyle and successful smoking cessation.
- Despite differences, the relationship between identity and behavior may not fundamentally vary between health-promoting and health-compromising behaviors.

Background: Moving from the recognition of WHO principles of health promoting school (HPS) to concrete practices is challenging. The Schools4Health project is an EU initiative with the aim to introduce, strengthen, and sustain the adoption of a participatory whole-school approach to health and wellbeing. The aim of this work is to present an update about the policy environment around HPS approaches in eight EU countries.

Methods: Between September-November 2023, Schools4Health partners from Spain, Belgium, Hungary, Greece, Latvia, the Netherlands, Romania and Slovenia carried out a preliminary scoping exercise to investigate the policy conditions which can influence the national uptake of HPS approaches. A three-step methodology was developed: a. identification of core stakeholders b. Rapid Situation Analysis survey and c. national roundtable meetings, to assess stakeholders' awareness of and engagement in health promotion programs in schools.

Results: In total, $n = 192$ responses from stakeholders from health, education, social and agricultural sectors were selected. Most experts were aware or partly aware of the HPS concept. While there is consensus that health promotion at school is essential, there is a lack of, or weak implementation of legislation and voluntary initiatives due to barriers such as limited time and financial resources, teachers burnout and insufficient interaction between education and health governmental bodies.

Conclusions: Effective advocacy can highlight the potential of HPS in addressing the urgent challenges related to wellbeing in youth, and the associated decline in educational performance across Europe. Policymakers, public authorities and the broader community should also be engaged.

Key messages:
- Creating HPSs should not solely fall on schools and teaching staff.
- Policymakers, public authorities and the broader community around schools have responsibility to ensure that policy measures and instruments embed the key considerations for HPS approach.

Determinants and strategies for successful scale-up of health interventions in the Netherlands

Djoeke Van Dale

D Van Dale[1], RA Smit[2], F Nassau[2]
[1]Healthy Living, RIVM, Bilthoven, Netherlands
[2]Amsterdam UMC, Amsterdam, Netherlands
Contact: djoeke.van.dale@rivm.nl

Background: Although many evidence-based health interventions are proven effective, the process of scaling up is often complex and challenging. Yet, some interventions have managed to achieve successful scale-up. This provides a window of opportunity to learn from those experiences to inform future scale up processes.

Objectives: This mixed-methods study aimed to assess determinants and scale-up strategies contributing to successful scale-up of health promotion interventions in the Netherlands.

Methods: Semi-structured interviews were conducted with intervention owners (i.e. the individual or team taking the responsible for several aspects related to implementation and scale-up) ($N = 25$) of successfully scaled interventions (implemented across various health behaviours and different settings), and other relevant stakeholders

(N = 10) involved in scaling up. Additionally, a survey was distributed among interventions (N = 306) registered in a national intervention database to assess scale-up experiences.

Results: Scale-up is often the result of a combination of determinants, such as persistent commitment of intervention owners and stakeholders, new funding opportunities, and accreditation by institutions. Several scale-up strategies were identified related to funding (e.g. reducing costs by setting up collaborations), organizational processes (e.g. infrastructure to support implementation), monitoring and evaluation, and dissemination and advocacy.

Conclusions: Achieving successful scale-up does not happen automatically and continuous effort of the intervention owner is crucial. There is no such thing as one successful scaling strategy which succeeds across all contexts. The intervention owner typically takes the lead in diverse scaling pathways, where sufficient time, funding, the right moment and added value form the critical ingredients for success. Funding: This study was funded by ZonMw.

Key messages:

- Crucial elements of achieving scale-up are the continuous effort of the intervention owner, sufficient time, funding, the right moment and added value of the intervention.
- Funding should not me allocated for new initiatives but also for continuous development of interventions, ongoing evaluation and covering overhead costs.

Engaging practitioners in developing a guide for citizen participation in community health promotion

Isolde Sommer

U Griebler[1], C Kien[1], P Klingenstein[1], M Seel[1]
[1]Department for Evidence-based Medicine and Evaluation, University for Continuing Education Krems, Krems an der Donau, Austria
Contact: isolde.sommer@donau-uni.ac.at

Background: Community health promotion aims to improve the living conditions in municipalities, cities, or regions to support health maintenance or promotion. Participation is a fundamental element in health promotion, as it enables community members to engage in decision-making, program development, and tailored health initiatives. This project focused on crafting a practical guide for citizen participation in community health promotion, involving experts and future users.

Methods: We conducted a literature review to identify existing guidelines and materials pertinent to community health promotion, with a focus on practical guidance for municipal practitioners. To delve deeper into the topic, we conducted interviews with 6 experts in the field of participation and community health promotion as well as with 6 practitioners working in “healthy municipalities” in Lower Austria. The guide was developed collaboratively, with two workshops being held to gather input on the draft concept of the guide and to prioritize topics. Moreover, experts and practitioners were involved to provide feedback on the drafted guidance document.

Results: Discrepancies emerged between theoretical concepts and real-life implementation of community participation. While the literature delineates up to 12 participation levels, practitioners identified three: contributing ideas, advising and co-deciding, and actively participating in planning and implementation. Informing the target group was conceptualized as a preliminary stage and basic requirement for citizen participation. Above all, practitioners sought low-key suggestions and short descriptions of methods that they could use directly in their everyday context.

Conclusions: Involving practitioners and potential users enhanced the accessibility and utility of the guide. Their input ensured that the guide remained practical, relevant and informative without excessive academic or theoretical abstraction.

Key messages:

- Involving health promotion practitioners helped shaping the practical guide in a way to be most useful for the intended audience.
- Experts and practitioners have different views regarding the theoretical distinctions of levels of participation in community health promotion.

Abstract citation ID: ckae144.1752

Empowerment and interprofessional collaboration in health promotion centre Murska Sobota

Ana Atalaia

A Atalaia[1], V Fischill-Neudeck[2], P Betznec[3], R Gorjan[4], C Peinhaupt[1], H-P Wiesinger[2], W Habacher[1]
[1]Institute for Health Care Strategies, Graz, Austria
[2]Paracelsus Medical University, Salzburg, Austria
[3]Centre for Health and Development Murska Sobota, Murska Sobota, Slovenia
[4]Health Centre Murska Sobota, Murska Sobota, Slovenia
Contact: ana.atalaia@epig.at

Background: Health promotion centres (HPCs) were introduced in Slovenian primary health care centres to provide interventions against risk factors for noncommunicable diseases (NCDs). HPCs integrate a multidisciplinary and community-based primary care approach to the prevention of NCDs and provide free lifestyle intervention programmes. This study aims to explore the perspectives of health care professionals on promoting health of local community members, as well as their perceptions of interprofessional collaboration in HPCs.

Methods: Two group discussions were conducted with a total of 11 health care professionals at the HPC Murska Sobota. Data collection was accompanied by a dual role interpreter in accordance with the principles of cross-language qualitative research. The data was transcribed, semantically translated and thematically analysed.

Results: Health care professionals emphasize the importance of health-related empowerment of individuals for the success of health promotion activities and therefore for the improvement of individuals’ quality of life. This is based on shared decision-making, self-management and educational measures in a combination of population- and individual-based approaches. The need for efficient interprofessional communication, characterized by a flat hierarchy, is stressed. Structured cooperation with other health care facilities, as well as close collaboration with communities and local media, are described as crucial for reaching all individuals and promoting health equity.

Conclusions: Interprofessional collaboration, health-related empowerment of individuals and collaboration with local communities are fundamental for the success of health promotion activities, achieving health equity and preventing NCDs. Understanding how these activities are implemented from the health care professionals’ perspective can help other health facilities developing and improving local health promotion strategies.

Key messages:

- Slovenian health care professionals see interprofessional collaboration as fundamental for the implementation of health-promotion strategies.
- Health-related empowerment of individuals and collaboration with local communities play an important role in achieving health equity in health promotion activities.

Abstract citation ID: ckae144.1753
Enhancing stroke awareness in schools: efficacy of the HOBIT program in Czechia's disadvantaged areas

Ekaterina Volevach

E Volevach[1,2], *H Maršálková*[1], *R Mikulik*[1,2,3]
[1]International Clinical Research Center, St. Anne's University Hospital in Brno, Brno, Czechia
[2]Medical Faculty, Masaryk University, Brno, Czechia
[3]Department of Neurology, T. Bata's Regional Hospital, Zlin, Czechia
Contact: ekaterina.volevach@fnusa.cz

Background: For stroke treatment to be effective, it must be given as soon as possible. Delays are often caused by stroke bystanders failing to recognize symptoms and activate emergency medical services (EMS). This is especially a problem in socially excluded localities. This study evaluated the efficacy of a school-based intervention (HOBIT) in improving determinants and behavior intentions of EMS activation for suspected stroke in Czech socially excluded localities.

Methods: The quasi-experiment was conducted from May to June 2023 in the Moravian-Silesian region, Czechia. Schools were allocated to the intervention or control group (1:1). The HOBIT is a school-based intervention used to change health-seeking behavior when stroke is suspected. The primary outcome was the percentage change from the pretest to the follow-up test in the intervention group compared to the control group. The primary outcome was assessed in 4 domains: 1) knowledge, 2) behavioral intentions, 3) self-efficacy, and 4) outcome expectations. The intervention and control groups were compared using an unpaired t-test.

Results: We recruited 138 students aged 10-16 from 4 schools. The absolute differences in improvement between the control and intervention groups were 18% (95% CI 9-26, $P < 0.001$) for knowledge, 15% (95% CI 2-26, $P = 0.01$) for behavioral intentions, 6% (95% CI -4-15, $P = 0.24$) for self-efficacy, and 13% (95% CI 5-21, $P < 0.001$) for outcome expectations. The subgroup analysis showed that the intervention effect on self-efficacy, outcome expectations, and stroke behavior intentions was significant only in females.

Conclusions: The HOBIT improved stroke determinants and behavior intentions of EMS activation at schools in socially excluded areas. This study presents a health promotion practice that has the potential to improve stroke outcomes on a community level. It underscores the potential of school settings as an appropriate way to reduce health inequalities in socially excluded communities.

Key messages:

- The HOBIT intervention improved determinants and behavior intentions of EMS activation for suspected stroke among students in socially excluded localities.
- The study underscores the potential of school settings in reducing health inequalities and improving stroke-related outcomes in socially excluded localities.

Abstract citation ID: ckae144.1754
Facilitators and barriers to improving beverage consumption among primary school children in Belgium

Lucille Desbouys

L Desbouys[1], *W Assakali*[1], *I Thiébaut*[2], *K Castetbon*[1]
[1]School of Public Health, Université Libre de Bruxelles, Brussels, Belgium
[2]Club Européen des Diététiciens de l'Enfance, Ath, Belgium
Contact: lucille.desbouys@ulb.be

Background: School is seen as a relevant setting to intervene in children's health behaviour, including their beverage consumption. A randomized controlled trial (DRINK) has been implemented to compare nutrition and sustainability-based interventions to reduce sugary beverages and to increase tap water consumptions among primary school children in French-speaking Belgium. The aim of this qualitative study was to describe the context before the intervention implementation and to identify the facilitators and barriers to implementing the project.

Methods: In 2021, the 48 schools included in the trial responded to a semi-structured interview prior to the intervention, and 30 were interviewed one year later. School characteristics (including socioeconomic index, SEI) and contextual components were summarised. The qualitative corpus was analysed using thematic content methods to identify emerging themes, then classified into obstacles and facilitators.

Results: Of the 48 schools, 70.8% were Walloon, 76.6% had a medium or high SEI, and 41.7% included less than 90 pupils. The majority had already implemented nutrition and sustainable development initiatives before the trial. While taps were available in classrooms and reusable bottles were used, the initiatives could be extended, e.g. to increasing the number of water points. The main facilitators were the interest to receive additional support by the schools already involved in other projects, and the flexibility of the intervention. The main barriers were related to lack of access to tap water; insufficient support for the implementation of the intervention; and poor availability of school staff to get involved in such a project.

Conclusions: Alongside the main trial findings, understanding the facilitators and barriers will enable the intervention to be further adapted and extended. Considering the school context and perceptions is essential to ensure effective and durable school health initiatives.

Key messages:

- Largely involved in promoting nutrition and sustainability, the schools were keen to receive support to continue.
- Strengthening access to water, communication and support for schools are essential.

Abstract citation ID: ckae144.1755
Unlocking Health Literacy: investigating Parental Health Literacy and Child Weight Outcomes

Rafaela Rosário

R Rosário[1], *MJ Silva*[1], *A Duarte*[1,2], *J Martins*[1,2], *S Martins*[3], *C Augusto*[1,2]
[1]School of Nursing, University of Minho, Braga, Portugal
[2]Health Sciences Research Unit, Nursing School of Coimbra, Braga, Portugal
[3]ProChild CoLAB Against Poverty and Social Exclusion, Guimarães, Portugal
Contact: rrosario@ese.uminho.pt

Background: While parental health literacy (HL) is widely recognized as crucial for child health, research on its impact on children's weight-related outcomes remains limited. This study aims to fill this gap by investigating the associations between parental HL and children's anthropometric measurements, with a focus on child BMI Z-score and waist-to-height ratio (WHtR).

Methods: As part of a cluster randomized trial in primary schools serving vulnerable populations, 735 children (51.7% boys, mean age 7.7 years) participated. Parental HL was assessed using the HLS-Q12 questionnaire, comprising 12 items. Health literacy levels, standardized from 0 to 100, were categorized into 'inadequate,' 'problematic,' 'sufficient,' and 'excellent' HL. General HL and three specific domains-health promotion, disease prevention, and health-care-were computed. Children's weight, height, and BMI were measured following standardized procedures. Regression analyses examined HL's impact on BMI Z-scores and WHtR.

Results: Parents with higher HL in disease prevention and health promotion had children with significantly lower BMI Z-scores, even after adjusting for parental education and children's sex sex [-0.010 (-0.18; -0.0001) and -0.10 (-0.019; 0.01). Similar associations were found for WHtR [-0.0004 (-0.001; -0.0001)]. Parents with excellent HL in general and health promotion had significantly lower WHtR [-0.027 (-0.046; -0.008)] and BMI Z-score [-0.74 (-1.2; -0.28)].

Conclusions: This study highlights the significant role of parental health literacy in shaping children's weight-related outcomes. Higher levels of parental HL in disease prevention and health promotion were linked to lower BMI Z-scores and WHtR in children, independent of parental education and children's sex. Enhancing parental HL, alongside promoting healthy behaviors and environments for children, could lead to more effective approaches for addressing this public health issue.

Key messages:

- Parental health literacy is associated with children's weight outcomes, emphasizing the need for HL-focused interventions.
- Higher parental HL is associated with lower child BMI Z-scores and waist-to-height ratios, highlighting potential HL's role in combating childhood obesity.

Contact: deluca.assunta@yahoo.it

Introduction: WHO wants to achieve the elimination of Cervical Cancer: all countries must achieve and maintain an incidence rate of less than 4 per 100,000 women. Three key pillars: 90% of girls fully vaccinated against HPV by 15 years of age; 70% of women aged 35-45 years screened; 90% of women with pre-tumour lesion and invasive tumour treated. Our study assessed the position of the Tuscany South East Local Health Authority(LHA TSE) with respect to these three pillars and how to improve it.

Methods: A retrospective observational study was conducted. The following were used: ISTAT data of incidence of cervical cancer standardised by age from 2013 to 2017;data from ISPRO on screening(PAP and HPV test)from 2013 to 2022;data of vaccination coverage taken from the Health Information System of Collective Prevention(SISPC) from 2012 to 2023 for children<12 years,

Results: The incidence rate of cervical cancer in LHA TSE is 9.4 per 100 thousand. About HPV vaccine coverage by age 12, for girls it has been rising from 80.5% in 2012 to a peak of 84.8% in 2019 and then progressively decreasing to 76.3% in 2023.Coverage for boys has also been progressively increasing from 0.8% in 2012 to a peak in 2019 of 74.9% and then decreasing to 69.8% in 2023. A total of 52 thousand children are vaccinated. As for the adjusted adherence to screening, we started from an average adherence of 51.8% in 2013 (75 thousand women invited with 102% coverage) to 53.2% in 2022 (54 thousand women invited with 107% coverage). In 2013, ASC-US+ lesions were found in 6.4 % of women by PAP Test and in 2022 in 6.3 % of women. In the examined period, more than 90% of women with pre-tumour lesion and more than 90% with invasive tumour were treated.

Conclusions: LHA TSE will have to implement actions to increase vaccination coverage and screening adherence rates through awareness campaigns and open days, also considering whether a change in the age range for starting screening is necessary as vaccination coverage increases.

Key messages:

- Cervical cancer is one of the most preventable cancers, but too few young women are vaccinated against HPV infection, the main causative factor.
- Prevention through adherence to screening enables early identification of lesions caused by HPV virus.

Abstract citation ID: ckae144.1757
A systematic review on the effect of identity-related interventions on physical activity and smoking

Milon van Vliet

MHM van Vliet[1,2], *KM Penfornis*[3], *WA Gebhardt*[3], *EF von Haeseler*[1,2], *NH Chavannes*[1,2], *A Versluis*[1,2], *E Meijer*[1,2]
[1]Department of Public Health and Primary Care, Leiden University Medical Centre, Leiden, Netherlands
[2]National eHealth Living Lab, Leiden University Medical Centre, Leiden, Netherlands
[3]Unit Health-, Medical and Neuropsychology, Institute of Psychology, Leiden University, Leiden, Netherlands
Contact: m.h.m.van_vliet@lumc.nl

Background: Identity (self-perceptions of 'who I am') is important for health behavior change. Hence, identity-related interventions, aiming to influence how people view themselves, show promise for health promotion. This systematic review describes the effect of identity-related interventions on physical activity (PA), a health-promoting behavior, and smoking, a health-compromising behavior, and PA- and smoking-related identities in adults.

Methods: A comprehensive search, updated in May 2023, identified 5801 publications across eleven databases. After screening, 19 quantitative and mixed-methods publications were selected, describing 20 different studies. Relevant data were systematically extracted and a quality assessment was conducted using the Mixed Methods Appraisal Tool.

Results: Identity-related interventions were more common for enhancing PA (n = 13) than for smoking cessation (n = 6). Only one study targeted PA- and smoking-related identities to change both behaviors simultaneously. Various identity-related interventions were used, e.g. possible (future) selves manipulations and avatar games. The target population was rarely involved in intervention development. The results are mixed; some studies showed (significant) positive effects of identity-related interventions on identities or behavior, and no significant negative effects were shown. Similar results were found for PA and smoking. The one study targeting both behaviors showed positive results.

Conclusions: Identity-related interventions hold promise in promoting PA and smoking cessation. Future research could investigate identity-related interventions targeting multiple health behaviors, e. g., PA-promotion and smoking cessation, leveraging the synergy between those identities and behaviors. Collaboratively developing these interventions with the target population (i.e., patient and public involvement) could optimize them for different populations, improving public health and reducing health disparities.

Key messages:

- Identity-related interventions could improve public health.
- Collaboratively developing identity-related interventions with the target population could optimize them for different populations.

Abstract citation ID: ckae144.1758
The impact of a rural school-based oral health intervention among primary schoolchildren in Armenia

Astghik Atanyan

A Atanyan[1], *D Muradyan*[1], *H Lylozian*[1], *A Demirchyan*[1]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
Contact: aatanyan@aua.am

Objectives: Oral health (OH) interventions are shown to be effective in improving children's OH status and behavior. This study evaluated the effectiveness of a school-based OH intervention combined with OH educational activities on rural schoolchildren's OH status and behavior in a rural setting in Armenia.

Methods: The study population were primary schoolchildren of Mrgashat village, Armavir province, Armenia, and their parents. The intervention included sealant application to eligible permanent molars of children and fluoridization of their teeth twice a year over a two-year period. Educational activities included a training session for children and their parents, and distribution of educational materials among them. Baseline (BL) and follow-up (FU) assessments were conducted before and after the intervention (in 2022 and 2024) to evaluate its impact. Both assessments included clinical examination of children's OH status by calculating their DMFT/dmft index, and telephone survey among parents on OH knowledge and behavior. The changes in DMFT/dmft index and OH knowledge and behavior scores were measured using paired t-test.

Results: Overall, 94 children and their parents participated in both BL and FU assessments. There was no significant change in the parental OH knowledge score: 77.4% (SD 14.0) at the BL and 78.7% (SD 13.2) at the FU. Yet, children's OH behavior score increased significantly: from 44.9% (SD 18.2) at the BL to 60.0% (SD 15.4) at the FU ($p < 0.001$). Children's DMFT/dmft index also improved significantly: from 7.31 at the BL to 5.09 at the FU assessment ($p < 0.001$).

Conclusions: The study demonstrated the effectiveness of the OH intervention in improving children's OH status and behavior. Therefore, we recommend expansion of the intervention with inclusion of more rural sites in Armenia, and targeting primary schoolchildren, considering the importance of timely preventive interventions and early development of healthy habits for better OH later in life.

Key messages:

- Oral health interventions among primary schoolchildren covering awareness raising and carries prevention activities result in positive changes in children's oral health habits and teeth health.
- Expansion of this type of interventions with inclusion of new rural sites and conduction of further assessments to explore the long-term effects of such interventions are recommended.

Increasing step count of employees through the Semmelweis Workplace Health Promotion Program

Dorottya Árva

D Árva[1,2], N Dósa[1], D Major[1], K Pártos[1], N Mózes[1], A Alliquander[1], A Terebessy[1], F Horváth[1], P Varga[2], V Fazekas-Pongor[1]

[1]Institute of Preventive Medicine and Public Health, Semmelweis University, Budapest, Hungary

[2]Clinical Centre, Semmelweis University, Budapest, Hungary

Contact: arva.dorottya@semmelweis.hu

Background: Lifestyle greatly contributes to the development of age-related diseases. The goal of the Semmelweis University's 'Semmelweis Workplace Health Promotion Program' is to develop interventions that facilitate healthy ageing. The aim of its first intervention was to increase the step count of participants by incorporating motivational elements offered through the university's Center of Preventive Services.

Methods: A randomized controlled trial was conducted in spring 2024 with three study groups: those undergoing motivational interviews (MI, $n = 49$), those receiving motivational emails (ME, $n = 51$), and a control group ($n = 53$). Intervention groups (MI+ME) received weekly emails for 8 weeks emphasizing the benefits of increased step count and providing feedback on achievements. The MI group also took part in 4 biweekly consultations. Mean step counts of last week and energy expended while walking (MET) calculated from the International Physical Activity Questionnaire were recorded five and three times, respectively. Mixed model regressions were conducted for two pre-planned comparisons: MI+ME vs. controls, and MI vs. ME.

Results: Intervention groups exhibited a significant increase in average step count (1001 steps; 95% Confidence Interval [95% CI]: 349-1651) as a result of the program, while the control group experienced a non-significant decrease. This was accompanied by a significant increase in energy expenditure for walking (45 MET; 95% CI: 4-87) in intervention groups and a non-significant decrease for the control group. The study found no significant differences in step count and energy expenditure between the two intervention groups (MI vs. ME).

Conclusions: Our results suggest that workplace health promotion programs may effectively increase physical activity, and thus may be key in tackling the challenges posed by aging demographics. Preliminary findings did not indicate a superiority between email-based and motivational interview-based motivation.

Key messages:

- Workplace health promotion is an essential tool in promoting healthy aging among the working-age population.
- Step-count programs based on motivational interviewing serve as an effective and simple tool in increasing physical activity.

Abstract citation ID: ckae144.1760

Discussing health behavior change during pregnancy: co-creation of a training and conversation tool

Rukiye Turkeli

R Turkeli[1], E Meijer[1], LJ Breunis[2], M Keij[3], JV Been[2], MR Crone[4], ME Numans[1], ES Smit[5], A Langedijk-Wilms[3]

[1]Public Health and Primary Care, Leiden University Medical Center, 's-Gravenhage, Netherlands

[2]Department of Obstetrics and Gynecology, Erasmus University Medical Center, Rotterdam, Netherlands

[3]Pharos, Utrecht, Netherlands

[4]Department of Health Promotion, Maastricht University, Maastricht, Netherlands

[5]Amsterdam Center for Health Communication, University of Amsterdam, Amsterdam, Netherlands

Contact: r.turkeli@lumc.nl

Background: Health risk behaviors during pregnancy are major risk factors for adverse health outcomes for mother and child, and they are more prevalent among vulnerable pregnant women. However, interventions often do not sufficiently meet the needs of disadvantaged groups. Changing behavior is more likely when people feel autonomous and when a behavior aligns with our identity (how we see ourselves). Despite the clear importance of identity in health behavior change, very few identity- based interventions exist for pregnant women, let alone for vulnerable pregnant women. Through co-creation, this study aims to develop an identity- and autonomy- based training program and conversation tool tailored to the needs and preferences of healthcare professionals and vulnerable pregnant women.

Methods: Four co-creation sessions were conducted with five professionals from medical and social domains, and five (expectant) parents in vulnerable situations. The Participatory Learning and Action research methodology was applied to ensure an equal and democratic process in designing the training and conversation tool.

Results: The training for professionals will focus on enhancing knowledge about the importance of identity and autonomy in behavior change, and on improving their self-efficacy through practicing the conversation tool. Example of the conversation tool, which can be integrated into daily practice, is a comic strip illustrating the conflict of being a smoker and a mother.

Conclusions: During intervention development, it is important to consider the needs and preferences of end-users, particularly for whom few appropriate interventions exist. Involving end-users yields valuable insights for feasible (e.g. one-consultation time frame) and accessible (e.g. easy-to-understand language) interventions. This study aligns with public health efforts toward early intervention and health promotion among vulnerable groups.

Key messages:

- During intervention development, it is important to consider the needs and preferences of end-users.
- This study aligns with public health efforts toward early intervention and health promotion among vulnerable groups.

Abstract citation ID: ckae144.1761
Experiences of weight discrimination were common in Finnish women with obesity

Katri Sääksjärvi

K Sääksjärvi[1], T Palosaari[1], A Lundqvist[1], S Männistö[1], L Lehtoranta[1], P Mäki[1], NE Kaartinen[1], T Jääskeläinen[1]
[1]Department of Public Health and Welfare, THL, Helsinki, Finland
Contact: katri.saaksjarvi@thl.fi

Background: The consequences of obesity stigma, particularly weight discrimination, are widely felt in different sectors of society. Our aim was to examine the prevalence of experiences of weight discrimination in the Finnish adult population.

Methods: Data (n = 2,849) consisted of participants aged 20-64 years from the nationally representative Healthy Finland Survey in 2023, pregnant women and people with underweight excluded (body mass index, BMI, ≤18.5 kg/m2). The questionnaire inquired about the experiences of weight discrimination with a question "Have you experienced unfair treatment because of your weight during the last 12 months?". Information on education (low, middle, high) was inquired too. Height and weight were measured during the health examination, and BMI was calculated (kg/m2). Obesity was defined as BMI ≥ 30 kg/m2. Weighted prevalence was analyzed using logistic regression, considering sampling design and non-response.

Results: Overall, 13% (95% confidence interval, CI, 11-15) of women and 7% (95% CI 5-8) of men had experienced weight discrimination during the last 12 months. The experiences of weight discrimination varied according to BMI, as the prevalence was 27% (95% CI 22-32) among women with obesity vs. 7% (95% CI 6-9) among women without obesity. The corresponding numbers for men were 16% (95% CI 12-20) vs. 4% (95% CI 2-5). The results were similar across all educational classes.

Conclusions: Individuals with obesity had experienced weight discrimination more often than those without obesity. The problem affects women (in particular), as almost one third of women with obesity had experienced weight discrimination. It is important to raise awareness and recognize this phenomenon across all sectors of society to enhance inclusion in a world struggling with overweight and obesity.

Key messages:

- People with obesity experience weight discrimination. Experiences of weight discrimination appear to be more common in women than men.
- More information and understanding of weight-related stigma through education, research and values work is needed in different sectors of society.

Contact: claudia.pischke@hhu.de

Background: Despite marked decreases in physical activity (PA) in Germany due to the pandemic, population-based intervention strategies to tackle this public health problem remain sparse. The 12-month PA intervention '10,000 Steps Duesseldorf' was composed of multiple components: at individual level, website to self-monitor steps; organizational level, step count competitions; environmental level, city-wide media campaign to increase awareness regarding benefits of PA and street signage indicating walking routes. This study aimed to replicate a research trial from Belgium addressing two questions: (1) Do individuals located in the city that the intervention is implemented in (Duesseldorf) engage in more PA compared to individuals located in the control city (Wuppertal) after one year? (2) Is the proportion of those reaching 10,000 steps/day higher in the intervention than in the control city after the intervention?

Methods: To investigate intervention effects, PA was assessed via pedometers in two representative samples of adults aged 25-75 years in the cities of Duesseldorf (intervention) and Wuppertal (control) at baseline (April 2021 - March 2022) and one-year follow-up (May-November 2023). Baseline differences in socio-demographic and health-related variables between intervention and control were adjusted for in a propensity score model with matching weights.

Results: 627 adults participated in the study at baseline and 553 at follow-up (60% female, 60% intervention). The results of the propensity score analyses revealed that intervention participants walked 462 steps more (95% confidence interval: -146 to 1070) than controls at follow-up. However, the proportion of residents reaching 10,000 steps/day was comparable between intervention and control city after the intervention (26%, both cities).

Conclusions: Our results suggest an intervention effect on daily steps taken in Duesseldorf experiencing intervention activities compared to the control city after one year.

Key messages:

- The complex PA intervention from Belgium was successfully adapted and implemented in Germany resulting in a higher level of daily steps taken in the intervention city (compared to control).
- A limitation of the study is that the recruitment process was hampered by the ongoing pandemic, resulting in selection bias, i.e. already active individuals were more likely to enrol in the study.

Abstract citation ID: ckae144.1763
Effectiveness of a check-up for rehabilitation and prevention needs in primary care

Jennifer Marie Burchardi

JM Burchardi[1], S Rossek[1], M Brünger[1]
[1]Institute of Medical Sociology, Charité – Universitätsmedizin Berlin, Berlin, Germany
Contact: jennifer-marie.burchardi@charite.de

Background: General practitioners play a central role in initiating rehabilitation and prevention services. However, systematic screening for rehabilitation and prevention needs has not been carried out in general practices so far. The legislation encourages the implementation and evaluation of so-called 'check-up 45+', which target individuals aged 45 and older. The study aims to evaluate the effectiveness of a check-up 45+ in primary care.

Methods: A pragmatic, randomized controlled trial was conducted in 26 general practices in the German states of Berlin and Brandenburg among patients aged 45 to 59 years (DRKS00028303). The control group (n = 695) received usual care plus a questionnaire on sociodemographic and health-related characteristics. The intervention group (n = 706) completed additionally the 2-page 'screening 45+', which captures rehabilitation and prevention needs in five dimensions. After algorithm-based ad hoc evaluation by practice staff, the general practice could modify the recommendation based on available information (e.g., diagnoses, social situation). Information and application documents were provided in case of identified needs. Applications (primary outcome) and approvals (secondary outcome) of rehabilitation and prevention services were recorded using routine data.

Results: In the intervention group, 64.2% were women, compared to 63.0% in the control group (mean age 52.1 (SD 4.3) and 52.5 (SD 4.4) years). In the intervention group, 85 applications (12.0%) for medical rehabilitation or prevention services were submitted within two months after the study participation, compared to 20 applications (2.9%) in the control group ($p < 0.001$). The number of approvals for these services was 59 vs. 17 ($p < 0.001$).

Conclusions: The application rate for rehabilitation and prevention services was significantly higher in the intervention group compared to the control group, with a relative risk difference by a factor of 4 and an absolute risk difference of 9.1%pt.

Key messages:

- The implementation of a check-up 45+ in primary care leads to a higher rate of applications for rehabilitation and prevention services compared to usual care.
- The check-up 45+ may assist general practitioners in systematically identifying rehabilitation and prevention needs of their patients and in applying for these services.

Developing mental wellbeing promotion practices in Finnish primary schools: The CONSENSUS project

Sanna Tuomela

J Nordmyr[1], *S Tuomela*[1], *AK Forsman*[1]
[1]Health Sciences, Åbo Akademi University, Faculty of Education and Welfare Studies, Vaasa, Finland
Contact: sanna.tuomela@abo.fi

Issue/problem: Schools constitute a key arena for promoting mental wellbeing among children and adolescents, and the Finnish welfare state has many beneficial structures in place for promoting mental wellbeing in schools. However, as mental health problems are prevalent, the need to advance this work is vital, ideally applying a holistic approach focusing on school-family interaction.

Description of the problem: The Finnish CONSENSUS project (2021-2025) focuses on the development of new practices and collaboration models in mental wellbeing promotion, targeting pupils in 13 primary schools in the Ostrobothnia region. The project answers question such as: What focal areas are prioritized by stakeholders in the development of mental wellbeing promotion in schools? How do participatory principles contribute to the development process and related outcomes?

Results: In 2024, a synthesis of previous project results (interviews, focus groups and longitudinal survey data collected among pupils, school personnel, school health care services and parents) was generated. The synthesis encompasses 20 possible priority areas to focus on in the development of mental well-being promotion actions, which are ranked by stakeholder representatives utilizing Delphi methods. Some pinpointed priority areas are implemented and evaluated in collaboration with self-selected schools during the academic year 2024-2025.

Lessons: Results highlight priorities in the development of mental wellbeing promotion in Finnish primary schools and describe focal areas being piloted, also illustrating opportunities and challenges when implementing participatory principles in action research projects.

Key messages:

- Project results highlight prioritized areas in the development of mental wellbeing promotion in Finnish schools, as well as new initiatives currently being piloted.
- The project approach emphasising participatory principles provides lessons for other initiatives focusing on mental wellbeing promotion development in schools.

Support mechanisms and obstacles for developing public health practitioners' core competences

Mari-Liisa Parder

M Parder[1]
[1]Tallinn Health Care College, Tallinn, Estonia
Contact: mari-liisa.parder@ttk.ee

Community health needs assessment is one of the central activities for local governments in Estonia, specifically under the health promotion strategic planning, and this includes developing health and well-being profiles for evidence-based public health promotion. For effective implementation of the profile, sufficiently trained public health practitioners are needed. Therefore, analysis of the needs of the additional study programmes according to the core competences of professional standard for health promotion was carried out among public health practitioners and the leaders of local governments. The study was based on the 19 semi-structured interviews carried out in 2022-2023 with leaders (10) and public health practitioners (9) in Estonian local governments. Based on the local government's size, status of the health and well-being profile and the employment and educational background of the public health practitioner three sub-groups were developed. The collected data was analysed using qualitative content analysis with focus on support mechanisms and obstacles of core competences of public health practitioners. The respondents indicated the need for training on communication (leadership and advocacy) and analytical skills (evaluation and research). Core competence training is however limited by resources (time, energy, motivation, funding), employer expectations (overload at work) and working full-time. Training is supported by personal motivation (e.g., wish to stay competent, understanding the need for training), employer support (including flexible work arrangements), and curriculum support (funding is covered). The results indicate there is a need for flexible education as the need for developing and maintaining core competences emerges in practical work. The results can be used for developing the public health curriculum, to assess and provide training for public health practitioners to better meet the needs of the labor market in the future.

Key messages:

- Local government employees performing health promotion tasks feel the need to upgrade various core competences: e.g., communication, management, data analysis and assessment.
- In health promotion, there is a growing need for flexible education, which creates challenges for higher educational institutions to meet the needs of the labor market.

Abstract citation ID: ckae144.1766

Needs and opportunities for developing health and well-being profiles in Estonian local governments

Liina Riisenberg

L Riisenberg[1]
[1]Health Promotion Curriculum, Tallinn Health Care College, Tallinn, Estonia
Contact: liina.riisenberg@ttk.ee

The creation and implementation of health and wellbeing profile, an evidence-based framework for planning health promotion as holistic process, is the responsibility of public health practitioners, who tend work part-time and sometimes lack professional competences. The current study maps the level of awareness, attitudes, needs and possibilities of local government leaders and public health practitioners to develop and implement profiles effectively in Estonian local governments. Semi-structured interviews with leaders in local governments (10) and practitioners (9) were conducted in 2022-2023. Data was analysed using qualitative content analysis. Sample included representatives from all Estonian local governments (79 in total) and were categorized into subgroups based on local governments size, status of the profile, public health specialist employment, and educational background. Preliminary results indicate that leaders find as a supportive factors for enabling and encouraging profile compilation process for example: mandatory requirement; motivated implementors; well organized and effective workplan. Specialists find supportive factors to be cooperation on the national level, good communication practices and joint responsibility. Barriers for health promoters are the lack of time, motivation, financial resources, stakeholders understanding and meaningful action. The first qualitative study on these topics in Estonia highlight that creating a profile is supported by previous positive experience and have per contra an opposite negative effect to start the process. In general, the profile was considered necessary for helping identify problems and support decision-making processes for managing resources, however, assessment whether the profile should be obligatory is needed. In addition, there is a need for further support for the evidence-based decision-making process on the local level in health promotion by offering education and guidance from the national level.

Key messages:

- Knowledge about the importance of public health, barriers and decision-making principles of local government leaders and specialists helps to develop interventions based on actual needs.
- Continuously updated health and well-being profile ensures sustainability of health promotion action and is useful knowledge to policymakers, local government leaders and public health practitioners.

Exploring health-related quality of life in Portuguese Informal Caregivers

Ana Rita Pedro

AR Pedro[1,2], D Brandão[1,2], B Raposo[2], AS Cunha[2], A Escoval[1]
[1]NOVA National School of Public Health, Comprehensive Health Research Center, NOVA University Lisbon, Lisbon, Portugal
[2]NOVA National School of Public Health, Public Health Research Center, CISP, NOVA University Lisbon, Lisbon, Portugal
Contact: rita.pedro@ensp.unl.pt

Background: Caregiving can be associated with several adverse health impacts, such as in terms of mental health, health services use, or health-related quality of life (HRQoL). This study assessed HRQoL levels in Portuguese Informal Caregivers, and their relationship with caregiver psychosocial characteristics (e.g., perceived general and mental health; perceived level of support) and caregiving circumstances (e.g., caregiving duration, caregiving hours).

Methods: A cross-sectional study was conducted through an online survey directed to informal caregivers. HRQoL was measured using the Portuguese translation of the EQ-5D-5L. This instrument yields two values for HRQoL: a health profile (EQvalue) covering five dimensions (mobility, self-care, usual activities, pain/discomfort, and anxiety/depression), and a visual analogue scale (EQvas). Bivariate analyses were performed and results with p-values below 0.05 were considered statistically significant.

Results: A total of 760 informal caregivers were surveyed (mean age 57 years (±9.9), 92.5% female, 41.5% at least university level, 44.4% works full or part-time). The mean total score for EQvalue ($n = 733$) was 0.8 ($SD = 0.2$). The mean total score for EQvas ($n = 760$) was 63.1 ($SD = 21.5$). The perceived general ($p < 0.001$) and mental ($p < 0.001$) health status, and the perceived access to healthcare ($p < 0.001$) were associated with EQvalue score. Also, EQvalue score was found to be directly correlated with the perceived level of support ($r = 0.142$; $p < 0.001$) and competence ($r = 0{,}237$; $p < 0.001$), and inversely correlated with the number of caregiving hours per day ($r= -0{,}150$; $p =< 0{,}001$) and the caregiving duration ($r= -0{,}109$; $p = 0.008$).

Conclusions: A significant relationship between caregiver HRQoL and several caregiver psychosocial variables was identified. Investing in and promoting the use of respite care services, as well as ensuring better access to healthcare for caregivers, appears important for improving caregivers' HRQoL.

Key messages:

- Improving caregivers' access to healthcare and education or training programs (promoting a greater sense of competence) can be important in helping them maintain their quality of life.
- Increasing the availability and promoting the use of respite care services by caregivers can be important in helping them maintain their quality of life.

Abstract citation ID: ckae144.1768

Exploring factors of HPV self-sampling acceptance:a qualitative study with hard-to-reach women

Walaa Kinaan

W Kinaan[1], A Gama[1], B Heleno[2], P Marques[1], B Vega Crespo[3], J Ortiz[3], B Verberckmoes[4], H Vermandere[4], O Degomme[4], S Dias[1]
[1]NOVA National School of Public Health, PHRC, CHRC, REAL, NOVA University Lisbon, Lisbon, Portugal

[3]Faculty of Medical Sciences, University of Cuenca, Cuenca, Ecuador
[4]International Centre for Reproductive Health, Department of Public Health & Primary Care, Ghent University, Ghent, Belgium
Contact: walaa.1993.k@gmail.com

Background: Cervical cancer disproportionately affects socially disadvantaged women, who tend to be underscreened and are generally called "hard-to-reach". HPV DNA testing based on self-sampling test is an alternative strategy to address women's low screening uptake and reduce inequalities. Psychosocial factors like self-efficacy, ethicality, and testing conditions should be considered when assessing the acceptability of HPV self-sampling. However, research on the acceptability of HPV self-sampling is scarce among hard-to-reach women. Our study aims to explore self-efficacy beliefs, perceptions of how well HPV self-sampling fits participants' values and their preferred testing conditions and understand how these factors influence the acceptability of HPV self-sampling test among hard-to-reach women.

Methods: This qualitative study used a semi-structured guide based on three constructs of the Theoretical Framework of Acceptability. Focus group discussions (FGD) were conducted with $n = 63$ hard-to-reach women in Portugal (2 FGD), Ecuador (4 FGD), and Belgium (3 FGD). Data were analysed using deductive content analysis.

Results: While some women viewed HPV self-sampling as acceptable, others questioned its compatibility with their ethical views and moral principles, stressing that the test cannot replace the clinical examination. Participants held conflicting views, with some expressing confidence in their sampling abilities while others feared making errors when taking the sample. Cultural disparities in preferred testing conditions emerged: Ecuadorian women preferred solo testing, while those in Europe preferred assistance.

Conclusions: This study indicated ambivalent attitudes towards self-sampling. Further research on HPV self-sampling acceptability is needed to explore socio-cultural nuances. Our study emphasises the importance of culturally attuned interventions to address these populations' needs and reduce inequalities.

Key messages:

- Hard-to-reach women harbour conflicting views about self-sampling.
- Screening policies may include opportunities for self- and clinician sampling.

Abstract citation ID: ckae144.1769
Influencers as a new source of health information: Insights from an Austrian youth survey

Elena Engel

E Engel[1,2], *S Gell*[1,2], *R Heiss*[1], *K Karsay*[2]
[1]Center for Social & Health Innovation, MCI - The Entrepreneurial School®, Innsbruck, Austria
[2]Department of Communication, University of Vienna, Vienna, Austria
Contact: elena.engel@mci.edu

Background: Social media influencers (SMIs) have become the dominant source of health information for youth. While some SMIs may share valuable content, critics raise concerns that they lack expertise, have commercial motives, or hold personal biases. Yet, little is known about the epidemiology of the health influencer phenomenon. This study offers first insights into the reach of SMIs among Austrian youth, informing public health strategies to promote positive health behaviors in young populations.

Methods: A cross-sectional study was conducted with a representative sample of 1003 Austrian adolescents and young adults aged 15-25. Key research questions focus on the epidemiology of health influencers, engagement with SMIs, prevalent health topics, advertising, and perceived impact of SMIs on health.

Preliminary results: Participants estimate that over 51% of social media posts they see are from SMIs, and 75.37% follow at least one SMI. Additionally, 37.19% follow SMIs who specifically share health content, and 30.91% have purchased health products recommended by them (e.g., foods, supplements, beauty products). Moreover, 40.27% trust their followed SMIs for health information, similar to trust in traditional media (43.47%). Finally, over a third find SMI content beneficial for health (32.34%), while 29.20% find it harmful, and 33.83% neither.

Conclusions: The study provides first insights into the epidemiology of health influencers, revealing their extensive reach and positive reception among young people. Despite concerns about conflicts of interest or expertise, SMIs are perceived as trusted sources for health information and product purchases. This research enhances our understanding of influencers' impact and informs public health strategies aimed at promoting positive health behaviors among youth. The insights from Austrian youth can inform future studies across Europe, deepening our understanding of the health influencer phenomenon and its implications for public health.

Key messages:

- This cross-sectional study shows the high reach of social media influencers among youth and their important role as emerging sources of health information.
- The study breaks new ground by investigating adolescents' engagement with health influencers, offering insights for public health to promote positive health outcomes among young populations.

Abstract citation ID: ckae144.1770
Procrastination and risky behaviors: preliminary results among Italian university students

Aida Bianco

A Bianco[2], *F Licata*[1], *R Maruca*[1], *G Di Gennaro*[1], *EA Citrino*[2]
[1]Department of Health Sciences, University of Catanzaro, Catanzaro, Italy
[2]Department of Medical and Surgical Sciences, University of Catanzaro, Catanzaro, Italy
Contact: a.bianco@unicz.it

Background: The study aims to investigate if the tendency to procrastinate has a relationship with engaging in risky behaviors among university students.

Methods: A cross-sectional study was conducted at the 'Magna Græcia' University of Catanzaro, in the Southern part of Italy, using a stratified random sample technique. Undergraduate students (ages 18 to 30) were provided with an anonymous online survey via the institutional email. The survey comprised five sections to assess procrastination levels, sleep quality, breakfast habits, alcohol and tobacco use, and social and demographic characteristics.

Results: Of the 404 participants, more than half were enrolled in medicine or life science majors. The procrastination mean score was 14.8(IQR 10-20). Poor sleep quality was found in 57.2% of students and women were the most affected part of the sample. The logistic regression model revealed that higher procrastination levels increased the likelihood of engaging in unhealthy behaviors such as breakfast skipping, alcohol abuse, and poor sleep quality. Furthermore, the study found that people who skipped breakfast were more likely to engage in smoking and alcohol abuse, suggesting the interconnectedness nature of unhealthy behaviors.

Conclusions: The study's findings shed light on the correlation between procrastination and unhealthy habits. Moreover, the results can offer recommendations for how universities might successfully support students by implementing integrated, evidence-based programs to assist students who struggle with procrastination. Indeed, universities can serve as centers for promoting wellness by increasing awareness of the need to change deeply rooted behavioral patterns. Hence, breaking the vicious cycle of procrastination can ultimately lead to improved academic performance and overall well-being for students. This will benefit both individuals' and the general public's health.

Key messages:

- The novel correlation between procrastination and risky behaviors among university students was shown.
- Targeted interventions must include procrastination tendency to improve academic results and general well-being.

Abstract citation ID: ckae144.1771
Evidence-Based Programs in France: Insights and Strategies for Implementation Support

Alexis Krache

T Delescluse[1], *F Berdougo*[1], *A Van Hoye*[2], *A Krache*[1], *M Villeval*[1]
[1]French Society for Public Health, Laxou, France
[2]UMR1319 INSPIIRE, University of Lorraine, Nancy, France
Contact: alexis.krache@sfsp.fr

Issue: In France, both regional and national health institutions increasingly support and fund the implementation of evidence-based programs (EBP), promoted at the national level by the French Public Health agency.

Description of the problem: practitioners who implement EBP face several operational questions: scaling issues, implementation in specific and varying contexts, integration and adjustment to daily regional practices.

Results/effects: In 2023, the French Society for Public Health initiated a collaborative effort to create a platform for discussion among practitioners, researchers, and decision-makers involved in EBP implementation. The first step was to assess EPB implementation experiences, using 3 types of data: an analysis of 6 documented EBP (capitalization works), an online questionnaire answered by 29 stakeholders, and four focus groups with funders, researchers, practitioners, and institutions. Data analysis was based on thematic content analysis and structural data analysis.

Lessons: Different ways to implement EBP were identified through a typology. The results highlight favorable conditions and levers for EPB implementation in France: • Facilitate access and adoption of EBP by concerned stakeholders, including through clear communication and knowledge sharing; • Strengthen and value support for implementation support (i.e., providing necessary resources and continuous monitoring); • A 'favorable environment' is also required (i.e. regional context acceptability and information on program themes or topics); • Breadthen perspectives and promote mutual learning through sharing and comparing implementation experiences across regions; • Value transferability and adaptation studies, which are key to enable EBP adaptations to account for context specificities while maintaining effectiveness. The platform's next steps are to develop deployment tools and structure an advocacy strategy to mobilize stakeholders around the issue.

Key messages:

- Achieving wide-scale implementation of EBP requires to tackle key implementation issues such as scaling, context adaptation, etc. and to give support to implementing stakeholders.
- A collaborative assessment helped identify levers and barriers to EBP implementation in France. Involvement in EBP fosters an evidence-based mindset among practitioners.

Abstract citation ID: ckae144.1772
Understanding influences of cervical screening attendance among women of low socio-economic position

Sophie Mulcahy Symmons

S Mulcahy Symmons[1], *A Drury*[2], *A De Brun*[1]
[1]Nursing, Midwifery and Health Systems, University College Dublin, Dublin, Ireland
[2]Nursing, Psychotherapy and Community Health, Dublin City University, Dublin, Ireland
Contact: sophie.mulcahysymmons@ucdconnect.ie

Women of lower socio-economic position (SEP) have a higher incidence of cervical cancer and lower uptake of cervical screening. The Integrated Screening Action Model (I-SAM) is a behaviour model aimed to guide intervention development that considers how individuals engage with screening through their environment, capability, opportunity, and motivation. The I-SAM can be used to understand behaviour of cervical screening. We aimed to understand perceptions and awareness of HPV screening among women aged 25-65 of low SEP living in an urban area in Ireland. Semi-structured interviews were conducted with women who self-reported regular or irregular screening attendance, no university-level education, low-income employment or not working, aged 25-65 and living in Dublin. Participants were recruited via community organisations. Data were analysed using I-SAM in a framework analysis to map barriers and enablers of attendance of regular and irregular attenders. Of the seventeen women interviewed, seven attended screening irregularly. Participants thought they had opportunity to attend when they were reminded and supported to attend by peers and healthcare professionals. Participants wanted to promote screening in the community and to normalise conversations on sexual health. Participants felt fear of cancer was a driver and deterrent to attend screening due to cancer running in the family, past health issues and abnormal cell treatments, and wanting to be there for their family. Few were aware of HPV or the switch to HPV screening. Irregular attenders were unsure how to book or find information on screening. Campaigns should involve communities that are less likely to attend to improve visibility of screening. Healthcare professionals could opportunistically promote HPV screening in primary care and community settings. Campaigns should be aimed at improving literacy of HPV screening, address concerns of cancer risk and support navigation through screening.

Key messages:

- Understanding of HPV cervical screening is limited and campaigns are needed to improve awareness and literacy.
- Public health campaigns should engage with communities to promote screening via community groups and healthcare professionals.

[5]Nutritional Sciences, King's College London, London, UK
[6]Basic and Clinical Sciences, University of Nicosia Medical School, Nicosia, Cyprus
Contact: koshiaris.c@unic.ac.cy

Breast cancer is a prevalent disease for women globally, with rising survival rates highlighting the need to address the breast cancer survivors' (BCS) quality of Life (QoL). Furthermore, adherence to a healthy lifestyle is associated with decreased mortality in BCS. Mapping the Lifestyle Medicine pillars and the World Cancer Research Fund/American Institute for Cancer Research recommendations identifies 7 healthy lifestyle components: weight management, physical activity, healthy eating, restorative sleep, avoidance of risky substances, positive social connections and stress management. This study examines adherence to these healthy lifestyle components and QoL among BCS. A cross-sectional study conducted in 2022-23 recruited primary adult BCS from the Bank of Cyprus Oncology Centre. Participants completed a survey assessing self-reported QoL and adherence to the aforementioned 7 healthy lifestyle components, through validated questionnaires. Out of 349 BCS approached, 272 were included in the final analysis. Mean age and time since main treatment completion were 51 (SD: 7.4) and 3.6 (SD: 2.5) years respectively. Amongst study participants 58% were classified as bad sleepers, 53.3% were overweight or obese, 23% were stressed, 78% reported to have moderate/high physical activity, and 60% adhered to the Mediterranean diet. Regarding substance use, 16% were current smokers, and 18% were hazardous drinkers. Median score for social support was 75 (IQR: 53-97; max score=100) and for QoL was 67 (IQR: 50-97; max score:100). BCS in Cyprus generally exhibit moderate adherence to the Mediterranean diet, engage in fairly active lifestyles and enjoy high levels of social support and QoL. On the other hand, a substantial proportion smoke or drink, are overweight or obese, are stressed and have poor sleep quality. Targeted interventions to increase the adherence of breast cancer survivors to the 7 healthy lifestyle components are required.

Key messages:

- Overall variability exists in the adherence to healthy lifestyle components among BCS in Cyprus.

- This population can benefit from intervention targeting sleep, stress and weight management.

Abstract citation ID: ckae144.1774
Physical activity promotion as intersectoral planning in Milan Health Protection Agency

Lia Calloni

L Calloni[1], F Elisa[1], E Bertolini[1], C Cassatella[1], M Pullano[1], C Melis[1], L Galessi[1], B Ieva[1], N Iannaccone[1], R Boni[1]
[1]SC Promozione della Salute, Ats Milano- Agenzia di tutela della Salute, Italy, Milan, Italy
Contact: liacalloni92@gmail.com

Issue/problem: Physical activity is a protective factor for preventing Noncommunicable diseases (NCDs) and, for this reason, it plays an important role in all the different guidelines for prevention and health promotion. The Italian Regional Prevention Plans and in particular the Lombardy one promote physical activity with a systemic approach, through both upstream and downstream actions to encourage the role of communities.
Description of the problem: Based on the regional plan, the Health Protection Agency (HPA) of the Metropolitan City of Milan developed locally validated actions and best practices for the promotion of physical activity, through the cross-sectoral involvement of different stakeholders (health system, companies, universities, local authorities, sports associations, etc.).
Results: Physical activity is embedded in all lines of health promotion activities in local planning documents. Sustainable and active mobility activities have been implemented in companies and schools with a comprehensive approach. Validated regional programs (Pedibus, Walking Groups, ecc.) have been implemented in the local community, along with the construction of permanent local laboratories for physical activity, structured through the development of specific territorial networks and providing for integration with the socio-sanitary setting.
Lessons: Promoting physical activity becomes an opportunity to both consolidate territorial networks and to develop evidence-based health promotion actions able to meet the different health needs of the population and to produce a structural change in living contexts.
Key messages:

- Physical activity is both a protective factor for health promotion and a tool for implementing intersectoral and equity-oriented system actions from a life-course perspective.
- Promoting physical activity becomes an opportunity to consolidate territorial networks.

Abstract citation ID: ckae144.1775
How does a Smoke-Free campus initiative generates changes in smoking? A theory-based evaluation

Etienne Gnonlonfin

E Gnonlonfin[1], K Gallopel-Morvan[1], E Breton[1]
[1]CNRS, Inserm, Arènes - UMR 6051, RSMS -U 1309, EHESP School of Public Health, Rennes, France
Contact: mahouna.gnonlonfin@ehesp.fr

Background: Smoke-free campuses (SFC) prohibit smoking and vaping on all university grounds and for all users. Despite their effectiveness in reducing smoking prevalence, passive smoking, and denormalizing tobacco use, the complex interplay between the programme activities and their impact on users and campus environments remain unclear. This study aims to improve our understanding of the transformation processes associated with SFC expected outcomes.
Methods: We conducted a retrospective qualitative study on the first SFC implemented in France by the EHESP School of Public Health. Guided by Mayne's theory of change framework that includes ten dimensions of an impact pathway (e.g. activities, reach/reaction, capacity, behaviour changes, etc.), the research examined the chain of effects and hypotheses driving this SFC. Our dataset included internal documents (e.g. minutes of meetings, administrative documents) and semi-structured interviews with stakeholders ($n = 16$) involved in the development and implementation of the analysed SFC. Data is currently being analysed.
Results: Initial results suggest that the EHESP's SFC activities included communication initiatives, student ambassadors, cessation support for smokers, installation of smoking shelters on campus periphery, etc. These activities were geared on capacity change (e.g. securing support and compliance among campus users, reduce smoking opportunities, promoting the use of cessation aids) and were intended to drive behaviour change (reducing smoking and facilitating cessation among students and staff). The goal of this SFC was not only to impact behaviors but also to educate future health service managers at EHESP to implement SFC policies and set an example for other institutions in France.
Conclusions: This study identifies some of the transformations that activities of the EHESP's SFC can generate in students and staff in order to fulfil its outcomes. It also highlighted its expected impact on other institutions.
Key messages:

- Understanding how a smoke-free campus generates its changes is essential in facilitating transferability of experiences to other universities.
- Smoke-free campus policies can also generate a broader impact on other institutions.

Associations between study conditions and students' mental health: Results from the StudiBiFra study

Jennifer Lehnchen

J Lehnchen[1], K Heinrichs[1], S Helmer[2], J Burian[3], Z Deptolla[3], E Heumann[1], C Stock[1]
[1]Institute of Health and Nursing Science, Charité – Universitätsmedizin Berlin, Berlin, Germany
[2]Institute of Public Health and Nursing Research, University of Bremen, Bremen, Germany
[3]Health Management, University of Bielefeld, Bielefeld, Germany
Contact: jennifer.lehnchen@charite.de

Background: Study conditions are relevant for university students' mental health and well-being. Previous research identified single factors associated with mental health, but it remains unclear, which study conditions at higher education institutions should be priority targets for institutional action. The aim of this study is to provide a comprehensive overview of students' satisfaction with their study conditions and to analyse their associations with students' mental health.
Methods: The cross-sectional StudiBiFra study encompasses data from 24,533 students across 13 higher education institutions in Germany. Data was collected between June 2021 and March 2023 using the Bielefeld Questionnaire on Study Conditions and (Mental) Health. Students rated study conditions in 22 domains and four scales of mental health outcomes. Mean scores for all scales were calculated and linear regressions were used to analyse bivariate associations.
Results: All domains of study conditions were associated with all domains of students' men-tal health with regression coefficients ranging from $r = 0.21$ to $r = 0.78$. The more satisfied students were with their study conditions, the higher the reported well-being, and the lower the depressive symptoms, cognitive stress symptoms, and exhaustion. The highest associations were found for the

domains of study conditions "examinations and academic achievements", "time requirements", and "fit of course content/competency development" with highest re-gression coefficients for the outcome of exhaustion.

Conclusions: The findings reveal significant moderate to high associations for all assessed study conditions with students' mental health. Institutional action should focus on these study conditions by emphasising topics such as applying competencies during studies and good co-ordination of content and examinations. Thus, decreasing student burden and time pressure has the potential to promote mental well-being.

Key messages:

- Study conditions are significantly associated with students' mental health.
- Higher education institutions should focus on study conditions to promote students' mental well-being.

Abstract citation ID: ckae144.1777
Is being a physically active parent related to having a physically active son/daughter?

Francesca Licata

F Licata[1], *G Di Gennaro*[1], *E Basile*[1], *S Angelillo*[1], *A Bianco*[2]
[1]Department of Health Sciences, University of Catanzaro 'Magna Græcia', Catanzaro, Italy
[2]Department of Medical and Surgical Sciences, University of Catanzaro 'Magna Græcia', Catanzaro, Italy
Contact: francesca17licata@gmail.com

Background: Engaging in physical activity (PA) during childhood and adolescence can promote lifelong healthy habits and improve overall health. Physically active parents could play a key role in influencing the sons' and daughters' PA. The study aimed to evaluate the levels of PA among children and adolescents and to investigate the possible relationship with PA levels of parents.

Methods: This cross-sectional study involved a random sample of parents of a son/daughter aged 5 to 17 years in the Southern part of Italy. Data were collected through an anonymous self-administered questionnaire designed to retrieve i) sociodemographic characteristics and anthropometric data, ii) parent's knowledge about the World Health Organization's (WHO) guidelines (GL) about PA, iii) levels of PA of son/daughter and parent.

Results: Preliminary findings refer to a sample of 230 parents, of whom, 52.2% were women with a mean age of 38.6 (SD ± 6.8) years. The vast majority of the sample was employed (79.6%) and married (89.1%). Less than half (48.7%) were knowledgeable about WHO's GLs for PA both in adults (52.6%) and children/adolescents (74.8%). Almost two-thirds (63%) of parents practised PA according to WHO's GLs. Among sons/daughters, 44.4% practised PA according to WHO's GLs. The results of the multivariate analysis showed that sons/daughters of physically active parents had higher odds of practising PA according to WHO's GLs (OR:6.48, 95%CI:3.29-12.79). Similarly, those with parents knowledgeable about WHO's GLs for PA (OR:3.19, 95%CI:1.75-5.83) were more likely to practise PA according to WHO's GLs.

Conclusions: Preliminary results reveal a lack of compliance with WHO's GL on PA, especially among children and adolescents. This is of concern since it is linked to negative health outcomes in the future. The figure that sons/daughters of active parents had a higher likelihood of being active highlights that public health organizations should prioritise family-based interventions for PA.

Key messages:

- Almost one-third of adults and more than half of the children and adolescents in the sample did not comply with WHO's recommendations for physical activity.
- Sons and daughters of physically active parents are more likely to be active, prompting the need for family-based public health intervention to promote physical activity.

Abstract citation ID: ckae144.1778
Exploring co-creator's experiences: a multiple case study addressing workplace sedentary behaviour

Lauren McCaffrey

L McCaffrey[1], *M Vogelsang*[1], *J de Boer*[2], *B McCann*[1], *M Giné-Garriga*[3], *P Dall*[1]
[1]School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
[2]Faculty of Medicine and Health Sciences, Ghent University, Ghent, Belgium
[3]Faculty of Psychology, Education and Sport, Blanquerna, Universitat Ramon Llull, Barcelona, Spain
Contact: lauren.mccaffrey@gcu.ac.uk

Co-creation is an innovative approach for addressing complex public health issues. Co-creator's experience of participating in co-creation can impact engagement yet research investigating co-creation experience is limited. A better understanding of co-creation experiences can inform optimal design and implementation of the co-creation process. This study's objective was to conduct a cross-case analysis of co-creator's experiences from 3 co-creation processes aimed at addressing workplace sedentary behaviour within 3 different small-to-medium sized companies in Scotland. Thirty-one co-creators were involved in the case study companies from Oct 2022 to Jun 2023. Data sources included observations, interviews, and researchers' reflections. A multiple case study design enabled the exploration of co-creator's experience across cases. A within-case thematic analysis was conducted to develop a deep understanding of cases before comparing findings between cases using Miles and Huberman's guide to cross-case analysis. Preliminary findings indicate co-creation experiences are associated with events occurring before, during and after the co-creation process and are influenced by company context (i.e., company structure, resources and demands) and co-creation context (i.e., design and facilitation of the process). Co-creators had various motivations for their involvement. During the co-creation process there was a range of common experiences such as a sense of belonging, enjoyment and frustration. After co-creation, there was an overall sense of satisfaction accompanied by positive outcomes, including an intention to adopt healthier behaviours. Insights into co-creator's experiences support the use of co-creation for addressing workplace sedentary behaviour. The findings have implications for researchers planning co-creation processes at small-to-medium sized companies. Tailoring co-creation to co-creator's needs and wider company context can enhance its innovative potential.

Key messages:

- This study's significance lies in its qualitative cross-case analysis of co-creation experiences which enhances research rigour and enables contextualised generalisation.
- The innovative potential of co-creation can be enhanced by tailoring it to meet the needs and preferences of the co-creators and considering the wider company context.

Abstract citation ID: ckae144.1779
Exploring the perceived dynamic system driving inequities in the community obesogenic environment

Suzannah D'Hooghe

S D'Hooghe[1,2,3], *Y Inaç*[1,2,5], *S Dury*[2], *B Deforche*[3], *K De Ridder*[1], *S Vandevijvere*[1], *D Van Dyck*[5], *N Van de Weghe*[4], *L Guariguata*[1]

[4]Department of Geography, Universiteit Gent, Gent, Belgium
[5]Department of Movement and Sports Sciences, Universiteit Gent, Gent, Belgium
Contact: Suzannah.Dhooghe@sciensano.be

Introduction: Persons in socioeconomically disadvantaged situations (PSEDS) are more susceptible and disproportionally exposed to obesogenic environments, resulting in poorer dietary outcomes and lower levels of physical activity. This study aimed to map the complex dynamic system within the community obesogenic environment driving unhealthy eating and insufficient physical activity among PSEDS in Flanders, and to identify potential local actions.

Methods: Participatory group model building (GMB), a qualitative system dynamics method, was used to engage PSEDS ($n = 7$), local decision makers ($n = 7$) and local stakeholders ($n = 5$) in two Flemish municipalities. A two-day GMB session was held in each municipality during which a causal loop diagram (CLD) was created and potential local actions were identified by considering causal pathways and reinforcing loops in the system.

Results: The CLD was designed around two main variables (i) healthy eating and (ii) physical activity among PSEDS. Seven subsystems could be identified: 1) social environment, 2) facilities and activities, 3) mobility options, 4) information, 5) affordability, 6) safety (specifically for physical activity), and 7) industry and advertisement (specifically for eating behaviour). Several actions to improve the local environment to promote eating behaviour and physical activity among PSEDS were identified.

Conclusions: The CLD illustrates the complex interactions between individual and environmental determinants contributing to inequalities in eating behaviour and physical activity by including multiple perspectives of community members in socioeconomically disadvantaged situations, local decision makers and local stakeholders. Both the participatory GMB approach and the final CLD visualization can provide the basis for planning local actions for promoting healthy eating behaviour and physical activity among PSEDS.

Key messages:

- Group model building is an effective approach to explore and understand a dynamic complex system through a shared understanding among diverse stakeholders.
- A systems approach is valuable to provide a more comprehensive and context-specific understanding of the perceived factors contributing to inequities in the obesogenic environment.

Abstract citation ID: ckae144.1780
Development and validation of the Behavioral Determinants of Deprescribing Questionnaire (BDDQ)

Stephan Van den Broucke

S Alves Jorge[1], *S Van den Broucke*[2]
[1]IRSS, Université Catholique de Louvain, Woluwe, Belgium
[2]IPSY, Université Catholique de Louvain, Louvain-la-Neuve, Belgium
Contact: stephan.vandenbroucke@uclouvain.be

Background: Deprescribing is a strategy to optimize medication use. While health behaviour can successfully be predicted by health behavior theories, the literature on deprescribing relies almost exclusively on questionnaires that measure attitudes only, such as the Beliefs about Medicines Questionnaire and the Patients Attitudes Towards Deprescribing, resulting in poor predictive validity. The aim of this study was to develop a new tool to measure the psychological determinants of deprescribing among people aged over 60, based on concepts derived from health behaviour theories.

Methods: A draft self-report questionnaire was developed consisting of 64 questions measuring 11 dimensions representing determinants of deprescribing. As well as previous deprescribing experience, current deprescribing behaviour and willingness to deprescribe. Face validity was assessed by asking 10 health professionals and 13 of older people to complete the questionnaire and comment in a small group discussion, resulting in the removal of 18 items. Construct validity was assessed on a sample of 103 participants aged over 60, using exploratory factor analysis (EFA). Internal consistency was assessed via Cronbach's alpha.

Results: The EFA could confirm 11 dimensions explaining 70,5% of the total variance, but revealed poor loadings for several items and inadequate alphas (<.50) for two factors. Removal of items and these two dimensions resulted in 26 items measuring 9 dimensions, all showing acceptable internal consistencies (between .52 and .77): perceived risk; relatives' involvement; deprescribing concerns; attitudes; medication beliefs; healthcare support; perceived difficulties; motivation to comply; communication accessibility.

Conclusions: This study produced a conceptually based and psychometrically validated questionnaire to assess behavioural determinants of deprescribing. It provides for a more comprehensive investigation of deprescribing intentions and behaviour of older adults.

Key messages:

- A conceptually sound, psychometrically validated questionnaire (BDDQ) was developed.
- BDDQ can be used for a more comprehensive study of de-prescribing in older people.

Abstract citation ID: ckae144.1781
Is harmonizing to social drinking norms associated with alcohol use in Danish high school students?

Lotte Vallentin-Holbech

L Vallentin-Holbech[1], *S Feldstein Ewing*[1,2], *K Rømer Thomsen*[1]
[1]Centre for Alcohol and Drug Research, Aarhus University, Aarhus, Denmark
[2]Department of Psychology, University of Rhode Island, Kingston, USA
Contact: lvh.crf@psy.au.dk

Background: Alcohol use is positively linked with perceived drinking norms within the peer group and the social plasticity hypothesis proposes that youth are very good at harmonizing to social norms (social attunement). Youth with high social attunement may adjust their drinking habits to the perceived drinking norms of the peer group to a higher extent potentially leading to a larger impact on personal alcohol use. This study examined if frequency of personal alcohol use was associated with perceived peer approval of drinking and the role of social attunement in Danish high school students aged 15-19 years.

Methods: An online survey was administered to 2977 first-year students from 16 public high schools in Denmark. Students reported past month alcohol use (drinking days, using TLFB) and perceived approval of alcohol use among peers of their grade. Social attunement was calculated as a sum score of the 11-item Dutch Social Attunement Questionnaire (SAQ) (range: 11-77; $\alpha = 0.81$). Number of drinking days was analysed as dependent variable, with age, gender, perceived peer approval and SAQ-score as independent variables.

Results: Older students were more likely to perceive peers to approve drinking ($\beta = 0.25$; $p = 0.004$) and getting drunk ($\beta = 0.22$; $p = 0.003$). More females (83.2%) than males (81.8%; $p = 0.003$) perceived peers to approve youth getting drunk. Multilevel regressions showed increased drinking days for students perceiving peers to approve of drinking ($\beta = 1.68$; $p < 0.001$) and getting drunk ($\beta = 1.80$; $p < 0.001$). We found interaction between SAQ-score and perceived drinking norms ($\beta = -0.10$; $p < 0.001$) indicating that perceived peer approval had less effect on drinking days for students with high SAQ-score.

Conclusions: Social attunement explained additional variance in the association between personal alcohol use and perceived drinking norms. Our findings stress the importance of addressing the influence of behavioural adaptation in e.g. school-based health promotion programs.

Key messages:
- Students perceiving peers to approve of youth alcohol use drink more frequent, but the link is weakened when the need to harmonize to perceived drinking norms are high.
- Social attunement needs to be considered when examining the link between individual alcohol consumption and perceived drinking norms and should be addressed in e.g. school health programs.

Abstract citation ID: ckae144.1782
First things first: measuring French Medical schools' deans motivation to engage in smoke-free campus

Diane Geindreau

D Geindreau[1], A Girault[1], K Gallopel-Morvan[1]
[1]CNRS, Inserm, Arènes - UMR 6051, RSMS - U 130, EHESP, Rennes, France
Contact: diane.geindreau@ehesp.fr

Smoke-free campuses (SFC) prohibit smoking and vaping on all university grounds and for all users. Around a hundred of papers was published on that topic revealing how they reduce initiation and increase smoking cessation among students. Whereas it is key for the success of all project, including SFC, very rare research has investigated attitude of high-level leaders of universities toward SFC, their perceived barriers and motivation to adopt it. To fill this gap, we interviewed deans of medical schools in France, where SFC are limited. In-depth individual interviews were conducted on 31 deans and two associate-deans (representing 31 out of 35 French medical schools). Questions rose knowledge of SFC, perception of this measure, self-role to play and other factors influencing implementation. We targeted medical schools because they train future prescribers of smoking cessation, and can act as a model for policy dissemination to other schools. The 23 hours of interviews were analyzed using thematic analysis with Nvivo14. Regarding diffusion in 2023, only one medical school had a SFC, six were implementing it, 23 had no SFC and one abandoned it. 28 held positive attitudes towards SFC, explained by its impact on health and the mission of medical schools. Most of them considered SFC feasible with resources and engagement of students. Identified barriers were competing priority, lack of funding and of support from users and risk of stigmatization of smokers. A majority of deans thought they had a role to play in initiating, promoting and moderating the policy. SFC are recommended by the WHO but there is important room for improvement for their diffusion in France. Yet, a majority of deans we interviewed appeared motivated to adopt it. Solutions to encourage them and overcome barriers must be found.

Key messages:
- Diffusion of SFC among medical schools remains limited in France.
- Deans's positive attitude towards SFC bring hope for a better diffusion of SFC among French universities.

Abstract citation ID: ckae144.1783
Promoting sexual health in schools: a systematic review of the European studies

Ronja Abrams

R Abrams[1], J Nordmyr[1], AK Forsman[1]
[1]Health Sciences, Faculty of Education and Welfare Studies, Åbo Akademi University, Vasa, Finland
Contact: ronja.abrams@abo.fi

Background: Sexual ill-health causes a high health burden. There is, therefore, a need for more effective sexual health promotion interventions. Previous research has focused on preventive sexual health interventions and the limited evidence concerning school-based sexual health promotion interventions has not been synthesized. Hence, this study aimed to systematically review the current evidence on the effects of sexual health promotion interventions conducted in European schools.

Methods: A systematic review based on the JBI and PRISMA standards was performed, encompassing searches in seven databases to identify sexual health promotion interventions conducted in European schools between 2012 and 2022. Data coding was performed according to a predetermined protocol and a narrative synthesis of the included studies was performed, highlighting the collective results.

Results: The review included 17 records, reporting 16 individual studies conducted in 7 European countries. Of the 16 included studies, 13 had a quantitative research design, and three had a qualitative design. All qualitative studies described positive effects as experienced by the participants, and ten of the quantitative studies showed statistically significant positive effects on at least one of the outcomes of interest.

Conclusions: The findings indicate good evidence for the effectiveness of interventions with a health promotion approach, underscoring the importance of sexual health resources such as respect, communication skills, and attitudes. Most sexual health promotion intervention studies have focused on sexual health resource outcomes connected to attitudes and skills, whereas, e.g., sexual health literacy is less studied and can be recommended to be included in future research.

Key messages:
- The synthesized evidence sheds light on the lack of evaluated interventions employing holistic and positive, resource-focused sexual health promotion interventions targeting European adolescents.
- The included school-based sexual health promotion studies, although limited in number, show evidence of promising effects on sexual health outcomes among participants.

Abstract citation ID: ckae144.1784
Analysis of parents' needs regarding sexual and reproductive health issues of their children

Silvia Gazzetta

S Gazzetta[1], I Iop[1], S Cherpessi[2], I Cudiz[2], E Bastiani[3], S Pascut[3], L Brunelli[1,4], L De Carlo[2], M Parpinel[1]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Bachelor's Degree in Health Assistance, University of Udine and Trieste, Trieste, Italy
[3]WHO Healthy Cities Project, Health Department, Municipality of Udine, Udine, Italy
[4]Accreditation Quality and Clinical Risk Unit, Friuli Centrale Healthcare University Trust, Udine, Italy
Contact: gazzetta.silvia@spes.uniud.it

Background: Promoting sexual and reproductive health is a key intervention for young people's health and well-being. Studies have shown that young people have a need to be supported by a strong network and that parents are considered an important source of information. The aim of our work was to understand the needs and critical issues parents face when raising the topic of sexual and reproductive health with their children in order to strengthen their skills and provide the best tools to support young people.

Methods: A qualitative focus group research methodology was used; a sexual psychologist facilitated the meetings. Parents of children attending secondary schools in Udine (Italy) in the 2022/2023 school year were invited to participate in the project. The meetings were recorded and transcribed verbatim by two independent researchers. Following an inductive method, recurring themes were extrapolated to represent the main categories and more specific subcategories.

Results: 46 parents participated in the focus group; 76% of them had no experience with sexual and affective education. Parents felt that sex education was useful in providing accurate information, preventing risks and promoting respect and relationships with others;

however, there were concerns that the values taught were not consistent with those of the family. The topic was found to be difficult to discuss with children, both in terms of technical/scientific aspects and addressing issues such as gender identity and sexual orientation. Parents would like to understand what the right communication key is to discuss with their children in an atmosphere of trust.

Conclusions: Parents recognized the importance of the topic and saw the need to deepen some aspects, especially in terms of relationship and communication. The results of this work will be a useful starting point for the creation of ad hoc pathways aimed at parents to strengthen the relationship with their children.

Key messages:

- Parents want to overcome difficulties by finding the right key to communicate with their children.
- Supporting young people and their network to promote sexual and reproductive health is essential.

Abstract citation ID: ckae144.1785

Improving intersectoral working in schools: learning for the future from the COVID-19 pandemic

Nicola J Gray

NJ Gray[1], S Manandhar[2], C Chabot[3], D Jourdan[3]
[1]UNESCO Chair 'Global Health & Education', University of Huddersfield, Huddersfield, UK
[2]School of Human and Health Science, University of Huddersfield, Huddersfield, UK
[3]UNESCO Chair 'Global Health & Education', Université Clermont Auvergne, Paris, France
Contact: N.J.Gray@hud.ac.uk

Background: The COVID-19 pandemic highlighted the challenge for school staff to integrate protective health measures into their academic daily responsibilities. The aim of this abstract, within a wider study of safe school re-opening, is to analyse improvements proposed for intersectoral working in schools by health and education professionals, based on their experience of the pandemic.

Methods: In 2021, an online survey was conducted in 6 languages with education and health professionals, followed by optional online semi-structured interviews. These methods explored the: 1-effect of the pandemic on schools/pupils/teachers; 2-reorganisation of schools; 3-experience of implementing infection control measures in schools; 4-intersectoral working; 5-important resources for keeping schools open. Interviews were transcribed verbatim and translated into English where needed. A directed content analysis was undertaken of interview transcripts and free-text survey responses regarding intersectoral working perspectives.

Results: The results are based on a combined analysis of data from 2072 survey responses from health and education professionals from 73 countries and 32 follow-up interviews (18 education professionals and 14 health professionals from 25 countries). Five themes of improvement for the future were identified: create formal coordination between the two sectors to support intersectoral working; that the health sector provide clear information and guidelines; bring health staff into school (especially medical staff); communicate more across all stakeholders (community, parents, students); and a call for capacity-building among education professionals by the health sector.

Conclusions: From the experience of the COVID-19 pandemic, the public health sector should lead the development of collaborative structures, implementation strategies and activities to support intersectoral alliances in the school environment for everyday well-being, ready for future health crises.

Key messages:

- During the COVID-19 pandemic, many education and health professionals felt the need for more - and strengthened - collaboration in schools for future health crises.
- Public health professionals could take a leading role in this strengthening strategy, supporting intersectoral alliances and promoting capacity-building in order to improve well-being and resilience.

Abstract citation ID: ckae144.1786

Improving health workers' well-being in Cittadella Hospital (Province of Padua)

Antonella Ruffatto

S Tikvina[1], E Zilli[2], D Bonaldo[2], M Varotto[2], S Bevilacqua[3], A Calzavara[1], A Madia[4], A Ruffatto[2]
[1]Hygiene and Public Health, Università degli Studi di Padova, Padua, Italy
[2]Medical Board of Directors, ULSS 6 Euganea, Hospital of Cittadella, Cittadella, Italy
[3]Health Profession Service, ULSS 6 Euganea, Hospital of Cittadella, Cittadella, Italy
[4]Sports and Exercise Medicine Unit, University of Messina, Messina, Italy
Contact: antonella.ruffatto@aulss6.veneto.it

Issue: A healthy workplace increases productivity, creativity and decreases absenteeism and turn-over. It also contributes to creating a more secure work environment with fewer risks of violence. In the past 3 years, the healthcare system has suffered the psychological, economic and social consequences of the COVID-19 pandemic. On the other hand, the healthcare staff reductions determine high levels of work related stress that are often unsustainable.

Description: In an effort to improve staff well-being, in the Hospital of Cittadella, which counts nearly 1,250 employees, a wide range of activities have been initiated. A questionnaire was submitted to the hospital's staff and the results showed that nearly 10% of workers had experienced physical symptomatology related to work. The most commonly experienced symptoms included: anxiety, nervousness, headache, stomach ache, excessive fatigue and insomnia. Participants also indicated feeling excessive mental fatigue and emotional overload at the end of their work shift.

Results: Psychomotor practice, held according to the Aucouturier method, is one of the projects intended especially for the staff operating in Intensive Care, Emergency and Pneumology Units. This method brings focus to controlled breathing, posture, muscle work and movement that help manage stress and fatigue. A Qigong course, which is an ancient Chinese practice designed to optimize the energy within the body reducing the stress levels and increasing general wellbeing, was held every two weeks for 5 months. And finally, Tibetan singing crystal bowls sessions consisted of monthly guided meditation sessions using the sounds of the crystal bowls.

Lessons: In conclusion, well-being and organizational performance are closely related to each other. It is crucial for any organization to encourage and maintain better physical and mental health of the healthcare staff as it directly affects productivity and consequently user's satisfaction of the services provided.

Key messages:

- Stress management is important amongst healthcare professionals as they are continuously exposed to different job stressors.
- Promoting self awareness and self care can help create a healthier work environment.

Abstract citation ID: ckae144.1787

Pediatric Allergy Management at ULSNE: Insights into Public Health Implications

Silvia Salvador

S Salvador[1,2], R Ferreira[1], I Rosa[1]
[1]Unidade de Saúde Pública, ULSNE, Bragança, Portugal
[2]Instituto Politécnico de Bragança, Bragança, Portugal
Contact: silvia.salvador@ulsne.min-saude.pt

Introduction: Pediatric allergies present a complex challenge to public health systems, affecting both policy-making and clinical management. This study explores the management trends and challenges of pediatric allergies at the Unidade Local de Saúde do Nordeste (ULSNE) in Portugal, emphasizing its implications for refining healthcare practices over a seven-year period.

Methods: A retrospective review of medical records was performed, from children aged 0 to 18 who presented with allergic reactions at ULSNE's emergency services between 2017 and 2023. The analysis concentrated on demographics, allergen types, reaction severity, and the management strategies deployed.

Results: The analysis revealed a wide range of allergens, from food to insect stings, with medication being the most prevalent triggers. Significant findings include observing severe allergic reactions across all age groups, highlighting the need for acute emergency interventions. The data underscores a critical demand for early diagnosis and tailored-made management plans to efficiently handle the diverse severity of allergic reactions observed.

Conclusions: This study demonstrates the complexity of managing pediatric allergies within ULSNE's public health framework. Standardized, evidence-based management methods should be adopted to strengthen emergency response capabilities, as shown by the frequency of severe responses and the prevalence of various allergens. As an outcome, our results support a comprehensive, interdisciplinary strategy that includes medical personnel, educational institutions, and family involvement to create a supportive community that is supportive of both immediate care and long-term preventive measures. Subsequent efforts should give precedence to educational programs designed to increase consciousness and encourage preventive measures in community environments.

Key messages:

- A rapid response is essential for healthcare systems to have fast, effective strategies ready for children's severe allergic reactions.
- Emphasizes a collective approach involving healthcare workers, schools, and families to prevent and manage children's allergies, enhancing safety and awareness.

Abstract citation ID: ckae144.1788

Parental concerns about the risks associated with harmful industries for their children

Hannah Pitt

H Pitt[1], *S McCarthy*[1], *E Hume*[1], *G Arnot*[1], *S Thomas*[1]
[1]Institute for Health Transformation, Deakin University, Burwood, Australia
Contact: hannah.pitt@deakin.edu.au

Background: Harmful industries including tobacco, vaping, alcohol, and gambling are causing significant harms to communities, including children and young people. These industries try to resist reform by deflecting blame and shifting responsibility, often by suggesting that parents need to educate and protect their children. This study aimed to explore parents' current concerns and risks relating to these industries and their children, and their attitudes about responses to prevent harm.

Methods: Australian parents (n = 455) who had at least one child aged between 11-17 years were invited through a panel company to complete an online qualitative survey. Participants were asked about their concerns and risks relating to each product, if and what they discuss about these products with their children, and who was responsible for protecting children from these industries. Thematic analysis was used to analyse the data.

Results: Parents were concerned about the short- and long-term consequences of their children engaging in these products. Many parents tried to talk to their children about the risks, however also believed that their child was influenced by their peers, and messages they see on social media. Although parents recognised their own role in protecting their children from harmful industries, they thought that a collective approach was needed, which included greater regulations and more effective education.

Conclusions: Parents are trying their best to protect their children from the harms associated with tobacco, vaping, alcohol, and gambling. However, they feel as though they are unable to counter the range of ways that their children are exposed to and influenced by these industries. Governments need to listen to parents and implement comprehensive regulations restricting marketing practices and increase evidence-based education that focuses on the tactics and harmful practices of these industries.

Key messages:

- Harmful industries try to shift blame and put responsibility for protecting children onto parents. However, parents feel they are unable to counter the positive messages that their children see.
- Parents are concerned about the range of risks these products could have for their children and want to see a collective response to address this issue, including government policy intervention.

[6]Department of Physiotherapy, Universidade Federal do Rio Grande do Norte, Natal, Brazil
Contact: tsentell@hawaii.edu

Background: The WHO has noted the importance of cultural insights for health. Culturally-relevant physical activity has a growing evidence base in many regions and specific populations, but the scope and scale for global health promotion is underexplored.

Methods: A multinational expert team used a critical literature review method to: (1) define culturally-relevant physical activity; (2) delineate relevant characteristics supporting inclusion in population-level health promotion and surveillance; and (3) provide agenda setting in research, policy, and practice from a global public health promotion perspective. The critical review method, which evaluates rather than summarizes literature, was chosen as the research evidence is complex, broad, and has not been synthesized previously from this perspective.

Results: Culturally-relevant physical activity was defined as practices that include physical activity based on a population's cultural customs. These can be Indigenous (e.g., hula, an Indigenous dance of Native Hawaiians) or regional (e.g., Shota (Shotë), an Albanian folk dance). Practices have shared characteristics that support multi-dimensional value for health, engagement, and healing. These include a collectivist, intergenerational component, passed from elders and shared forward with children as part of a community. Many have foundations in nature, a strength for health and wellbeing in green and blue spaces. Many include traditional art, clothing, accessories, and music with deep significance, including care for the tools and location of practice (e.g, drums, boats, land). Many practices would not be captured in harmonized public health surveillance systems despite their value. From this synthesis, research hypotheses were created and next steps proposed.

Conclusions: This evidence synthesis supports engagement, planning, uptake, policy, surveillance, and study of culturally-relevant physical activity for public health promotion locally and globally.

Key messages:

- An important strength of culturally-relevant physical activity is that it is context and population specific. However, this may hide the scope and scale of the existing evidence supporting this work.
- This evidence synthesis confirms how culturally-relevant physical activity is valuable globally across shared assets in research and practice, supporting next steps for public health promotion.

Sporting clubs' perceptions about harmful industry sponsorship: Lessons from gambling research

Simone McCarthy

S McCarthy[1], *S Thomas*[1,2], *H Pitt*[1], *G Arnot*[1], *M Randle*[3], *M Daube*[2]
[1]Institute for Health Transformation, Deakin University, Geelong, Australia
[2]Faculty of Health Sciences, Curtin University, Perth, Australia
[3]School of Business, University of Wollongong, Wollongong, Australia
Contact: simone.mccarthy@deakin.edu.au

Background: Unlike tobacco, there are no restrictions relating to gambling sponsorship in Australian sports. While some sporting teams have voluntarily refused sponsorship deals with gambling companies and other harmful industries, many are still actively entering into or renewing such deals. There is limited understanding of why, despite widespread public concern, sporting organisations continue to engage in commercial partnerships with gambling companies and venues. This study aimed to qualitatively explore the ethical and related practical issues associated with gambling sponsorship.

Methods: In-depth interviews were held with 24 key decision makers in Australian community sporting organisations. Participants were asked questions relating to attitudes towards gambling, decisions about gambling sponsorship within their clubs, and issues relating to alternative sponsors and sponsorship disparities. Data was analysed using reflexive thematic analysis.

Results: Interviews revealed the difficulty for sporting organisations to avoid harmful industry sponsorship. When deciding to align with gambling companies, sporting organisations had to consider their own values and the reputational impact of such deals, and balance this with the financial viability of the sporting organisation. Despite sporting organisations relying heavily on sponsorship deals, some stated they would refuse gambling sponsorship for ethical reasons but recognised that sporting clubs in poorer financial positions may be more vulnerable to taking up gambling sponsorship.

Conclusions: As elite sporting organisations begin to move away from gambling sponsorship, gambling companies may target community sport. The authors consider practical strategies to protect communities from sponsorship from harmful industries.

Key messages:

- Sporting organisations navigate ethical dilemmas when considering gambling sponsorships, weighing values, reputation, and financial viability. Policy action is needed to protect local communities.
- Community sporting organisations face increased risk of gambling sponsorship as elite sporting clubs move away, prompting the need for protective strategies.

Abstract citation ID: ckae144.1791
A global research agenda for understanding the role of alcohol consumption in older women's lives

Simone McCarthy

S McCarthy[1], *H Pittt*[1], *K Benjamin*[1], *J Stafford*[2], *D Keric*[2], *G Arnot*[1], *S Thomas*[1]
[1]Institute for Health Transformation, Deakin University, Geelong, Australia
[2]Cancer Council, Western Australia, Australia
Contact: simone.mccarthy@deakin.edu.au

Background: The alcohol industry has targeted women for profit and resisted global efforts to address the impact of alcohol on women's health. Scholars have called for research that moves beyond individual determinants of alcohol consumption in women, to investigate the range of social, environmental, and commercial factors that may contribute to women's alcohol attitudes, risk/benefit perceptions, and consumption behaviours. While qualitative research has explored younger and midlife women's perspectives on alcohol consumption, there is a notable lack of research focusing on older women.

Methods: This study investigated the factors that influence how older Australian women drinkers conceptualised the role of alcohol in their lives, using data collected from an online qualitative survey with $n = 144$ women aged 60-88 years. Qualitative responses were analysed using a 'Big Q' reflexive approach to thematic analysis.

Results: Participants perceived alcohol consumption as a socially accepted and normalised activity within Australian culture. For some women, alcohol served as a coping mechanism for life changes, such as retirement, and for managing stressful situations. Alcohol also formed part of daily routines and rituals, such as having wine with dinner. Participants had personal expectancies regarding 'responsible drinking', often aligning with alcohol industry messaging and resulting in a reduced perception of alcohol-related risks.

Conclusions: This research provides global lessons for future public health research examining the factors that may shape older women's alcohol consumption beliefs and behaviours. The authors consider the unique needs and potential vulnerabilities of older women drinkers, and how these may be potentially exploited by the alcohol industry. Further public health research and policy attention should focus on the impact of alcohol industry messaging on older women's knowledge, attitudes, and behaviours about alcohol risks and harms.

Key messages:

- This research highlights the role of alcohol in older women's lives, urging further public health research and policy attention to prevent alcohol-related harms in older women.
- Older women's perceptions of responsible alcohol consumption mirror the ambiguous messaging employed by the alcohol industry, highlighting the necessity for targeted interventions.

Abstract citation ID: ckae144.1792
Surfing a culturally-relevant physical activity: a new wave for health promotion

Tetine Sentell

T Sentell[1], *M Thompson*[1], *M Phillips*[1], *S Schmid*[1,2], *M Look*[3], *K Saiki*[1], *R Rodericks*[1], *C Soo Hoo*[1], *R Weldon*[1], *C Pirkle*[1]
[1]Office of Public Health Studies, University of Hawaii at Manoa, Honolulu, USA
[2]Chronic Disease and Health Promotion Division, Hawai'i Department of Health, Honolulu, USA
[3]Department of Native Hawaiian Health, John A Burns School of Medicine, University of Hawaii, Honolulu, USA
Contact: tsentell@hawaii.edu

Background: Surfing originated with Native Hawaiians prior to Western contact. It has since gained worldwide popularity, with an estimated 50 million surfers globally, and recently became an official Olympic sport. Associations have been reported between surfing and mental and physical health outcomes, greater community cohesion, and stronger intra-family relationships. Despite this evidence, surfing is deeply understudied in the context of health promotion.

Purpose: Surfing was analyzed from a mixed methods perspective to explore factors associated with lifetime participation and current engagement, including gender, race/ethnicity, chronic disease, social context, meaning, and average time of participation.

Methods: Hawai'i adult residents ($n = 1066$) completed an online or phone questionnaire. Modified Poisson regression models were fit for lifetime engagement and having a self-reported chronic disease, adjusting for primary race/ethnicity, age, gender, and education.

Results: Over their lifetime, 42% of respondents (50% men and 37% women) had participated in surfing. Engagement was highest during youth and young adulthood, and decreased with age, yet trends varied notably by race/ethnicity, gender, and generation. Lifetime surfing engagement was significantly related to lower likelihood of diabetes (aPR:0.72; 95%CI:0.56-0.92;p=0.009). Individuals who regularly participated in surfing typically did so with friends (78%) or family (61%); average surfing session duration was 209 minutes. Qualitative results revealed the relevance of surfing across levels of influence for health and wellbeing from physical fitness to community, culture, history and spirituality.

Conclusions: This work provides insights on the health promotion opportunities of surfing across the life-course and populations, including disease prevention and management. This study has implications for planning and policy locally and globally to achieve optimal community and planetary health.

Key messages:

- Surfing is not only a sport for elite athletes, but also an activity that can support community and individual health and wellbeing in many populations over the lifespan.
- Promotion of surfing and public ocean access can support multi-dimensional influences for wellbeing and should be a focus of cross sector collaborations for optimal community and planetary health.

Abstract citation ID: ckae144.1793
Population-based physical activity promotion with a focus on health equity: evidence challenges

Simone Kohler

S Kohler[1], *D Dippon*[1], *P Weber*[1], *A Ruetten*[1], *K Pfeifer*[1], *J Semrau*[1]
[1]Department of Sport Science and Sport, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany
Contact: simone.kohler@fau.de

Issue: Physical activity (PA) approaches that target the entire population hold great promise for public health particularly in terms of health equity due to their broad reach. During the process of developing national recommendations for PA and PA promotion in Germany, followed by a partial update, it became evident that there is limited evidence regarding population-based PA interventions with a focus on health equity. Our objective was to present an overview of the underlying reasons for this scarcity of evidence.

Methods: The methodology used in the development of the German recommendations to identify evidence for population-based health equity interventions was applied. Five scientific databases were searched for reviews published between 2015-2021. References of the included reviews were checked for additional reviews. Publications without any focus on health equity were not considered. The identified evidence was summarized narratively, followed by a description of existing challenges in evaluating.

Results: Our search yielded 4,411 reviews, of which 79 met the inclusion criteria but 75 were excluded because approaches did not focus on the whole population, or did not address health equity. Two reviews were found in the search for gray literature. Thus, the result is a total of 6 articles. None of these reviews reported the application of a theory. The consideration of quality criteria used before, during and after the practical implementation of interventions is not common. The complexity of population-based approaches proved to be a challenge.

Conclusions: Overall, there is a need for more emphasis on health equity in the implementation and evaluation of population-based PA approaches. The consideration of a theoretical underpinning of such complex approaches in complex systems and the application of standardised quality criteria are an important prerequisite for the generation of evidence.

Key messages:

- There is little evidence of population-based PA approaches aimed at health equity.
- A standardized and comprehensive evaluation assessment that is accepted by all public health stakeholders is needed.

Abstract citation ID: ckae144.1794
Characteristics of users of oral nicotine products according to smoking status in Denmark

Cecilie Toxvaerd

C Toxvaerd[1], *C Pisinger*[1,2], *S Bergman Rasmussen*[1], *C Juel Lau*[3], *M Helene Jacobsen*[2], *N Gøtzche*[1], *M Holm Eliasen*[1]
[1]Center for Clinical Research and Prevention, Frederiksberg, Denmark
[2]University of Southern Denmark, Copenhagen, Denmark
[3]Nordea Pension Denmark, Copenhagen, Denmark
Contact: cecilie.goltermann.toxvaerd@regionh.dk

Background: Oral nicotine products e.g., snus, chewing tobacco, and tobacco-free nicotine pouches gain increasing popularity. The aim of the study was to estimate the prevalence of use of oral nicotine products in the Capital Region of Denmark in 2021, to describe associations with socio-demographic characteristics and to explore if smoking status moderated these associations.

Methods: The study was based on the Danish Capital Region Health Survey 2021 including 56,245 persons aged ≥16 years old (response rate 54.9%) which included self-reported information on use of oral nicotine products and smoking status. Information on socio-demographic characteristics were assessed in national registries. Descriptive analyses and multivariate logistic regression models including interaction terms with smoking status and weighted for survey-sampling and non-response were performed.

Results: In total, 3.5% used oral nicotine products. Men showed higher odds of using oral nicotine products compared with woman (OR = 3.70) while there were no associations with education and occupational affiliation when adjusted for sex and age. The associations with age and place of residence were moderated by smoking status. Among smoking participants, young persons aged 16-19 years showed the strongest association with use of oral nicotine products (sex-adjusted OR = 21.71) while persons aged 20-24 years showed the strongest association in non-smoking participants (OR = 11.08).

Conclusions: Especially men and young age were strongly associated with use of oral nicotine products. For age, the association was moderated by smoking status. Interventions should address these high-risk groups and pay attention to smoking status.

Key messages:

- Sex and age play a siginificant role in use of oral nicotine products.
- Interventions and public health campagins should adress high-risk groups

Abstract citation ID: ckae144.1795
Promoting active ageing: The positive impact of older people's participation in Urban Gardens

Noelia Fernández Salido

N Fernández Salido[1], *A Gallego Valadés*[1], *C Serra Castells*[1], *J Garcés Ferrer*[1]
[1]POLIBIENESTAR, Universidad de Valencia, Valencia, Spain
Contact: Noelia.fernandez@uv.es

Background: The socio-health and economic consequences of the progressive population ageing constitute a global challenge for public health, which is committed to the promotion of active and healthy ageing as a strategy to mitigate these consequences. The European project U-GARDEN has evaluated from a comprehensive and innovative approach the impact of urban gardens on the promotion of active ageing through the participation of older people in urban agriculture.

Methods: A qualitative methodology was designed and implemented in order to analyse the information provided by people over 65 years of age, who actively participated in urban gardens, from a personal and subjective perspective through semi-structured in-depth interviews. The benefits obtained from participation in urban gardens were analysed, considering the different dimensions that make up the paradigm of active ageing: physical, psychological, economic, health, behavioural and personal impact. A total of 20 interviews were used to reach the saturation point.

Results: Qualitative analysis showed multiple benefits of active and healthy aging. Participants reported increased physical activity and psychosocial improvements such as higher personal satisfaction, reduced stress, and enhanced self-esteem, strengthening community connections and fostering a sense of belonging. Economically, they reported savings on food costs and increased food security. Overall, respondents noted improvements in general health and quality of life, highlighting urban gardening as valuable for well-being and social-economic integration.

Conclusions: The findings reported in the framework of the U-GARDEN project support the importance of implementing innovative strategies that encourage participation in urban gardens as a tool to improve the overall wellbeing and health of older people, effectively addressing some of the main challenges of ageing such as loneliness unwanted frailty and disability.

Key messages:

- The U-GARDEN project is an example of good practice in the use of urban gardens as a platform for promoting active and healthy ageing.
- The promotion of green spaces through the establishment of urban gardens should be considered by health and political authorities for their ability to promote the general well-being of society.

Abstract citation ID: ckae144.1796
Factors associated with use of active transport in users of HEVS Program of Ministry of Sports

Jessica Sánchez Revilla

C Castro Ramírez[1], *D Mendoza*[1], *HR Triana-Reina*[1], *A Gálvez*[1], *N Ruiz*[2], *R Leandro*[2], *A Díaz del Castillo*[2], *N Saenz*[2], *J Serrato*[2], *J Sánchez Revilla*[3]
[1]División Ciencias de la Salud, Universidad Santo Tomás, Bogotá, Colombia
[2]GIT Actividad Física, Ministerio del Deporte, Bogotá, Colombia
[3]Faculty of Sports, Autonomous University of Baja California, Tijuana, Mexico
Contact: jessica.sanchez11@uabc.edu.mx

Background: Sedentary behavior and physical inactivity are associated with an increased risk of chronic disease and mortality. Studies have shown the benefits of active transport to reduce NCDs. In Colombia, studies have been developed to determine the factors associated with the use of active transport, in cities such as Bogota but not nationally, therefore, this study seeks to determine the factors associated with the use of active transport in users of the National Program of Habits and Healthy Lifestyle (HEVS) led by the Ministry of Sport of Colombia in partnership with municipal sports and departmental.

Methods: The research presented a quantitative approach on a retrospective basis. The population consisted of 75,086 users of the HEVS program in 2019, over 18 years old (average = 44.04 and D.E. = 15.75 years old) of which 87.7% were women. For the statistical analysis a forward logistic regression model was carried out, with the dependent variable: active transport use (0 = no active transport use and 1 = active transport use).

Results: 41.6% of 75086 participants reported using active transport, corresponding to 31,211. Regular users, who attend physical activity programs 3 times a week, report a higher probability of using active transport OR = 1.38 (95% CI 1.31 to 1.45), compared to those who attend less than 3 times a week. Being female represents a greater probability of using active transport compared to men, OR = 1.39 (95% CI 1.32 to 1.47), those who add salt to food are also more likely to use active transport than those who do not add, OR = 2.04 (95% CI 1.92 to 2.26) and in terms of physical activity, those who meet the minimum recommendations in minutes a week use active transport more likely than those who do not comply, OR = 1.49 (95% CI 1.4 to 1.6).

Conclusions: Using active transport is associated with greater compliance with weekly physical activity recommendations. Women are more likely to use active transport just like people who add salt to food.

Key messages:

- In order to reduce NCDs in the Colombian population, walking or cycling is proposed because it is associated with a greater probability of compliance with weekly physical activity recommendations.
- Formulating public policies in Colombia that encourage the use of active transport would contribute to meeting weekly physical activity requirements.

Abstract citation ID: ckae144.1797
Co-Creating Tailored Solutions to Combat Sedentary Behaviour: Insights from Scottish SMEs

Mira Vogelsang

M Vogelsang[1], *L McCaffrey*[1], *G Ryde*[2], *M Verloigne*[3], *P Dall*[1]
[1]School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
[2]School of Cardiovascular & Metabolic Health, University of Glasgow, Glasgow, UK
[3]Department of Public Health and Primary Care, Ghent University, Ghent, Belgium
Contact: mira.vogelsang@gcu.ac.uk

Background: Prolonged sedentary behaviour (SB) poses health risks for office workers, especially in small-to-medium-sized enterprises (SMEs) often overlooked by current interventions. This abstract aims to report and examine solutions developed through co-creation for SB in SMEs.

Methods: Three Scottish SMEs, a construction company (n = 150) and two charities (n = 100; n = 30), participated in a co-creation process to create SME-specific actions on SB. Each formed an action group of employees (n = 9-12) as co-creators. The process consisted of between 6-8 workshops (each 1.5h) depending on the company, with workshops improved during the process based on formative reflection from co-creators. The co-creation workshops, facilitated by two researchers, initially involved jointly mapping the company's current situation and building knowledge and awareness of SB. Further workshops focused on action planning, including brainstorming, feasibility, piloting, and final action(s) development. Following the co-creation of actions, researchers identified the Behaviour Change Techniques (BCTs) underlying the developed actions.

Results: Each company created a set of actions unique to them, e.g. standing desk promotion, a games room, and innovative meeting strategies. Regarding the BCTs, all companies included adding objects to the environment, physical restructuring, prompts or cues, and addressing health or social and environmental consequences. Additionally, they all incorporated 'step challenges' with behaviour self-monitoring and feedback techniques. Two companies offered incentives or rewards; one emphasized role modelling, and another included social support.

Conclusions: The three companies created tailored actions through the co-creation process. While there were some commonalities, the differences in actions and BCTs among companies underscore the necessity for solutions tailored to the organizational context and the importance of involving employees in creating solutions.

Key messages:

- Co-created actions to combat SB used diverse strategies, emphasising a multifaceted approach to address workplace SB.

- Variability among SMEs' co-created actions underscores the importance of stakeholder involvement to tailor solutions to organisational contexts.

Abstract citation ID: ckae144.1798
The Workplace Health Promotion project in an Italian manufacturing

Domitilla Marconi

D Marconi[1]*, C Moscatelli*[2]*, L Centi*[3]*, F Erba*[4]*, G Lazzeri*[1,5]*, N Nante*[1,5]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Health Promotion Unit, Local Health Authority Tuscany South-East, Siena, Italy
[3]Department of Prevention Amiata, Val d'Orcia, Local Health Authority Tuscany South-East, Arezzo, Italy
[4]Department of Chemical Sciences, Tor Vergata University, Rome, Italy
[5]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: domitilla.marconi@gmail.com

Introduction: The Workplace Health Promotion (WHP) program aims to improve employee's health and well-being in the workplace by intervening in lifestyles. The objective of our study was to assess the impact of the WHP promoted by the Local Health Authority Tuscany South-East at a manufacturing.

Methods: The program was set at the STOSA Company in Radicofani (Siena, Italy) between 31 May 2017 to 31 December 2021, with a one-year interruption due to the COVID-19 pandemic. Based on an assessment of the workers' health status, we identified nutrition and fighting smoking as areas of intervention. The WHP project was integrated into the company policy and targeted all staff. Evaluation of interventions was conducted using an anonymous paper questionnaire (Regional Decree no. 1565, Annex 3) administered in three moments: at the beginning of the project (T0), one year later (T1), and at the end (T2). We conducted a descriptive and inferential analysis (chi-square test) with R.

Results: We collected 131 (T0), 136 (T1), and 123 (T2) responses. The cohort is composed entirely of males (T0 M:F 122:8, T1 130:6, T2 109:14). The median age is 40 years (SD 8.24 (T2)). There is a statistically significant difference in the perception of health status by education ($p<.001$), type of work ($p<.001$), smoking habit ($p<.001$), and the change in smoking habit ($p<.001$). The whole sample positively evaluated the interventions on nutrition and fighting to smoke. Moreover, the entire sample reported improvements in their diet since the beginning of the project.

Conclusions: The COVID-19 pandemic caused difficulties in carrying out the project and possible changes in workers' lifestyles. However, positive outcomes were observed in the targeted areas. The company has evaluated positively the WHP's project and decided to maintain the good practices acquired.

Key messages:
- The workplace represents a privileged setting to promote healthy lifestyles and prevent non-communicable diseases.
- Collaborations between health authorities and other sectors are strategic to reach the general population.

Abstract citation ID: ckae144.1799
Social prescribing for healthy ageing: insights from older people referral and uptake in Portugal

Louíse Hoffmeister

L Hoffmeister[1,2]*, B Gonçalves*[1,2]*, A Gama*[1,2]*, AM Canas*[1,2]*,
C Figueiredo*[1,2]*, S Dias*[1,2]
[1]NOVA National School of Public Health, NOVA University of Lisbon, Lisbon, Portugal
[2]Public Health Research Center, Comprehensive Health Research Center, REAL, Lisbon, Portugal
Contact: lv.hoffmeister@ensp.unl.pt

The population ageing presents multifaceted challenges for health systems, with implications for healthcare delivery and health and well-being outcomes. Innovative integrated-care approaches are needed to promote healthy aging and the quality of life of older people. Social Prescribing (SP) has emerged as a promising strategy to address the complex health and social needs of populations, including those older, offering non-medical interventions that encompass social, cultural, and community-based activities. SP has been implemented in Portugal since 2018 and currently target different subgroups, including elderly. This study aims to examine referral and uptake of older people to SP in Portugal. This cross-sectional study analysed sociodemographic, health condition, referral and uptake-related data from older patients ($\geq$65 years) engaged in SP, collected through a survey and registries at primary healthcare units in Lisbon between 2018-2023. Of the 1060 patients referred to SP, 43.9% ($n = 465$) were aged 65 years or older. Within this age group, 38.1% were 71-80 years old and 36.1% were 81-90 years old; 67.5% were female. Around 48% were referred to SP for social isolation, 40% for social and financial support, and 32.5% for functional dependency. Two thirds had two or more chronic conditions, with cardiovascular disease (59,1%), mental health disorders (29,2%), and obesity (27,1%) being the most frequent. The SP consultations uptake rate was 59.1%, and patients were referred to a range of activities provided by third-sector organisations, as psychosocial support, home care, senior university classes, arts activities, and support in medicine management. The elderly population accounts for a large proportion of SP referrals. Further efforts are needed to identify the factors that influence patients' acceptability and adherence and to promote the sustainability of SP and the well-being of the population.

Key messages:
- Older people referred to SP initiative in Portugal have complex health-social needs, which reinforces the relevance of adopting a holistic centred-care approach to respond to the aging challenges.
- Through SP older people have been integrated in community-based activities that promote their health and wellbeing, thus it is needed to develop tailored strategies to improve patient uptake.

Abstract citation ID: ckae144.1800
Culture on organ and tissue donation in the community of Medical School, Veracruz Region

Karla Vazquez Hernandez

J Viñas Dozal[1]*, F Roesch Dietlen*[1]*, K Vázquez Hernández*[1]*, F Ruiz García*[1]*,
V Duarte Cruz*[1]*, JE Villegas-Dominguez*[1]
[1]Facultad de Medicina, Región Veracruz, Universidad Veracruzana, Veracruz, Mexico
Contact: qarlyvh@outlook.com

Introduction: Organ donation is a life-saving activity, yet there is a disparity between the high number of recipients and the minimal number of donors.

Objetives: To determine the level of organ and tissue donation culture for transplant purposes among faculty members and undergraduate medical interns at a Medical School

Methods: A cross-sectional and prospective study was conducted from January 2023 to 2024, including faculty members and undergraduate medical interns from the Medical School at the University of Veracruz - Veracruz Region. The main study variable was the culture of organ and tissue donation for transplant purposes, quantified through three dimensions: knowledge, attitude, and training, assessed using a validated instrument (Cronbach's alpha: 0.6). The entire described population was included, and they were approached in different areas to invite them to participate in this research.

Results: 225 subjects (55 faculty members) agreed to participate. 97% of participants expressed support for organ donation. Among those not in favor of donation, 33% feared receiving poor medical care as donors, and 17% viewed donation as a business. Organ donation culture was deemed sufficient in 10.98% and outstanding in 71.76% of participants. The most common level of knowledge was outstanding (52%), 70% of the studied population showed a 'very positive' attitude towards organ and tissue donation. Training history was evaluated as an associated factor with knowledge about organ donation (OR/CI95%), identifying an association between lack of training and levels of sufficient knowledge (2.5/1.2-4.9) and outstanding knowledge (0.3/0.1-0.7), as well as with sufficient culture (9.6/1.2-73.0) and outstanding culture (0.1/0.04-0.4) ($p < 0.05$)

Conclusions: It is imperative to strengthen training programs for faculty and undergraduate personnel, as quality training enhances knowledge and culture within this essential area of healthcare personnel formation.

Key messages:

- University professors should have accurate information on organ donation and sensitize future physicians on the subject, as this could be a crucial step for future interactions in favor of donation.
- It is necessary to eradicate misinformation about organ donation in teachers and students of medical schools, since they are the basis for education and awareness on this issue in the population.

Contact: alice.chinelli@gmail.com

Background: School-based comprehensive sexuality education (CSE) is the best approach to disseminate scientific evidence and promote healthier sexual behaviours among young people. However, in Italy, CSE is not included in schools curricula. This study, funded by the Ministry of Health, seeks to investigate information uptake and attitudes towards sexuality among adolescents included in a pilot CSE intervention in 6 Italian regions, from December 2023 to June 2024.

Methods: A 10-hours education intervention was implemented in a convenient sample of 26 upper and lower secondary schools (U/LSS), covering topics such as changes in adolescence, relationships and consent, sexual identity, sexually transmitted infections (STIs), contraception and sexual health services. Students' evaluation comprised pre/post tests assessing knowledge, attitudes towards sexuality and satisfaction. A Solomon 4-group design study was used to compare intervention and control classes. A follow-up test will be conducted 4-6 months post-intervention.

Results: Preliminary analysis of available data as of 30 April, 510 pre-tests and 266 post-tests, showed incremented correct answers in all items. A significant increase ($p<.05$) was found in 12/21 items for USS and in 9/19 items for LSS, especially in the domain STIs symptoms and prevention, among those mostly appreciated. Over 90% of students considered schools as suitable setting to receive CSE, preferably by external experts. Ongoing qualitative and long-term analysis will provide further insights of the overall impact of the activity.

Conclusions: The pilot CSE intervention increased the knowledge and attitudes of the students involved. Additional insights will be available after study completion. Findings from this study will contribute to evaluate the effects of CSE initiatives on sexual health knowledge and attitudes among Italian secondary schools students, as well as the effectiveness of such programs in fostering healthier behaviours.

Key messages:

- Providing evidence-based, relevant information and education on sexual health to young people in secondary schools increases their knowledge and improves attitudes towards sexuality.
- CSE should be included in Italian school curricula in order to promote an incremental uptake of information and to improve young people's sexual health.

Introduction: Up to 40% of cancer cases could be avoided through effective primary prevention. However, cancer prevention tends to be fragmented across Europe, leading to geographical health differences. The dissemination and scale-up of effective primary cancer prevention interventions may address this. Although effective cancer prevention programs exist, finding them and their materials (especially regarding implementation) can be challenging. Repositories of evidence-based interventions provide insight into "what is out there" and can support dissemination within and across national borders. The PIECES project aims to develop and disseminate a repository of evidence-based primary cancer prevention programs adaptable to European contexts, with information to aid adaptation and implementation across countries.

Methods: The development of the PIECES repository has been informed by established repositories such as NCI's Evidence-Based Cancer Control Programs. The project team developed a scoring sheet with a selection of items that could be included in the repository. All participants rated each item on relevance and applicability and provided comments and suggestions. A final framework, including a set of minimal requirement items, was agreed upon during three online consensus building meetings.

Results: We created a repository of evidence-based primary cancer prevention interventions targeting modifiable risk factors suitable for implementation in European healthcare settings. This 22-item repository provides information about an intervention's logic model, implementation practices, and appraisal of published evidence of effectiveness.

Conclusions: This repository is innovative as it includes practical information and tools to facilitate implementation. While initially built to serve the PIECES project, the repository is designed to be a valuable tool for European policymakers, researchers, and implementers. Lessons learned from this process will inform future developers.

Key messages:

- A comprehensive cancer prevention intervention repository avoids "reinventing the wheel" and allows for more efficient use of existing interventions by building upon the best available evidence.

- The ongoing efforts of the PIECES project represent a significant contribution to reduce cancer prevention disparities and to facilitate the adoption of evidence-based interventions in Europe.

Visualizing patterns of factors influencing school health promotion implementation

Katharina Sterr

K Sterr[1], *F Butscher*[1], *S Blaschke*[1]
[1]Department of Health and Sport Sciences, TUM School of Medicine and Health, Technical University of Munich, Munich, Germany
Contact: katharina.sterr@tum.de

Background: The school setting offers a special opportunity for health-promotion (HP) interventions, as children spend 1/3 of their daily time there. Yet, implementing HP remains challenging due to the complexity of schools and unique contextual factors influencing implementation. While common influencing factors have been described, the aim of this study is to explore how influencing factors co-occur within and vary across schools, forming potential patterns of barriers and facilitators.

Methods: As part of a school HP program involving 258 institutions across Germany, nine schools were selected using maximum heterogeneity sampling for in-depth interviews on influencing factors by employing the Consolidated Framework for Implementation Research (CFIR). The interviews were transcribed verbatim and analyzed deductively using the CFIR as category system. Identified influencing factors were quantified [-5; +5] whether being a major barrier (-5) or a major facilitator (+5). To visualize potential patterns, a matrix heat map (MHM) displaying all influencing factors across all schools was created.

Preliminary results: Influencing factors in almost all CFIR categories were identified and all schools reported factors as barriers, such as parental engagement or (in)sufficient time. From the MHM, patterns of influencing factors, co-occurring within and differing across schools, emerged. For instance, some schools found the physical environment to be a barrier, while others considered it a facilitator, often in conjunction with financing as another facilitator.

Conclusions: Qualitative analysis and visualization of results with a MHM served as a way to navigate the complexity of the school setting and to highlight patterns of factors influencing implementation. Understanding these patterns can enhance tailoring implementation strategies, thereby improve implementation of school HP interventions and, ultimately, foster child health outcomes.

Key messages:
- Influencing factors for school HP implementation manifest in varied patterns of barriers and facilitators across schools, which has implications for tailoring implementation strategies.
- Using qualitative analysis guided by the CFIR and a MHM for visualization can aid in navigating the complexity of schools.

Abstract citation ID: ckae144.1804
Burnout and perceived stress among health visitors in Hungary

Anikó Gyulai

A Gyulai[1], *A Ötvös*[1], *E Kiss-Tóth*[1], *A Rucska*[1], *P Szokol*[2], *CS Lakatos*[1]
[1]Faculty of Health Sciences, University of Miskolc, Miskolc, Hungary
[2]Faculty of Informatics, University of Debrecen, Debrecen, Hungary
Contact: aniko.gyulai@uni-miskolc.hu

Background: In Hungary, the health visitors are responsible for the health promotion of families and communities. However, as a consequence of the structural reorganization of the health visitors service and the emotionally situations (e.g. the war in a neighboring country, the economic crisis) that have arisen, there has been an increased prevalence of chronic stress, burnout and career abandonment among health visitors. The objective of the cross-sectional study was to ascertain the prevalence of burnout among health visitors and to examine the relationship between burnout and job stress.

Methods: The data was collected via an online questionnaire tool. In addition to questions pertaining to sociodemographic data, the questionnaire employed the Maslach Burnout Inventory (MBI Human Services Survey) and the Perceived Stress Scale (PSS). Hypotheses were tested using analysis of variance (ANOVA), Kruskal-Wallis test, Dunett test. The source population of the study was health visitors. A total of 178 health visitors constituted the target population.

Results: The average age of the study participants was 45.2 years. It can be observed that health visitors who perceive less appreciation from their colleagues, employers and caregivers are more likely to experience higher levels of burnout and stress ($p < 0.05$). The lowest levels of stress were observed in school health visitors, while the highest levels were seen in health visitors covering villages ($p < 0.05$). Those who remained in the field due to a passion for working with families and children, a sense of vocation, and a desire to help others exhibited lower levels of burnout ($p < 0.05$). The high number of clients served by health visitors was found to increase burnout and stress levels ($p < 0.05$).

Conclusions: The findings of this research will assist in the comprehension of the phenomenon of burnout among health visitors, thereby enabling the development of more efficacious methods for the treatment and prevention.

Key messages:
- Preventing burnout among health visitors is a priority, as it affects their work and their relationship with the families they care for in the short and long term.
- Health visitors frequently encounter families in crisis during the course of their work, necessitating regular supervision to maintain their mental health.

Abstract citation ID: ckae144.1805
Hindering factors of pneumococcal vaccination: a survey among an Italian university hospital staff

Giulia Congedo

G Congedo[1], *F Pattavina*[2], *R Mancini*[1], *C Cadeddu*[3], *S Bruno*[1,2], *D Pascucci*[1,2], *U Moscato*[1,2], *P Laurenti*[1,2]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, RM, Rome, Italy
[2]Policlinico Universitario A. Gemelli, IRCCS Foundation, Rome, Italy
[3]Erasmus School of Health Policy and Management, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: giulia9134@gmail.com

Background: The pneumococcal vaccination targets individuals aged over 65 and people with chronic conditions. Data on vaccination coverage among healthcare workers are generally lacking. Our goal is to assess the knowledge and behaviors of a sample of Italian healthcare workers and administrative staff to understand barriers to pneumococcal vaccination like vaccine hesitancy.

Methods: From February to May 2024, an anonymous online validated questionnaire was administered to a sample of Italian healthcare workers and administrative staff at the Policlinico Universitario A. Gemelli in Rome. Descriptive and inferential statistical analyses are performed using the STATA 16 software.

Results: 1042 participants completed the questionnaire. Preliminary descriptive analysis shows that the majority are women (69.4%). 20.5% of respondents are medical doctors, 23.3% administrative staff, 39.6% nurses or obstetricians, 1.6% rehabilitative healthcare professionals, 5.7% technical healthcare professionals and 4.1% preventive healthcare professionals. 27.8% among healthcare workers and 28.11% among administrative staff suffer from chronic illnesses. 27.6% of respondents are unaware of the health effects caused by acquiring pneumococcal infection. Although initial inferential analyses seem to show a generally positive trend regarding vaccine awareness, some categories appear to demonstrate a potential underestimation of the importance of vaccination against the spread of infectious diseases. It even appears that some of the interviewees consider the complications of the disease less serious than the risk of severe adverse effects of vaccines.

Conclusions: Although further analysis is needed, preliminary results seem to highlight some knowledge gap that could lead to a certain degree of vaccine hesitancy among partecipants. In this case, it would be crucial to promote educational activities that increase hospital staff's vaccine adhesion in order to improve their health and the patients'one.

Key messages:

- A pneumococcal vaccine hesitancy rate may exists among an Italian university hospital staff.
- It is crucial to boost healthcare workers' awareness and knowledge about pneumococcal vaccination benefits.

Abstract citation ID: ckae144.1806
Sexual health communication targeting adolescents in public service Media: the case of Finland

Ronja Abrams

R Abrams[1], *J Nordmyr*[1], *K Gunnarsson*[2], *AK Forsman*[1]
[1]Health Sciences, Åbo Akademi University, Vasa, Finland
[2]Department of Education, Stockholm University, Stockholm, Sweden
Contact: ronja.abrams@abo.fi

Background: Given the substantial time adolescents spend online, sexual health promotion and education through online media constitute a promising public health action. However, monitoring of sexual health-related online media content is warranted, and considering the scope and aims of public service media, this forum can be regarded as being of particular interest. This study aimed to analyze how and to what extent sexuality and sexual health-related content targeting adolescents is communicated and portrayed in public service media in Finland, with a particular interest in health promotion perspectives and participatory practices.

Methods: Based on predetermined inclusion criteria and guidance from professionals at the Finnish public service company Yle, podcasts were specified as the media format of interest. Three Finnish podcasts (a total of 66 episodes) produced during the years 2021-2023, targeting young people and focusing on sexual health, were included in this study and subject to critical content analysis.

Results: Most podcast episodes focused equally on the sexual health resource and risk perspectives, while a third emphasized a resource perspective. Concerning participatory practices, adolescents participate in only five episodes in total, and most often, the podcast hosts' own experiences are at the center of the episodes.

Conclusions: The findings highlight how sexuality and sexual health content is communicated in public service media podcasts targeting adolescents in Finland, as well as how the communication aligns with health education and promotion guidelines. The study sheds light on participatory practices, emphasizing a lack of stakeholder involvement, i.e., dialogue between podcast hosts and listeners. Results carry implications for developing sexual health promotion through public service media targeting young people in Finland and other European countries alike.

Key messages:

- The findings highlight how sexuality and sexual health content is portrayed in public service media podcasts in Finland and how the communication aligns with health promotion values and principles.
- The findings show a lack of participatory practices in Finnish public service media podcasts targeting adolescent sexual health - a health promotion concern also pertinent to other countries.

Abstract citation ID: ckae144.1807
Barriers and facilitators of implementing a health literacy-based intervention in Portugal

Ana Gama

A Gama[1], *W Kinaan*[1], *P Marques*[1], *R Peruhype*[1], *S Dias*[1]
[1]NOVA National School of Public Health, PHRC, CHRC, REAL, NOVA University Lisbon, Lisbon, Portugal
Contact: ana.gama@ensp.unl.pt

Background: Despite the effectiveness of cervical cancer screening (CCS) in reducing mortality rates, disparities persist in access to screening among women with low health literacy, often termed 'hard-to-reach women'. Health literacy-based interventions can help promote screening uptake. Based on a health literacy-based intervention for CCS implemented in Lisbon with the support of community workers, this study explores barriers and facilitators of the implementation process as perceived by these actors.

Methods: The intervention consisted of educational sessions on cervical cancer and CCS aimed at 246 women, implemented in community settings in 2023-2024. Within a mixed-methods approach, a pre-and post-intervention survey was applied to assess willingness to screen, and two focus groups were conducted with 10 community workers on their implementation experiences. Descriptive analysis and content analysis were performed where appropriate.

Results: Of the 665 women invited, 37% were enrolled in the sessions; 91% completed the follow-up. Community workers valued the informative content as adequate to raise awareness. Implementation facilitators included women's trust in collaborating organisations and a complement of peer recruitment. Challenges included the additional workload of community workers, finding creative strategies to engage women, scheduling the sessions that best suited women's time demands, and limited spaces to accommodate several group sessions. Proposed solutions to overcome barriers included increasing the time availability of community workers to support participants' recruitment and session delivery, conducting itinerant and open sessions, and integrating the sessions within the organisation's health-promoting activities.

Conclusions: Health literacy-based interventions are helpful in raising CCS awareness. Tailored interventions sensitive to context demands may contribute to successful actions.

Key messages:

- Health literacy interventions can be key to promoting cervical cancer screening among hard-to-reach women.
- Tailored community-based interventions may help address barriers to cervical cancer screening.

Background: The COVID-19 pandemic has highlighted the need for equitable and timely access to vaccination. Limited evidence is available on how to implement vaccination campaigns (VCs) that are sustainable and responsive to changes in real-world health policy and practice contexts. We present lessons learned from the implementation of a COVID-19 VC in the Boeny region of Madagascar.
Methods: Informed by the Dynamic Sustainability Framework, VC implementation was continuously reviewed during multisectoral stakeholder feedback rounds, key informant interviews, and problem-solving meetings to identify and put key adaptations throughout the campaign process into practice. Outcome indicators include pre- and post-VC vaccine hesitancy and trends in vaccine doses deployed were analyzed using generalized linear models.
Results: Key adaptations of the implementation strategy included community-led awareness-raising and outreach activities also in remote areas, strengthening VC through the training of 340 staff, and addressing gaps identified in the cold chain, waste management, vaccine transportation, and IT equipment. Overall, 24888 COVID-19 vaccines were administered in six months. Changes in campaign strategy increased the number of doses administered by 8% (RR = 1.08; CI 95%: 1.01; 1.15) per week. No changes in vaccine hesitancy post-VC were observed in an unvaccinated population ($\Delta = 0.02$, CI 95%: -0.04; 0.08).
Conclusions: Collaborative and dynamic multi-sectoral VC strategies that combine healthcare-based approaches with pro-active outreach and community-led awareness-raising activities are essential in increasing vaccine uptake in limited-resource settings. Our findings show that despite boosting vaccination coverage, such initiatives may not have an impact on COVID-19 vaccine hesitancy at the community level

Key messages:

- Multisectoral stakeholder collaboration and engagement are key to successful vaccination campaign implementation.
- A Dynamic Sustainability Framework approach can be effective in ensuring a continuous fit between campaign and its setting.

Abstract citation ID: ckae144.1809

Vaccines are coming closer to you: the experience of the Corporate Healthcare Company (ASL) Rome 4

Maria Teresa Sinopoli

MT Sinopoli[1], C Fusillo[1], D Scognamiglio[1], G Belfiori[1], M Marini[1], L Razzetti[1], S Ursino[1], C Matranga[1]
[1]ASL Roma 4, Civitavecchia, Italy
Contact: mtsinopoli@alice.it

Issue: The post-Covid period is characterised by vaccine fatigue and declining coverage, especially among children. Access to vaccination for adults and the elderly, outside of the influenza vaccination campaign, has historically been very low due to limited awareness of opportunities and difficulties in accessing vaccination centres.
Description of the problem: ASL Roma 4 is characterised by a dispersed population across a large territory of 28 municipalities, many of which are small and predominantly populated by elderly people. In order to reach this population, 'proximity clinics' were opened in 6 small municipalities in 2023, where the vaccination service offers a wide range of vaccines every 1-2 months. Since June 2023, two mobile vaccination units have also been used to extend the reach of vaccination activities.
Results: In 2023, vaccination activities at nearby clinics reached 343 people (166 males and 177 females), with a total of 473 vaccines administered. More than 70% of those vaccinated were over 65 years of age, including 47% over 80 years of age. Between September and December 2023, vaccination vans were deployed in high-traffic areas such as markets, supermarkets, squares, or in locations with hard-to-reach populations such as migrant reception centres, volunteer centres, and senior centres. As a result, 1183 people (585 men and 557 women) with an average age of 49 years were reached and 1699 vaccines were administered. 62% were over 65, 37% over 80, 41 were homeless and 87 were migrants. 56% of the vaccines administered were influenza and covid, but all types were provided.
Lessons: Although this method of vaccine delivery is still being implemented, its value lies mainly in vaccinating people who would not have voluntarily sought vaccination services, demonstrating the need to bring prevention as close to the user as possible.

Key messages:

- The post-Covid period is characterised by vaccine fatigue and declining coverage.
- It is necessary to bring vaccination prevention as close to the user as possible.

Abstract citation ID: ckae144.1810

The Icehearts Europe Implementation Guide to promote a mentoring programme for youth mental health

Giovanni Capelli

M Valli[1], I Luzi[1], A Gigantesco[2], D Del Re[2], I Cascavilla[2], P Faella[1,3], A Iannaccone[3], C Ponchon[4], D Conti[5], G Capelli[1]
[1]National Center for Disease Prevention and Health Promotion, Italian National Institute of Health, Rome, Italy
[2]Center for Behavioural Sciences and Mental Health, Italian National Institute of Health, Rome, Italy
[3]Department of Human Sciences Society and Health, University of Cassino and Southern Lazio, Cassino, Italy
[4]International Sport and Culture Association, Copenhagen, Denmark
[5]Italian Union of Sport for All, Rome, Italy
Contact: giovanni.capelli@iss.it

Issue/problem: In Europe, 9 million young people (10-19) suffer from mental disorders and 70% of children and adolescents with mental health problems do not receive appropriate interventions at a sufficiently early age. Moreover, during the Covid-19 pandemic a high prevalence of depressive symptoms, anxiety and sleep disorders was observed in the population aged 4-19 years. The Icehearts Europe project (funding: EU4Health 2022 Programme) aims to disseminate at EU level a long-term programme for supporting health and wellbeing of disadvantaged children and adolescents. It is inspired by the Finnish best practice Icehearts, a 12-year long mentoring programme. Five pilot countries (Italy, Denmark, Spain, Slovenia, Estonia) will test the model to raise European awareness of how it works and to get more countries and organisations involved.
Description of the problem: Icehearts Europe is a preventive mentoring programme based on team sports, recreation and school support activities, with a child-centred community approach. To facilitate its implementation, a practical guide has been developed for grassroots sport and social promotion organisations to help them implement the model in their own contexts. The guide is the result of both a multisectoral cooperation between grassroots sport, health, universities, NGOs, and qualitative study activities (bibliographic research, study visit, group work, analysis of the situation and needs of local contexts).
Results: From February 2024 the Icehearts Europe Implementation Guide is available in six languages at https://www.icehearts.eu/resources. It is now being adapted by the Icehearts Europe partners into an online training programme for managers.
Lessons: The guide has incorporated lessons learnt from the Finnish model, considered as an evidence-based approach. It contains several operational tools to implement Icehearts Europe and

can be adopted using different approaches: there is no one-size-fits-all solution.

Key messages:

- Developed as a support to the Icehearts Europe piloting partners and as a basis for a fully-fledged online training programme for future Icehearts Europe managers.
- To facilitate the implementation of early interventions to promote health and wellbeing of children and adolescents and enable them to cope with disadvantaged conditions.

Abstract citation ID: ckae144.1811
Health promotion interventions for children and adolescents using e-health: a systematic review

Eunjeong Bae

E Bae[1,2], *M Jang*[3]
[1]College of Nursing, Yonsei University, Seoul, South Korea
[2]Brain Korea 21 FOUR Project, Yonsei University, Seoul, South Korea
[3]Department of Nursing, Yonsei University Graduate School, Seoul, South Korea
Contact: benjandsy@gmail.com

Background: The utilization of e-health in healthcare interventions has become increasingly prevalent due to its cost-effectiveness. Nevertheless, there is a paucity of evidence regarding the use of e-health in children, as the majority of e-health interventions are focused on adults. This study aimed to identify the components and effects of e-health intervention for the promotion of children's health and to suggest strategies for their implementation.

Methods: A systematic review was conducted in accordance with the PRISMA guidelines. A literature review of relevant studies published between January 2013 and November 2023 was conducted. A search of databases including PubMed, EMBASE, CINAHL, MEDLINE, and Cochrane Review Library was conducted using a combination of medical subject headings (MeSH) and keywords. A qualitative appraisal of the studies was conducted using the revised Cochrane risk-of-bias tool for randomized trials (RoB 2).

Results: Sixteen studies were selected. Most studies showed good methodological quality. The majority of studies ($n = 15$) focused on improving children's physical health, while only one study focused on mental health. There were a variety of components to the intervention, including internet education, web-based home-exercise, serious games, mobile apps, email counseling, and active video games, and only one type of intervention was provided, or a combination with additional methods such as phone calls and counseling. A review of the literature indicates that e-health interventions have been effective in increasing children's physical activity, reducing weight, relieving stress, and reducing depression.

Conclusions: This study identified the effectiveness of e-health interventions for improving children's physical and mental health. The use of e-health to promote children's health should be actively developed and implemented in a variety of clinical and community settings.

Key messages:

- E-health interventions have been demonstrated to be an effective means of improving the physical and mental health of children and adolescents.
- It is recommended that health promotion interventions utilizing e-health be developed and tested in a variety of communities and settings for children and adolescents.

Abstract citation ID: ckae144.1812
School teachers' perceptions of intersectoral working with health in the COVID-19 pandemic

Nicola J Gray

NJ Gray[1], *S Manandhar*[2], *C Chabot*[3], *M-C Tsai*[1], *D Jourdan*[3]
[1]UNESCO Chair 'Global Health & Education', University of Huddersfield, Huddersfield, UK
[2]School of Human and Health Sciences, University of Huddersfield, Huddersfield, UK
[3]UNESCO Chair 'Global Health & Education', Université Clermont Auvergne, Paris, France
Contact: N.J.Gray@hud.ac.uk

Background: The COVID-19 pandemic highlighted the challenge for teachers to integrate protective health measures into their academic daily responsibilities. The aim of this abstract is to analyse how school teachers' views on intersectoral collaboration with health professionals during COVID-19 vary by country, seeking insights for future directions.

Methods: In 2021, an online survey was conducted in 6 languages with education and health professionals, followed by optional online semi-structured interviews. We explored the: 1-effect of the pandemic on schools/pupils/teachers; 2-reorganisation of schools; 3-experience of implementing infection control measures in schools; 4-intersectoral working; 5-important resources for keeping schools open. Interviews were transcribed verbatim and translated into English. Analysis of a survey question seeking professionals' rating of intersectoral working led to a directed content analysis of transcripts and free-text survey responses regarding intersectoral working experiences.

Results: Data were analysed from 1046 school teacher survey responses from 6 countries/territories and 21 follow-up interviews. Ratings varied considerably across countries. A large majority of teachers in Taipei (83%) reported excellent or good collaboration with health professionals, about half in China (53%) and Portugal (51%), and far fewer in Brazil (38%), Morocco (29%) and France (15%). Taipei respondents cited the key role of school nurses as a positive factor; others added clear national guidelines and local protocols. Negative ratings related to health professionals' rare visits or absence.

Conclusions: The direct support of health professionals in schools was offered as explanation for teachers' positive ratings of intersectoral working in the pandemic. Policy and practice varied geographically; thus, understanding contextual factors that influence the effectiveness of intersectoral working in schools is crucial to orient future public health strategies.

Key messages:

- This highlights the importance of understanding contextual factors that influence the effectiveness of intersectoral working in implementing protective health measures in schools.
- This suggests that policy support and the presence of dedicated health personnel within schools play a pivotal role in ensuring effective collaboration between the education and health sectors.

Key Factors Influencing Quality of Life in the Disabled Based on Multifaceted Life Satisfaction

Eun Hye Choi

EH Choi[1], *JH Cho*[1], *KE Yeob*[1,2], *SY Kim*[1,2,3], *YS Lee*[1,4], *JH Park*[1,2,4]
[1]Chungcheongbuk-do Public Health Policy Institute, Chungcheongbuk-do, South Korea
[2]Institute of Health & Science Convergence, Chungbuk National University, Chungcheongbuk-do, South Korea
[3]Department of Public Health and Preventive Medicine, Chungbuk National University Hospital, Chungcheongbuk-do, South Korea
[4]College of Medicine, Chungbuk National University, Chungcheongbuk-do, South Korea
Contact: cehope16@gmail.com

Background: Healthy life of the disabled is considered a global social issue, and enhancing the quality of life (QoL) of the disabled is an important task. The disabled have lower multifaceted life satisfaction due to various daily restrictions, which negatively affects their QoL. Research on the QoL of the disabled is ongoing, but there are few comprehensive studies addressing multifaceted life satisfaction. To enhance the QoL of the disabled, it is essential to understand their multifaceted life satisfaction and investigate key factors influencing their QoL.

Methods: We used data from the 2021 Disability and Life Dynamics Panel (nationwide survey). On the base of Patrick's model of disability health promotion, we analyzed the impact of multifaceted life satisfaction of the disabled on their QoL by using multiple regression analysis adjusted for gender, age, education level, daily living activities, type and severity of disability, and presence of multiple disabilities.

Results: The satisfaction with social relationships(β=.535, $p<.0001$), income(β=.146, $p<.0001$), housing environment(β=.132, $p<.0001$), occupation(β=.130, $p<.0001$), and health(β=.111, $p<.0001$) was found to have a significant positive impact on the QoL of the disabled. Particularly, satisfaction with social relationships exerted the greatest impact on their QoL.

Conclusions: Not only health satisfaction, but also social relations, income, housing environment, occupation had a substantial impact on the QoL of the disabled. These findings can support the government in prioritizing health policy development for the disabled and contribute to improving the QoL for the disabled through a comprehensive and integrated approach. The government should develop health policies to enhance social connections and support networks for the disabled, while also considering aspects for improving income, housing environment, occupation, and health.

Key messages:

- Not only health satisfaction, but also social relations, income, housing environment, occupation had a substantial impact on the QoL of the disabled.
- The government should prioritize developing health policies aimed at enhancing social relations for the disabled, while also considering income, housing environment, occupation, and health.

Abstract citation ID: ckae144.1814
Adapting, expanding and embedding community and culture into health ecosystems

Joanne Trigwell

J Trigwell[1], *M Gamsu*[1], *AM Bagnall*[1], *J South*[1], *O Mosteanu*[2], *B Redwood-Turner*[3], *M Bharadwa*[3], *J Harris*[4]
[1]Centre for Health Promotion Research, Leeds Beckett University, Leeds, UK

[3]Locality, London, UK
[4]School of Medicine and Population Health, University of Sheffield, Sheffield, UK
Contact: j.trigwell@leedsbeckett.ac.uk

Background: Community anchor organisations (CAOs) work with communities who experience health inequalities and disadvantage, providing a range of activities and services to meet individuals' needs in an integrated way. This study explored how CAOs use art, cultural and nature-based activities as part of their work to respond to the needs of people facing inequalities and considered how activities can be scaled in this health setting.

Methods: This study used community-based participatory research within a case study approach to work with four purposively sampled CAOs. Participants were community members, volunteers, staff, trustees, partner organisations and commissioners. Data collection methods included: document analysis, interviews ($n=45$), workshops ($n=5$) and focus groups ($n=11$). This study was also supported by data collected by trained community researchers ($n=18$). Framework analysis was conducted for within- and cross-case analysis.

Results: In the context of CAOs, the delivery of art, cultural and nature-based activities were found to be an important mechanism for developing trusted relationships with marginalised groups, who may lack trust in statutory services and health focused activities. Other facilitators to community engagement were the CAOs' longevity, localness and co-location of services within a trusted and familiar place that connect people to personalised support. Barriers to scaling up included funding models as well as insufficient dialogue and understanding between CAOs and the local public health ecosystem.

Conclusions: CAOs have long term trusted relationships with disadvantaged communities and are influential in connecting individuals with projects and services. Findings suggest that the effectiveness of action to address inequality through art, cultural and nature-based activities could be improved if the role of CAOs was recognised more coherently in place-based public health plans.

Key messages:

- Creative activities enable meaningful engagement with disadvantaged groups within place-based settings.
- CAOs must be recognised more coherently in place-based strategies to reduce health inequalities.

Abstract citation ID: ckae144.1815
Health-promoting school. Mediation effects on health behaviors and the socio-economic level of pupils

Carine Simar

C Simar[1], *R Coudert Chevreau*[1], *M Monier*[1], *PH Cury*[1], *J Pironom*[1]
[1]UR4281, Clermont Auvergne University, Chamalières, France
Contact: carine.simar@uca.fr

Pupils health indicators and behaviors are marked by social and territorial inequalities which develop early (DREES, 2015, 2019). In order to combat these inequalities and improve the health behaviors and well-being of pupils, the "health-promoting school" approach is recognized as convincing. It is endorsed by the World Health Organization (Langford, 2015; WHO, 2021). The health policy currently implemented in French schools is convergent (MEN, 2018, 2021). In order to disseminate this policy, since 2019, the Alliance project has been implemented in 101 French schools (9 - 12 years old) and 97 municipalities in the AURA region. Each school and community are trained and supported to promote the development of professional practices and a health promotion project to improve the health behaviors of pupils. The question arises as to the extent to which the development of health-promoting teaching projects and practices participating in the strengthening of health protective factors - life skills and health literacy - of pupils would have a mediating effect from the point of view of socio-economic level and health behaviors of pupils? Each year, data are collected from pupils by questionnaire, mesuring their well-being, health habits, psychosocial competencies and their families' socio-economic level. 11500 questionnaires collected during 3 years have been analyzed. Descriptive and bivariate analysis indicate sevreral improvements between years in their health habits like for example daily physical activities (6% for T0 and 16% for T2) or daily consumption of sweets (17% for T0 and 13% for T2). They confirm negative influence of risk factors as low socio-economic level on health habits. But mediation analysis show that psychosocial competencies, especially emotionnal and social competencies, mediate significatively this influence (mediation effect range from 5% to 21%).

Key messages:

- The health indicators and behaviors of young people are marked very early on by social and territorial health inequalities.
- Health-promoting school approach and particularly – life skills and health literacy – would have a mediation effect on health behaviors and the socio-economic level of students.

[3]CINTESIS, Porto, Portugal
Contact: andreia.kaji3@gmail.com

Background: One of the main causes of death in developed societies are chronic non-communicable diseases, often originated by risky behaviors as tobacco consumption, poor diet, excessive alcohol consumption and lack of physical activity. Changing lifestyles can thus lead to a reduction in chronic diseases and in their economic costs. The objective of this study is to understand what the main factors associated with health behaviors are.

Methods: We used the data collected through the Portuguese National Health Surveys from 2014 and 2019. The sample analyzed was composed of individuals aged 15 or more years old living in the national territory at the time the surveys were conducted. Data on demographics, socio-economic variables and health related variables was used. A maximum likelihood estimation was performed using a multivariate probit model, by using health behaviors (weekly exercise, healthy diet, non-smoking, and prudent alcohol consumption) as the outcomes of the analysis.

Results: The results point to a strong association between social class and health behaviors, particularly between higher income and healthy diet. It is important to highlight that having an appointment with a General Practitioner is positively associated with all healthy behaviors. For all behaviors but healthy diet, the coefficients are statistically significant at a 5% significance level and non-smoking displays the highest one (0.135).

Conclusions: This study presents the first step to understand the determinants of health prevention behaviors, which is important to design policies targeting lifestyles. One of its main conclusions indicates that social class (income and education) and GP appointments are associated with health behaviors. Further research would be needed to study the underlying mechanisms through which some of these factors impact behaviors. This presentation was supported by National Funds through FCT, I.P., within CINTESIS, R&D Unit (reference UIDB/4255/2020).

Key messages:

- This study is an important step in the formulation of policies targeting lifestyles since it allows us to understand which factors are associated with health behaviors.
- From this study one can conclude that social class characteristics, particularly income, and access to GP appointments are associated positively with health behaviors.

Contact: maria.joao.mrqs@gmail.com

Background: Loneliness and social isolation are increasing among young people, particularly those in vulnerable NEET (Not in Education, Employment or Training) situations, potentially leading to poor health and well-being outcomes. We aim to explore these challenges from the perspective of NEET youngsters and link workers who support them in co-creating individual action plans for their social and economic integration.

Methods: Data were collected through in-depth and semi-structured interviews with 15 young people in NEET situations, aged 18-34, and 7 link workers from several social organisations in rural and urban areas in Portugal. The young participants were selected based on their age, educational level, mental health needs, and urban/rural regions. Thematic analysis was used to analyse the interviews.

Results: The results showed a convergence between the perspectives of young people and link workers on the factors that influence social isolation and loneliness, including social and emotional skill deficits, excessive use of social media platforms, and mental health problems. Young people reported to being heavily involved in social media platforms, which often did not translate into meaningful relationships in real life. Youngsters also highlighted the lack of local support and community resources in rural areas. Link workers identified specific challenges young migrants face in community integration, including language barriers (for the youth with a migrant origin) and lack of familiarity with local resources.

Conclusions: This study highlights social media platforms, mental health and social and emotional skill deficits as main factors contributing to the social isolation and loneliness of young people in a NEET situation. This emphasizes the importance of integrated proximity-based interventions that incorporate community resource mapping and local support networks, including mental health support services, and promote multi-sector collaboration.

Key messages:

- Social media platforms, mental health needs, and social and emotional skill deficits drive social isolation in NEET youth, stressing integrated, community-focused interventions.
- Proximity-based strategies with community mapping and mental health support enhance NEET youths' social integration, urging cross-sector collaboration.

Factors Influencing Quality of Life in the Disabled: Focus on Household Members Mental Health

Eun Hye Choi

EH Choi[1], *JH Cho*[1], *KE Yeob*[1,2], *SY Kim*[1,2,3], *YS Lee*[1,4], *JH Park*[1,2,4]
[1]Chungcheongbuk-do Public Health Policy Institute, Chungcheongbuk-do, South Korea
[2]Institute of Health & Science Convergence, Chungbuk National University, Chungcheongbuk-do, South Korea
[3]Department of Public Health and Preventive Medicine, Chungbuk National University Hospital, Chungcheongbuk-do, South Korea
[4]College of Medicine, Chungbuk National University, Chungcheongbuk-do, South Korea
Contact: cehope16@gmail.com

Background: Household members of the disabled experience various difficulties such as social isolation and the burden of caregiving. These difficulties can lead to mental health problems, which in turn affect the quality of life(QoL) of the disabled. Research on the QoL of the disabled is ongoing, but there are few studies addressing the mental health of household members. We aimed to investigate the impact of household members' mental health on the QoL of the disabled.

Methods: We used data from the 2021 Disability and Life Dynamics Panel(nationwide survey). On the base of Patrick's model of disability health promotion, we analyzed the impact of household members' mental health on the QoL of the disabled by using correlation analysis and multiple regression analysis adjusted for gender, age, income level, employment status, education level, activities of daily living, participation in social activities, type and severity of disability, presence of multiple disabilities, and health status.

Results: The level of depression(r=-.316, p<.0001) and self-esteem (r=.248, p<.0001) of household members were found to be significantly correlated with the QoL of the disabled. The level of depression of household members had a significant negative impact on the QoL of the disabled(β=-.153, p<.0001), while self-esteem had a significant positive impact(β=.144, p<.0001). It was found that the level of depression had a greater impact on QoL than self-esteem.

Conclusions: Lower levels of depression and higher levels of self-esteem of household members are associated with higher QoL for the disabled. Improving the mental health of household members is crucial in improving the QoL of the disabled, enabling them to interact more positively with society. Additionally, as 27% of household members experience depressive issues, enhancing their mental health positively impacts on the overall well-being of families with disabilities. Efforts to enhance household members' mental health are crucial.

Key messages:

- Household members' mental health significantly influences the quality of life of the disabled.
- To improve the quality of life of the disabled, strengthening programs for promoting the mental health of household members and policy improvements are necessary.

Abstract citation ID: ckae144.1819
Cardiac risk confrontation in primary care as a teachable moment towards improved health outcomes

Michelle Brust

LM Gefeke[1], M Brust[2], NE Van Hattum[2], JC Kiefte-de Jong[2]
[1]Health, Medical and Neuropsychology Unit, Institute of Psychology, Leiden University, Leiden, Netherlands
[2]Department of Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands
Contact: m.brust@lumc.nl

Background: Urgent life events, such as acute coronary events, can evoke a teachable moment (TM) for lifestyle change. This study aims to investigate whether less urgent events, such as being confronted with an increased risk of cardiovascular disease, can evoke a TM, what psychosocial factors are associated with it, and whether experiencing such a TM predicts improved health outcomes.

Methods: The study included 114 patients who were informed about their elevated cardiovascular risk during a primary care visit. Participants completed a survey assessing whether they experienced a TM and several psychosocial factors linked to experiencing it: perceived risk, affective impact, changed self-concept. Participants monitored their weight and blood pressure for six months using an at-home self-monitoring device. Univariate and multivariate regression analyses were conducted to examine the associations between the psychosocial factors and the lifestyle change intentions with changes in blood pressure and weight.

Results: Of the participants, 55.3% experienced increased lifestyle change intentions. Lower risk perception ((B = -0.27; CI = -0.39-(-0.15)) and higher change in self-concept (B = 0.34; CI = 0.23-0.44) were associated with higher intention to change lifestyle. Higher risk perception (B = 0.23; CI = 0.06-0.42) and higher change in self-concept (B = 0.54; CI = 0.37-0.72) predicted a lower weight reduction at six months. A higher change in self-concept predicted a higher blood pressure reduction (B = -3.32; CI = -6.55-(0.09)). Lastly, a higher lifestyle change intention predicted bigger reductions blood pressure (B = -5.04; CI = -9.08-(-0.29)).

Conclusions: Results suggest that less urgent cardiac events, such as a confrontation with an increased cardiac risk, can be experienced as a TM that urges lifestyle change intentions and affects health outcomes. Risk confrontations in primary care therefore offer a unique opportunity to provide lifestyle counseling at the right moment.

Key messages:

- A confrontation with an increased cardiac risk in primary care can be experienced as a teachable moment.
- Experiencing a teachable moment after a cardiac risk confrontation in primary care affects health outcomes.

Abstract citation ID: ckae144.1820
Trends in overall and abdominal obesity among Korean adults, 2007-2022: an Age-period-cohort analysis

Dabin Jeong

D Jeong[1,2], G Jo[3], H Oh[1,2,4]
[1]Department of Public Health Sciences, Korea University, Seoul, South Korea
[2]Interdisciplinary Program in Precision Public Health, Graduate School of Korea University, Seoul, South Korea
[3]Institute for Bio Materials, Korea University, Seoul, South Korea
[4]Division of Health Policy and Management, Korea University, Seoul, South Korea
Contact: dbjeong@korea.ac.kr

Overall and abdominal obesity, often defined as having high body mass index (BMI) and waist circumference (WC), are associated with an increased risk of chronic disease. A comprehensive understanding of trends and contributing factors is necessary to reduce the disease burdens. This study investigated the nationwide trends and independent effects of age, period, and birth cohort on BMI and WC in Korean adults. We conducted hierarchical age-period-cohort (cross-classified random-effects models) analyses using measured BMI and WC data from 85,292 Korean adults (aged $\geq$19) in the Korea National Health and Nutrition Examination Survey 2007-2022. We also examined whether the age, period, and cohort effects varied by socioeconomic subgroups. In 2007-2022, the age-standardized mean BMI (23.6 to 24.2 kg/m2) and WC (81.7 to 83.5 cm) increased in the overall population. An upward trend was evident among men, while only a slight change was observed in women. The mean BMI was highest at age 47 (25.1 kg/m2) in men and age 60 (24.2 kg/m2) in women and it decreased at older ages. Controlling for age and period effects, mean BMI was lowest among the birth cohorts of 1960-1964 (24.15 kg/m2), with the highest mean BMI observed among the birth cohorts of 1919-1939 (24.97 kg/m2) and 1990-2003 (24.99 kg/m2). The mean WC was highest at age 55 (88.0 cm) in men and age 79 (83.4 cm) in women. Similar U-shaped birth cohort effect was observed with WC, with the lowest mean observed among the birth cohorts of 1960-1964 [82.92 (0.30)]. At most age, period, and birth cohorts, mean BMI and WC were consistently higher among adults at lower income and education. The overall period effect was consistently found in all socioeconomic subgroups, but the gap in BMI between income and education subgroups widened over time. Our findings suggest that BMI and WC slightly increased in overall Korean adults in 2007-2022, with some inequalities among age, sex, birth cohort, and socioeconomic subgroups.

Key messages:

- The obesity indices increased from 2007 to 2022, but the cohort effect on BMI and WC showed a U-shaped pattern with the lowest mean among birth cohorts of 1960-1964.
- The obesity prevalence is varied by socioeconomic status, suggesting that more intense interventions may be needed to target the susceptible groups.

Development and Implementation of Health Education Tools for Excluded Areas in the Czech Republic

Hana Maršálková

H Maršálková[1], *E Volevach*[1,2], *M Ely*[1]
[1]International Clinical Research Center, St. Anne's University Hospital, Brno, Czechia
[2]Neurological Department, Masaryk University, Brno, Czechia
Contact: hana.marsalkova@fnusa.cz

Background: Reducing health inequalities among population groups is imperative, however, health communication strategies tailored to ethnic minorities remain under-researched. To address this issue, various health communication strategies were developed and tested within the 3 year Saste Roma project, focused on improving health literacy and disease prevention in the excluded Czech Roma population.

Methods: A planning group comprising of doctors, sociologists, psychologists, NGOs and community health workers was established to create tailored health communication tools. The tools were developed with consideration of the sociocultural specifics of the Roma community, using focus groups, in-depth interviews, and the Delphi method. A PR agency was hired to implement the tools. Reach, engagement and Price Per Click = PPC were measured for online tools; feedback on offline tools was collected via surveys and interviews.

Results: From April 2021 to March 2024, 12 online and offline tools addressing 10 diseases were developed for various age groups and implemented. These tools, such as health literacy brochures and leaflets (78,500 pcs distributed), music videoclips (viewed 150,000 times), a mobile application (with over 500 users), social media profiles dedicated to health (with 140 followers), preventative events, school-based e-learning modules (implemented in 86 elementary schools in excluded areas), online campaigns (reaching 556,337 people; PPC of 0.85 EUR in case of in-house campaign Vs. PPC of 3.21 EUR by PR agency) or poster campaigns (engaging 3,046 individuals) focusing on excluded areas.

Lessons: This project represents the first extensive use of diverse communication tools targeting the Roma population. The involvement of community representatives (patients, artists, actors, and residents) in tool development is crucial. Training and support for health community workers are essential to achieve effective engagement with the community.

Key messages:

- Tools must be delivered in a culturally sensitive and comprehensible manner by members of the communities.
- Commercial PR agencies failed with this specific campaign. Cooperation with Roma artists and influencers is essential.

Contact: d.clutterbuck@soton.ac.uk

Background: Long Covid (also known as Post-COVID19 Condition or Post-COVID Syndrome) is characterised by persistent symptoms following SARSCoV2 infection not explained by other pathology. Some evidence suggests that people from marginalised communities are more likely to experience Long Covid but are less likely to be represented in post-covid care in England.

Objectives: Findings from the STIMULATE-ICP case finding and HI-COVE studies show that some people living with Long Covid struggle to get adequate healthcare and social support. Barriers to obtaining support include a lack of awareness of Long Covid and supports available, uncertainty around the cause and complexity of symptoms, as well as experiences and expectations of stigma. The new Supporting Long Covid Care (SLCC) webtool was developed based on these findings and aimed to both facilitate help-seeking for people with probable Long Covid who are not receiving care and raise awareness among professionals. Extensive engagement with people with lived experience and professionals shaped the webtool. SLCC content was then beta-tested with stakeholders.

Results: SLCC (long-covid-care.org.uk) was launched in March 2024. One of its features is the acknowledgement that Long Covid can be a stigmatising condition. SLCC includes real-life quotes to connect emotionally with users, highlights the shared experiences of people living with Long Covid and illustrates the difficulties faced when seeking recognition and support. It encourages conversations with professionals, friends, family and others who may be relied on for support and offers resources to facilitate those conversations and inform next steps. SLCC is also an informative tool for healthcare professionals around Long Covid stigma.

Conclusions: SLCC is open to use by members of the public. Real-world evaluation and translation to other languages are now needed to explore if this webtool is beneficial and contributes towards addressing health inequalities.

Key messages:

- SLCC encourages people with probable Long Covid to seek help and support.
- SLCC raises awareness among healthcare professionals about the barriers and stigma people, particularly those from disadvantaged backgrounds, may face when considering reaching out for support.

Abstract citation ID: ckae144.1823
'HepGenç': A youth festival to promote health and well-being via films, photography, music, and arts

Ozge Karadag

O Karadag[1], *EN Orhon*[2], *S Karabey*[3]
[1]Faculty of Medicine, Bahcesehir University, Istanbul, Türkiye
[2]Faculty of Communication Sciences, Anadolu University, Eskisehir, Türkiye
[3]Faculty of Medicine, Istanbul University, Istanbul, Türkiye
Contact: ozgekaradag.2021@gmail.com

Background: The 'Lifelong Health' framework of WHO emphasizes that investing in health during young ages fosters better health and higher quality of life in later years. When working with and for youth, using innovative and participatory approaches have become more important for effective health communication, especially in an era of increased environmental stimuli, digitalization, and decreased attention span for many young people, who are less attracted with traditional/ didactic health education and communication methods.

Objectives: This paper aims to share practical experiences of a multidisciplinary team of professionals with backgrounds in public health, psychiatry, communication, music, and arts, in collaboration with young people to organize a series of youth health festivals in different cities of Turkiye to promote youth health literacy and access to health care, with a special focus on mental health and well-being.

Results: HepGenc (ForeverYoung) Festivals are organized by academics and youth from different universities in Turkiye, in collaboration with NGOs and local municipalities of cities, where the events take place. These events encourage young people to think about health and well-being, including social and environmental determinants of health via short films, photography, music, and arts. The series of festivals use creative workshops to introduce different health and well-being topics to youth, who may not always find these issues ‘attractive.’ Social and mental health, including resilience and ability to adapt are also addressed, which help young participants to build a holistic and comprehensive look on health and its determinants.

Conclusions: Organizing health-focused festivals using films, photography, music, and arts encourages young people to be creative and productive, while raising their awareness on healthy lifestyles and healthy cities, and how they can be agents of positive change.

Key messages:

- Using films, music, and arts help with greater engagement of young people and facilitates their learning, as well as their creativity and productivity.
- Collaboration of health, communication, and arts professionals strengthens health communication/ education programs, with additional beneficial outcomes for all disciplines including shared learning.

Abstract citation ID: ckae144.1824
Combined HIV prevention: knowledge and attitudes among higher education students in Portugal

Aliete Cunha-Oliveira

AP Holzmann[1], AP Forte Camarneiro[2], D Aparec Barbosa[3], A Cunha-Oliveira[2,4]
[1]Enfermagem, Universidade Estadual de Montes Claros, Montes Claros, Brazil
[2]Enfermagem, Escola Superior de Enfermagem, Coimbra, Portugal
[3]Enfermagem, Universidade Federal de São Paulo, São Paulo, Brazil
[4]Enfermagem, Escola Superior de Enfermagem, UICISAgação, Coimbra, Portugal
Contact: alietecunha@esenfc.pt

Introduction: Combined Prevention is a strategy that combines different methods of HIV prevention that can be used simultaneously or sequentially, depending on the characteristics and life stage of everyone. Among the methods are condom use, regular HIV testing, pre-exposure prophylaxis (PrEP), and post-exposure prophylaxis (PEP). Combined prevention is particularly important for more vulnerable groups, such as adolescents and young adults.

Objectives: To investigate the knowledge and attitudes related to combined HIV prevention among college students.

Methods: A cross-sectional study was conducted with college students from two institutions in a Portuguese city in the year 2022. Sampling was non-probabilistic, by convenience. Students aged 18 to 29 who had initiated sexual activity were included. The data collection instrument was a structured questionnaire sent to students online. Data were analyzed descriptively. Ethical aspects were respected.

Results: A total of 424 students participated in the study; majority were female (79.2%), white (92.9%), single (96.7%), Catholic (67.2%), with a mean age of 20.8 years (SD = 2.3). The number of sexual partners in the last semester ranged from none to 19, with an average of two partners (SD = 1.9). Nearly all students (94.3%) agreed that condoms are the main form of HIV prevention, however, 45.2% did not use condoms in their last casual sexual encounter. Only 15.5% and 13.9% of participants reported knowing about pre- and post-exposure prophylaxis, respectively. The majority had never been tested for HIV (81.8%) and did not know where tests could be done for free (70.9%).

Conclusions: Despite higher education, students are vulnerable to HIV and have unsatisfactory knowledge about combined prevention measures.

Key messages:

- College students are young individuals with high vulnerability to contracting HIV and other sexually transmitted infections.
- Universities should assume their role as promoters of health and develop strategies that contribute to students’ knowledge and reflection on HIV and its prevention methods.

Abstract citation ID: ckae144.1825
Association between fitness levels and physical activity in apparently healthy Colombian men

Natalia Stephany Morales Eraso

NS Morales Eraso[1], YP Caviativa Castro[1], MP Murcia Doncel[1], OF Rubiano Espinosa[2], V Jaramillo Guzmán[3]
[1]Research Vice-chancellorship, Manuela Beltrán University, Bogotá, Colombia

[3]Faculty of Education, Distrital University, Bogotá, Colombia
Contact: natalia.morales@docentes.umb.edu.co

Physical condition (PC) such as strength and endurance favor functional independence and disease prevention (Melo, 2014). Objective: To characterize the levels of Physical Activity (PA) and CP in apparently healthy men who practice PA in different settings in Bogotá-Colombia. This study is observational cross-sectional, 485 Men (M) participated, mean age 42±17.8 years. To measure the levels PA the IPAQ (International Physical Activity Questionnaires) was applied. The Confidence Interval (CI) and Standard Error (SE) were taken into account. For PA levels, data were analyzed with Rstudio v2022.12.0, with empirical distribution tests, Kolmogorov-Smirnov normality and independence with Chi-Square (χ^2), in addition, mean ($\bar{X}$), percentage (%) and standard deviation (±). 90.6% of the H met the overall PA recommendations (Leisure Time+Active Transportation) with 95% CI (88.0-93.0) and SE (0.012). The PC variables such as; Body Mass Index (BMI), Body Adiposity Index (BAI), Abdominal Circumference (AC), Grip Strength (GS) and Maximal Oxygen Consumption (Vo2max). The results showed that 35.6% (26.9±1.48) of H were Overweight (Ow) and 10.6% (32.7±2.39) were Obese (Ob), 39.7% (98.4±6.8) with Cardiovascular Risk (Rcv) by AC and 24.3% (29.7±3.45) with risk by BAI. As for GS 41.5% (27.1±6.39) is weak and 32.3% (33.3±6.3) is low Vo2max. According to independence tests with χ^2 there is association between the G and BMI (χ^2=1452.1, df = 1427, p-value=0. 315), G and AC (χ^2=394.9, df = 382, p-value=0. 313), G and Vo2max (χ^2=155.5, df = 6, p-value<2.2e-16), G and BAI (χ^2=2970.3, df = 1502, p-value<2.2e-16), G and GS (χ^2=6015.5, df = 1502, p-value<2.2e-16). This project was approved by the bioethics committee.

Conclusions: 149 men corresponding to 30.7% of the sample present an increased possibility of Rcv, despite compliance with global PA recommendations. It is recommended that PA programs reinforce the improvement and promotion of PC to prevent possible Rcv.

Key messages:

- The capacities that define physical fitness (FC) such as strength and endurance favor functional independence and disease prevention (Melo, 2014).
- Apparently healthy men in Colombia present a higher possibility of Cardiovascular Risk due to low levels of physical fitness, despite compliance with global BP recommendations.

Abstract citation ID: ckae144.1826
Evidence of association between gender and physical fitness in physically active people in Colombia

Natalia Stephany Morales Eraso

NS Morales Eraso[1,4], YP Caviativa Castro[1], MP Murcia Doncel[1], OF Rubiano Espinosa[2], V Jaramillo Guzmán[3]
[1]Research Vice-chancellorship, Manuela Beltrán University, Bogotá, Colombia
[2]Faculty of Education, Pontificia Universidad Javeriana, Bogotá, Colombia
[3]Faculty of Education, Distrital University, Bogotá, Colombia
[4]Master in Epidemiology - Faculty of Health, University Foundation of the Area Andina, Bogotá, Colombia
Contact: natalia.morales@docentes.umb.edu.co

Background: Physical Condition (PC) is an important health marker (Colley, 2019), as a predictor of morbidity and mortality from cardiovascular diseases, among other causes (Cruz, 2018).

Aim: To perform association tests between gender (G) and CP in physically active people in Colombia. This study is observational cross-sectional, 1,503 people participated, 1,019 Women (W) (68.6%) and 485 Men (M) (31.4%) in Colombia, mean age 52± 16.2 in W and 42±17.8 in M. Data were analyzed with Rstudio v2022.12.0. The statistical protocol was: 1- Empirical distribution. 2- Normality tests with Kolmogorov-Smirnov. 3- Tests of independence with Chi-square (χ^2). The mean ($\bar{X}$), percentage (%) and standard deviation (±) were taken into account. PC was measured in body composition variables; Body Mass Index (BMI), Body Adiposity Index (BAI) and Abdominal Circumference (AC), Grip Strength (GS) and Maximal Oxygen Consumption (Vo2max).

Results: In W, 38.3% (27.2±1.37) were overweight (Ow) and 19.1% (33.0±2.83) obese (Ob), 69.6% (90.9±8.14) cardiovascular risk (CVR) for AC and 50.4% (32±4.73) risk for BAI. Regarding GS 43.4% (15.8±6.38) is weak and 54.6% (27.7±4.98) Vo2max is low. In M 35.6% (26.9±1.48) presented Ow and 10.6% (32.7±2.39) in Ob, 39.7% (98.4±6.8) with Rcv by AC and 24.3% (29.7±3.45) at risk by BAI. As for GS 41.5% (27.1±6.39) are weak and 32.3% (33.3±6.33) under Vo2max. According to independence tests with χ^2 there is association between the G and BMI (χ^2=1452.1, df = 1427, p-value=0. 315), G and AC (χ^2=394.9, df = 382, p-value=0. 313), G and Vo2max (χ^2=155.5, df = 6, p-value<2. 2e-16), G and BAI (χ^2=2970.3, df = 1502, p-value<2.2e-16), G and GS (χ^2=6015.5, df = 1502, p-value<2.2e-16). This project has been approved by the bioethics committee.

Conclusions: Test of independence with (χ^2), being a non-homogeneous sample, there is a strong association between G and PC with BMI, BAI, AC, GS and Vo2max, each variable depending on the others, evidencing higher Rcv in women with respect to men.

Key messages:

- Several studies consider Physical Condition (PC) is an important health marker (Colley, 2019), as a predictor of morbidity and mortality of cardiovascular disease, among other causes (Cruz, 2018).
- There is a strong association between G and the levels of BMI, BAI, AC, SG and Vo2max variables, each variable depending on the others, showing a higher Rcv in women compared to men.

Abstract citation ID: ckae144.1827

Caffeine intake, chronotype, and student sleep quality at Polytechnic of Leiria

Sara Simões Dias

SS Dias[1,2], *M Leal*[1], *I Capitão*[1], *J Gomes*[1], *M Ferreira*[1]
[1]School of Health Sciences, Polytechnic of Leiria, Leiria, Portugal
[2]ciTechCare - Center for Innovativ, Polytechnic of Leiria, Leiria, Portugal
Contact: sara.dias@ipleiria.pt

Introduction: Higher education students ingest very high doses of caffeine, on average twice the recommended safe dose. This excessive consumption can become problematic, ultimately affecting sleep quality and, consequently, academic performance. The aim of this work is to describe caffeine consumption, sleep quality and to characterize the chronotype and academic performance of students at Polytechnic of Leiria.

Methods: An online self-completion questionnaire was developed, consisting of several instruments: The Caffeine Consumption Questionnaire; Horne and Ostberg morningness-eveningness Questionnaire; Pittsburgh Sleep Quality Index (PSQI), to describe caffeine consumption, characterize chronotype and assess sleep quality, respectively. The mean, standard deviation, minimum and maximum values were calculated for the quantitative variables. Absolute and relative frequencies were calculated for the qualitative variables. Parametric tests were used to compare groups; when this was not possible, non-parametric tests were used. $P < 0.05$ was considered statistically significant.

Results: Of the 261 students (mean age: 23.26 ± 6.60 years), 64.2% had poor sleep quality and 45.3% reported an afternoon chronotype. It was found that men consumed more coffee and energy drinks than women, although women consumed more caffeine-containing food products. The average academic score was 14.56 ± 1.61. There was a statistically significant association ($p < 0.01$) between the afternoon chronotype and poor sleep quality and between the consumption of coffee and chocolate drinks and poor sleep quality.

Conclusions: Students at Polytechnic of Leiria tend to have poor sleep quality and an intermediate chronotype. Those with an afternoon chronotype or who drink coffee and chocolate drinks have poor sleep quality.

Key messages:

- Accurately assessing the situation is essential for crafting suitable solutions.
- Higher students should adjust their coffee consumption to achieve better sleep quality.

ISCO-08 Classification and scope of practice of nurses: Survey among WHO-Europe member states

Sule Kurt

S Kurt[1], *W Sermeus*[1]
[1]Katholieke Universiteit Leuven, Leuven, Belgium
Contact: sule.kurt@kuleuven.be

Background: The expansion of nurse's roles in the delivery of care needs transparent defining of roles, extra education/training opportunities, and complementary legislative regulations.

Methods: This cross-sectional study was planned to explore status of nursing and midwifery workforce in WHO Europe member states. Data were collected from December 2020 until September 2023.

Results: ISCO-08 2221 is used to classify for only bachelor prepared-nurses in 2 of countries (Bulgaria and Spain). Besides, it is used only for vocational prepared-nurses in 2 of countries (Kyrgyzstan and Tajikistan). Those countries only have vocational or bachelor education. ISCO-08 2221 is used in 1 of countries which have two entry levels with vocational and bachelor prepared-nurses (Georgia). ISCO-08 3221 is referred to vocational training in 5 (20%) countries (Armenia, Finland, the UK, Croatia, Hungary). ISCO-08 2221 is main classification for all levels prepared nurses in 18 countries including Switzerland, Cyprus, Czechia, Germany, Denmark, Ireland, Israel, Iceland, Kazakhstan, Lithuania Latvia, Malta, Poland, Portugal, Romania, Sweden, Slovakia, Türkiye. Scope of practice of vocational and bachelor prepared nurses is defined by law/legislation in 25 of member states. Scope of practice vocational versus bachelor depends on conduct scientific tasks

(Switzerland), being broader (Kazakhstan), competency level (Hungary, Croatia, Portugal) exceptionally there is no difference in Malta. Scope of Registered Nurse, Specialist Nurse and Advanced Nurse Practitioner differ in 22 of countries of those which on activities/practice/roles, expanded authority, working with determined care group. As a result, while scope of practice of professional nurses varies in line with their education level, ISCO-08 2221 is used for nurses' classification from all education levels in member states.

Key messages:

- There is no classification for postgraduate trained nurses (as is the case for physicians), even though scope of practice is different across education levels.
- When revising the ISCO-08 classification, it should be recommended that a common terminology is needed to define postgraduate nurses in region.

Abstract citation ID: ckae144.1829
The Population-Centered Medical Model: a method of practice for public health physicians

Sudit Ranade

S Ranade[1], *T Freeman*[1], *A Thind*[1], *JB Brown*[1]
[1]Centre for Studies in Family Medicine, Western University, London, Canada
Contact: sranade@uwo.ca

Background: Public Health Physicians (PHPs) in Canada occupy a liminal space between medicine and public health. Current practice frameworks for the care of individual patients by physicians do not account for the complexity of working with communities and populations for health. Similarly, frameworks for public health practice do not account for the roles and responsibilities of physicians in public health. A method of practice that outlines how public health physicians care for populations is vital for training and development of practice for this specialty group within medicine and public health.

Methods: Constructivist Grounded Theory methods were used in this study. Ethics approval was obtained through The Western University Health Sciences Research Ethics Board. Semi-structured interviews were conducted with eighteen (18) currently practicing PHPs across Canada. Data was analysed iteratively using constant comparison, multi-level coding, and memo writing. Thick description and reflexivity were employed to enhance rigour.

Results: The key finding is the elucidation of the Population-Centered Medical Model. In this empirically grounded model, PHPs bring values, knowledge and stances to their practice of Public Health Medicine. PHPs consider the population as patient, along with ethical obligations that flow from the physician to the population as a consequence. The process of caring for populations involves both diagnosis and intervention, with a focus on systems and prevention. It relies on knowledge sharing and relationship building between the physician and the population.

Conclusions: This is the first empirical model to describe the practice of PHPs. The model firmly grounds PHP practice in both medicine (diagnosis and intervention, the construction of a patient) and public health (focus on populations, systems and prevention). It also presents an opportunity to develop a general model of medical practice for n patients, where n can range between 1 and N.

Key messages:

- The Population-Centered Medical Model is an empirically grounded model that describes the work of Public Health Physicians in Canada and grounds practice firmly in medicine and in public health.
- Public Health Physicians consider populations as patients. They diagnose and intervene for health, with a focus on systems and prevention, by building relationships and sharing knowledge.

Abstract citation ID: ckae144.1830
Is the medical curriculum failing patients with obesity? - A public health concern

Sarah Cuschieri

D Sant[1]
[1]University of Malta, Msida, Malta
Contact: sarah.cuschieri@um.edu.mt

Introduction: Despite the global surge in obesity, it often receives insufficient attention in medical curricula, potentially impacting its management. This study aims to assess the preparedness of medical students in managing obesity.

Methods: A cross-sectional survey was conducted by disseminating a mixed-methods anonymous questionnaire to medical students studying at the University in Malta. A sample size of 117 participants was determined a-priori. Descriptive statistics and chi square testing were conducted. and coupled with thematic two-stage coding analysis of qualitative data.

Results: 189 participants were recruited. The majority expressed dissatisfaction with the teaching of obesity and its management during the MD course (pre-clinical = 90%; clinical = 74.4%, $p = 0.006$). Clinical students expressed dissatisfaction regarding the adequacy of their pre-clinical education (82.65%) and clinical attachments (70.40%), in equipping them with the theoretical knowledge and foundational skills necessary for managing patients with obesity. No significant difference between clinical and pre-clinical students' knowledge was noted except concerning diagnostic criteria (preclinical: 63.33% versus clinical: 89.90 %; $p < 0.001$). Thematic analysis highlighted the importance of curricular obesity teaching, need for a holistic approach towards obesity, and hesitancy in treating patients with obesity.

Conclusions: The gap between medical students' perceived readiness and the growing obesity epidemic is a public health concern. Without proper training, future doctors may struggle to manage obesity, posing risks to health outcomes and healthcare systems. Urgent curricular reforms are necessary to prioritize obesity education and ensure physicians are equipped to address obesity, to meet national needs. This requires collaboration among stakeholders, especially post-COVID-19, to align medical education with public health needs while addressing the severity of the obesity epidemic in Europe.

Key messages:

- A gap between students' attitudes and their understanding of obesity education was identified in this study, indicating a need for curriculum reform.
- This presents a critical public health issue, as it leaves the new generation of doctors ill-equipped to address the growing obesity epidemic across European countries.

Abstract citation ID: ckae144.1831
Navigating Burnout: Exploring Pharmacists' Attitudes toward Patient Care

Dušanka Krajnović

D Jocić[1], *D Krajnović*[2]
[1]University Business Academy Novi Sad, Faculty of Pharmacy, Belgrade, Serbia
[2]University of Belgrade, Faculty of Pharmacy, Belgrade, Serbia
Contact: dusica.krajnovic@pharmacy.bg.ac.rs

Background: The study aimed to investigate the link between pharmacists' burnout levels and their attitudes toward patient care, crucial for addressing burnout's impact on service quality and fostering positive patient interactions.

Methods: The study utilized the Shirom-Melamed Burnout Questionnaire (SMBQ) to assess burnout levels among 442 community pharmacists. Additionally, the five-point Likert Scale of

General Attitudes and Beliefs of Pharmacists about their Work with Patients (SOSUF), developed by the authors, was employed to measure pharmacists' cognitive, affective, and behavioral attitudes toward patient care. Statistical analyses involved correlation and regression procedures.

Results: Moderate burnout levels among pharmacists observed (mean SMBQ score: 4.18 ± 0.96, range: 1.45 to 6.55), alongside generally positive attitudes toward patient care (mean SOSUF score: 3.44 ± 0.37). Regression analysis revealed a moderate positive correlation between burnout and attitudes toward patient care ($R = 0.336$, R Square = 0.113, Adjusted R Square = 0.111, $p < .001$). Burnout impacted pharmacists' attitudes, notably in perceptions of patients not appreciating their efforts ($r = -0.317$, $p < 0.001$), finding patient interactions challenging ($r = -0.409$, $p < 0.001$), and disregarding their advice ($r = -0.333$, $p < 0.001$).

Conclusions: Despite generally positive attitudes toward patient care, burnout moderately correlates with negativity, notably impacting perceptions of patient appreciation, interaction challenges, and adherence to advice. Addressing burnout is crucial for maintaining positive patient care attitudes and ensuring quality service delivery.

Key messages:

- Burnout impacts pharmacists' patient care attitudes, emphasizing the need for intervention to enhance healthcare delivery.
- Implementing strategies to reduce burnout among pharmacists can improve patient care outcomes.

Strengthening data management skills amongst public health professionals during the war in Ukraine

Olha Kostetska

O Kostetska[1,2], V Boyko[1,2], M Caillaud[2,3], B Matthys[3,2], D Koch[3], G Delvento[3,2], A Dumcheva[4,3,2], Y Vernyhor[5], N Bugaienko[6], O Karkishchenko[7]
[1]USAID, Kyiv, Ukraine
[2]University of Basel, Basel, Switzerland
[3]Swiss Tropical and Public Health Institute, Basel, Switzerland
[4]Tampere University, Tampere, Finland
[5]National University, Kyiv, Ukraine
[6]Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine
[7]Lviv Regional Center for Disease Control and Prevention, Lviv, Ukraine
Contact: olha.kostetska@swisstph.ch

Background: The current war in Ukraine has led to disturbances in public health surveillance and epidemiological data flow, which impacts timely decision-making at regional and national levels. The five-year USAID project "Public Health System Recovery and Resilience Activity" (PHS R&R) aims to strengthen the Public Health system of Ukraine, including through the training of specialists in data management and disease surveillance.

Objectives: An innovative mixed-method, multi-module course was piloted in January 2023 to provide epidemiologists and other public health professionals with up-to-date knowledge and practical skills in disease surveillance and data management. The course was designed based on a needs assessment study carried out across the regional Centres for Disease Control (CDCs) in 2022. Modules were delivered both in person and online to reach a wider audience.

Results: 1,540 public health specialists attended the first module on Excel skills, online. A further 26 completed a second module, covering disease surveillance methods, data management, and data flow across regions, in person. Over 85% of participants in the second module reported that it was highly relevant to their day-to-day work, especially practical sessions on data analysis and reporting. The second module is currently under revision based on participants' feedback before being scaled up. A more advanced module on data management is being developed and aimed to launch at the end of 2024.

Conclusions: The course was timely and relevant for Ukrainian public health specialists in need of enhanced surveillance and data management skills to detect and respond to public health threats. Its innovative format allowed it to train a large cohort of specialists across a variety of essential public health functions despite the full-scale war. This experience would be relevant for any country aiming to strengthen its preparedness for potential public health emergencies, especially in fragile settings.

Key messages:

- The comprehensive training course on epidemiological surveillance and data management will equip Ukrainian public health specialists with data-driven decision-making skills in the war context.
- The described training approach would be relevant for the countries which seek sustainable workforce development solutions to strengthen public health systems in fragile settings.

[10]Faculty Human and Health Sciences, University of Bremen, Bremen, Germany
Contact: laura.maass@uni-bremen.de

Background: Digital public health (DiPH) professionals are crucial for a successful digital transformation in social and health care. However, the extent to which academic professionals are taught DiPH-related content in their public health studies in Germany remains unclear.

Methods: We used a systematic module handbook analysis to assess accredited full-time public health-oriented degree programs at German Universities for DiPH-related modules. Programs were identified through the Hochschulkompass platform and among the German Public Health Association member programs. We used MAXQDA for the content analysis of the included module handbooks.

Results: We identified 79 public health programs. Of these, 10 Bachelor's and 6 Master's offered at least one DiPH module, all being highly heterogeneous in their overall addressed public health subfields. Regarding DiPH, 6 programs lectured on the ethics of digitalizing health and data protection, 5 programs each offered modules on DiPH in health policy, on data science in healthcare and software used for eHealth, or on the digital determinants of health. 4 programs each included modules on digital health promotion and alternative evaluation methods. 3 programs each addressed digital science communication and health technology assessment. Finally, 2 programs had modules on digital epidemiology. We found differences between the common understanding of DiPH in academia and the content in the module handbooks. The content identified in the analysis focused mainly on technical areas. Social and health science content was only marginally present.

Conclusions: The diverse DiPH study programs allow academic public health specialists in Germany to develop specific profiles. There is a need for further development of modules with relevance to the respective degree program to achieve comprehensive competencies in DiPH. We encourage the uptake of our analysis to develop a core curriculum in DiPH among European public health programs.

Key messages:

- Digitalization affects all areas of life, including healthcare systems and public health. Preparing the future workforce already during their training is crucial to enable them to lead the change.
- German public health programs are not fit to prepare students for their professions. Developing DiPH curricula with pre-defined and updated competencies will strengthen programs in Germany and beyond.

Abstract citation ID: ckae144.1834
Training for migrant live-in care workers in Austria: results from an online survey

Silvia Wojczewski

S Wojczewski[1], *V Adler*[1], *R Bagheri*[2], *A Ernst*[3], *S Durisova*[1]
[1]Department of Primary Care Medicine, Medical University of Vienna, Vienna, Austria
[2]SYNYO Research GmbH, Vienna, Austria
[3]International Development, University of Vienna, Vienna, Austria
Contact: silvia.wojczewski@meduniwien.ac.at

Background: In Austria, almost 60.000 migrant “24-hour” live-in caregivers work in two- or four-week shifts, travelling between Austria and their countries of origin (mostly Romania, Slovakia, Croatia, Hungary and more) to care for frail older people at home. As opposed to other social and healthcare professions, live-in care workers do not require any formal training at all to be able to work in Austria.

Methods: With the aim of gaining an in-depth insight into the working conditions of live-in caregivers and with the aim of recording their problems and needs, an online survey including 40 questions was conducted from 15 July to 15 September 2023 in four languages (Slovak, Romanian, Bulgarian and German). The study is part of the MigraCare project which focuses on improving working and living conditions for migrant live in care workers.

Results: Results show that many live-in caregivers are not fully aware of their job profile: what are nursing and medical tasks they are only allowed to do when delegated by professional healthcare staff? Most respondents have to take on tasks that are outside their job profile. Many state that it is difficult to care for people with dementia. In addition, some caregivers report physical and psychological violence and sexual harassment. Most wish for training possibilities regarding topics like dementia, communication with client and family, legal framework regarding their job in the long-term care sector and others.

Conclusions: Live-in care workers wish for continuous education activities and for a better relationship with the family relatives and the care recipient. Based on the results of the survey short multilingual training videos have been developed easily accessible on a video platform for live-in care workers. Also, a connection to community nurses has been established in order to improve communication between care recipient, family members and live-in care workers.

Key messages:

- Results from an online survey show that live-in care workers face challenges at work which are partly due to an unclear job profile as well as communication problems with the care recipient.
- Results of an online survey show that live-in care workers wish for education and training opportunities (mother tongues) in the field of dementia care, communication with family or legal framework.

Abstract citation ID: ckae144.1835
Forecasting the future demand on health workforce – the Austrian model

Elisabeth Rappold

E Rappold[1]
[1]Austrian Public Health Institute, Vienna, Austria
Contact: elisabeth.rappold@goeg.at

Background: An aging population and upcoming retirements of health care professionals pose new challenges to the Austrian health care system. On the one hand the health care and nursing needs will increase while at the same time a shortage on health care personnel threatens adequate supply. We as the Austrian Public Health Institute estimate the risk of an undersupply with model-based health workforce forecasting and are therefore able to advise the federal states and the ministry of health on early measures.

Methods: We developed a forecasting model to estimate the future supply and demand. The main influencing factors are the demographic development as well as the upcoming retirements and graduates. Different environments and needs in different federal states (e.g. changing future skill mix) are considered and can be implemented as additional influencing factors. Usually a baseline scenario as a forward projection of the status quo is developed for defined professions and workplace settings. Then depending on the stakeholder needs additional scenarios are calculated and discussed. A usual forecast horizon is 10 to 15 years.

Results: Model output are time series of yearly workforce personnel numbers (heads and full-time equivalents) and demand in the defined settings. An analysis of possible gaps shows the need for action.

Conclusions: The Austrian health workforce model is a flexible tool to estimate future needs on health workforce based on different assumptions. But as assumptions and influencing factors must be represented as data, the data collection can be quite laborious. Comprehensive data is the basis for a comprehensive health workforce planning. Further work is needed to develop practical and evidence-based nursing-sensitive indicators for nursing workfoce reportings on a country level. In Austria the health professionals register forms the basis for the description of the nursing workforce structure, but that there is a need for data sources on care effectiveness.

Key messages:

- Comprehensive data is the basis for a comprehensive health workforce planning.
- An aging population and upcoming retirements of health care professionals pose new challenges to the Austrian health care system.

Abstract citation ID: ckae144.1836
A Training-of-Trainers program for health facilitators fighting malaria in a vulnerable community

Carlotta Carboni

C Carboni[1], *I Jimeno Maroto*[1], *M Galindo*[1], *L Plessis*[1], *Y Lambert*[1], *S Vreden*[2], *M Suarez-Mutis*[3], *J Miller Bordalo*[4], *M Douine*[1], *A Sanna*[1]
[1]CIC Inserm 1424, Cayenne Hospital, Cayenne, France
[2]SWOS Foundation, Paramaribo, Suriname
[3]Laboratory of Parasitic Diseases, Oswaldo Cruz Institute, Rio de Janeiro, Brazil
[4]DPAC Fronteira, Oiapoque, Brazil
Contact: dr.carbonicarlotta@gmail.com

Background: When Public Health is challenged by issues related to migrant and vulnerable populations, health facilitators’ profiles are crucial to accessing communities and increasing intervention effectiveness and acceptability. The French overseas region, French Guiana, is concerned with a migrant population living in vulnerable conditions far from healthcare and being a major reservoir of malaria. Curema is an intervention implemented to fight malaria in this population by distributing RDTs, and treatments after an appropriate training of participants. Facilitators from the community are employed to provide health education and enroll participants.

Objectives: An intensive theoretical-practical training program was realized to enable facilitators to master procedures related to the intervention. The training was designed using the CDC Training-of-Trainers (ToT) framework and adult learning principles. It was composed of initial and on-the-field training, both based on bidirectional, participative, and dynamic working spaces. A mixed-method evaluation was carried out to assess training effectiveness and quality.

Results: Group dynamics and adaptations driven by facilitators' needs were key elements of a high-quality training program. Satisfaction was elevated for training format and learning results. Statistically significant improvements in knowledge level demonstrated good effectiveness. During the initial training, difficulties persisted regarding some tasks to be performed during the intervention: further on-the-job training addressed them, improving facilitators' practices in the field.

Conclusions: High-quality, effective, and appropriate training programs are required for intervention involving facilitators' profiles. Training design is crucial to achieve it. ToT model has been shown to allow high satisfaction, learning results, and good implementation in the field. Initial and on-the-job training are an indispensable continuum to sustain good practices and motivation.

Key messages:

- If health facilitators from the community are actors in public health interventions, appropriate training is necessary to ensure good implementation.
- ToT seems an optimal model for training health facilitators.

Assessment of healthy worker survivor bias among middle-aged manufacturing employees in Korea

Byungyoon Yun

B Yun[1,2], *J Oh*[3], *J Sim*[1], *H Park*[3], *J Lee*[3], *J-H Yoon*[1,2,4]
[1]Preventive Medicine, Yonsei University, Seoul, South Korea
[2]Institute for Occupational Health, Yonsei University College of Medicine, Seoul, South Korea
[3]Public Health, Yonsei University, Seoul, South Korea
[4]Institute for Innovation in Digital Healthcare, Yonsei University Health System, Seoul, South Korea
Contact: yby3721@yuhs.ac

Background: Healthy Worker Survivor Bias (HWSB) describes a selection bias where those continuously employed tend to exhibit superior health outcomes compared to their unemployed counterparts. This bias challenges for adjustments due to its time-dependent nature. This study aims to evaluate the extent of HWSB related to changes in employment status among middle-aged manufacturing workers using comprehensive national data from Korea.

Methods: The study analyzed data from the National Health Insurance Service, targeting individuals aged 40-49 who maintained consistent insurance coverage-either as manufacturing employees or non-employees (self-employed or unemployed)-from 2008 to 2010. The observation period spanned from January 2011 to December 2022, with all-cause mortality as the primary outcome. We employed landmark analysis to quantify HWSB related to employment status by comparing age-standardized mortality ratios between employees and the general population from the initial assessment to the last landmark period (up to 7 years), calculating 95% confidence intervals (CI) using Poisson distribution.

Results: The cohort included 4,621,983 participants (726,616 manufacturing employees and 3,895,367 (84.3%) non-employees). Throughout an average follow-up of 10.9 years (43.1% male; median age of 44), there were 116,418 deaths (11,530 (1.6%) among manufacturing employees and 104,888 (2.7%) among non-employees). Analysis revealed a consistent linear increase in HWSB over time. Notably, the bias was more pronounced among females (7-year HWSB-ES [95% CI]: 0.27 [0.17-0.37]) compared to males (7-year HWSB-ES [95% CI]: 0.18 [0.14-0.22]).

Conclusions: This study quantifies the extent of HWSB among middle-aged manufacturing workers in Korea, highlighting its significant impact, notably in females. These findings are vital for occupational health research, emphasizing the necessity to consider HWSB to prevent the underestimation of health risks associated with hazardous exposures.

Key messages:

- Findings suggest HWSB is more pronounced in female manufacturing workers, indicating the need for targeted occupational health interventions.
- The study underscores the importance of accounting for HWSB in occupational health studies to avoid underestimating health risks associated with workplace exposures.

Abstract citation ID: ckae144.1838
Working in emergency services in Germany: cross-sectional data on violence experience and perception

Ana Zhelyazkova

A Zhelyazkova[1], *M Bonigut*[1]
[1]Institut für Notfallmedizin und Medizinmanagement, LMU Klinikum, Munich, Germany
Contact: Ana.Zhelyazkova@med.uni-muenchen.de

Background: Violence in emergency medical services (EMS) continues to be a topic of concern. Experiencing violence impedes the workers' wellbeing, thus impairing the coverage and quality of EMS. We explored employment-related factors associated with violence experience and perception.

Methods: We conducted an anonymous online-based survey among EMS staff in Germany (09.2023-01.2024). Participants reported on their work setting, frequency of violent experiences and perception of violence. Descriptive statistics and logistic regression were calculated.

Results: Of 224 participants with completed questionnaires, 86 reported to have been exposed to physical violence (PV) in the past 12 months (Median number of events=2.00) and 129 reported to have experienced non-physical violence (NPV; Median number of events=5.00) with the majority of participants reporting that all cases occurred during assignment (n(PV)=79; n(NPV)=86). Of those, 78 reported PV by patients and 5 by colleagues, while in NPV cases 113 participants experienced violence by patients and 40 by colleagues. Women had a higher probability of reporting PV experiences compared to men (OR = 2.214, p=.010). Reporting NPV experiences was negatively associated with age between 45 and 49 (compared to $\leq$ 24 years, OR=.291, p=.019) and having worked for the current employer for $\geq$16 years (OR=.339, p=.035). Participants who have experienced violence in the past year had a higher likelihood of perceiving a general increase in the prevalence of violence in EMS (PV: OR = 6.766, p<.001; NPV: OR = 1.688, p=.047).

Conclusions: Younger EMS workers with juniority have a higher probability of reporting experiencing NPV. Women are more likely to report experiencing PV. It remains to be explored, if these associations refer to the experiences of violence, to reporting frequency or both. Regardless, the majority of respondents perceive an increase in violence within the work setting of EMS, especially if they have been subjected to it themselves.

Key messages:

- EMS professionals experience significant levels of physical and non-physical violence originating from patients and colleagues.
- Sex, age and seniority may affect the likelihood of EMS professionals of experiencing physical or non-physical violence.

Abstract citation ID: ckae144.1839
The pivotal role of positive emotions in maintaining nurses' trust and preventing pandemic fatigue

Shiran Bord

S Bord[1], *S Sharabani*[2], *H Admi*[3]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel valley, Israel
[2]Economics and Management, The Max Stern Yezreel Valley College, Yezreel valley, Israel
[3]Nursing, The Max Stern Yezreel Valley College, Yezreel valley, Israel
Contact: Shiranb@yvc.ac.il

Background: Nursing is a challenging profession that demands quick adaptation to changing conditions. The COVID-19 pandemic has placed unprecedented pressure on nursing teams, leading to high-stress levels and uncertainty. This study examines how nurses' emotional response at the start of the pandemic predicts their trust in the healthcare system and pandemic fatigue after three morbidity waves.

Methods: This study included collecting self-reported data among Israeli nurses in three time periods: 346 nurses during March-May 2020 (T1), 260 nurses during June-July 2020 (T2), and 91 nurses during February 2022 (T3). Change in the study variables was assessed using repeated-measure ANOVA. Two multiple linear regression models were calculated for trust and pandemic fatigue at T3, with the emotions at T1 and professional seniority as predictors.

Results: A significant increase in negative emotions was observed between T1 and T2 ($M = 2.65$, $SD = 1.12$ and $M = 3.20$, $SD = 1.29$ respectively). Furthermore, there was a significant decrease in trust levels between T1 and T3 ($M = 4.68$, $SD = 1.14$ and $M = 4.07$, $SD = 1.08$ respectively). The regression model for trust was significant, with 20% of the variance explained in it, revealing that higher positive emotions at T1 predicted higher trust at T3. Similarly, the regression model for pandemic fatigue was significant ($R2=22\%$), showing that lower professional seniority and lower positive emotions at T1 were predictors of higher pandemic fatigue at T3.

Conclusions: During a crisis, nurses may experience intense negative emotions like fear and anxiety. However, positive emotions, such as pride and a sense of mission, are crucial in maintaining their trust and preventing the onset of pandemic fatigue. Healthcare organizations should promote emotional support and provide emotional resources so that nurses can continue to deliver high-quality care even during challenging times.

Key messages:

- During times of crisis, it's crucial to foster positivity and encourage a sense of pride and accomplishment in nursing staff.
- Healthcare organizations must provide emotional support to nursing teams in routine and crisis situations to prevent burnout and maintain trust and long-term functioning.

Abstract citation ID: ckae144.1840
Workshops: Enhancing communication for nursing students with patients with hearing disabilities

Contact: carolinata@mta.ac.il

Background: Nursing students need guidance on effective communication strategies for interacting with patients with hearing disabilities, emphasizing the importance of addressing this gap in their education as future healthcare professionals.

Methods: A cross-sectional survey was conducted among nursing students at seven institutions before and after workshops led by guides with hearing disabilities from a non-profit organization Ma'agalei Shema and funded by the National Insurance Institute. Data was collected from 2023 to March 2024 and analyzed using SPSS software.

Results: 279 participants completed the survey before the workshops. and 136 responding afterward. Almost 80% were female. Before the workshops, 68.46% of students expected to gain communication tools for patients with hearing disabilities. About one-third believed the healthcare system offers accessible treatment to these patients, while only 22.22% foresaw no barriers. One-third reported no clinical contact with such patients. Among those who did, lip-reading (25.53%), writing (17.73%), assistance from family members (15.6%), and sign language (9.22%) were commonly used. Only 2.84% used professional sign language interpreters, and 20.57% reported never meeting a patient with hearing disabilities (8% reported "other"). Post-workshop surveys showed that around 82.48% of participants felt the workshops would significantly enhance their communication skills with such patients, with only 5.11% reporting a lack of practical tools received.

Conclusions: Practical workshops can significantly enhance communication skills and improve patient care. This study underscores the potential impact of minor adjustments in communication strategies on patient care, such as increasing the use of professional interpreters. Main messages: Providing training to nursing students in effective communication with these patients can streamline interactions, diminish reliance on family intermediaries, and enhance medical care.

Key messages:

- Nursing students need guidance on communicating with patients with hearing disabilities to improve future healthcare interactions.
- Practical workshops enhance communication skills, stressing the importance of minor adjustments for better patient care.

Abstract citation ID: ckae144.1841
"We want to get out" – A qualitative study on reasons for nurses' early retirement intentions

Anu-Marja Kaihlanen

A-M Kaihlanen[1], *E Aktas*[2], *M Sadauskas*[3], *D Sezgin*[3]
[1]THL, Helsinki, Finland
[2]Department of Public Health and Primary Care, KU Leuven, Leuven, Belgium
[3]School of Nursing and Midwifery, University of Galway, Galway City, Ireland
Contact: anu.kaihlanen@thl.fi

Background: Nurses, the largest workforce in healthcare, play a central role in health systems. There is a severe global shortage of nurses, which is expected to worsen as a significant portion approaches retirement age. Early retirements can harm care quality and healthcare access, thus significantly impacting public health. Identifying reasons is crucial to prevent this trend. This study examined factors behind nurses' early retirement intentions.

Methods: A descriptive qualitative study was conducted in an Irish hospital (July to September 2023) including individual interviews with 10 nurses aged 55 and over. A thematic analysis was conducted collaboratively by three researchers to identify key factors influencing nurses' intentions to retire early.

Results: Five main themes emerged: 1) Health concerns, encompassing physical strain and psychological stress, significantly influencing early retirement intentions; 2) Struggling to balance job demands with personal responsibilities such as caring for ageing parents due to inflexible work schedules; 3) Need for more support from senior leaders to address staffing shortages and investment in aging nurses' career and retirement planning to make staying more desirable and easier; 4) Feelings about nurses' experience being undervalued in the evolving healthcare; and 5) Facing constant heavy responsibility in guiding new nurses, while simultaneously fearing patient safety risks and encountering generational differences.

Conclusions: Developing support systems for ageing nurses, encompassing strategies to ease workload strain, enhancing career opportunities, and promoting intergenerational collaboration are critical for reducing early retirement trends and sustaining a resilient healthcare workforce. By implementing tailored approaches, such as flexible scheduling and mentorship programs for ageing nurses, healthcare organisations can promote workforce longevity and enhance public health outcomes through improved care delivery.

Key messages:

- Health challenges and struggles in work-life balance influence early retirement intentions among nurses, urging flexible work arrangements and improved recognition and leadership in healthcare.
- To extend work careers, organisations must invest in ageing nurses' career and retirement planning, value experience, and acknowledge potential challenges and benefits in intergenerational nursing.

Virtual Children's Hospital for Learning Pediatric Nursing

Christiana Nicolaou

C Nicolaou[1], O Kolokotroni[1], J Menikou[1], N Middleton[1], M Asi[3], P Matikainen[2], K Vesanen[2], A Treiman-Kiveste[3], S Läänelaid[3], M Toivonen[2]
[1]Department of Nursing, Cyprus University of Technology, Nicosia, Cyprus
[2]Faculty of Health on Well-being, Turku University of Applied Sciences, Turku, Finland
[3]Nursing and Midwifery Department, Tartu Health Care College, Tartu, Estonia
Contact: c.nicolaou@cut.ac.cy

Background: In the context of a funded Erasmus+ program, a platform of a Virtual Children's Hospital for Learning Pediatric Nursing - VLPN is being developed. The education of nurses working with children, adolescents and families, needs to include specialized knowledge, skills, attitudes and behaviors that will empower them to provide optimal and high-quality care. The virtual platform enables the improvement of pediatric nursing competences of the nursing students through interactive and self-paced activities and content.

Objectives: 1. To develop an immersive and interactive virtual reality learning environment (VRLE), a virtual children's hospital and new teaching and learning methods and practices, utilizing virtual reality and simulation in teaching. 2. To promote the international collaboration of students and lecturers through the VRLE

Results: The results are preliminary. 1. The VRLE includes educational materials developed to be integrated in the pediatric nursing studies, easy to access and use by the students and teachers with innovative self-pace learning material i.e. videos, 3D-models, interactive tests. Digital patients can react to the provided care with speech, movement, facial expressions and gestures, something that is not possible with the manikins in the Labs. 2. Nursing students and lecturers from different countries can participate in joint remote seminars or workshops in the VRLE, sharing and comparing their country and culture-specific differences and similarities in the nursing practices. VRLE and digital materials enables synchronous and asynchronous learning.

Conclusions: VRLE is highly conducive to clinical and procedure-focused training by enabling simulation. VR methods offer nursing students the opportunity to practice skills in a safe and risk-free environment in an immersive way. It can be accessed by multiple students, teachers or nurses at the same time from different locations in different countries.

Key messages:

- New innovative VRLE enhances nursing students' knowledge and skills that are needed when working with sick children and their families.
- International collaboration, interaction and mobilization are enabled by using a virtual platform instead of traveling, thus strengthening the co-operation in European higher educational institutes.

Depressive symptoms among medical students

Jovana Vidojevic

J Vidojevic[1], Z Stamenkovic[1], Z Terzic-Supic[1], M Mirkovic[2], A Stevanovic[1], I Sotirovic[1], J Todorovic[1]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Department of Preventive Medicine, Faculty of Medicine, University of Kosovska Mitrovica, Kosovska Mitrovica, Serbia
Contact: jovana.vidojevic96@gmail.com

Background: Adolescence is a period of psychological development which is associated with an increased risk of developing mental health disorders. Medical students have a higher prevalence of depression compared to the general population, but they are given low priority in the healthcare system. The aim of this study was to examine the prevalence of clinically significant scores on the Patient Health Questionnaire 9 (PHQ-9), and factors associated with clinically significant scores.

Methods: The research was conducted through a cross-sectional study among fifth-year medical students, using a 95-item questionnaire anonymously filled out. The questionnaire examined: socio-demographic and socio-economic characteristics of the students; students' lifestyles (including alcohol consumption, binge drinking, smoking cigarettes, electronic cigarettes, use any of other tobacco products); Patient Health Questionnaire (PHQ-9); International Physical Activity Questionnaire (IPAQ); Zung's Anxiety Scale; and Problematic Internet Use Scale. Based on the score on PHQ-9, the participants were classified in two groups: with clinically significant scores (score ≥ 10) and without clinically significant scores (score <10).

Results: The study included 461 medical students who completed the PHQ-9. Average score on PHQ-9 scale was 5.25±4.53 and total of 66 students (14.3%) had the PHQ-9 indicative of clinically significant depressive symptoms (PHQ-9 ≥ 10). The clinically significant depression was associated with smoking of any tobacco product (OR:3.02, 95% CI: 1.37-6.63), score on social support scale (0.94, 95% CI: 0.90-0.98), age (OR: 1.42, 95% CI: 1.06-1.90) and score on Zung anxiety scale (OR: 1.15, 95% CI: 1.16-1.34).

Conclusions: Considering that medical students, are at higher risk of developing clinically significant symptoms of depression, it is crucial to form psychological and social support programs.

Key messages:

- Monitoring the mental health of young individuals holds significant importance.
- It is crucial to detect risk factors in time and develop prevention programs.

[4]Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands
[5]Department of Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands
Contact: dott.tommaso.osti@gmail.com

Background: Precision health, encompassing personalized and proactive health solutions, aims to address this gap by integrating genetic, behavioral, and environmental factors. However, challenges persist in its integration, necessitating new healthcare competencies, particularly in leadership, to expedite the transition. Our goal is to identify barriers and solutions for the implementation of precision health and build a core curriculum of leadership competencies to mitigate challenges and barriers for the implementation of precision health.

Methods: A systematic literature review of qualitative primary studies on barriers and facilitators to precision health implementation was conducted. Data extracted from included articles were analyzed thematically, adapting leadership competencies outlined in the CanMEDS Physician Competency Framework. This approach identified key leadership traits crucial for precision health implementation.

Results: 51 articles meeting inclusion criteria yielded 985 barriers and facilitators. Thematic analysis identified 9 primary leadership competencies essential for precision health implementation: application of quality improvement science (30%); fostering a culture of patient safety in data use (10%); advocacy for innovative data management (4%); resource allocation advocacy (9%); evidence-based cost management (4%); driving practice change (8%); prioritization and time management (11%); and optimization of healthcare workforce practices (14%).

Discussion: The synthesized leadership competencies provide a useful framework for addressing barriers and fostering precision health implementation among healthcare professionals. The high representation of competency related to quality improvement science is emblematic of how cultural elements specific to leadership and management in medicine could represent a strategic asset to foster the implementation of innovative solutions, like precision health, in healthcare.

Key messages:

- Leadership skills are a crucial element in the curriculum of health professionals to support the implementation of precision health in clinical practice.
- Incorporating elements of ‘quality improvement science’ in the healthcare professionals education emerged as essential to foster precision health implementation.

Abstract citation ID: ckae144.1845
Predicting PTSD among labour ward staff: The role of burnout, intent to leave, and emotional support

Ofra Halperin

O Halperin[1], G Yakov[2], N Idilbi[1,3]
[1]Nursing, The Max Stern Yezreel Valley College, Emek Yezreel, Israel
[2]Health Systems Management, The Max Stern Yezreel Valley College, Emek Yezreel, Israel
[3]Nursing Research Unit, Galilee Medical Center, Nahariya, Israel
Contact: ofrah@yvc.ac.il

Background: Healthcare professionals in delivery rooms frequently encounter stressful situations. Following an examination of how midwives coped and functioned during the unfamiliar and chaotic period of the Covid-19 pandemic, it is crucial to understand their challenges and the support they receive to enhance well-being and patient care. This study aimed to examine the relationship between burnout, intentions to leave, and PTSD (Post-Traumatic Stress Disorder) symptoms among healthcare professionals, and to identify predictors of PTSD.

Methods: We employed a mixed-methods design, consisting of a survey of 196 midwives and gynecologists assessing burnout, intentions to leave, exposure to negative work experiences, and PTSD. Additionally, we conducted 15 semi-structured interviews and 13 interviews with labour ward head nurses.

Results: Most participants experienced difficult events in the delivery room or multiple such events, reporting insufficient emotional support. The main themes identified were stress, fear, anxiety, and frustration. Burnout and a lack of emotional support were significant predictors of PTSD symptoms, with participants highlighting the need for more support to manage complex situations.

Discussion: Addressing burnout through prevention and intervention programs is essential. Emotional support plays a crucial role in mitigating PTSD symptoms, enhancing resilience and well-being among midwives and gynecologists. Implications for Nursing Management: Understanding the psychological impact of stressful situations on healthcare professionals is crucial for guiding policies and interventions aimed at maintaining staff psychological well-being. Midwives’ managers can leverage this research to identify actions that improve staff resilience and cohesion during crises. Strengthening the resilience of health teams is pivotal in providing optimal health services.

Key messages:

- Burnout and insufficient emotional support are key predictors of PTSD among healthcare workers in labour wards.
- Enhancing support and resilience for midwives and gynecologists is crucial for their well-being and patient care.

Abstract citation ID: ckae144.1846
General Practitioner Availability and Accessibility in Serbia Before and During the Pandemic

Milena Šantrić Milićević

M Šantrić Milićević[1,2], A Stevanović[1,2]
[1]School of Public Health and Health Management, Faculty of Medicine University of Belgrade, Institute of Social Medicine, Belgrade, Serbia
[2]Laboratory for Strengthening the Capacity and Performance of Health System & Workforce for Health Equity, Belgrade, Serbia
Contact: milena.santric-milicevic@med.bg.ac.rs

Background: During the COVID-19 pandemic in Serbia, state-owned primary health centres’ general practitioners (GPs) served as the first point of care for adults (the population aged 19 years and older) and gatekeepers of the health system. The study highlights changes in the overall availability, accessibility, and workload of GPs during the pandemic.

Methods: We used routine health facility data at the national level to describe the changes in GPs over the past three years, before the pandemic (2017-2019) and during the pandemic (2020-2022). Specifically, we looked at the total number of GPs, the percentage of specialists, the average number of citizens per GP, the services used per capita, the average number of visits per GP, and the leading causes of morbidity.

Results: The study found a decrease in the total number of GPs in both periods (before: -10%, during: -9%) and in the number of specialists (before: -2%, during: -3%). During the pandemic, the average number of citizens per GP varied. In 2022, the average number of visits per GP decreased noticeably to 3557 GPs, of which 37% were specialists. In the same year, each GP received 6661 annual visits and served 1509 citizens on average. However, these figures exhibit considerable regional and geographical differences. Circulatory and respiratory diseases were the most common reasons for visiting a GP (about 14% and 13% of all visits, respectively). Up to 10% of all visits resulted in either a diagnosis of external factors that influence health status or in ill-defined symptoms, clinical and laboratory findings.

Conclusions: This study's findings underscore the critical reductions in availability, accessibility, and workload of general practitioners in the Serbian public sector and emphasize the importance of strengthening the primary healthcare system to better respond to future challenges.

Key messages:

- Public health officials should prioritize the development of effective strategies and policies that focus on improving the quality and accessibility of primary health care services in Serbia.
- A greater investment in general practice is necessary to ensure it can effectively meet the population's needs during health emergencies.

Abstract citation ID: ckae144.1847
Indicators of primary health care workforce equity for attaining health equity

[7]United Nations University - CRIS, Bruges, Belgium
[8]World House Medicine, New York, USA
Contact: milena.santric-milicevic@med.bg.ac.rs

Background: Healthcare workforce crises are often the result of inequities faced by healthcare workers. This study aims to discuss the primary policy questions related to health equity regarding the primary healthcare (PHC) workforce indicators.

Methods: Following the purposive review of published literature on HWF equity in PHC services, we applied an intersectional analysis of the compendiums of HWF indicators (e.g., supply, flows, skill mix, working conditions, promotion, training, funding, governance, etc.) to strategically link them to PHC policy issues for health equity and categorized qualitatively under each policy pillar against HWF crises.

Results: The proposed indicators address the measurement of multiple dimensions of health workforce equity. These include financial and non-financial incentives to monitor worker attrition reduction, gender pay gap, fairness in employment arrangements, remuneration, and working conditions. By monitoring the minimum wage for financially vulnerable health workforce groups, we can identify the need for potential increases to support well-being, reduce turnover, and increase productivity. Equally important is monitoring equity in health workforce education, planning, and management, which is crucial for achieving population health equity. By implementing indicators of health workforce diversity to address rural and underrepresented communities, primary healthcare managers can effectively plan the reduction of their unmet needs and minimize avoidable referrals.

Conclusions: To ensure equitable access to primary healthcare, we must measure workforce equity and its impact on population health. Monitoring the indicators of equitable health workforce policies and evaluating the improvement in retention and recruitment processes can more effectively address workforce crises.

Key messages:

- Health workforce crises often stem from healthcare workforce inequities.
- Health workforce equitable policies require a clear set of indicators.

Abstract citation ID: ckae144.1848
Hospital employees' perceived racism, ethnically offensive behavior, and patient violence

Liron Inchi

L Inchi[1], *A Gur*[1]
[1]Health Systems Management, The Max stern Yezreel Valley College, Yezreel Valley, Israel
Contact: lironi@yvc.ac.il

Background: Hospitals are sensitive environments with complex interactions between employees and patients. Israeli society is ethnically diverse, and Israeli hospitals reflect this diversity and may create opportunities for rapprochement between different ethnic groups or might raise conflicts between them. In radical situations, such encounters might lead to violence. The phenomenon of physical or verbal violence towards caregivers and hospital employees exists. However, the uniqueness of this study is in examining whether the origin of the violence stems from racist reactions and how offensive behavior on an ethnic background could develop into actual violence.

Methods: Data were collected through an online close-ended survey among 370 hospital employees. 83% were Jewish, 68% were female, and 38 years old on average, with a mean hospital tenure of 6.5 years. The survey explored respondents' perceived racism toward them, their exposure to offensive patient behavior based on ethnicity, and their exposure to general violence. Data were analyzed by SPSS 28.

Results: Preliminary results suggest positive correlations between study variables ($r=.42$-$.52$, $p< .001$). Regression analysis revealed that perceived racism contributed to general violence ($\beta=.43$, $p< .001$; $R^2=.19$). Next, ethnic-based offensive behavior was added to the model ($\beta=.36$, $p< .001$). The analysis shows that general violence can be explained by these variables [$F(2, 359)= 70.42$, $p< .001$; $R^2=.28$]. The R^2 of the general model increased significantly by 9.6%. The weight of perceived racism dropped yet is still significant ($\beta=.24$, $p< .001$). These results indicate that patients' ethnic-based offensive behavior partially mediates the relationship between employees' perceived racism and general violence.

Conclusions: The results suggest that employees who suffer from racism experience patients' offensive behaviors based on ethnicity, which finally results in higher exposure to general violence in the workplace.

Key messages:

- Understanding the phenomenon of violence in hospitals and examining the relationship between it and racism may amend policy and improve the quality of care and working conditions in the health sector.

- The hospital environment involves diverse groups of society. Hence, the awareness of offensive behavior on an ethnic background is a condition to reduce racism and violence proactively.

Abstract citation ID: ckae144.1849
Infodemic management in higher education: Mapping opportunities at the University of Belgrade

Aleksandar Stevanović

A Stevanović[1,2], S Mandić-Rajčević[1,2], A Rowland[3], M Zdujić[1,2], J Vidojević[1,2], I Sotirović[1,2], P Zelić[4], R Martin[3]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Laboratory for Infodemiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[3]Emory Global Health Institute, Emory University, Atlanta, USA
[4]Managing Director's Office, Medicines and Medical Devices Agency of Serbia, Belgrade, Serbia
Contact: aleksandar.stevanovic@med.bg.ac.rs

Background: Effective infodemic management (IM) requires a multidisciplinary approach and the use of various skills originating from natural, social, and medical sciences. Personnel involved in IM activities have diverse backgrounds from medical doctors and data scientists to communication specialists and journalists. However, the IM framework is rarely introduced into the existing teaching programs, compromising the training of a competent workforce.

Objectives: Our goal was to identify opportunities for integrating the IM framework into the existing teaching programs at the University of Belgrade. A team of researchers reviewed the curricula of 31 faculty and identified the courses that already covered IM skills or had the potential to include them in their teaching programs. The research was conducted as part of the U.S. Federal Assistance Award within the University Partnership Program between Emory University and the University of Belgrade.

Results: After conducting independent reviews and reaching a consensus, over 40 different courses and/or teaching programs have been identified to include or could potentially integrate IM skills and competencies. These courses are found across all major academic clusters (natural sciences and mathematics, technology and engineering, medical sciences, social sciences, and humanities). Faculties of medicine, pharmacy, and dentistry lead with the number of courses and interested teaching staff, followed by social sciences (psychology, sociology, political science). Most of the identified courses are related to information, data science, and communications.

Conclusions: There is a promising opportunity to introduce IM skills into the current teaching programs at the University of Belgrade. Faculties from the medical sciences group have a solid potential to lead such a process. Collaborative efforts are needed to establish comprehensive teaching programs to ensure a competent public health workforce and certification.

Key messages:

- University of Belgrade has the potential to introduce infodemic management skills into its existing teaching programs, respecting the multidisciplinary nature of this discipline.
- Medical and social sciences faculties can lead the process of mainstreaming infodemic management in their curricula, ensuring a competent public health workforce and certification.

Burnout as a multidimensional phenomenon: How can workplaces be healthy environments?

Tania Gaspar

T Gaspar[1,2], T Gaspar[2], M Carvalho[3], M Matos[4]
[1]Hei-Lab, Lusofona University, Lisbon, Portugal
[2]CHRC, Universidade NOVA Lisboa, Lisbon, Portugal
[3]Psychology, ISMAT, Faro, Portugal
[4]Psychology, Universidade Catolica, Lisbon, Portugal
Contact: tania.gaspar.barra@gmail.com

Purpose: Burnout was already a significant problem before the pandemics, but in the aftermath became a serious concern and a public health and occupational health priority. This study had two aims. First, it investigated how different healthy workplace dimensions and other health individual-level variables are related to burnout. Second, it examined differences in terms of presentism, absenteeism, quality of life between employees who report burnout symptoms and those who do not.

Methods: Participants were 1702 Portuguese employees from various organizations. 69.68% were female, age ranged from 18 to 72 years (M = 43.25 years, SD = 10.40). Almost half of the participants (49.9%; 851 participants) reported having at least one burnout symptom.

Results: Participants reported that they have felt exhausted (43.7%), irritated (34.5%) and sad (30.5%) always or very often in the last 4 weeks. Regression analysis revealed that the global score on burnout symptoms was negatively related to leadership engagement, psychosocial work environment, personal health resources, health behaviours, and satisfaction with salary. In addition, the global score on burnout symptoms was positively related to worker involvement, enterprise community involvement, perceived stress, and screen time at work. Furthermore, females tend to report a higher level of burnout symptoms compared to males. In addition, burnout has an impact on sickness absenteeism, presentism, and quality of life.

Conclusions: Our findings have an important contribution to understanding and promoting a healthier work environment and reinforce the need for measures and policies to promote mental health, manage stress, and prevent burnout in the workplace.

Key messages:

- What best explains the burnout symptoms is the workers' perceived stress, followed by psychosocial risk factors at work.
- There is a positive relationship between perceived stress and burnout: effective work stress management is one of the protective factors that prevents burnout.

Abstract citation ID: ckae144.1851
Self-reported mistreatment of Danish medical students

Janne Sorensen

J Sorensen[1], A Krasnik[1], AL Hindhede[1,2]
[1]Danish Research Centre for Migration, Ethnicity and Health, University of Copenhagen, Copenhagen, Denmark
[2]Center for Health Research, University Hospital of the Capital Region, Copenhagen, Denmark
Contact: jans@sund.ku.dk

Background: Evidence suggests that mistreatment of medical students (MS) exists and that it is associated with stress, anxiety, burnout, substance abuse etc. Mistreatment encompasses discrimination and sexual harassment and impacts MS' ability to partake their education with increased risk of dropout. The aim of the study is therefore to explore whether Danish MS and junior physicians enrolled in the Clinical basic education (CBE) have experienced mistreatment during their studies.

Methods: An online survey was conducted by email and sent to 5234 MS enrolled in one of four medical Master programs in Denmark or in the CBE. Reminders were distributed by email, shared in Facebook groups, and presented during lectures, accompanied by cards with QR codes for the survey. Data collection took place during spring 2023 and 645 completed the questionnaire giving a response rate of 12 %. The questions were based on the

Everyday Discrimination Scale. Descriptive statistics and multivariate logistic regression were used for data analysis.

Results: MS most often encounter mistreatment from physicians, other health professionals and patients during their clinical internships. They also encounter mistreatment from lecturers and peers. MS who self-identify with another ethnicity than Danish/European were 3.2 times more likely than MS identifying with Danish/European ethnicity to report mistreatment from other students (95% CI 1.76 -5.95). Men were also less likely than women to report mistreatment. The mistreatment reported by MS is predominantly based on gender, ethnicity, religion, and age. The most frequent experiences are stereotypical statements (71,8%), lack of respect (65,1%) and being ignored (54,1%).

Conclusions: Our results indicate that Danish MS experience mistreatment, which can potentially impact their mental health. These results underscore the need for targeted interventions to create an inclusive educational environment that fosters the well-being and success of MS.

Key messages:

- Danish medical students often face mistreatment from peers and health professionals, and more often reported by woman and students identifying with ethnic backgrounds other than Danish/European.
- Action by University management is needed to implement targeted interventions such as diversity training, as mistreatment can negatively impact students' mental health and educational outcomes.

Abstract citation ID: ckae144.1852
Experts in promotion and prevention - The 100th Anniversary of Finnish public health nurse education

Johanna Saastamoinen

J Saastamoinen[1], *T Putkuri*[1,2]
[1]Laurea University of Applied Sciences, Espoo, Finland
[2]Department of Nursing Science, University of Turku, Turku, Finland
Contact: johanna.saastamoinen@laurea.fi

Issue/Problem: Two key public health issues at present are mental health problems and obesity. Both typically begin before adulthood and once occurred, typically persist. Prevention would be important but also economically and humanely sensible. For this, competent experts in preventive work and health promotion are needed.

Description of the problem: Public health nurse education, originally known as health sister education, was initiated in Finland in 1924, by the Mannerheim League for Child Welfare. The six-month health sister education was targeted at nurses and began from the desire to focus not only on treating diseases but also on promoting health. In the 1940s, education was reformed and in the 1950s significantly expanded. In the 1970s, the professional title changed from 'health sister' to 'public health nurse'. In 1987, the education was extended to 3 years, including the education of registered nurses. In 1992, the education was further extended to 3.5 years. By the beginning of the 21st century, education evolved into 4 years bachelor's degree.

Results: In 2024, eighteen Universities of Applied Sciences provide public health nurse education in Finland. The 4-year Bachelor of Health Care in Public Health Nursing -degree (240 ECTS credits) also qualifies for a registered nurse. Nearly half of the education consists of clinical training. In addition, registered nurses can supplement their degrees by completing a one-year education (60 ECTS credits) that qualifies them as public health nurses.

Lessons: In Finland, approximately 700 new public health nurses graduate annually. They are trained to work independently as experts in preventive work, health promotion, and public health. Around 9,500 Finnish public health nurses work in settings such as maternity and child health clinics, school health services, occupational health care, and outpatient clinics.

Key messages:

- Due to the overcrowding in many healthcare services providing treatment, educating experts in health promotion and disease prevention is crucial now and in the future.
- By ensuring competent experts in health promotion and disease prevention, future healthcare services can continue to provide economically and humanely sensible and effective help for people.

Abstract citation ID: ckae144.1853
Perception of stress among healthcare workers in hospitals in Belgrade during COVID-19 pandemic

Mladen Babić

M Babić[1], *Z Bukumirić*[2], *A Nešković*[1], *K Tripković*[1]
[1]Center for Analysis, Planning and Organization of Health Care, City Institute of Public Health Belgrade, Belgrade, Serbia
[2]Institute for Medical Statistics and Informatics, Faculty of Medicine, Belgrade, Serbia
Contact: mladen.babic@zdravlje.org.rs

Background: The COVID-19 pandemic has affected healthcare institutions and workers, exposing them to unfamiliar and hazardous conditions, increased workloads, and changing directives. This has led to work-related stress, resulting in burnout, depression, anxiety disorders, and other health issues among healthcare workers.

Methods: This cross-sectional study utilized an anonymous questionnaire with closed-ended questions. To assess stress levels among healthcare workers, a Likert-type scale was used. Over 6.000 healthcare workers completed the questionnaire in 2022. The relationship between the dependent variable (perceived stress level) and predictors was modelled using generalized ordinal univariate and multivariate logistic regression.

Results: Almost a third (30.7%) of respondents felt a very high amount of tension, stress, or pressure while performing their jobs under the conditions of the COVID-19 epidemic, while 422 (6.8%) did not feel tension, stress, or pressure at all. In the multivariate logistic regression model, statistically significant predictors of higher levels of perceived stress in the conditions of the COVID-19 epidemic include female sex (OR = 0,80), older age (OR = 1.19), being in a managerial position (OR = 1.32), lower satisfaction with available work time (OR = 0.82), patient relations (OR = 0.81), financial compensation (OR = 0.83), and cooperation with colleagues (OR = 0.93).

Conclusions: Through the identification of potential stress predictors, valuable insights are gained to aid policymakers in the planning and enhancement of healthcare personnel's work during pandemics, as well as in situations characterized by heightened stress levels.

Key messages:

- These findings emphasize supporting healthcare workers during the pandemic.
- Strategies for reducing stress should be directed towards healthcare professionals who experience higher stress levels.

Elective placements for medical students in a regional Public Health Department in Ireland

Ciara Kelly

C Kelly[1,2], *I Gorman*[2], *C Carroll*[2], *U Fallon*[2], *N McCarthy*[3], *F Cooney*[2]
[1]National Health Service Improvement, Public Health, HSE, Dublin, Ireland
[2]Department of Public Health HSE Dublin and Midlands, Dr Steevens' Hospital, Dublin, Ireland
[3]Public Health and Primary Care, Institute of Population Health, School of Medicine, TCD, Dublin, Ireland
Contact: kellyc42@tcd.ie

Exposure to different specialties during medical school influences the subsequent career choice of students. We describe the development of elective student placements in Public Health in a regional Public Health Department (PHD) in Ireland which serves a population of just over one million. In September 2023, a collaboration to oversee the electives was established between our PHD (HSE Dublin and Midlands) and an academic institution (Trinity College Dublin (TCD)). An Elective Working Group (WG) was formed which developed learning objectives and an elective plan. The electives were scheduled for October and November 2023. The key learning objectives were for students to: • Develop an understanding of the role of Public Health across all domains, in our regional PHD and in Ireland; • Develop an understanding of the career pathway in Public Health Medicine in Ireland; • Contribute to a public health project within the PHD. The elective plan included approximately 15 1:1 tutorials across the public health domains, attendance at PHD meetings and a literature review-based project. Between October and November 2023, two students (one per month) were attached to the PHD. At the end of each elective, students presented project findings to the WG for discussion. Debrief sessions gathered feedback from the students, the WG and the TCD partner. Student feedback was overwhelmingly positive. Feedback suggested taking pairs of students at the same time may increase efficiency and capacity for future electives in our PHD. A collaborative approach to planning and coordinating the electives was crucial to its success. We are building on this experience to expand the electives with an increased number of students being facilitated by our PHD in 2024, providing students with greater opportunity to gain exposure to Public Health Medicine during medical training. Application and evaluation materials were refined which can be shared.

Key messages:

- The success of the Public Health electives in our regional Public Health Department was underpinned by a collaborative academic partnership and a structured, coordinated approach.
- Availability of Public Health electives during medical school training can support students to gain exposure to this specialty in a time when they are considering future career choices.

Abstract citation ID: ckae144.1855
Honors Track in Global and Occupational Health: a students' perspective from Humanitas University

Luigia Ferrante

L Ferrante[1], J Ertmer[1], M Pagano[1], IO Oyedele[1], F Serazzi[1], L Lopedote[1], F Barbic[1], S Stranges[2]
[1]Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy
[2]Epidemiology and Biostatistics, Western University, London, Canada
Contact: luigia.ferrante@st.hunimed.eu

Background: To meet an increasing interest in global health, more opportunities for medical students should be created. Humanitas University (Milan, Italy) has debuted a new extracurricular activity called "Honors Track in Global and Occupational Health" (HT-GOH), to allow students critical insights into the field at the beginning of their career.

Objectives: HT-GOH is a two-year programme, led by expert professors in the field. The main aim is to circumvent limitations of global health education at individual institutions, achieved through a combined presence and online approach that allows for international collaboration with experts and attendance of online lectures and travel abroad for practical experiences. Complemented by monthly meetings, participation to workshops, seminars, conferences, and the discussion and literature review of crucial global health topics.

Results: The six participating students are actively promoting discussions, exchange of ideas, and literature findings on many global health issues. They audited courses in other universities and are building connections within the field. The active involvement of the students and their increasing interest in the global health debate can be seen by their participation in this abstract and the conference. The effectiveness of the programme is being evaluated through monthly feedback by students.

Conclusions: The programme allows for an initiation to research work, promoting collaboration between students and exploration of a variety of topics under the guidance of experts. The nature of a specific programme allows for a more individualized approach and greater development of skills unique to each student. This HT represent a valid approach to global health education, especially in settings in which this field is only taught in the context of a public health course.

Key messages:

- A new programme at Humanitas University offering an innovative approach to the field of global health to interested students.
- The students' perspective towards an integrated approach to global health in medical schools.

Abstract citation ID: ckae144.1856
Opportunities for nursing and midwifery research in Bulgaria

Milena Saleva

M Saleva[1], E Mineva-Dimitrova[1], A Anov[1], M Draganova[1]
[1]Faculty of Public Health, Medical University of Pleven, Pleven, Bulgaria
Contact: msaleva@abv.bg

Background: The training of nurses and midwives today is at university level and follows established standards. The 2009 Global Standards for the basic nursing and midwifery education of the World Health Organization requires that the curricula should include basic knowledge and skills for scientific research to implement evidence-based health care. In Bulgaria, scientific research among nurses and midwives began in 2000 and has seen more serious development in the last 5 years.

Methods: A content analysis of normative documents was carried out, to regulate the conduct of scientific studies and the curricula for the two specialties.

Results: In all documents on the activities of graduate nurses and midwives, activities related to conducting scientific studies are regulated. No mandatory discipline for these competencies is included in the basic education. In Bulgaria, there is a bachelor's and master's program only in Health Care Management, in which sociology, statistics, and research methodology are studied. From 2000 to 2016 nurses and midwives defended doctoral dissertations in a program for medical doctors. The first doctoral program for nurses and midwives is from 2016. There are no legal norms for stimulating and provide conducting clinical research, and to ensure evidence-based practice by nurses and midwives.

Conclusions: The normative regulation of scientific activity among nurses and midwives in Bulgaria corresponds to international and European requirements, but the opportunities for training are limited. The responsibility of nurses and midwives to modern society is to ensure high quality in health care provided by: a. providing opportunities for clinical studies; b. implementation of evidence-based health care and practice; c. developing programs for training for research in health care.

Key messages:

- In Bulgaria, there is a legal norms for conducting nursing research, but not for evidence-based practice.
- There is a need for more opportunities to train and encourage clinical nursing research.

Abstract citation ID: ckae144.1857
Preferences regarding the Booster Dose of Covid-19: a cross-sectional study in Central Italy

Giovanni Guarducci

G Guarducci[1], G Mereu[2], F Gemmi[3], G Galletti[3], E Guerreschi[1], A Sergi[4], N Nante[1,5]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Department of Technical Health Professions, Central Tuscany Local Health Authority, Florence, Italy
[3]Quality and Equity Unit, Regional Health Agency of Tuscany, Florence, Italy
[4]Healthcare Management, Central Tuscany Local Health Authority, Florence, Italy
[5]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: giovanni.guarducc@student.unisi.it

Background: Examining information sources, communication channels, and preferred content formats is crucial for adapting and improving future communication strategies in vaccination campaigns. This study aims to evaluate the information and communication preferences regarding the booster dose of Covid-19 among employees of the Central Tuscany Local Health Authority (CT-LHA).

Methods: From July to October 2022, a questionnaire was administered to 7,000 out of approximately 15,000 CT-LHA employees. The questionnaire analyzed communication, organizational, and access aspects regarding preferences for the Covid-19 booster dose. The sample was stratified into healthcare workers (HCWs) and non-healthcare workers (NHCWs). Chi-squared tests were performed using STATA, with the significance level set at 95%.

Results: The returned questionnaires were 1,885 (26.9%), with the majority being HCWs (64.4%). HCWs rated the quality of communication significantly lower compared to NHCWs, who rated it very high ($p < 0.05$). HCWs also rated the ease of booking the Covid-19 booster dose and access modalities to vaccination significantly lower than NHCWs ($p < 0.05$). NHCWs expressed a preference for receiving scientific information from Ministry of Health tutorials, while HCWs preferred information from their general practitioner ($p < 0.05$). HCWs preferred to receive organizational information from healthcare management, while NHCWs preferred information from vaccination physicians ($p < 0.05$). Additionally, HCWs preferred company operating procedures for disseminating information, whereas NHCWs preferred corporate communications circulars ($p < 0.05$).

Conclusions: HCWs and NHCWs showed differences in perceived quality of communication, ease of access to vaccination services, and preferred sources of information. HCWs rated the quality of communication and access to vaccination services lower than NHCWs. This results suggest the need for tailored communication strategies to effectively reach both groups.

Key messages:

- Health organizations need to develop targeted communication approaches that address the specific needs and preferences of their employees.
- Flexibility and adaptability are crucial to adapt communication methods and channels to strengthen vaccination initiatives and promote public health outcomes.

Abstract citation ID: ckae144.1858
Addressing the complexities of evaluating comprehensive sexuality education: an Italian case study

Domenico Martinelli

D Martinelli[1], G Paparatto[2,3], M Ubbiali[4], L Bonaldo[2], M di Nino[2], L Mortari[4], A Chinelli[2], L Tavoschi[2]
[1]Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy
[2]Department of Translational Research, University of Pisa, Pisa, Italy
[3]Health Science Interdisciplinary Research Center, Sant'Anna School of Advanced Studies, Pisa, Italy
[4]Department of Human Sciences, University of Verona, Verona, Italy
Contact: domenico.martinelli@unifg.it

Background: Existing evaluation methods for assessing sexuality education programs may not be suitable for Comprehensive Sexuality Education (CSE) interventions, which are globally indicated as the most effective approach for promoting sexual health and preventing STIs. This holds particular significance in countries, such as Italy, where CSE is not integrated into school curricula. In a pilot project funded by the Italian Ministry of Health since 2019 (EduForIST), we aimed to develop a composite evaluation framework to test the CSE intervention we implemented in lower and upper secondary schools over the past 4 years.

Methods: Based on the latest available evidence, evaluating a CSE intervention requires addressing various dimensions. These include assessing the quality of programs and their implementation, as well as measuring outcomes and impact. Through iterative consultations with experts and providers, methods, criteria, and metrics were chosen and tested for each dimension.

Results: Program quality was evaluated by an expert advisory board. Instruments for implementation quality assessment included: satisfaction survey among students; reflective journals and SWOT analysis drawn up by educators delivering intervention, exploring their perceptions, practices, and attitudes; surveys among teachers and parents, measuring knowledge, attitude, and practice on CSE, and observed changes among adolescents. A four-arm, Solomon, cluster design study was designed to evaluate outcomes in terms of changes in students' knowledge. Clinical and behavioral indicators in the short, medium and long term were selected as measures of the impact of the intervention.

Conclusions: In the field of CSE implementation research, a multi-component approach to evaluation is needed to provide a solid basis for informing policymakers. The involvement of providers, recipients and contextual adults is essential in evaluating CSE interventions. However, assessing long-term impact requires long time frame.

Key messages:

- Assessing CSE interventions requires a multi-component evaluation approach, considering the impact on the personal and emotional development of individuals in order to sustain behavior changes.
- The proposed evaluation framework may inform scientific community, professionals, and decision-makers on effectiveness of interventions in settings where CSE is not yet included in school curricula.

Abstract citation ID: ckae144.1859
Organizational peer support for second victims in Vienna, Austria: The KoHi-project

Victoria Klemm

V Klemm[1], H Rösner[1], E Krommer[2], R Strametz[1]
[1]Wiesbaden Business School, RheinMain University of Applied Sciences AS, Wiesbaden, Germany
[2]Karl Landsteiner Institute for Clinical Risk Management, Vienna, Austria
Contact: victoria.klemm@hs-rm.de

Background: Healthcare workers negatively affected by adverse events are known as Second Victims (SV). The Second Victim Phenomenon (SVP) is widespread globally and can result in various consequences, such as anxiety, loss of confidence, and defensive medicine. To address this, the KoHi-project offers organizational peer support for SVs at the Clinic Hietzing (KHI) in Vienna, Austria.

Methods: A five-hour training program prepared 122 volunteers as peer supporters (KoHis) at KHI. Initial assessment (KoHi-I) in 2019 using the SeViD-questionnaire was followed by a repeat (KoHi-V) in 2022. Additionally, peer supporters underwent quantitative evaluations after training (KoHi-II), each session (KoHi-III), and after three sessions (KoHi-IV). KoHi-I-III were descriptively analyzed, while KoHi-IV and -V await evaluation.

Results: Initial study showed a 43% SVP prevalence at KHI. Most KoHis joined for ethical reasons and skill improvement, displaying high motivation. Post-training, they reported increased competency in supporting SVs. KoHi-III showed 53.3% of sessions initiated by KoHis, often triggered by personal distress. KoHis rated their support as highly helpful ($M = 8.57$ on a ten-point Likert-scale) and felt minimal burden ($M = 3.42$ on a ten-point Likert-scale) afterward. No significant correlations were found.

Conclusions: SVP is widespread at KHI. The five-hour training adequately prepared KoHis. Underreporting or underutilization of the program is suspected, possibly due to self-stigmatization of SVs. Being a peer supporter appears safe for KoHis. Psychological safety of voluntary supporters should be prioritized in hospital peer support programs. European hospitals lack organizational support for SVs, highlighting the importance of interventions like KoHi.

Key messages:

- The SVP is common among healthcare workers at KHI.
- The implemented organizational peer support seems to not negatively impact the voluntary peer supporters' wellbeing.

Abstract citation ID: ckae144.1860
Factors influencing emigration decisions among Bulgarian health professionals

Iliyana Georgieva

I Georgieva[1]
[1]Health Economics and Management Department, Medical University of Varna, Varna, Bulgaria
Contact: iliyanageorgieva@mu-varna.bg

Background: Migration patterns of health professionals are influenced by a variety of factors, including personal, economic, social, political, and cultural ones. This study aims to investigate the factors that influence the emigration decisions of both Bulgarian health professionals who have been abroad and those without such experience.

Methods: A cross-sectional study was conducted in 2022 using an online questionnaire among 447 health workers in Bulgaria. The influence of factors on health professionals' decision to migrate was measured on a 4-point scale (from "no influence" to "very strong influence"). The factors were grouped into three levels - macro (country and health system), meso (health facility) and micro (individual). Mann-Whitney U test was used to examine differences between the two groups of health professionals at a 0.05 significance level.

Results: At macro level, a higher standard of living in the destination country was the primary factor influencing the emigration decisions of the individuals who have been abroad ($n = 109$), with a mean value of 3.62 ($p < 0.001$). Conversely, the opportunity to work in a better-organized health system was the predominant motivator for those without such experience (3.36, $p < 0.035$). At meso level, remuneration received (3.70, $p < 0.001$) was the most significant driver for the individuals with a migration background, while better working conditions (3.31, $p < 0.006$) had the strongest influence for the other group. At micro level, both groups agreed on the importance of enhanced recognition of the medical profession abroad (3.69 vs. 3.49, $p < 0.013$) as a key determinant.

Conclusions: On the whole, health professionals with no migration experience exhibited lower mean values for the observed factors. Furthermore, economic drivers appeared to be more significant for respondents with a migration background, while the other group attached greater importance to the motives related to the health system and the profession.

Key messages:

- Health workers migrate for a variety of reasons with economic motives playing a pivotal role in shaping migration decisions.
- Recognizing the motives that predominantly impact migration attitudes is a crucial step in the development of appropriate retention policies.

Abstract citation ID: ckae144.1861
Unveiling pharmacogenomics: insights from Portuguese pharmacists on quaternary prevention

Maria Luis Cardoso

ML Cardoso[1,2], *A Costa*[1,2], *C Rasga*[1,2], *AR Marques*[1,2], *A Vicente*[1,2]
[1]Department Health Promotion & NCDs Prevention, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
[2]Biosystems & Integrative Sciences Institute, Faculty of Sciences, University of Lisbon, Lisbon, Portugal
Contact: m.luis.cardoso@insa.min-saude.pt

Background: Public health genomics recognises the potential of genomic knowledge for enhancing population health. Adverse drug reactions (ADR) and lack of efficacy have significant clinical and economic burdens, which can be mitigated by pharmacogenomics (PGx) testing. Pharmacists can play a vital role in facilitating the implementation of PGx into routine clinical care. This will promote quaternary prevention, to protect individuals from medical intervention that can cause more harm than good.

Objectives: To assess attitudes, opinions, expectations, practices, and concerns of Portuguese pharmacists regarding PGx implementation.

Methods: An observational cross-sectional web-based survey was developed based on literature review, adapted to the national context, and validated in a focus group. The target population were adults residing in Portugal with a degree in Pharmaceutical Sciences or equivalent, with convenience sampling. Descriptive statistics were performed.

Results: From 303 participants, 98% believe that PGx is an important area of pharmaceutical sciences and 97% indicate that PGx should be included in continuing education. Almost all (99%) anticipate that PGx implementation will prevent the administration of ineffective drugs and inappropriate doses, 98% expect PGx will reduce ADR. Major concerns are related with direct-to-consumer sale of PGx tests via internet (78%) and unauthorized access to test results (91%). Currently, 25% are familiar with reliable sources of information on PGx, but only 11% feel qualified to recommend PGx testing, and 10% have analysed PGx reports.

Conclusions: There are positive opinions and expectations regarding the potential benefits of PGx tests. However, there are regulatory concerns and lack of readiness for immediate application. Pharmacists express interest in learning more about PGx, highlighting the need for continuous education and training to integrate it effectively into routine pharmaceutical practice.

Key messages:

- Pharmacists recognize the benefits of PGx implementation for quaternary prevention.
- Regulatory concerns and readiness gaps in PGx emphasise a need for training and life-long education of pharmacists.

Abstract citation ID: ckae144.1862
Diversity challenges in German nursing teams: a participatory organizational development approach

Anna Schneider

M Feisst[1], *L Peppler*[2], *A Schneider*[2], *L Schenk*[2], *M Apelt*[1]
[1]Faculty of Economics and Social Sciences, Potsdam University, Potsdam, Germany
[2]Medical Sociology and Rehabilitation Science, Charité-Universitätsmedizin Berlin, Berlin, Germany
Contact: anna.schneider@charite.de

Background: Migration of health care professionals, demographic change and the transformation of the health care system result in highly diverse nursing teams in German hospitals and nursing homes. Different orientations (regarding qualification, generation or migration background) collide in a working environment characterized by staff shortage, time pressure and decisions about life and death. But team cooperation not only has a strong impact on patient safety, but on job satisfaction and therefore retention management. Little is known on how teams cope with diversity challenges and how this is linked with organizational structures.

Methods: Based on qualitative content analysis of 197,5 hours of participatory observation, 8 group discussions and 25 interviews in 6 nursing teams in 2 hospitals and 2 nursing homes situated in a major German city, we developed workshops on the topic of team diversity and cooperation. 10 workshops (4-16 participants each) were in held in 2023/24 both on team- and management-level.

Results: All teams are struggling with diversity-related problems, but in their specific ways, depending on the particular neighbourhood of the facility and team composition among other things. Due to the strong team spirit and identity, the teams have a fundamental tendency to integrate diverse perspectives and orientations. But they need time capacities and supportive organizational structures. The workshops created a space to discuss the team specific problems. Starting points for structural changes could be identified and further discussed in the workshops at the next higher hierarchical level.

Conclusions: Organisational structures provide the framework conditions that enable teams to integrate different perspectives resulting from diversity in a productive way. One-fits all solutions are not suitable to address those problems and improve teamwork. A participatory bottom-up process seems to be the most appropriate approach.

Key messages:

- Institutions need to provide structures in which diversity is not perceived as an additional burden.
- The best way to initiate improvements is through a participatory bottom-up approach.

Abstract citation ID: ckae144.1863
A healthcare workforce assessment model using reimbursement data in Luxembourg

Sonia Leite

S Leite[1], C Goetzinger[1], M Urbain[1], F Berthet[1], C Shinn[2]
[1]National Health Observatory, Strassen, Luxembourg
[2]General Inspectorate of Social Security, Luxembourg, Luxembourg
Contact: sonia.leite@obs.etat.lu

Background: The assessment of the healthcare professional (HCP) headcount and level of activity is a real challenge for policy makers. In Luxembourg, there is no uniform definition of practicing HCP. This work focused on identifying a method to assess HCP headcount and their level of activity in Luxembourg, while finding national consensus.

Methods: A thorough literature review was conducted to find methods that assess practicing HCP and identify their level of activity. Eligible were scientific papers or national reports discussing methods on employed and self-employed HCP. National reimbursement data were used for preliminary data explorations conducted alongside the 'General Inspectorate of Social Security' in Luxembourg and discussed with the 'Institut national d'assurance maladie-invalidité (INAMI)' in Belgium. Two working groups were planned with national stakeholders to discuss HCP assessment methodologies. Both the collaborations and the working groups led to a preliminary validated HCP assessment method. To reach national consensus, a Delphi study is planned in June 2024, using the eDelphi.org platform. Invited panelists include researchers, professionals, healthcare practitioners, decision makers and policy makers, patient representatives, and insurers.

Results: The literature review found 16 eligible papers on HCP headcount and HCP' level of activity. Finally, the Belgian method, developed by experts from INAMI, using reimbursement data and establishing a median reimbursement for each medical specialty was retained for Luxembourg. The results of the Delphi study will inform on the level of agreement on relevance, clarity and completeness of the proposed methodology for Luxembourg.

Discussion: Finding national consensus represents a strong foundation for efforts to advance the use of the proposed methodology in healthcare workforce assessment and planning.

Key messages:

- Counting something as simple as healthcare professionals requires a strong methodology that held the buy-in of all major stakeholder.
- As working behavior of HCP evolves over time, it is crucial to not only count professionals but also full-time equivalents for policy makers to plan ahead in an accurate manner.

Abstract citation ID: ckae144.1864
Which diversity factors influence the attribution of competences and co-operation in nursing teams?

Anna Schneider

A Schneider[1], AM Khouri[1], L Peppler[1], M Feißt[2], M Apelt[2], L Schenk[1]
[1]Institute of Medical Sociology and Rehabilitation Science, Charité - Universitätsmedizin Berlin, Berlin, Germany
[2]Faculty of Economics and Social Sciences, Potsdam University, Potsdam, Germany
Contact: anna.schneider@charite.de

Background: Diversity within nursing teams increases due to staff shortages in Germany, nurse migration and the current academization of the profession. Quality of patient care is associated with intraprofessional teamwork. Little is known about how nurse's own diversity factors and those of team members impact nurse's perception and behavior in team situations.

Methods: A quasi-experimental, cross-sectional study with a factorial online survey with fictional case studies (vignettes) was conducted in two German hospital operators in 2023. Nurses of legal age working in hospitals or nursing homes were eligible to participate. Associations of diversity factors, i.e., gender, age, migration background, and qualification, on the participant and vignette level on perceived competences and willingness to cooperate were preliminary analyzed via multi-level fixed effects models in SPSS.

Results: $N = 684$ nurses participated (76% female; mean age: 44.2 years; 88% born in Germany; 75% completed vocational training). Competency of team members in patient's personal hygiene was rated higher by respondents born in Germany (.36), when fictional colleagues were of middle age (.06) compared to higher age and were from Germany (.22) or France (.08) compared to China. Competency in inserting infusions was rated higher by respondents born in Germany (.56), when fictional colleagues were from Germany (.29) or France (.20) compared to China and when one worked together for months compared to days (-.39). Willingness to swap shifts was affected by the fictional length of collaboration (-.08). All significance levels were $p<.02$.

Conclusions: How nurses perceive their colleagues' competences is mainly influenced by their own and the other's migration background, while willingness to cooperate is only affected by length of collaboration. Improving the onboarding process of new nurses in teams, and providing the time and space for professional exchange might improve mutual trust and teamwork.

Key messages:

- Diversity in German nursing teams increases due to nurse migration and plurality of qualifications.

- Facilitating professional exchange about individual competences might improve team work in nurses.

Abstract citation ID: ckae144.1865
Empowering Educators: Integrating Sustainable Health in Healthcare Professionals' Training

Karin Båge

M Niemi[1], J Valcke[2], N Viberg[1], S Guidetti[3], H Mölsted Alvesson[1], F Tariro Tanaka Hungwe[1], D Hellden[1], T Alfven[1]
[1]Global Public Health, Karolinska Institutet, Stockholm, Sweden
[2]Unit for Teaching and Learning, Karolinska Institutet, Stockholm, Sweden
[3]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
Contact: karin.bage@ki.se

Despite efforts to realize Agenda 2030, the sustainable development goals (SDGs) may not be achieved. This already now impacts public health and healthcare, including the training of providers. "Sustainable health" addresses this urgency by emphasizing health as key to achieving the SDGs. While the UN developed a competency framework for teachers in 2011, the specific competencies needed to train in sustainable health remain unclear. Transformative learning (TL) is crucial to integrating sustainable development in higher education (HE), yet its application in the education of health professionals is limited. TL entails a profound transformative journey that reshapes perceptions and experiences, necessitating a shift in the educator's role from information provider to facilitator of transformative processes. According to a 2019 literature review on TL for healthcare students, teachers need detailed and practical guidelines on how to implement TL. We aimed to develop an evidence-based matrix outlining a) the educational strategies needed to ensure that students develop sustainable health competencies, and b) the competencies teachers need to use these strategies in a quality-assured way. We conducted a literature review to identify key dimensions of teacher competencies and educational strategies for sustainable health. We surveyed teachers at Karolinska Institutet to assess the relevance of these competencies and teachers' confidence in using them. Focus group discussions were conducted, to explore barriers and enablers to develop competencies and use educational strategies. We present a competency framework for HE teachers, accompanied by recommended educational strategies and self-assessment tools to gauge further training needs. To be used by teachers and educational developers, it will be openly accessible in Swedish and English. This study contributes to enhancing competencies in training health professionals to contribute to achieving sustainable health for all.

Key messages:

- Educators need to be equipped with competencies to lead transformative learning processes to enable future generations of health professionals to achieve sustainable health for all.
- Educators need to be supported to transform their role and practice to provide relevant training for future health care providers.

Abstract citation ID: ckae144.1866
Global health education in Europe: an insight into the student's perspective

Marta Pagano

I Oyedele[1], M Pagano[1], L Ferrante[1], F Serazzi[1], J Ertmer[1], L Lopedote[1], F Barbic[1], S Stranges[2]
[1]Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy
[2]Epidemiology and Biostatistics, Western University, London, Canada
Contact: marta.pagano@st.hunimed.eu

Background: As the world grows ever connected, more importance is placed on aptness in Global Health. For medical students, incorporating social, environmental, cultural, and global issues in the curriculum is pivotal to their success as future medical professionals. In spite of this, students are dissatisfied with ongoing pedagogy. In review of existing evidence, we discovered that there is no set standard for European medical schools to follow in Global Health teaching. This is evidenced by variation in the course requirement and in the topical content covered. Consequently, students have self-perceived and actual gaps in their Global Health knowledge. Another point highlighted in our research was that despite the importance students have placed on Global Health education, they have viewed it as less relevant in comparison to other aspects of Medicine. To improve this lack of engagement, students have made suggestions that could potentially have a positive impact on teaching methods if they were to be implemented.

Objectives: Our background review and evidence gaps inspired us to conduct an online survey in our university. Examining this, together with reviewing existing evidence on student opinions and experiences from all over Europe, will give us the opportunity to uncover student sentiment towards Global Health education.

Results: Our survey is underway; its results will be discussed in our presentation.

Conclusions: In analysing existing survey results and in executing a survey in our medical school, we have gained some insight and understanding into the perspectives, knowledge gaps, and suggestions of medical students as concerns their Global Health education in Europe. These should be considered in forming and refining the Global Health curriculum of European medical schools.

Key messages:

- Explore the attitudes and opinions of European students towards Global Health education.
- The medical student's perspective should be considered to guide a better-suited education in Global Health across Europe; this is of the utmost importance in a now globalised world.

[6]Programs in Public Health, Sumy State University, Sumy, Ukraine
[7]All-Ukrainian Association of Public Health Specialists, Ivano-Frankivsk, Ukraine
Contact: william.aaronson@temple.edu

Background: Strengthening the public health workforce is among top priorities for the transformation of Ukraine's public health system. As part of the USAID Public Health System Recovery and Resilience Activity, an Academic Partnership Collaborative brought together three Ukrainian universities (National University Kyiv-Mohyla Academy, I. Horbachevsky Ternopil National Medical University, Sumy State University), two American universities (Temple University and Drexel University), and the All-Ukrainian Association of Public Health Specialists (UPHA) to enhance the competencies of public health graduates in Ukraine.

Objectives: The collaborative focuses on strengthening the Ukrainian universities' public health curricula and the teaching and research competencies of the Ukrainian faculty, making the curricular changes in Ukraine better aligned with US and European academic standards. The university partners are collaborating with the newly established UPHA in building partnerships with peer organizations in the US (American Public Health Association) and Europe (EuPHA) and sharing advancements in public health education with the broader community of public health practitioners in Ukraine to enhance their competencies to improve population health and align with European systems of public health.

Results: We have established linkages among all partners via an initial meeting in Uzhhorod, Ukraine in April 2024. We anticipate results by November 2024 to include curriculum review recommendations, coaching on prioritized topics for the Ukrainian partners, faculty development plans, and the establishment of continuing professional development programs in collaboration with UPHA.

Conclusions: Through this partnership, selected Ukrainian universities will have an enhanced and sustainable capacity to train the public health workforce and will become leading examples for other public health programs to simulate and collaborate with beyond the project.

Key messages:

- Ukraine's resilience and recovery relies upon the strength of the current and future public health workforce; mechanisms for building public health training are essential to a healthy population.
- A collaborative process of strategic activities among American and Ukrainian universities and professional associations can be effective in building a resilient public health system in Ukraine.

Abstract citation ID: ckae144.1868
Analysis of medical doctor supply in Bulgaria, Croatia, Romania, and Serbia in the last two decades

Aleksandar Stevanović

A Stevanović[1,2], M Šantrić-Milićević[1,2]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Center - School of Public Health, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: aleksandar.stevanovic@med.bg.ac.rs

Introduction: The shortage of medical doctors in Europe has become a priority issue, especially in the Eastern European region, where many countries are making large investments to ensure adequate supply. Training future medical professionals is a lengthy and costly process that significantly impacts healthcare accessibility and quality. As part of the project of the Laboratory for Strengthening Capacity and Performance of Health System and Workforce for Health Equity, we aimed to assess the changes in the medical doctor supply in several Balkan countries over the last two decades.

Methods: Data on the total number of graduated medical doctors (MD) and their rate per 100,000 population from 2000 to 2021 was retrieved from the Eurostat database. This open-access database contains the reported number of students who have graduated from medical schools for each year and selected countries (Bulgaria, Croatia, Romania, and Serbia). The standard methods of descriptive statistics were used to perform the analysis.

Results: During the observed period, the number of MDs graduating annually and their rates per 100,000 population have increased in all countries. Romania leads with the highest rate of MD graduates at 26.18 per 100,000 people, followed by Bulgaria (22.74), Serbia (19.15), and Croatia (16.56). From 2000 to 2021, Bulgaria experienced the highest increase in the number of medical doctor graduates, with a rise of 169.1% in absolute numbers and 200.9% in rate. In contrast, Serbia had the lowest increase, with only a 135.5% rise in the total number of medical doctor graduates and a rate increase of 152.3%.

Conclusions: In the last 20 years, Bulgaria, Croatia, Romania, and Serbia have seen an increase in the number of MD graduates and their rate per 100,000 population. Policymakers should consider the investments and education trends of medical professionals in relation to their employment and migrations to predict the future supply of doctors in this region.

Key messages:

- Bulgaria, Croatia, Romania, and Serbia have seen an increase in the number of MD graduates and their rate per 100,000 population in the last twenty years.
- Considering the trends in the number of newly graduated doctors, policymakers should address additional factors to ensure an adequate supply of medical doctors.

Abstract citation ID: ckae144.1869
Strengthening youth mental health capacities in Albania: Training primary healthcare professionals

Gentiana Qirjako

G Qirjako[1,2], A Qosja[3], R Çumashi[2], A Meksi[2], R Hala[2], L Zikaj[4], S Qirjako[5], E Tollozhina[6], A Pilika[7], E Tomini[1,2]

[2]Health Promotion Unit, Institute of Public Health, Tirana, Albania
[3]Department of Pediatric, University of Medicine, Tirana, Albania
[4]Polyclinic of Specialties No. 3, Local Health Care Unit, Tirana, Albania
[5]Faculty of Medicine, Tirana, Albania
[6]Ministry of Health and Social Protection, Tirana, Albania
[7]Department of Neuro Science, University of Medicine, Tirana, Albania
Contact: gentaqirjako@gmail.com

Background: Addressing mental health issues among children and adolescents globally is crucial, necessitating interventions at the primary healthcare (PHC) level. The training programme in Albania equipped PHC professionals with skills for early identification, support, and referral for youth mental health issues. Given the global prevalence of such challenges, our intervention serves as a valuable model for enhancing mental health services in communities.

Objectives: The training aimed to develop the capacities of Albanian PHC professionals in improving mental health and psychosocial wellbeing among youth. Through innovative training sessions using participatory action methods, it was sought to answer key questions: How can Albanian PHC professionals better identify and support youth mental health issues? What innovative approaches can enhance mental health training for Albanian healthcare personnel? How can community engagement be strengthened to support youth mental health initiatives in Albania?

Results: Following the programme, 525 healthcare professionals in Albania received training, showing improved knowledge and skills in youth mental health support. They emphasized the importance of community engagement, standardized documentation, and specialized mental health services. Preliminary results indicate increased awareness and readiness among Albanian PHC professionals to address youth mental health needs.

Conclusions: The programme underscores the significance of equipping Albanian PHC professionals with comprehensive skills to tackle youth mental health challenges. Lessons learned have broader implications for strengthening mental health services globally, emphasizing collaboration, standardized protocols, and targeted interventions.

Key messages:

- Strengthening PHC capacity in Albania improves early identification and support for youth mental health, enhancing overall wellbeing.
- Tailored training and community engagement are vital for effective mental health interventions at the grassroots level in Albania.

Abstract citation ID: ckae144.1870
A Good Practice for Learning with Public Health Professionals Globally: Humphrey Fellowship Program

Sabanur Cavdar

S Cavdar[1,2]
[1]Public Health Services, Istanbul Eyupsultan District Health Directorate, Istanbul, Türkiye
[2]Health Management Doctorate Program, Uskudar University, Istanbul, Türkiye
Contact: sabanur.cavdar@gmail.com

Background: International collaborations are valuable yet often undervalued assets that enhance the quality of public health education and bolster the development of the public health workforce.

Objectives: The Humphrey Fellowship Program, part of the Fulbright Exchange Program, facilitates mid-career professionals' visits to US-based host universities for an academic year. Fellows engage in a semi-structured fellowship period to achieve self-defined goals, emphasizing professional development, expanded experience, and intercultural exchange. This study advocates for the program's contribution to enhancing public health education.

Results: Currently, two universities host fellows in public health. Over decades, fellows have engaged with faculty and professionals, participated in classes and meetings, visited institutions for development purposes, and completed US-based affiliations, contributing significantly to their own and the public health workforce's advancement. This interaction-based learning approach aids in navigating social and ethical challenges by fostering a deeper understanding of public and global health issues across countries.

Conclusions: The Humphrey Fellowship Program in public health stands as a commendable model. Similar initiatives could be beneficially replicated in the European region, leveraging local and global successes to strengthen ties with public health education institutions, student communities, and beyond.

Key messages:
- Programs that facilitate international interactions can enhance public health professionals' understanding of global perspectives.
- The Humphrey Fellowship Program in the US stands as a commendable practice for mid-career public health professionals, contributing significant value to the education at host universities.

Abstract citation ID: ckae144.1871
How to rank schools of public health? The PHAR project

Arnaud Chiolero

A Dugerdil[1], *A Chiolero*[2,3,4], *A Flahault*[1]
[1]Institute of Global Health, University of Geneva, Geneva, Switzerland
[2]Population Health Laboratory, University of Fribourg, Fribourg, Switzerland
[3]Institute of Primary Healthcare, University of Bern, Bern, Switzerland
[4]School of Population and Global Health, McGill University, Montreal, Canada
Contact: arnaud.chiolero@unifr.ch

Background: Since the shattering and abrupt withdrawal of several Ivy League universities from ranking systems in 2022, the debate on rankings has been raging in the academic world and beyond. Despite this, rankings have undeniable advantages and continue to be used on a daily basis by a variety of stakeholders. As a previous work has demonstrated that there is no ranking specifically designed for schools of public health, the aim of this project was to create one.

Methods: To create the Public Health Academic Ranking (PHAR), the InCites Benchmarking and Analytics$^{\text{TM}}$ software and the Web Of Science$^{\text{TM}}$ Core Collection database were employed. Bibliometric data on 26 schools of public health, from each continent, were collected between August and September 2022. Eleven research indicators and scores, covering four criteria (productivity, quality, accessibility for readers, international collaboration), for the period 2017-2021, were used. For some schools whose affiliation was not mentioned directly in the software, a specific methodology was designed and tested, with unique research queries applied to the database.

Results: The five top schools of the PHAR were: the London School of Hygiene and Tropical Medicine, the Public Health Foundation of India (PHFI), the Harvard T.H. Chan School of Public Health, the Swiss School of Public Health (SSPH+), and the Johns Hopkins Bloomberg School of Public Health.

Conclusions: The PHAR provides an international bibliometric ranking of schools of public health. As this is a pilot project, the results should be taken with caution and future improvements should be developed.

Key messages:
- The PHAR is the first university ranking system specifically designed for schools of public health and focuses on the research field of this discipline.
- The PHAR makes it possible to rank schools of public health with an unusual structure (such as the PHFI and the SSPH+), which are generally overlooked by traditional rankings.

Abstract citation ID: ckae144.1872
The influence of post-traumatic stress on the intention to leave among Korean child welfare workers

Shan Shan Chen

C Nho[1], *L Cui*[1], *S Chen*[1], *H Jun*[1]
[1]Department of Social Welfare, Ewha Womans University, Seoul, South Korea
Contact: ruth_chen0633@ewhain.net

Background and aims: Previous research have highlighted the challenges faced by social workers who are exposed to traumatic events, such as client violence, and vicarious traumas. These experiences often lead social workers to leave their agencies. However, it is commonly assumed that child welfare workers are immune to such experiences as they primarily work with non-violent children. This study aims to investigate whether post-traumatic stress among Korean child welfare workers influences their intention to leave, and whether peer support and organizational culture mediate this relationship.

Methods: A total of 246 participants were recruited in 2021 through purposive sampling. Due to the ongoing Covid-19 pandemic, a self-administered online survey method was employed. Only workers who reported direct and/or indirect traumatic experiences at their workplaces were included in the final analysis. Structural equation modeling was utilized to examine the relationships among variables in this study.

Results: While organizational culture had a partial mediating effect in the relationship between post-traumatic stress and intention to leave, peer support did not show a significant effect. This suggests that fostering a supportive organizational climate may be crucial in reducing work-related stress, including post-traumatic stress. It also highlights the need for social work administrators to actively promote such climates to prevent turnover within the child welfare workforce.

Discussion and conclusions: The findings of this study suggests that child welfare organizations can take proactive measures to address this issue. Creating a supportive organizational culture that fosters resilience and provides resources for coping with post-traumatic stress is crucial. Organizations may explore additional strategies for reducing workforce turnover, which will have negative effects on their clients and organizations as well.

Key messages:
- Fostering a supportive organizational climate may be crucial in reducing work-related stress, including post-traumatic stress.

- Child welfare organizations may explore additional strategies for reducing workforce turnover, which will have negative effects on their clients and organizations as well.

Abstract citation ID: ckae144.1873
Global insights of AMR education within One Health

Avis Anya Nowbuth

Contact: anya.a.nowbuth@ntnu.no

Introduction: Amidst rising concerns over antimicrobial resistance (AMR), traditional educational models fall short in addressing the complexities of AMR which spans environmental, animal, and human health. Education plays a key role in equipping students with skills to combat AMR effectively. We analyzed the difference in knowledge, attitude, and practices (KAP) regarding AMR across medical, dental, and veterinary students, in relation to the quality of AMR education they receive.

Methods: Pubmed, Scopus, Web of Science and Google Scholar were searched for articles related to KAP and education until 3 August 2023. The inclusion criterion was the presence of KAP data related to AMR, and details on the AMR education curriculum. Meta-analysis is currently being performed.

Results: We retrieved 1301 articles, and 90 articles met inclusion criteria for final analysis. Articles spanned 42 countries, first to final year, sample sizes ranging from <100 to >3000 participants. Across medicine and dentistry, 79% of studies were done, compared to 17% in the veterinary sector and 5% that adopted a One Health approach. HICs prioritize improving current educational frameworks with practical skills and innovative teaching methods. LMICs deal with challenges like raising awareness about AMR and addressing educational deficiencies at a basic level. Findings indicate a wide variance in AMR knowledge levels, with some studies reporting as low as 32.4% of participants having “good knowledge” on AMR. Attitudes towards antibiotic use and resistance were casual, with a significant number of students expressing the need for more education. Practices varied widely, from high rates of self-medication to better-informed antibiotic use in regions with more comprehensive AMR curricula.

Conclusions: Enhancing the quality of AMR education across medical, dental, veterinary, and environmental health is imperative to equip future health professionals with the knowledge and attitudes necessary to combat AMR.

Key messages:
- Traditional educational models are insufficient for addressing the complexities of AMR which crosses multiple health sectors.
- Improving AMR education quality is crucial to equip future health professionals to effectively combat AMR.

Abstract citation ID: ckae144.1874
Skill mix among healthcare workers during the Covid-19 pandemic – a scoping review

Natalia Petka

N Petka[1], K Nowak-Zając[2], K Badora-Musiał[2], A Domagała[2], I Kowalska-Bobko[2]
[1]Doctoral School of Medical and Health Science, Jagiellonian University Medical College, Cracow, Poland
[2]Institute of Public Health, Jagiellonian University Medical College, Cracow, Poland
Contact: natalia.petka@doctoral.uj.edu.pl

Background: The problem of human resource shortages in health care was highlighted during the Covid-19 pandemic in many countries around the world. Various solutions have been implemented to cope with the crisis, one of which is the skill mix of medical and peri-medical staff. The aim of the scoping review was to systematise knowledge about the skill mix of healthcare workers during the Covid-19 pandemic.

Methods: The review was conducted in five scientific databases including Cinahl Ultimate, Web of Science, Medline (PubMed), Embase and Scopus. The review included studies published from 2020 until July 2023, presenting original research on the skill mix of health care workers.

Results: A total of 5039 records were identified in the databases and 27 articles were included in the final analysis. Of the included studies, 14 were conducted in Western and Southern Europe. Most of the studies included in the review were conducted among nurses (n = 12), pharmacists (n = 11) and doctors (n = 6). The majority of studies concerned re-allocating tasks (n = 9) and re-allocating tasks and introducing or changing teamwork (n = 7). Research covered psychological aspects of work, patient safety, work reorganisation and training and collaboration. Many studies also focused on difficulties and barriers related to skill mix, such as blurring of responsibilities and role ambiguity. The review did not identify any studies conducted among laboratory diagnosticians, medical coordinators or surgical assistants. In addition, there were no studies of skill mix in Central and Eastern Europe during the pandemic.

Conclusions: Given that skill mix may be one of the solutions to reduce the negative impact of staff shortages, more research should be conducted in this area. Healthcare professionals should be involved in decision-making processes related to the granting of new competencies or the creation of new professions/functions in healthcare.

Key messages:
- It is necessary to involve health professionals in the process of creating new skill mix solutions.
- More research is needed on skill mix in times of crisis, particularly in Central and Eastern Europe.

Abstract citation ID: ckae144.1875
Promoting healthy ageing at work through the development of coping strategies among senior workers

Min-Chien Tsai

M Tsai[1], S Thoral[2,3], D Jourdan[4]
[1]UNESCO Chair ‘Global Health & Education’, University of Huddersfield, Huddersfield, UK
[2]CESI Lyon, Villeurbanne, France
[3]JC Bouy, Saint-Hilaire-de-Voust, France
[4]UNESCO Chair ‘Global Health & Education’, Université Clermont Auvergne, Clermont Ferrand, France
Contact: m.tsai@hud.ac.uk

Background: In France, the employment rate for individuals aged 50-64 has risen to almost 67% by 2023, with projections indicating that nearly one in three citizens will be over 60 by 2040. This demographic shift presents a significant labour challenge. To address this, the study explores how senior workers tackle workplace challenges and how their coping strategies influence healthy ageing at work.

Methods: This study explores critical factors in healthy ageing at work using a mixed QUAL/Quant methodology. 15 interviews provided insight into senior workers, while 28 participants from a French company completed an online questionnaire. Qualitative data were analysed using template analysis, and quantitative data were analysed using SPSS version 20.

Results: The interviews revealed that senior workers' problem-solving methods were grouped into three approaches: technical solutions (ergonomic adjustments, supportive equipment), coping strategies (help-seeking, utilisation crafting and developmental crafting), and mindset changes (metacognition, positive reappraisal). Among the senior group, the survey results showed that developmental crafting was a significant positive predictor of work engagement ($\beta = 1.52$, $p < .05$). Utilisation crafting and relational crafting were significant positive predictors of general health ($\beta = .53$, $p < .05$, and $\beta = .50$, $p = .05$, respectively).

Conclusions: This study not only emphasizes the significance of technological solutions but also underscores the critical roles of help-seeking, utilisation crafting, developmental crafting, metacognition, and positive reappraisal in fostering healthy ageing at work. These insights emphasize the need for ongoing development of human resource management strategies to address the challenges associated with ageing at work.

Key messages:

- Our study finds senior workers employ diverse strategies - technical solutions, coping strategies, mindset shifts - to promote healthy ageing at work.
- The insights highlight the importance of human resource strategies for addressing challenges of the ageing workforce, emphasizing proactive approaches.

Abstract citation ID: ckae144.1876
Postgraduate medical education in Public Health: the Italian scenario and a call to action

Flavia Pennisi

F Pennisi[1], *GE Ricciaridi*[1], *M Minerva*[1], *C Signorelli*[1]
[1]Università Vita Salute San Raffaele, Milan, Italy
Contact: pennisi.flavia@hsr.it

Introduction: Public health training in Italy takes place within postgraduate medical training in Hygiene and Preventive Medicine. With 39 university schools of public health, spread across 17 of Italy's 20 regions, the landscape is diverse. The government determines the number of available contracts annually. This study aims to provide an up-to-date analysis of the saturation of places in Public Health programmes, as well as an assessment of mobility trends between northern and southern Italy from 2017 to 2023.

Methods: Data on admissions, withdrawals and resignations were obtained from the Ministries of Universities and Health and from the archives of the 'Associazione Liberi Specializzandi' (ALS). Mobility was assessed as moving from the central-northern regions to the southern-islands of Italy, and vice versa, between registration with the Medical Council and specialisation programme enrollment.

Results: Between 2017 and 2023, a total of 2301 residents enrolled across Italy, out of 2953 available positions nationwide. During this period the number of available national places, increased from 180 to 576, impacting overall seat saturation. In 2017, 98.3% of positions were covered, compared to only 46.5% in 2023. Regarding the mobility trend, southern students attending northern schools increased from 8.3% in 2017 to 22.4% in 2023, while northern students attending southern schools decreased from 17.9% to 1%. However, the number of dropouts and withdrawals was higher in the North. Mobility students scored lower than non-mobility students nationally.

Key messages:

- From 2017 to 2023, the number of residents enrolled increased, while the allocation rate decreased. There was a shift in mobility patterns, with more southern students moving north.
- Addressing the identified inequalities and understanding the underlying factors driving mobility patterns is crucial for effective planning and allocation of resources.

Abstract citation ID: ckae144.1877
Informing infodemic management capacity building by piloting an adaptable capability tool

Sandra Machiri

B White[1], *C Bertrand-Ferrandis*[1], *K Von Harbou*[1], *L Latinovic*[1], *N Emiroglu*[1], *S Varaidzo Machiri*[1]
[1]Country Readiness and Strengthening, WHO, Geneva, Switzerland
Contact: machiris@who.int

Background: Infodemic management competencies and indicators have been included in key WHO pandemic preparedness documents and guidance such as the Preparedness and Resilience for Emerging Threats (PRET) initiative, the Health Emergency preparedness and response (HEPR) framework and in the WHO benchmarks for strengthening health emergency capacities. Training and capacity building is needed to strengthen infodemic management skills and capacity, and a tool to define capabilities and inform training needs was needed.

Objectives: An adaptable tool was developed and piloted to measure infodemic management capacity to inform training and capacity building needs. The tool was informed by previous work and adapted to cover a wide set of capabilities. It was piloted in March - May 2024.

Results: The tool was developed to cover the breadth of infodemic management work practice and structural support and included: who is conducting infodemic management work; structures in place to support; main activities; health topics focus areas; partnerships with other organisations; social listening and infodemic insights generation; as well as challenges, opportunities and training needs. The tool can be adapted to the specific situation, with a full survey able to be disseminated via an online survey platform as well as a modified interview guide for key informants or settings where that is more appropriate.

Conclusions: Preliminary results show that this tool can be a useful way to measure infodemic management competencies and to inform training and capacity building needs. The ability to adapt to specific settings is important to ensure the results are as useful and tailored as possible. As further testing in different setting continues the tool will continue to be iterated upon.

Key messages:

- Infodemic management is an important component of pandemic preparedness and resilience and across the whole emergency response cycle.
- A new adaptable tool to measure capabilities can help inform infodemic management trainings and capacity building.

Abstract citation ID: ckae144.1878
Field Visits as a Pedagogical Tool to Understand Health Determinants

Inês Morais Vilaça

I Morais Vilaça[1], *D Sampaio Viana*[1], *M Ramos Castro*[1], *A Vicente*[1], *C Martins Machado*[1], *B França*[1], *C Pratas Valente*[1], *T Leão*[2]
[1]Public Health, Unidade Local de Saúde de Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal
[2]Public Health, Forensic and Medical Education, Faculty of Medicine of Porto University, Porto, Portugal
Contact: ines.morais.vilaca@gmail.com

Background: Medical education often focuses on curative medicine, neglecting health determinants. Field visits, common in other educational contexts, enhance understanding of these factors. We aim to offer insights into pedagogical methods applicable to similar educational settings.

Objectives: Medical students completing an internship at the Gaia-Espinho Public Health Unit participated in field visits to enhance their understanding of health determinants. Guided through two economically distinct areas within a walkable distance of 2km, students documented health determinants through notes and photos. Discussions were held on-site and after visits integrating the real-world experience with theoretical frameworks. An inductive thematic analysis of students' satisfaction and pedagogical effectiveness of the activity was performed on the internship reports from the 2023/2024 academic year.

Results: Out of 18 internship reports, 10 described the activity as positive and enriching, of which six highlighted it as a crucial part of the internship. Thirteen reports noted that the activity led to new perceptions about health determinants, and nine highlighted its practical value. Nine students included photos in their reports, bike paths being the most featured. Seventeen provided a clear description and listed the determinants they were able to detect. Discussions highlighted sensory experiences that are uniquely discernible through physical site visits including unpleasant odours, loud noises, and the cooling effect of blue areas on hot days. Three did not provide any evaluative comments, but correctly listed the determinants identified.

Conclusions: Field visits may enhance medical students' understanding of health determinants, being recognized as an engaging pedagogical tool. Potential biases in assessments that rely on student satisfaction reports must be considered. Findings support the continuation and expansion of visits in other Public Health internships.

Key messages:

- Field visits, used as a pedagogical tool, may enhance medical students' ability to understand health determinants.
- User Field visits provide a new perspective on previously acquired theoretical knowledge regarding prevention.

Abstract citation ID: ckae144.1879
Working conditions in OOH-PC centres in Romania: an interview study with healthcare professionals

Simona Ciotlăuș

S Ciotlăuș[1,2], IM Ungureanu[2], F Oprescu[3]
[1]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania
[2]Babeș-Bolyai University, Cluj-Napoca, Romania
[3]University of the Sunshine Coast, Maroochydore, Australia
Contact: simona.ciotlaus@umfcluj.ro

Considering the amplifying primary care workforce shortage, the existing knowledge gaps in out-of-hours primary care delivery (OOH-PC) in Romania, as well as the extreme county-to-county variation in the number of functioning OOH-PC centers across the country, from 0 to 32, we set out to document health workers' perspectives on existing challenges in after hours primary care. Using a qualitative study design, we conducted semi-structured interviews with a purposive sample of 20 healthcare professionals (HCPs): family doctors and nurses providing clinical services in urban and rural OOH-PC centres, family doctors with coordinating and administrative roles, representatives of professional associations and health authorities, as well as emergency doctors and paediatricians. We examined interview transcripts employing thematic analysis. The data collected and analysed revealed several challenges in the provision of care, including physician shortages, increasing workload, low payments, and an organisational model that lacks coordination with other levels of care and services. The analysis of the interview data identified five key themes related to adverse working conditions in OOH-PC: working hours and shift length, increasing workload and patient influx, obstacles to achieving work-life balance, inconveniences related to OOH centre premises (rest space, security), and insufficient financial compensation for after-hours health service provision. Working conditions in OOH-PC centers in Romania constitute a drawback to after hours primary care service provision. Health workers shortage and extreme variation in the number of functioning centres across the country suggest inconsistencies in the governance of OOH-PC. Improving working conditions to recruit and retain health professionals in OOH-PC, combined with targeted policies to optimise organisation and coordination of OOH-PC with other levels of care are as timely as ever to ensure equitable services to the population.

Key messages:

- Current working conditions in OOH-PC Romania impact negatively the health workforce and lead to uneven access for the population.
- Improvements in working conditions, service integration, and organisation model are timely for the alleviation of OOH-PC provision.

Abstract citation ID: ckae144.1880
Harassment of interns, medical interns and residents: consequences and complaints

Karla Vazquez Hernandez

J Villegas-Dominguez[1], CO Teczon Castellanos[1], N Suárez Hernández[1], M Andrade Martinez[1], F Ruiz Garcia[1], JC Viñas Dozal[1], V Duarte Cruz[1], YR Sosa Gonzalez[1], M Hernandez Rico[1]
[1]Facultad de Medicina, Campus Veracruz, Universidad del Valle de Mexico, Veracruz, Mexico
Contact: qarlyvh@outlook.com

Introduction: Workplace harassment manifests in various forms for healthcare students, potentially leading to modifications in their lives and academic activities.

Objectives: To describe the type of harassment experienced by interns, medical interns, and residents, and its consequences.

Methods: A cross-sectional and prospective study was conducted, including medical interns, social service interns, and residents from Veracruz who reported experiencing harassment in their assigned areas during their last academic year. Direct and virtual invitations were sent through various electronic means.

Results: 58 students were included, with 39 (67.2%) being women. 50% reported experiencing psychological abuse, and 65.5% reported experiencing sexual harassment. The most severe sexual harassment incidents included sexual assault with physical force (1.7%) and three instances of non-consensual sexual relations (5.2%), while the most common were sexual jokes/comments (72.4%). Following harassment experiences, 25% of participants reported feeling anxious, 22% stressed, and 17% angry. Students who perceived psychological abuse reported anger (69%), stress (58.6%), and anxiety (58.6%) as the most frequent consequences, while those reporting sexual abuse indicated anger (73.7%), shame (68.4%), and anxiety as primary consequences. The most frequently identified harassers were attending physicians (56.9%), senior students (34.5%), and non-medical personnel (34.5%). Students filed complaints with hospital authorities (6.9%), university authorities (6.9%), and external agencies (5.2%). The individual who experienced sexual assault with physical force did not file any complaint, while only one person reported non-consensual sexual relations to hospital authorities.

Conclusions: It is crucial to establish safe spaces for students within the hospital environment to promote their overall well-being and academic success, as well as to encourage a culture of reporting.

Key messages:

- Highlighting the need for intervention within the work teams where our students are placed, promoting a violence-free environment.

- Annexing a therapist as part of the work team could favor the well-being of students, since mental health is one of the main points affected within a violent environment.

Abstract citation ID: ckae144.1881
Factors associated with perception of harassment in interns, trainees and residents of Veracruz

Josue Eli Villegas Dominguez

J Villegas Dominguez[1]*, N Suárez Hernández*[1]*, CO Teczon Castellanos*[1]*, M Andrade Martínez*[1]*, F Ruiz Garcia*[1]*, V Duarte Cruz*[1]*, JC Viñas Dozal*[1]*, YR Sosa Gonzalez*[1]
[1]Facultad de Medicina, Campus Veracruz, Universidad del Valle de Mexico, Veracruz, Mexico
Contact: josue_eli@hotmail.com

Background: Harassment among resident physicians remains prevalent, with reports of abuse at 20% in Mexico, potentially creating a hostile learning environment that does not foster comprehensive learning for students.

Objectives: To determine the factors associated with harassment among interns, medical interns, and residents in Veracruz.

Methods: This is a prospective cross-sectional study, including interns, social service interns, and residents in the state of Veracruz, excluding those diagnosed with oppositional defiant disorder or mythomania. Workplace harassment was assessed using the Cisneros scale (Cronbach's alpha 0.98), in addition to perceptions of workplace, psychological, and sexual harassment. Within the statistical analysis, the association was determined using chi-square test, odds ratio, and 95% confidence interval (OR/CI95%).

Results: A total of 81 participants were included, with a perception of workplace harassment in 42% and sexual harassment in 51.9%; the Cisneros scale shows 2.5% of subjects free from any harassment behavior. Female gender showed association with workplace harassment (0.7/0.01-0.2); meanwhile, attending a public university (OR: 0.22 / CI: 0.07-0.6) and being a pregraduate intern (OR:2.6/CI:1.03-6.6) were associated with perception of psychological harassment. Furthermore, being female (OR:9.28/CI:3.3-25.4), bisexual (OR:11.8/CI:1.4-97.8), a pregraduate intern (OR:3.44/CI:1.32-8.97), an R1 resident (OR:0.09/CI:0.01-0.79), and being affiliated with Veracruz (OR:2.6/CI:1.05-6.58) or Xalapa (OR:0.1-CI:0.05-0.7) were identified with association for experiencing sexual harassment ($p < 0.05$).

Conclusions: Gender and level of education are the main factors associated with harassment, while the type of university of origin plays an important role in psychological harassment, warranting further study of these interactions while considering the limitations of this research.

Key messages:

- The results of this research show that the roles of violence within hospital medical education are still maintained despite the social evolution with respect to gender roles and equality.
- It is necessary to promote the culture of denunciation and offer courses to eliminate abuse and promote equality and respect among hospital staff.

Fairer Training in public health, the UK FPH example

Samia Latif

S Latif[1,2]*, R Fardon*[1]*, D Chappel*[1]*, A Vusirikala*[1]
[1]Education, Faculty of Public Health, London, UK
[2]Health Protection Ops, UKHSA, London, UK
Contact: Samia.Latif@ukhsa.gov.uk

Background: Public Health (PH) advocates for health equity and social justice. The UK Faculty of Public Health (FPH) is committed to tackling inequalities across the public health career pathway. The Fair Training project is a multi-phased programme which focuses on fair recruitment into PH, reducing differential attainment during PH training and postgraduate examinations.

Objectives: • Analyse available data from various sources; • Identify gaps in fair training culture and any biases; • Identify where support or interventions may best be focussed to minimise disadvantages; • Identify improvements in data that could be used to monitor actions; • Identify areas of good practice. Variables explored were demographic characteristics e,g, age, sex, ethnicity, disability status, professional background, candidate status (UK or overseas), place of primary qualification.

Results: Results show that candidates from ethnic minority backgrounds, those who are older, from international medical graduate backgrounds and backgrounds other than medicine are under-represented at the end of recruitment. Multivariable analysis of the diplomate exam shows that an attainment gap exists across increase with age, and those from black, Asian or white other ethnicity, professional background other than medicine, and overseas candidates. For the membership exam, multivariable analysis shows the attainment gap persists across those of increasing age and black ethnicity.

Conclusions: Recognising differential attainment as a structural problem requires organisational and individual leadership. Recommendations include an action plan to ensure: • Equality of opportunity for learning and career progression; • Collaborative working to eliminate discrimination in the design of education; • Ensure that training and the working environment are inclusive and diverse; • Inform future PH workforce planning; • Share good practice. FPH will implement the recommendations and share with other organisations and countries.

Key messages:

- Structural causes of differential attainment during recruitment and training in public health do exist and should be mitigated.
- FPH aims to promote Fair Training and excellence in public health practice.

Public Health In Conflict And War: A Response To An Ever Evolving Landscape

Karl F Conyard

KF Conyard[1,2,7]*, MB Codd*[1,2,8]*, A Mason-Jones*[3,2]*, C Cunningham*[4,2]*, J Middleton*[5,6,2]
[1]SPHPSS, University College Dublin, Dublin, Ireland
[2]Core Curriculum Programme for Public Health, ASPHER, Brussels, Belgium
[3]Department of Health Sciences, University of York, York, UK
[4]School of Public Health, University College Cork, Cork, Ireland
[5]Global Network for Academic Public Health
[6]School of Health and Society, Wolverhampton University, Wolverhampton, UK
[7]School of Medicine, RCSI, Dublin, Ireland
[8]Executive Board, ASPHER, Brussels, Belgium
Contact: karl.conyard@aspher.org

Background: The bases for this proposal are the current and ongoing conflict and war situations around the world, causing turmoil for nations and hardship and public health crises for people. We can no longer ignore the critical and time-sensitive need to address issues of Public Health (PH) in conflict and war in our education and training programmes.

Objectives: To consider appropriate themes and topics in Conflict and War that should be included in PH education and training programmes; and to consider how and where they are best represented. Member schools of the Association of Schools of PH in the European Region (ASPHER) were asked to provide details of their curricula relating PH in Conflict and War. Submissions on this topic were received from over 10 schools. Information was collated into logical themes, to which elements of the curriculum were mapped. In a modified Delphi process, respondents were asked for their level of agreement for inclusion in a curriculum and at what level content should be delivered.

Results: Findings from the survey allowed identification of seven main themes from topics provided: Contextual Factors; Preventive Strategies; Emergency Preparedness; Impact and Response; Conflict Resolution and Solidarity, Rehabilitation and Recovery. Respondents had high levels of agreement that content should be included in curricula and be delivered at every level in PH education and training.

Conclusions: PH education and training have been deficient in not including PH in Conflict and War as a subject area in programmes. The knowledge and expertise developed of necessity in some places can be shared across the ASPHER network and beyond to increase awareness of the PH considerations of conflict and war.

Key messages:
- Public health in war and conflict zones is critical due to unique challenges and urgent needs of affected populations.
- An Integrated curriculum is vital for addressing conflict's long-term health impact and preparing skilled workforce for health, resilience, action and laying the path to peace.

Abstract citation ID: ckae144.1884
Health and Care Horizons Leeds: Attracting, navigating and inspiring the future workforce

Cara Gates

C Gates[1]
[1]School of Health, Leeds Beckett University, Leeds, UK
Contact: c.gates@leedsbeckett.ac.uk

Health and social care (H&SC) partners in Leeds connect and collaborate across seven shared workforce priorities, including 'growing and developing registrants" and "narrowing inequalities". A range of programmes across the Leeds H&SC system promote collaborative, person-centred recruitment, and developing diverse & accessible talent pipelines. Through these programmes and the aims of the NHS long-term workforce plan we have identified a need to draw together information, insight and opportunities to attract, navigate, inform and inspire young people into H&SC careers. The Leeds partnership co-designed an interactive career exploration tool with young people to meet these aims. This person-centred digital tool is designed to dispel misinformation and equip young people with personalised actions and pathways to work anywhere in the sector based on their skills, values and lifestyle. The framework of our approach to designing the tool and lessons learned is applicable to other settings and localities. An academically embedded evaluation of the co-design phase demonstrated the importance of reaching out to a diverse audience. We worked with over 400 young people across 12 unique and representative networks and made them feel valued. Our partners were persuaded by the potential for the tool to boost recruitment and retention strategies, aligning with the NHS long-term workforce plan and the vision for a Social Care Workforce Strategy. The platform will be launched in September 2024 so process findings will be combined with results around usage, appraisal from the sector and careers services, and impact on employers and educators. Through co-design we have challenged our assumptions at all stages of the project and created a transformational tool to address the needs of the sector and young people in Leeds. We will continue to work closely with our H&SC sector partners to embed the tool in their organisations and expand the tool's functionality.

Key messages:
- We have created a system-wide operational career exploration tool to attract young people in Leeds to the right Health and Care career for them.
- We will highlight the core values that have underpinned the creation of the tool, its functionality and lessons learned post-launch.

Abstract citation ID: ckae144.1885
Health workers' perceptions on refugees' access to healthcare and right to health in Turkiye

Faize Deniz Mardin

FD Mardin[1], *N Ozgulnar*[2], *S Karabey*[2]
[1]Public Health Officer, Istanbul, Türkiye
[2]Department of Public Health, Istanbul University, Faculty of Medicine, Istanbul, Türkiye
Contact: drdenizmardin@gmail.com

In Turkey, over the past decade, the influx of refugees has significantly influenced migration policy and consequently, health policy for refugees, shaping the perspectives of healthcare workers towards refugees. To gauge healthcare workers' perceptions regarding refugees' access to healthcare and their right to health, a survey was conducted across three hospitals in two cities (n = 547). The drop-collect methodology was used, obtaining consent in advance. Healthcare workers (HCWs) were classified into four groups: doctors (n: 139), nurses and midwives (n: 201), other healthcare professionals (n: 58) and non-healthcare professional (n: 137). Additionally, twelve people who did not want to disclose their profession were excluded from the statistics when comparing responses by profession. According to HCWs' experiences, the most common obstacles faced by refugees included language barriers due to not knowing Turkish, the absence of interpreters in hospitals, cultural disparities, and financial constraints. Among HCWs, 89.8% (n = 491) believe that health constitutes a fundamental human right, yet only 55.8% (n = 305) advocate for free emergency services for all. Furthermore, 43.1% express concerns that providing healthcare to refugees might attract more refugees, and 38% suggest that only individuals deemed healthy through health screening upon entry should be permitted into the country. Responses to inquiries about the prevalent issues varied across cities and occupational groups. Despite the majority of HCWs adopting a right-based approach to health, it is evident that some lean towards a deservingness perspective regarding refugees' access to healthcare. Consequently, there is a pressing need for collaboration among various sectors to furnish adequate information and training for HCWs on migrants' rights and prejudice. This should be a part of migration policy, leading to a more migrant-friendly health system.

Key messages:
- Collaboration among diverse sectors is urgently needed to provide healthcare workers with thorough information and training on the rights of migrants and addressing prejudice.
- Implementing training programs for healthcare workers as a component of migration policy is essential for building a migrant-friendly healthcare system.

Abstract citation ID: ckae144.1886
Ready to act? Factors associated with nurses' desire to work in Primary Health Care in Italy

Erika Renzi

E Renzi[1], *N Panattoni*[1], *E Di Simone*[2], *M Peltrini*[1], *V Baccolini*[1], *G Migliara*[3], *C Marzuillo*[1], *C De Vito*[1], *P Villari*[1], *A Massimi*[1]
[1]Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]DITRAR Direction, IRCCS Istituti Fisioterapici Ospitalieri – IFO, Rome, Italy
[3]Life Sciences, Health and Health Professions, Link Campus University, Rome, Italy
Contact: erika.renzi@uniroma1.it

Background: The rapid increase in demand for primary healthcare (PHC) services after the pandemic requires reconsidering nursing staff planning and availability. The objectives of the study were to i) identify knowledge, attitudes, practices and work expectations of future nurses in primary care; ii) estimate the prevalence of nursing students who desire to be employed in PHC and Family and Community Health Nursing (FCHN) services after graduation.

Methods: A cross-sectional study is being conducted on a sample of nursing students enrolled in universities in the Lazio Region. A structured instrument was built based on the literature and national regulations and validated (Cronbach's alpha=0.81).

Results: In this first phase, 163 nursing students were enrolled. The majority of the sample was female (N = 125, 76.7%), with a mean age of 22 (SD ± 5) years and were enrolled in the last year of degree program (N = 85, 52.1%). A total of 49 students (30%) reported adequate knowledge of PHC service reorganization policies and nursing practice in this setting. While 74% (N = 122) of the sample intended to undertake a PHC curricular internship during their degree program, only seven students (4%) participated in one. 52 individuals (30%) expressed their intention to be employed in PHCs after graduation, and 29 (17.8%) indicated their desire to work as FCHN practitioners. The main factors contributing to the undesirability of employment in PHC reported by students were: i) preferring the hospital settings (N = 53, 48%); ii) not having adequate skills to be employed in the PHC (N = 21, 19%); and iii) believing that the PHC does not offer attractive services for nursing practice (N = 14, 13%).

Conclusions: A multivariable analysis will be conducted to identify predictors of nursing students' desire to work in PHCs after graduation. Preliminary results of the study showed that only one-third of nursing students indicated a desire to work in PHCs.

Key messages:

- Only one-third of nursing students express a desire to work in PHC and in Family and Community Health Nursing (FCHN) services post-graduation.
- Collaboration between the PHC workforce, academics, stakeholders, and policymakers is needed to create tailored initiatives that increase the attractiveness of PHC.

Abstract citation ID: ckae144.1887
Enhancing Interprofessional Skills with SKY Campus: A Pilot Study on Mental Well-being at UCD

Jwenish Kumawat

J Kumawat[1], *K Conyard*[2], *P Wall*[1], *M Codd*[1]
[1]School of Public Health, University College Dublin, Dublin, Ireland
[2]School of Public Health, University College Dublin, ASPHER, Dublin, Ireland
Contact: jwenish.kumawat@ucdconnect.ie

Background: Public health professionals and students face increasing mental health challenges. Sudarshan Kriya Yoga (SKY), known for its mental health benefits such as stress reduction and improved emotional regulation, offers a promising strategy for enhancing well-being in public health education.

Objectives: To evaluate the immediate effects of a three-day participatory SKY workshop on mental well-being of Master of Public Health students at University College Dublin, Ireland.

Methods: A non-randomized, controlled pilot study will involve MPH students at UCD. Participants, aged 18 and above, enrolled in the MPH programme, will provide informed consent to attend a three-day SKY workshop in September 2024. The workshop, delivered by certified trainers, includes three sessions of three hours each. Standardised and validated Patient-Reported Outcome Measures (PROMs) such as the Perceived Stress Scale (PSS-10) and WHO-Five Well-being Index (WHO-5) will be used to assess perceived stress and mental wellbeing at baseline and immediately after the workshop.

Results: Based on previous literature, it is hypothesized that participants will show a significant reduction in perceived stress and improvement in mental wellbeing scores. Data will be analysed using descriptive statistics and Wilcoxon signed-rank tests to evaluate changes in PROM scores.

Conclusions: This pilot study aims to provide preliminary evidence on the effectiveness of SKY in improving mental wellbeing among public health students. Successful outcomes could support integrating SKY into the public health curriculum, promoting its adoption across other institutions, and enhancing the professional skills development of future public health professionals. This component is proposed in the ASPHER core curriculum programme for public health as an important cross curricular subject area

Key messages:

- Integrating SKY Campus workshops into public health education enhances interprofessional skills and mental well-being, offering a holistic approach to professional development in global health.
- This study uses standard PROMs to assess the SKY workshop's impact, aiming for significant improvements in stress and mental well-being to shape global public health curricula.

Abstract citation ID: ckae144.1888
In development intervention, professionals aim to enhance working practices and interaction

Tiina Koivisto

T Koivisto[1]
[1]Finnish Institute of Occupation Health, Tampere, Finland
Contact: tiina.koivisto@ttl.fi

Background: The social services and healthcare professions are experiencing a global labor shortage. Enhancing the appeal and retention requires the development of work and processes through community-level interventions that reduce workload and bolster resources. Further research into such interventions is necessary. This study focuses on a systematic community-based practice development model (Breakthrough Collaboratives) to evaluate the change in alignment with the development intervention's objectives and the prerequisites for change. The evaluation will utilize the process evaluation model for well-being at work projects and health promotion interventions.

Methods: This qualitative process evaluation employs a multi-case study approach to depict the changes occurring during the development intervention. It assesses the development processes of fifteen workplaces across Finland. The research material includes recorded group discussions from the initial workshop, where professionals establish goals and development targets for their work. The qualitative data are analyzed using content analysis. The analysis is guided by questions such as: What goals and development objectives do participants set for their work? What workplace-specific characteristics inform these objectives?

Results: Preliminary findings indicate that the work units' development objectives concentrate on updating the unit's common rules, enhancing the induction process for new employees, improving work behavior, and refining meeting practices. Workplace-specific characteristics differ based on the work unit's sector, the level of trust among professionals, and their willingness to critically evaluate management. Additionally, competence and professionalism emerge as prominent themes in group discussions.

Conclusions: In a workplace development intervention, professionals aim to enhance common working practices and interaction, with the goal of improving well-being at work.

Key messages:

- Enhancing operational practices and promoting positive interpersonal conduct among colleagues constitutes a pivotal goal in advancing social and health care work units.
- The Community based intervention provides workplaces with concrete models to support co-creation and permanent changes in working practices.

Abstract citation ID: ckae144.1889
Barriers to the application of simulation technologies in the education of health care students

Natalya Usheva

N Usheva[1], *K Bliznakova*[1], *D Grancharov*[1]
[1]Faculty of Public Health, Medical University, Varna, Bulgaria
Contact: nataly_usheva@hotmail.com

Simulation technologies (ST) in health and medical education are undergoing rapid development due to the undoubted advantages of the methods and forms of simulation used - high quality, significant efficiency, economy, reliability and safety for the patient. At the same time, the application of ST is still underrepresented in the education of health care students. The main aim of this study was to identify the barriers and perspectives for the application of ST in the education of health professional students in Bulgaria from the perspective of the respondents' expertise. A qualitative study of the expert (n = 17) opinion of those directly involved in the introduction, application, and evaluation of the use of ST in the education of healthcare students was conducted in 2023 in Varna. The questionnaire regarding the barriers and perspectives in the use of ST in the education of undergraduate and postgraduate students in health specialties students was used. The main barriers to the widespread use of ST in the training of students were identified as follows: the lack of adapted curricula that combine traditional practical sessions with patients and those on simulators; the lack of a sufficient number of trained and motivated trainers; the reluctance of trainers to introduce or more widely use ST; lack of or insufficient space to locate a simulation centre or equipment in relevant core units; the high cost of purchasing and maintaining ST and limited financial resources, as well as the large number of students in the groups. According to one of the experts, 'there are no barriers to the use of ST, but real patient contact and a personalized approach to the patient is impossible to replicate through technology,' highlighting the importance in combining traditional training with real patients and modern with the use of technology. Ethical issues in training healthcare professionals with simulators appear to be a new aspect of medical education with the application of ST.

Key messages:

- In the effort for widespread implementation of ST in the training of health professions students, it is important to achieve a balance with traditional training experienced with real patients.
- Identifying and overcoming barriers is an important prerequisite for the rapid and widespread application of ST in the training of health care students.

Factors associated with the intention to vaccinate children: a Finnish population survey on influenza

Idil Hussein

I Hussein[1,2], *S Vänskä*[1], *J Sivelä*[1], *T Leino*[1], *H Nohynek*[1]
[1]Department of Health Security, THL, Helsinki, Finland
[2]Doctoral Programme in Population Health, University of Helsinki, Helsinki, Finland
Contact: idil.hussein@thl.fi

Background: Influenza vaccination for children aged 6 months to 6 years is included in the national vaccination programme in Finland. Although all vaccines in the programme are free of charge, national coverage of influenza vaccination among children under 3 years and 3-6 years during 2020/21 was 43% and 35% respectively, with regional differences. Our aim was to assess factors underlying parental vaccination intention in order to increase influenza vaccine uptake among children in Finland.

Methods: We conducted a survey among parents (n = 17,844) of eligible children (aged 6 months-6 years), selected randomly from five Finnish municipalities. Children and their parents were selected from high and low coverage areas, and the study was conducted in February-March 2022. Logistic regressions were used to determine associations between vaccination intention and e.g., sociodemographic factors, attitudes and knowledge. Linkage to the national vaccination register was used to confirm realisation of vaccination intention after the study.

Results: Participation rate was 13% (n = 2,322 parents). Influenza knowledge, trust in official information, responding parent's education level, adherence to the vaccination programme, number of children and changes in attitudes towards vaccination since COVID-19 were all associated with intention to vaccinate. Vaccination intention for children was 64% and realised vaccination 51%.

Conclusions: Despite the low participation rate, both vaccinated and unvaccinated children were represented. Influenza vaccine uptake is not dependent on a single factor. Our results identified the need for open dialogue between parents and healthcare professionals, as the lack of vaccine being offered by healthcare professionals was the most reported reason for not vaccinating.

Key messages:

- Parental vaccine decision-making in settings where the vaccination is given free of charge is complex, and not always driven by intention to vaccinate.
- Most parents had the intention to vaccinate, but some children still ended up not receiving their influenza vaccine.

Abstract citation ID: ckae144.1891
A prolonged outbreak of tuberculosis associated with an intellectual disability daycentre in Ireland

Therese McGlacken

T McGlacken[1], *K O'Connor*[2], *C O'Hare*[2], *A O'Connell*[2], *E Dwan*[2], *S Doyle*[2]
[1]Department of Public Health Area C, HSE, Lacken, Kilkenny, Ireland
Contact: theresemcglacken@doctors.org.uk

One of the factors impeding tuberculosis elimination in low burden countries is its persistence and concentration in vulnerable populations. This is a complex, prolonged Tuberculosis (TB) outbreak in a daycentre for adults with intellectual disability in Ireland. This is a particularly vulnerable population with special considerations for Public Health (PH) management. There are eight cases of active TB, 46 cases of Latent TB Infection (LTBI) and a cumulative total of 116 contacts associated with this outbreak, with diagnosis spanning 15 years. The last three cases were identical on Whole Genome Sequencing. The index case was an Irish-born, Caucasian, social care worker, with smear positive pulmonary TB, who was symptomatic in the facility for three months prior to diagnosis. Case 2 was a household contact of the index case and the other 6 cases were Service Users (SUs) at the facility. At least five of the subsequent seven cases are secondary cases of the index case. Significant to this outbreak was the change in Irish guidance, 2010, relating to the management of contacts of cases. Following the notification of the most recent case, July 2023, the Outbreak Control Team decided a retrospective review be conducted of all SU contacts of the seven cases associated with the facility. The contacts were stratified according to hierarchical risk. A total of six contacts met the criteria for review and offered screening, re-screening or treatment as appropriate. In this outbreak 21.8% of the total contacts and 16.1% of SU contacts completed treatment for LTBI. The significance of this outbreak lies in its duration, infectivity of the index case and particular vulnerabilities of the SUs. There were issues with overcrowding and difficulties in relation to symptom recognition, diagnosis and treatment. The PH team tailored their approach to meet the SU needs, demonstrating the importance of person-centred contact tracing in the disruption of transmission.

Key messages:

- A factor impeding tuberculosis elimination in low burden countries is it's persistence and concentration in vulnerable populations.
- Adapting a patient-centred approach to contact tracing can lead to higher participation rate and the disruption of infection transmission.

Abstract citation ID: ckae144.1892

The resurgence of pertussis in Central Serbia in the period from June to December 2023

Edita Grego

E Grego[1], H Gospodinovic[1], M Cabrilo[1], M Ivanovic[1], J Ivanovic[1], N Simic[1], LJ Pavlovic[1], M Veljkovic[2], S Jovanovic[3], V Jovanovic[4]
[1]Center of Microbiology, Institute of Public Health of Serbia, Belgrade, Serbia
[2]Department for Vaccine-Preventable Diseases, Institute of Public Health of Serbia, Belgrade, Serbia
[3]School of Medicine, PhD Module: Public Health, University of Belgrade, Belgrade, Serbia
[4]Center for Disease Control, Institute of Public Health of Serbia, Belgrade, Serbia
Contact: grego_edita@batut.org.rs

Background: There was a registered increase in the number of confirmed pertussis cases in Central Serbia between June and December 2023. Among the possible causes of pertussis resurgence are increased awareness of pertussis among healthcare workers, availability of the sensitive RT PCR method in diagnostic, the limited duration of vaccine-induced immunity as well as decline of immunization coverage influenced by the COVID-19 pandemic.

Methods: The nasopharyngeal samples from clinics and primary care departments were transferred to Institute of Public Health of Serbia. DNA was extracted from each sample using the MagMAX Viral/Pathogen kit. The presence of B. pertussis was determined using two PCR assays, VIASURE Bordetella Real Time PCR Detection Kit and Bosphore B. pertussis/parapertussis Genotyping Kit, Anatolia Geneworks.

Results: RT-PCR confirmed a total of 338 pertussis cases in Institute of Public Health of Serbia during the observed period. Most of confirmed cases were among children 9-14 years old (49,7%) followed by infants younger than 12 months (21,9%). The more severe cases were among the unvaccinated and uncomplete vaccinated infants, 78,4% of which required hospitalization with two deaths in this age group.

Conclusions: Based on the analysis of the obtained results, we can highlight the importance of using sensitive methods in pathogen detection. Rapid diagnosis, laboratory confirmation and notification ensure early public health intervention to minimize the spread of disease. Despite long tradition of mandatory immunization against pertussis in the Republic of Serbia, wanning of vaccine induced immunity poses potential risk for the resurgence of pertussis. For pertussis control, in the future, it will be essential to achieve high immunization coverage as well as to introduce a booster dose of pertussis containing vaccine for children aged 14 and to implement vaccination of pregnant women.

Key messages:

- For the better pertussis control vaccination of adolescents and adults, as well as vaccination of pregnant women should be considered in the future vaccination policies.
- Clinicians should consider pertussis in the differential diagnosis of persistent cough illness in people of all ages, even those previously immunized.

Abstract citation ID: ckae144.1893

Seroepidemiological study of Epstein-Barr virus infection in reproductive age women in Bulgaria

Stela Georgieva

T Petkova[1], S Pachkova[2], S Georgieva[3]
[1]Department of Infectious Diseases, Epidemiology, Parasitology and Tropical Medicine, Medical University, Pleven, Bulgaria
[2]Medical Center, Clinical Institute for Reproductive Medicine, Pleven, Bulgaria
[3]Department of Social Medicine and Health Management, Medical University, Pleven, Bulgaria
Contact: georgieva_sl@yahoo.com

Background: At the present stage, studies on the involvement of Epstein-Barr virus (EBV) in neonatal pathology are rare. Establishing seroprevalence among women of reproductive age has important epidemiological significance in order to determine the risk of infection during pregnancy and intrauterine infection of the fetus. The aim of the study is to determine the seroepidemiological status of EBV in reproductive age women.

Methods: We conducted a prospective seroepidemiological study in which 96 healthy women of reproductive age (18 to 49 years) were tested during the period December 2023 - January 2024 in Medical Center "Clinical Institute for Reproductive Medicine"- Pleven, Bulgaria. Participants were surveyed on a voluntary basis. The exclusion criteria were: presence of autoimmune disorder, immunosuppressive states, malignancy and populations at risk such as persons under 18 years of age and pregnant women. The presence of specific antibodies were detected using a standardized Anti-EBV VCA IgM, Anti-EBV VCA IgG and Anti-EBV EBNA-1 IgG ELISA kits. The demographic and anamnestic data were collected for each participant in Case Report Form.

Results: The average age of the women was 34.41±5.44 years. Dominating were women with higher education (76.04%) living in urban areas (91.67%). The results of the seroepidemiological study of markers for EBV show that 98.96% of women of reproductive age are seropositive. There was no significant correlation between the presence of antibodies and socio-demographic indicators (living area, education and number of family members).

Conclusions: The results of this study imply that only 1.04% of the reproductive age women in Pleven region are susceptible to infection with EBV. Although interpretation of the serological status indicates a low risk of primary infection, active monitoring of high-risk groups pregnant women is necessary because of the possibility of EBV reactivation.

Key messages:

- On-going monitoring of the seroepidemiological EBV status in reproductive age women is necessary to determining the possibility of EBV reactivation and to reduce the teratogenic risk of the infection.
- Seroepidemiological surveillance of markers for EBV infection in reproductive age women is part of effective preventive measures at the public health level.

Abstract citation ID: ckae144.1894
Reflective model assessment of adherence to COVID-19 non-pharmaceutical interventions

Shelly Melissa Pranic

MP Pavić[1], SM Pranić[2], T Matelić[3], Z Kljucević[1], M Gotovac[1], A Jurčev Savicević[2,4,5], T Kozina[6], S Kozina[7]

[6]Department of Professional Studies, University of Split, Split, Croatia
[7]Department of Medical Psychology, University of Split School of Medicine, Split, Croatia
Contact: spranic@mefst.hr

Background: Non-pharmaceutical interventions (NPIs) decrease COVID-19 transmission. We identified behavioral factors that affected NPI adherence according to Normalization Process Theory (NPT) in medical students, travel seekers, and people with substance use disorder using reflective model measurement, which previously had not been conducted. Public health officials should consider factors that influence adherence to create preventive strategies for COVID-19.

Methods: In a cross-sectional design, medical students and people with substance use disorders in treatment comprised a probabilistic sample, and travelers and COVID-19 suspected persons comprised a convenience sample. Participants were from Split-Dalmatia County ($n = 656$) in the Mediterranean and consented to self-administered surveys in 02/2021. Sociodemographic data, locus of control (LoC), and moral behavior were collected. Partial least squares structural equation modeling (PLS-SEM) was used to measure reflective assessment of NPI adherence according to NPT.

Results: PLS-SEM reflective model assessment provided two-group specific factors in inverse relationships which determined NPI adherence with excellent goodness of fit ($\chi 2=1.292$, $df = 1$; $p = 0.297$). Significant negative factors covariance estimate (-0.716) revealed an increase in adherence to the first factor, NPIs and internal LoC [0.640], as the second factor, age (≤ 25) and highest education level (1.362), decreased. LoC was the mechanism by which sex (MLsex=-0.017, $SE = 0.007$, $p < 0.016$) and being a student or person with substance use disorder (MLgroup=-0.008, $SE = 0.003$, $p = 0.015$) showed indirect effect on NPI adherence.

Conclusions: Students and people with substance use disorders more adhered to NPIs. Higher-educated younger adults with a tendency toward external LoC facilitated the normalization. Public health interventions could encourage these subgroups to act as promoters to increase NPI adherence in similar settings.

Key messages:
- COVID-19 non-pharmaceutical interventions and psychological factors of students and people with substance abuse disorder influenced adherence. Targeted interventions could promote adherence.
- Public health officials should consider that preventive strategies may be more effective in highly educated adults younger than 25 years of age.

From agent-based simulations of disease dynamics to expert support on public health interventions

Michael Moeckel

M Moeckel[1]
[1]Laboratory for Hybrid Modeling, University of Applied Sciences Aschaffenburg, Aschaffenburg, Germany
Contact: Michael.Moeckel@th-ab.de

Agent-based epidemiological simulators have long been used to predict the dynamics of infectious diseases. They allow to combine compartment approaches with representing contact networks derived from real or synthetic populations. Often, scenario techniques are applied to model the impact of public health interventions. During the COVID-19 pandemics the agent-based simulator COVASIM has been established for modelling the spreading of SARS-CoV-2. It includes four different contact networks related to homes, schools, workplaces and environment. During the pandemic it became obvious that the current simulation techniques were not sufficient to cover important needs in public health administrations and society. While most simulations were based on scenarios predicting expected numbers for the infected, hospitalized or critically ill, these studies could not provide easily strategic options on a variety of equivalent public health interventions, which are all suitable to keep disease dynamics within acceptable bounds, set e.g. by hospital capacity. Knowing about a variety of equivalent options, however, is of crucial importance to enable a fair burden sharing throughout all groups of society. Therefore, we applied machine learning techniques to create an inverse model for epidemiological simulations based on COVASIM. For given transmission rates it outputs a range of quantitative interventions which are equivalently suitable to keep epidemiological dynamics within predefined bounds. Currently, it covers interventions like school and workplace closings and other mobility restrictions. Future work will be directed to include other interventions, like vaccination campaigns, and we will work to make the approach more generalizable for other infectious diseases. The tool may turn out helpful fur public health administrations and stimulate the public debate on the best way a society may take in a pandemic event or other situations where public health action has to be imposed.

Key messages:
- Machine Learning allows to invert agent based simulators.
- Instead of disease dynamics simulations a set of equivalent public health interventions consistent with pre-defined constraints can be calculated.

Antimicrobial resistance and infection prevention in care for people with intellectual disabilities

Soemeja Hidad-Nuh

S Hidad-Nuh[1,2], SC de Greeff[1], A Haenen[1], F de Haan[1], GL Leusink[2], A Timen[1,2]
[1]Centre for Infectious Disease Control, RIVM, Bilthoven, Netherlands
[2]Department of Primary and Community Care, Radboud University Medical Center, Nijmegen, Netherlands
Contact: soemeja.hidad@rivm.nl

Background: Antimicrobial resistance (AMR) has become one of the major public health threats worldwide. However, little is known about antimicrobial resistance and infection prevention and control (IPC) in long-term care facilities for people with intellectual disabilities. This study aims to assess knowledge, attitudes and perceptions towards AMR and IPC among healthcare professionals working in long-term care facilities for people with intellectual disabilities (ID-LTCFs) in the Netherlands.

Methods: We conducted a web-based cross-sectional survey study among medical and nonmedical trained healthcare professionals working in ID-LTCFs in the Netherlands. The survey study was carried out between July and November 2023 and consisted of validated survey items expanded with expert opinion and setting-specific items.

Results: In total, 109 medical and nonmedical trained healthcare professionals working in 37 long-term care organizations for people with intellectual disabilities throughout the Netherlands completed the questionnaire. Overall, knowledge levels about AMR and IPC differed between medical and nonmedical trained healthcare professionals working in ID-LCTFs, with medically trained professionals having a significant overall higher score on both topics. Knowledge regarding the perceived protective value of glove use was found to be insufficient. Moreover, healthcare professionals expressed a need for easy-to-read resources and tailored setting-specific information on AMR and IPC targeting both healthcare professionals as well as people with disabilities.

Conclusions: There is room for improvement regarding setting-specific IPC and hygiene policies, such as appropriate glove use in ID-LTCFs. As nonmedically trained professionals comprise most of the workforce within this setting, it is important to further tailor follow-up studies to the underlying factors that influence knowledge, attitudes and perceptions of these specific professionals within ID-LTCFs.

Key messages:

- Developing setting and context-specific policies for infection prevention and control is crucial, particularly in long-term care facilities for people with intellectual disabilities.
- Inclusive policy-making is key to combating antimicrobial resistance, and improving infection prevention and control in long-term care facilities for people with intellectual disabilities.

Abstract citation ID: ckae144.1897
Adult Immunization Board: A platform to provide guidelines for implementation of adult immunization

Angela Bechini

J Pattyn[1]*, M Del Riccio*[2]*, G Hendrickx*[1]*, S Boccalini*[2]*, A Bechini*[2]*, P Van Damme*[1]*, P Bonanni*[2]
[1]Centre for the Evaluation of Vaccination, University of Antwerp, Antwerp, Belgium
[2]Department of Health Sciences, University of Florence, Florence, Italy
Contact: angela.bechini@unifi.it

Background: Several organizations, including governments, (inter) national public health organizations and vaccine manufactures are currently considering how adult immunization can be further improved to increase health impact and promote a lifelong approach to vaccination. Despite many organizations thinking about ways to improve adult immunization, there is currently no multidisciplinary discussion platform focusing on this topic at the European level. Therefore, a group of experts in the field of adult immunization established the Adult Immunization Board (AIB).

Methods: AIB is established with the aim of contributing to the reduction of the impact of vaccine-preventable infections and diseases in European adults. AIB works by organizing 2 meetings per year: 1) a technical meeting to discuss specific technical aspects on adult immunization with subject-matter experts, and 2) a country meeting to discuss country specific aspects of adult immunization together with local experts.

Results: In April 2023 and 2024 the AIB organized its first technical meetings on "Assessing the health burden of vaccine-preventable infections in European Adults (2023)" and "Strategies for introducing and implementing vaccines for adults into National Immunization Programs in Europe (2024)". In December 2023, the AIB organized its first country meeting in Italy with local experts to learn out best practices in adult immunization and address aspects to improve.

Conclusions: AIB is a platform that brings together the different key European stakeholders in adult immunization to effectively contribute towards the implementation and optimization of adult immunization programs in Europe.

Key messages:

- Continued efforts to promote research, implementation, awareness, accessibility, and vaccine uptake are crucial to mitigate the burden of (future) infectious diseases in the adult population.
- The AIB represents a significant step towards bolstering adult immunization efforts in the EU.

Abstract citation ID: ckae144.1898
Exploring PrEP awareness among addiction service professionals: an Italian cross-sectional study

Giuseppina Lo Moro

G Lo Moro[1]*, L Rosset*[1]*, MG Varì*[1]*, G Scaioli*[1]*, R Balestra*[2]*, A Lucchini*[3]*, F Bert*[1,4]*, R Siliquini*[1,5]
[1]Department of Public Health and Pediatric Sciences, Università di Torino, Turin, Italy
[2]FeDerSerD, Trieste, Italy
[3]FeDerSerD, Milan, Italy
[4]Hygiene and Infection Control Unit, Azienda Sanitaria Locale Torino 3, Turin, Italy
[5]A.O.U. Citta della Salute e della Scienza di Torino, Turin, Italy
Contact: giuseppina.lomoro@unito.it

Background: Pre-exposure prophylaxis (PrEP) is an effective HIV prevention strategy. Since 2023, in Italy, PrEP has been subject to reimbursement, making it freely available to individuals who meet specific criteria, including those who engage in substance use during sexual activity (chemsex). In this context, all healthcare professionals (HCPs) in Addiction Departments and Services (ADS) play a crucial role from the intake interview in identifying potential PrEP candidates, providing an essential gateway to services. Thus, this study primarily aimed to explore the knowledge of ADS professionals regarding PrEP.

Methods: In 2024, an ongoing nationwide cross-sectional study has been conducted in Italy, enrolling a convenience sample of HCPs employed in ADS. The online questionnaire comprised items assessing knowledge regarding PrEP, training on PrEP, and experiences related to daily practice. The primary outcome was the awareness of PrEP existence, while secondary outcomes included knowledge regarding reimbursement.

Results: Preliminary analyses were conducted based on 269 questionnaires. Participants had a median age of 52 years (IQR=45-59). Physicians represented 26.0% of the sample, followed by nurses (23.0%). Awareness of PrEP stood at 43.5%, while knowledge of the existence of reimbursement conditions was at 29.9%. A vast majority (93.7%) felt inadequately informed, while 97.0% believed HCPs in ADS should receive training. Physicians demonstrated significantly higher awareness of PrEP existence, whereas there were no significant differences in reimbursement knowledge compared with other HCPs.

Conclusions: Intermediate findings revealed substantial gaps in PrEP awareness and reimbursement knowledge. These results emphasize the critical importance of tailored education and training programs to bridge these gaps and facilitate effective PrEP implementation in diverse healthcare settings, ultimately advancing HIV prevention efforts and promoting equitable access to care.

Key messages:

- Substantial knowledge gaps about PrEP among healthcare professionals working in Addiction Departments and Services in Italy were highlighted.
- Effective PrEP implementation hinges on empowering professionals with the necessary expertise to identify and support PrEP candidates, underscoring the critical role of tailored education initiatives.

Abstract citation ID: ckae144.1899
Pertussis seroprevalence and related factors in 15-49 years old women in Mersin, Turkey

Burcu Ecem Uğuz

BE Uguz[1]*, R Bugdayci*[1]
[1]Public Health Department, Mersin University, Mersin, Türkiye
Contact: burcuecem@gmail.com

Background: Pertussis is an acute, contagious respiratory disease with high mortality and morbidity, especially in early infancy. If the mother is immune to pertussis, infants too young to be vaccinated are protected against pertussis infection after birth by maternal immunity. This study aimed to investigate pertussis seroprevalence and associated factors in women aged 15-49 years.
Methods: The cross-sectional study was conducted on women aged 15-49 years in Mersin city between December 2023 and February 2024. A total of 352 women from family health centres in four central districts of Mersin were included in the study. In this study, anti PT-IgG levels in blood samples were investigated by enzyme-linked immunosorbent assay ELISA method. In the analysis of the data, descriptive statistics, chi-square analysis, and binary logistic regression analysis were used. The results were presented at a 95% confidence interval, at a significance level of $p < 0.05$.
Results: Anti-PT IgG seropositivity was detected in 150 (%42.6) of the women. In seven (2%) of women, the anti-PT IgG value was greater than 100, indicating an acute infection. Individuals who did not receive or could not recall having received school vaccinations were found to be 2.18 times more likely to be seropositive than those who had received vaccinations at school. Individuals residing in the same household with a healthcare professional were found to be 1.78 times more likely to be seropositive than those who did not.
Conclusions: Half of our region's newborns lack protection from whooping cough. Maternal immunization with pertussis-containing vaccines is crucial. Many countries have safely used such vaccines for years. Replacing Td with Tdap in Turkey's pregnancy immunization can better shield mothers and newborns from pertussis.
Key messages:

- Maternal immunization is crucial for protecting newborns from pertussis, reducing mortality and morbidity.
- Addressing vaccination disparities is vital to ensure community-wide protection against pertussis, saving lives.

Contact: eleonora.marziali@outlook.com

Healthcare-Associated Infections (HAIs) are a global concern, requiring surveillance strategies as Point Prevalence Surveys (PPS) to estimate their burden and investigate associated risk factors for targeted interventions in high-risk areas. This study aims to assess the prevalence of HAIs, identify determinants and evaluate antimicrobial use in a teaching hospital in Rome. A PPS was carried out from June 19th to 23rd, 2023, in accordance with the European Centre for Disease Prevention and Control (ECDC) protocol for HAIs and antimicrobial use in European acute care hospitals (version 6.1). Pearson's chi-squared test was employed to investigate correlations between potential risk factors and HAIs. The survey included 829 patients with an average age of 56.3 years (SD: ± 24.6). Of these, 48.4% were female and over half had visited the hospital's Emergency Department (53.7%). The prevalence of active HAIs was 8.7%, with 72 patients diagnosed. Furthermore, 51.0% of all patients received at least one systemic antimicrobial agent, and 16.7% of those treated had an HAI. Penicillins (39.7%) and third-generation cephalosporins (37.8%) were the most frequently prescribed antimicrobials. The primary HAIs were bloodstream infections (34.1%), followed by urinary tract (27.3%), surgical site (23.9%), lower respiratory tract (6.8%), and gastrointestinal infections (7.9%). Escherichia coli (13.2%), Staphylococcus aureus (9.2%), and Clostridium difficile (6.6%) were the most frequently isolated pathogens. Intensive Care Unit admission, use of medical device, recent antibiotic therapy and prior hospitalization or surgery significantly correlated ($p < 0.05$) with increased HAIs risk. The detected prevalence of HAIs is lower than the national rates observed in 2022 (10.2%), which have increased since 2016. HAIs surveillance is essential for developing effective infection prevention and control programs and for optimizing resource allocation in hospital settings.
Key messages:

- Surveillance of Healthcare-Associated Infections is crucial for developing targeted Infection Prevention and Control programs and optimizing hospital resource allocation.
- Point Prevalence Surveys offer essential information for assessing the burden of Healthcare-Associated Infections and directing intervention strategies in hospitals.

Abstract citation ID: ckae144.1901
Interventions to prevent Neonatal Healthcare-associated Infection: a systematic review of RCT

Jessica Iera

C Reale[1], A Pistollato[1], M Ceparano[1], G Migliara[1], C Marzuillo[1], P Villari[1], V Baccolini[1]
[1]Sapienza University of Rome, Rome, Italy
Contact: jessica.iera@uniroma1.it

Background: Healthcare-acquired infections (HAI) in neonatal intensive care unit (NICU) specifically refer to infections that occur in newborn infants within the healthcare environment. Preterm infants, often more vulnerable to infections, in the NICU may be exposed to various medical interventions, devices, and environments that can increase the risk of infections. This systematic review aims to evaluate the effectiveness of interventions proposed to prevent neonatal healthcare-associated infections.
Methods: PubMed, Scopus and Web of Science databases were searched to identify any RCT study coming from high income countries, published from 2004, that investigated the efficacy of any intervention to prevent HAI in NICU. All type of HAI were considered.
Results: A total of seven studies were included (2 from USA, 5 from UE). Three studies focused on: administration of donor milk; probiotic Bifidobacterium breve; intravenous Staphylococcus aureus immune globulin; all failed to demonstrate any protective action. Of the four remaining studies that investigate different aspect of the vascular catheterization process only two lead a a statistical significant reduction of HAI. Garland et al. demonstrate in 85 neonates how vancomycin-heparin lock solution is capable to reduce catheter related blood stream infection (CRBSI) 8/43 neonates (18.6%) in the control group vs 0/42 in the vancomycin-heparin-lock group ($P = 0.006$). Bertini et al. demonstrate in 86 preterm infants how utilization of AgION catheter in Umbelical vein catheterization (UVC) lead to CRBSI rate reduction (2 vs. 22%; $p = 0.005$), shorter hospital stay ($p = 0.04$), lower case fatality rate due to Blood stream infection ($p = 0.01$).
Conclusions: Among the proposed methodology only the one acting on the catheterization process provide a statistical significant reduction of HAI onset. Widespread observation of proposed protocol may results in reduction of HAI in NICU.

Key messages:

- Modfiication on the catheterization process provide a statistical significant reduction of HAI onset.
- Knowing these measures assure reduction of HAI.

Epidemiological characteristics of the 2019 Measles outbreak in central Tunisia

Cyrine Ben Nasrallah

C Ben Nasrallah[1,3]*, A Maatouk*[1,3]*, S Grira*[2]*, M Kacem*[1,3]*, W Dhouib*[1,3]*, H Abroug*[1,3]*, I Zemni*[1,3]*, M Ben Fredj*[1,3]*, I Bouanène*[1]*, A Belguith Sriha*[1,3]
[1]Department of Epidemiology and Preventive Medicine, Fattouma Bourguiba University Hospital, Monastir, Tunisia
[2]The Regional Direction of Primary Health, Ministry of Health, Monastir, Tunisia
[3]LTIM - LR12ES06, University of Monastir, Monastir, Tunisia
Contact: cyrine.bennasrallah@gmail.com

Background: Measles is still an important public health problem worldwide causing significant morbidity and mortality. Measles represents a vaccine-preventable disease. In Tunisia, vaccination against measles was launched in 1983. In spite of the progress made towards measles elimination, Tunisia experienced an outbreak in 2019. We aimed to describe the measles outbreak in the central region of Tunisia in 2019.

Methods: We carried out a descriptive study using surveillance data from January to December 2019 in four governorates in Tunisia (Monastir, Mahdia, Kairouan, and Kasserine). All suspected measles cases and declared to regional directorate of primary health care were included. A suspected measles case was defined as any person with fever and generalized maculo-papular rash plus one of the following symptoms: cough or coryza or conjunctivitis. A laboratory confirmed measles case is a suspected case of measles that has been confirmed positive by testing (IgM+).

Results: A total of 2,688 suspected cases were recorded, of which 369 cases were (14.7%) were confirmed measles through serological testing. The sex ratio was 1.06 for suspected cases and 1.12 for measles cases. Infants under one year old accounted 42.2% of suspected cases. The majority of suspected cases (67.3%) were not vaccinated. Among confirmed measles cases, positivity rates were 81.8% for unvaccinated, 70.0% for those with one dose and 27.2% for those with two doses. The hospitalization rate was 61.5 %; highest rates were observed in infants under one year of age (65.7%) and in the age group over 38 years (69.0%). In total, 27 deaths were reported. The highest lethality rate was observed in the age group under 12 months (2%).

Conclusions: The 2019 measles outbreak in Tunisia highlighted that this disease remains a serious viral infection. Unvaccinated populations could be a potential source for new outbreaks, imposing substantial public health burdens.

Key messages:

- The country needs to establish a national review committee to monitor measles elimination status.
- To address future challenges, immunity gaps in the population should be closed.

Abstract citation ID: ckae144.1903

Knowledge, Attitudes and Behaviors of Healthcare Workers Working in Malatya Towards COVID-19 Vaccines

Ali Ozer

G Boz[1]*, A Ozer*[2]
[1]Provincial Health Directorate, Ordu, Türkiye
[2]Inonu University, Medical Faculty, Department of Public Health, Malatya, Türkiye
Contact: aliozer91@hotmail.com

Background: The rapid production of vaccines and the introduction of new vaccine technologies have raised concerns among some individuals regarding anti-vaccination, while others have expressed worries about vaccines. Given that healthcare professionals' recommendations significantly influence people's vaccination decisions, this study aimed to examine the knowledge, attitudes, and behaviors of healthcare professionals working in family health centers towards COVID-19 vaccines.

Methods: Questionnaires for this descriptive cross-sectional study were administered between February and April 2022. The population comprised 408 health workers employed in family health centers in Malatya, with 292 individuals completing the study. The questionnaire included questions about sociodemographic, COVID-19, COVID-19 vaccines and the COVID-19 Fear Scale.

Results: Although 97.3% of the research group reported having received the COVID-19 vaccination, 47.9% expressed concerns about these vaccines. The median score of the COVID-19 Fear Scale was 15 (7.00-35.00). 86.6% of the participants indicated that they recommended COVID-19 vaccines. 16.4% of the participants agreed with the statement 'there are no studies proving the safety of vaccines,' and 49% agreed that 'vaccines pass through clinical trials quickly and are put on the market'. Those who did not recommend COVID-19 vaccines, those who agreed with the statement 'there are no studies proving the safety of vaccines' and those who agreed with the statement 'vaccines pass through clinical trials quickly and are put on the market' were concerned about COVID-19 vaccines with their level of concern significantly higher ($p < 0.05$).

Conclusions: Almost all members of the research group had received the COVID-19 vaccine, yet almost half of them expressed concerns about vaccines. Those who do not recommend vaccines, those who believe they are released quickly, and those who have safety concerns are more likely to be concerned.

Key messages:

- Identify the reasons for health workers' concerns about vaccines and provide remedial interventions for concerns that may arise regarding other vaccines.
- It should be ensured that healthcare professionals, who are expected to be role models for society in terms of immunization, possess scientific and up-to-date knowledge on vaccines.

Abstract citation ID: ckae144.1904

Evaluation of Covid-19 risk perception and psychological status of transplant patients

Ayşe Baran

A Baran[2]*, N Bağcı*[1]*, M Aslan*[2]*, S Akbulut*[3]
[1]Surgical Nursing, Inonu University Faculty of Nursing, Battalgazi, Türkiye
[2]Public Health, Inonu University Faculty of Medicine, Battalgazi, Türkiye
[3]Surgery and Liver Transplant Institute, Inonu University Faculty of Medicine, Battalgazi, Türkiye
Contact: abaran88@hotmail.com

Background: Liver transplant patients are in the more at-risk group in terms of COVID-19 infection and mortality due to both immunosuppressive treatment and underlying chronic diseases. The aim of this study was to evaluate the COVID-19 risk perception, compliance with preventive measures, and psychosocial status of liver transplant patients.

Methods: This descriptive cross-sectional survey study included 311 patients who underwent liver transplantation between 2002 -2021 and presented to the outpatient clinic for routine controls. Data were collected via a questionnaire administered through face-to-face interviews. The questionnaire form used to collect the data of the study included a demographic and clinical characteristics form, the Short Depression-Happiness Scale, the COVID-19 Prevention Guidelines Compliance Scale, and the COVID-19 Risk Perception

Scale. The Mann-Whitney U, the Kruskal-Wallis test and Spearman's Rho correlation analysis were used in statistical analyses.

Results: The median age of the transplant patients who participated in the study was 56 (18-76) years. Of the transplant patients, 84.9% stated that they had COVID-19 vaccination. There was a statistically significant, very weak relationship between the scores of the Brief Depression-Happiness Scale and the COVID-19 Compliance with Preventive Measures Scale ($r = 0.132$; $p = 0.02$), and a weak, significant relationship in the same direction between the scores of the COVID-19 Compliance with Preventive Measures Scale and the COVID-19 Risk Perception Scale ($r = 0.344$; $p = 0.001$).

Conclusions: The vaccination rates of the patients were high. As the depression status of the patients decreases, their compliance with preventive measures increases, and as their compliance with preventive measures increases, their risk perception increases.

Key messages:

- Since transplant patients are a vulnerable group, their vaccination status is important in terms of mortality risk.
- Psychological factors such as depression-happiness scores influence adherence to COVID-19 preventive measures among transplant patients.

[5]Department Health Sciences, Hamburg University of Applied Sciences, Hamburg, Germany

[6]Department of Public Health, Institute of Tropical Medicine, Antwerp, Belgium

[7]Heidelberg Institute of Global Health, Heidelberg University Hospital, Heidelberg, Germany

Contact: m.belau@uke.de

Background: Dengue fever is a major public health problem because it is a widespread and rapidly transmitted mosquito-borne viral disease. We developed a framework for early detection of dengue outbreaks in Tanzania, starting with detection of suspected and/or confirmed cases, followed by site-specific risk characterization, both useful for planning and prioritizing outbreak interventions or epidemic preparedness.

Methods: Our initial focus was on the identification and categorization of indicators that are specifically tailored to the early detection and classification of outbreak events. The framework was then evaluated using (i) available cases with syndromic and laboratory-confirmed disease information from ProMED emails using decision tree analysis, and (ii) available historical dengue epidemic data at the local level from 2019 with 6,795 confirmed cases using negative binomial regression analysis adjusted for month and area.

Results: The laboratory-confirmed diagnosis (dengue yes or no) was consistent with the results of the suspected case classification algorithm for clinically defined syndromic cases. There was strong evidence of an increase in dengue cases with higher site-specific risk (rate ratio = 2.51 (95% CI = [1.76, 3.58])) when regressing confirmed dengue cases in 2019 as the dependent variable and site-specific risk as the independent variable.

Conclusions: The rapid dengue outbreak risk assessment developed may be useful in controlling the epidemic in Tanzania. The suspected case classification algorithm can be a very useful tool to better assess whether a potential dengue case is present and thus requires laboratory confirmation. The framework can be used to rapidly predict the risk of dengue outbreaks, which is useful for planning and prioritizing interventions or for epidemic preparedness.

Key messages:

- Framework for a novel rapid risk assessment for early detection of dengue outbreaks in Tanzania.
- Framework relevant to epidemic preparedness.

Abstract citation ID: ckae144.1906
The disease severity and death outcomes of COVID-19 outpatient cases in Almaty, Kazakhstan 2021-2022

Nailya Kozhekenova

N Kozhekenova[1], Y Semenova[2], M Santric-Milicevic[3], N Glushkova[1]

[1]Higher School of Public Health, Al-Farabi Kazakh National University, Almaty, Kazakhstan

[2]Department of Neurology, Semey Medical University, Semey, Kazakhstan

[3]Institute of Social Medicine, University of Belgrade Faculty of Medicine, Belgrade, Serbia

Contact: nailyakozhekenova@gmail.com

Background: The global pandemic COVID-19 presented a serious burden on primary health care. We analyzed the association between the age, sex, and comorbidity on the severity and outcomes of COVID-19 in outpatient care in Almaty, Kazakhstan, between 1.1.2021 to 31.12.2022.

Methods: We assessed Odds ratio and 95% Confidence interval (OR, 95% CI) in a retrospective analysis of data on 174.540 COVID-19 patients on outpatient follow-up collected from an primary care electronic database (108,234 women and 66,306 man). Among outpatients 88.9% ($n = 155{,}127$) had mild disease, 8.3% ($n = 14{,}537$) asymptomatic; and moderate/severe disease was observed in 2.8% of cases.

Results: Among the COVID-19 outpatients, the incidence of diabetes mellitus was significantly higher in women (3.1%) then man (2.4%) ($p < 0.001$), obesity was more common in women (0.6%) than in men (0.4) ($p < 0.05$), and arterial hypertension was more common in men (10%) versus women (6.2%) ($p < 0.001$). The probability of developing moderate/severe disease increased significantly with age, especially in those 60 years and older, where it was 9 times higher ($p < 0.001$, $OR = 9.01$, 95% CI: 7.7-10.5), and where the probability of lethal outcome was very high ($OR = 61.8$, 95% CI: 8.5-446.2, $p < 0.001$) too. The odds of developing moderate/severe COVID-19 were 1.4 times higher in patients with diabetes mellitus ($p < 0.001$, $OR = 1.43$, 95% CI: 1.27-1.6), 2.5 times higher in obese patients ($p < 0.001$, $OR = 2.51$, 95% CI: 1.9-3.15), and in patients with chronic obstructive pulmonary disease ($p < 0.001$, $OR = 2.5$, 95% CI: 2.13-3.02), and the presence of arterial hypertension increased the risk 1.2-fold ($p < 0.001$, $OR = 1.16$, 95% CI: 1.07-1.26).

Conclusions: In Almaty outpatients, an association between the moderate and severe COVID-19 and age and comorbidity (diabetes mellitus, obesity, arterial hypertension, and COPD) was found, which underscores the necessity of more research on primary care organization and delivery in health emergencies.

Key messages:

- An increase of severe COVID-19 in elder outpatients and with comorbidity emphasizes the need for their effective protection.
- The research on the impact of various factors on the disease severity and outcomes in outpatients can assist in optimizing primary care.

Background: HPV vaccine coverage (VC) remains lower than expected in many countries, particularly France. We developed and evaluated the PrevHPV multicomponent intervention to improve HPV VC among French adolescents. We evaluated the implementation of the school-based components of the intervention.

Methods: We carried out a mixed-method study embedded in a cluster randomized controlled trial (July 2021-April 2022; 14/25 French school districts). The cluster was the municipality (n = 91). The school-based components of the intervention were 'education and motivation' and 'at-school vaccination'. Quantitative data were collected through standardized activity reports and self-administered questionnaires; the implementation outcomes were fidelity, dose, reach, acceptability and sustainability. Qualitative data were collected through semistructured group interviews with school staff and analyzed using the Consolidated Framework for Implementation Research.

Results: We found high rates for: fidelity (e.g., 69% of the targeted classes had two educational sessions and 89% of schools invited all pupils for at-school vaccination, as planned); acceptability (e.g., pupils' participation satisfying in 90% of the sessions, 96% of vaccinated pupils and 78% of school staff satisfied with at-school vaccination); and sustainability (e.g., respectively 91% and 76% of schools considered conducting sessions and vaccination days during the following year). However, the withdrawal of 1/3 of schools before the trial started and difficulties in mobilizing parents negatively impacted dose and reach. Several facilitators and barriers influenced the implementation of the components; they were related to the components' design, the characteristics of both the external and internal environment of the school, the numerous stakeholders and individuals involved, and the implementation strategies used.

Conclusions: These results can guide policy making on school-based HPV vaccine promotion in France and Europe.

Key messages:

- The PrevHPV study is supported by the French health authorities and conducted by a multidisciplinary consortium to tackle a long-lasting public health concern in France.
- These findings have practical implications for implementing effective and acceptable school-based interventions in real life to improve HPV vaccine uptake and reduce HPV-associated burdens.

Breastfeeding knowledge, attitudes and practices of HIV-positive women in Africa, a systematic review

Maria Romay-Barja

N Cuenca-Viñas[1], R Sánchez-Marqués[2], A Benito[2], M Romay-Barja[2]
[1]Medicina Preventiva y Salud Pública, Hospital Central de la Cruz Roja San José y Santa Adela, Madrid, Spain
[2]Centro Nacional de Medicina Tropical, Instituto de Salud Carlos III, Madrid, Spain
Contact: mromay@isciii.es

Background: Breastfeeding (BF) is essential to ensure the health and survival of children, especially in regions where diarrhoea, pneumonia and malnutrition are common causes of child mortality. The WHO currently recommends, along with antiretroviral treatment, exclusive BF (EBF) for the first six months and mixed BF for the next six months and extending it to 24 months. In sub-Saharan Africa, more than one million HIV-positive women face the challenge of infant feeding due to limited access to treatment and safe water. The aim of this study was to understand the knowledge, attitudes, and practices of HIV-positive mothers in Africa to provide evidence for public health strategies.

Methods: We conducted a systematic review of studies on Knowledge, Attitudes and Practices of BF among HIV-exposed children in African countries, following the principles of the PRISMA statement and identified by searching major databases of records published between 2013 and 2023.

Results: Of the 498 articles identified, 21 met the inclusion criteria. 70% of the studies were conducted in Ethiopia, South Africa, and Kenya. 95% of the studies were conducted in health care facilities. Mothers showed good knowledge, attitudes and practices regarding EBF of HIV-exposed children, but low knowledge and fear of continuing to practice BF later on. The HIV-positive mothers mentions a range of recommendations received from health workers, identified as their main source of information. Stigma against mothers who practice EBF was found. The primary reason for early cessation of BF was due to work.

Conclusions: Knowledge, attitudes, and practices of the infant feeding currently recommended by WHO for HIV-positive mothers was weak. There is little evidence of what happens in other African countries and in women with limited access to the health system. Public health policies need to be strengthened to ensure that health workers are trained in the current guidelines to improve HIV-positive women's BF.

Key messages:

- HIV-positive mothers are afraid to continue breastfeeding their babies after 6 months.
- More studies about the breastfeeding practices of children of HIV-positive mothers with limited access to health services are needed.

Abstract citation ID: ckae144.1909
Screening for congenital Chagas disease in a non-endemic area: a cost-effectiveness analysis

Pietro Marraffa

P Marraffa[1], M Dentato[1], A Angheben[2], G Barbera[1], MC Nurchis[3], A Heidar Alizadeh[3], L Olivo[3], G Damiani[3,4], MM Gianino[1]

[4]Woman and Child Health and Public Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: marraffa.pietro@gmail.com

Background: Due to climate changes, immigration, and globalization, Chagas Disease (CD) also afflicts nations without vector transmission. In Europe, congenital CD (cCD) is a significant public

health issue, perpetuating the disease: it is crucial to perform CD screening in pregnant women at risk, as the treatment of infants is effective in eradicating the infection. Only a few European regions have a definite algorithm for diagnosing cCD, but no official guidance has been published at the national or European level. To support policymakers, this study aims to outline a cost-effectiveness analysis of CD screening in non-endemic areas, such as Italy, in pregnant women born or arriving from endemic countries and in their newborns.

Methods: To measure the economic impact of cCD screening, a decision tree model will be used to compare the test option (screening, diagnosis, treatment, follow-up) with no test option (no screening, progression of disease). Model parameters will be taken from relevant scientific literature. The primary outcome will be the Incremental Cost-Effectiveness Ratio (ICER) between the two options. Sensitivity analyses will be conducted to determine how changes in prevalence, transmission rate, screening adherence, and treatment adherence may affect the ICER.

Results: We expect the ‘test’ option to be cost-effective even with significant reductions in prevalence, transmission rate, adherence to screening or treatment. Threshold levels of these variables will allow to critically extend the results to areas with reduced immigration, patchy distribution of migrants at risk, health logistical limitations, and limited access to care for immigrants.

Conclusions: Our findings can help policymakers implement official screening programs and diagnostic algorithms for cCD in Italy and other non-endemic countries. This contributes to SDG 3 by combating the spread and burden of neglected tropical diseases and contributing to maternal, child, and migrant health.

Key messages:

- Screening for congenital Chagas Disease in a non-endemic area may be cost-effective and cost-saving.
- Study findings could provide useful information for health policymakers to combat Chagas Disease in Europe.

Abstract citation ID: ckae144.1910
Advancing data-driven decision-making for human papillomavirus (HPV)

Sibilia Quilici

LL Louette[1]
[1]Vaccines Europe, Brussels, Belgium
Contact: sibilia.quilici@vaccineseurope.eu

Background: HPV is among the most important infections associated with cancers in men and women, including cervical cancer which is the second most common cancer affecting women aged 15-44 years in the EU. Yet, data on vaccine uptake, HPV infection rates and incidence of related cancers is lacking across Europe, obstructing policymakers’ ability to build adequate prevention strategies towards the EU’s goal of eliminating HPV-related cancers.

Methods: Vaccines Europe analysed the landscape of data collection practices for HPV, highlighting discrepancies across Europe as well as successful initiatives.

Results: Our analysis reveals stark gaps in data collection across Europe. Some countries do not report disease levels and vaccination coverage for HPV. When reporting does occur, methods and timelines often differ between countries. Limited data availability exists for vaccination uptake in boys and young adults. This lack of standardisation hinders the comparability and reliability of collected data. It also impedes the integration and analysis of data within and across countries, hindering the development of effective elimination strategies. Concrete actions are needed at EU and national level to further develop and strengthen data collection, sharing and use in decision-making. Our research calls on strengthening ECDC’s role, promoting best practice sharing between countries, ensuring sustained resource allocation for data systems/surveillance, establishing electronic vaccination registries, an EU implementation roadmap to support countries in achieving the objectives of Europe’s Beating Cancer Plan, and translating data into policy recommendations. The Council Recommendation on vaccine-preventable cancers provides a framework for EU Member States to establish electronic vaccination registries and the ECDC to develop an HPV dashboard by the end of 2024.

Key messages:

- Current data collection practices leave Europeans more vulnerable in the fight against cancer.
- Robust data can guide policy and support elimination strategies for vaccine-preventable cancers.

Abstract citation ID: ckae144.1911
Do the prevention procedures work in reducing infections?

Federico Viti

[3]Department of Molecular Medicine and Developmental Medicine, University of Siena, Siena, Italy
Contact: federico.viti@hotmail.it

Introduction: Healthcare-associated infections (HCAIs) pose significant challenges in healthcare settings. Poor environmental hygiene contributes to HCAI. This study aims to evaluate and to assess the effectiveness of HCAI containment practices in nursing homes (NH).

Methods: The study examined infection prevention procedures in eight NHs supervised by the Multidisciplinary Commission of the Tuscany South-East Local Health Authority of Italy. Infection frequencies were obtained from NHs management and compliance with preventive procedures was assessed by inspection reports. Infection prevention protocols, including cleaning and disinfection procedures, were referenced from ministerial guidelines for hospital and territorial facilities. Comparisons was done whit Mann-Whitney test, using STATA.

Results: In 2023 more frequent infections were SARS-CoV-2 (19.5%), urinary tract infections (17%), pharyngitis (15.7%), influenza-like syndromes (ILI) (15%), and pneumonia (9%). Compared to 2022, significant improvements were observed in legionellosis surveillance, laundry, sanitary procedures, instrument disinfection, and hairdressing services. Non-compliance to specific procedures revealed differences in infectious onset like cleaning process verification with fungal infections ($P = 0.01$; $M = 2,5$), gastrointestinal infections ($P = 0.04$; $M = 1.5$); cleaning sanitary pans with Clostridium Difficile gastrointestinal infections ($P = 0.04$; $M = 2$); instrument disinfection with gastrointestinal infections ($P = 0.04$; $M = 1.5$) conjunctivitis ($P = 0.01$; $M = 8$); laundry procedures with pneumonia ($P = 0.04$; $M = 18$) and ILI ($P = 0.04$; $M = 35$).

Conclusions: These findings emphasize the importance of well-defined procedures in reducing HCAIs. While preventive measures demonstrate efficacy, continuous efforts are necessary for their consistent implementation. Continuous monitoring and stakeholder engagement are essential for developing sustainable strategies in preventing healthcare-associated infections.

Key messages:

- Healthcare-associated infections are a significant complication in the healthcare sector and require effective practices in nursing homes.
- Prevention measures are effective, but continuous and collaborative effort is needed to ensure their uniform implementation and develop more effective strategies in preventing HCAI.

Background: Sexually transmitted infections are a major public health problem, and their number is increasing in Italy. However, affective sexuality education is not yet part of the curricula. Therefore, a project entitled ESPRIT was launched, involving 3 regions (Friuli-Venezia Giulia, Lazio and Sicily), the IRCSS 'Burlo Garofolo' and the Istituto Superiore di Sanità, and implemented with the technical and financial support of the Ministry of Health - CCM.

Methods: A multicenter prospective intervention study was designed involving public upper secondary school students (grade 10-11). All target groups completed a KAP (knowledge, attitude, practice) questionnaire before and after participation in the educational intervention to measure its effectiveness. The questionnaires from the first phase were collected between January and April 2024, and the results were analyzed using R statistical software.

Results: The analysis of the overall results (463 students in total; female 58%, male 39%, other 2%; FVG 49%, Lazio 25%, Sicily 26%) showed that the group of upper secondary school students, targeted by peer education answered the knowledge part correctly by 56.6± 13.8% on average. Applying the Kruskal-Wallis test showed that the percentage was significantly higher for females than males (p-value=0.005) and for licei students compared to technical and vocational schools (p-value=0.000). In terms of to attitudes, only 17% of students talked at length about sexually transmitted infections, and in 86.6% of cases, the interlocutors were friends or peers.

Conclusions: The results of the first phase show differences between the sexes and between the different types of educational institutions. The current level of knowledge still leaves much room for intervention and improvement. Analyzing the results of the follow-up phase will allow us to understand the effectiveness of the peer education intervention.

Key messages:

- Adolescents' knowledge of sexually transmitted infections needs to be improved.
- Gender and the type of school attended affect the level of knowledge.

Issue: A National Action Plan (PNCAR) to fight antimicrobial resistance has been launched in Italy in 2017, further revised in 2022. In order to reduce inappropriate exposure to antibiotics and infections from multidrug resistant bacteria, a structured system of surveillance and monitoring according to PNCAR standards has been set up in all Italian regions. In the Hospital of Cittadella (District of Padua, Veneto region), special focus has been given to the reduction of antibiotic consumption, in particular quinolones, third generation cephalosporins, carbapenems and macrolides.

Description: Multidisciplinary meetings have been monthly organized by the hospital Antimicrobial Stewardship Group, with the aim of coordinating the implementation of specific stewardship actions. A quantitative estimate of antibiotic consumption (defined daily dose - DDD - consumption per 100 days of hospitalization) has been provided by the Regional data warehouse from 2019 to 2023 regarding all classes of antibiotics.

Results: Between 2019 and 2023 a clear decrease in the consumption of quinolones (from 8 to 5,8 DDD, -28%) and carbapenems (from 2,5 to 1,3 DDD, -48%) was observed but, at the same time, an increase in the consumption of third generation cephalosporins (from 9 to 15,7 DDD, +74%) has been reported. This can be explained as a direct consequence of the correct application of therapy guidelines, which in several cases suggest the use of ceftriaxone instead of meropenem. Finally, after an increase in the consumption of macrolides during the first COVID-19 pandemic wave, the consumption of this class of antibiotics has returned to pre-pandemic level.

Lessons: Constant monitoring of antimicrobial consumption and the identification of warning situations that may need to implement specific actions are the cornerstone of Antimicrobial Stewardship programs. Targets must be defined analyzing data of bacterial resistance rates and infections from multidrug resistant bacteria.

Key messages:

- In Antimicrobial Stewardship programs it is important to adopt constant monitoring of antimicrobial consumption.
- Antimicrobial stewardship programs need to be adapted according to the characteristics of each hospital.

An international comparison of Long-term Care Facility outcomes during the COVID-19 pandemic

John Loughrey

J Loughrey[1]*, M Codd*[1]*, P Wall*[1]*, E Gormley*[1]*, K Conyard*[1]*, P Jalili*[1]*, J Kumawat*[1]
[1]School of Public Health, Physiotherapy and Sports Science, University College Dublin, Dublin, Ireland
Contact: john.loughrey@ucd.ie

Background: The COVID-19 pandemic has had huge repercussions for public health internationally and different countries had different outcomes based on preconceived policy interventions. Lessons influencing future policy have been learned, notably how best to manage vulnerable populations, particularly those living in long-term care facilities (LTCFs). In Ireland LTCF residents accounted for 56% of deaths during the first wave of the pandemic and it is imperative to establish the causes of this. International research has highlighted how factors including county incidence rate, facility size, occupancy, LTCF ownership and compliance with health inspection regulations influenced LTCF COVID-19 outcomes. The aim of this research is to explore the impact of these factors in an Irish context and compare to best international standards.

Methods: The main outcome considered was deaths per 100 beds. Data on crude mortality were available for 580 Irish LTCFs up to 28 May 2020. Data regarding occupancy, ownership, facility size and compliance with regulations were obtained for these LTCFs from a novel dataset of 1130 available LTCF regulatory inspection reports between 2018- 2022. Regression analysis was carried out to show how LTCF mortality was predicted by examined variables.

Results: The most significant predictor of deaths from COVID-19 in Irish LTCFs resulting from this research was LTCF occupancy (Odds ratio:1.029, significance <0.001). Regional community incidence, in concordance with international literature was also an important factor. Other stated predictors in this model were either non-significant or only marginally significant. These results are analysed in conversation with international research of the same variables.

Conclusions: To protect LTCF residents for potential future pandemics, attention should be paid to monitoring and suppressing local incidence rates and moves should be implemented towards designing smaller facilities with individual rooms for vulnerable residents.

Key messages:

- Irish long-term care pandemic mortality was predicted by high occupancy of facilities and high regional COVID-19 incidence.
- Comparing International COVID-19 outcomes in long-term care facilities can provide guidelines for the future.

Abstract citation ID: ckae144.1915
Uncovering the health system burden of pneumococcal infections in adult and elderly populations

Zach Desson

Z Desson[1], *J Levi*[1], *F Margheri*[1]
[1]European Health Management Association, Brussels, Belgium
Contact: zachary.desson@ehma.org

Background: Health system resources dedicated to vaccination and infectious disease prevention are often directed towards infants and children, through extensive childhood vaccination schedules. This focus has led to the near eradication of several preventable childhood diseases and had positive impacts on population health, but despite this track record of success, the ability of our health systems to make vaccinations accessible throughout the full life course has been less consistent. This project aims to address this issue by providing new data about the burden that pneumococcal infections, which are vaccine-preventable, have on adult and elderly populations.

Methods: This research aims to uncover the health system burden of invasive pneumococcal disease and pneumococcal pneumonia at all levels of the health system in 5 EU countries (Austria, Belgium, France, Italy & Portugal). This involves a survey of managers and care providers working in hospitals, long-term care facilities, and primary care centres who may be affected by the health system impacts of pneumococcal infections. The survey covers several dimensions of health service delivery to collect a broad range of data on existing disruptions. The survey was translated into the study country languages and its formulation was further validated through interviews with experts in each study country to ensure that it can capture context-specific health system insights. The data collected through this survey will be further enhanced through a series of in-depth interviews before being synthesised, analysed and eventually published in a detailed report.

Results: Data collection begins as of 15 May 2024, and full results are expected to be published and available for the EPH Conference in November 2024. The results of this research will offer valuable evidence to public health professionals, health managers and policymakers across Europe who are working to improve life-course access to pneumococcal vaccination.

Key messages:

- Effective vaccination programmes for adult and elderly populations require expanding focus beyond childhood.
- Data about the health system burden of pneumococcal infections in adult and elderly populations improves evidence-based decision-making and public health services.

Abstract citation ID: ckae144.1916
Antibiotic use and resistance: knowledge, attitudes and practices in Italian healthcare workers

Nicolò Panattoni

N Panattoni[1], *E Renzi*[1], *E Di Simone*[1], *S Costantino*[1], *V Baccolini*[1], *G Migliara*[2], *C Marzuillo*[1], *C De Vito*[1], *P Villari*[1], *A Massimi*[1]
[1]Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Life Sciences, Health and Health Professions, Link Campus University, Rome, Italy
Contact: nicolo.panattoni@uniroma1.it

Background: Antimicrobial resistance (AMR) is one of the most significant public health challenges globally. The misuse or incorrect use of antibiotics has led to the emergence of resistant bacteria, making it increasingly difficult to treat infections. This study aims to identify knowledge, attitudes, and practices among Italian healthcare workers (HWs) - medical doctors (MDs) and nurses - regarding antibiotics, antibiotic use, and antibiotic resistance.

Methods: Cross-sectional study; a validated questionnaire from the European Centre for Disease Prevention and Control was distributed via web survey starting from April 2024 to a voluntary sample of healthcare workers employed in Italy. Descriptive analysis and multivariable logistic regression were performed to investigate predictors of knowledge regarding antibiotic use and AMR. Ethical approval was obtained from the local ethics committee.

Results: So far, 154 HWs were enrolled, of which 132 were nurses (85.7%). The average level of knowledge regarding AMR and antibiotic use was 6.8/7 (± 0.2) for MDs and 6.1/7 (± 0.2) for nurses, with an overall score, among HWs of 6.19 (± 0.99), compared to a European average of 6.35. The multivariable analysis highlighted that the medical profession reported higher knowledge regarding prudent antibiotic use and AMR (aOR 6.90; 95% CI 1.83-26.01, p-value = 0.004), while concerning professional practice, the unavailability and difficulty of access to guidelines seemed to increase the risk of reporting inadequate knowledge (aOR 2.04; 95% CI 1.01-4.13, p-value = 0.046).

Conclusions: Our preliminary results provide an insight into the importance of structuring and actively disseminating procedures/protocols and guidelines to deepen the issues of AMR and prudent antibiotic use. Also, there appears to be a need to enhance the delivery of refresher courses targeting HWs, with particular attention to settings at high infection transmission risk. EU funding: Project no. PE00000007, INF-ACT.

Key messages:

- Although a higher knowledge about prudent antibiotic use and AMR, more efforts are needed to increase access to guidelines.
- Constant updating of knowledge and practices is necessary to face the challenges of antibiotic resistance in public health.

Abstract citation ID: ckae144.1917
Infectious disease prevention among internally displaced people: Perspectives from Lviv, Ukraine

Karolina Shumylo

K Shumylo[1,2], N Ivanchenko[1,2], M Kuziuk[1], W Aaronson[3], AM Tomosky[3]
[1]Research Department, All-Ukrainian Association of Public Health Specialists, Ivano-Frankivsk, Ukraine
[2]Infection Prevention and Control Department, Lviv Regional Center for Disease Prevention and Control, Lviv, Ukraine
[3]College of Public Health, Temple University, Philadelphia, USA
Contact: karolina.shumylo@gmail.com

Background: The ongoing war in Ukraine has increased the risk of infection spikes, especially among internally displaced people. The healthcare challenges in the war context necessitate teaching the population of preventative measures, which have become the primary vector of the activities of the Ukrainian Regional Centers for Disease Control and Prevention.

Objectives: The research aimed to highlight the activities of the Lviv Regional Center for Disease Control and Prevention (CDC) in relation to internally displaced people.

Methods: The research project analyzed the incidence rate of infectious diseases and vaccination coverage data among the population and internally displaced people in the region. The data were collected from monthly reports of CDC's departments and alert messages sent by primary care institutions to the CDC.

Results: According to the Single register of internally displaced people (IDP), 13% of internally displaced people were permanently staying in the Lviv region (the second place was Zakarpattia region - 9% of IDP, and the third was Kyiv - 7% of IDP). In the Lviv region, 237,000 people registered as forcibly displaced. Total, over 700, 000 people are in the area, including the unregistered and 68,000 children. In 2022-2023, the morbidity rates among IDPs did not exceed the rates among the general population in the area. Each IDP residence place had its physician; 11 thousand IDPs were vaccinated, and 3,235 of those were children. In general, 46 mobile medical brigades worked on-site in the Lviv region. Only one spike of gastrointestinal infection was registered. CDC employees provided lectures and workshops on hygiene and food storage in 56 IDP residence places.

Conclusions: The review results show that coordination between CDCs, local physicians, and mobile medical brigades in the IDP residence areas prevents outbreaks of infectious diseases and swiftly responds to emerging threats.

Key messages:

- The tragic events in Ukraine resulted in healthcare access issues. Lviv CDC, fighting at its own forefront, quickly assessed the risks and efficiently managed the potential hazards.
- The Lviv region remains one of the biggest hubs in Ukraine for the temporary residence of internally displaced people, with CDC employees ensuring that preventive measures are effectively carried out.

Contact: gabrynasi@gmail.com

Antimicrobic resistance (AMR) continues to rise, whereas development of new agents to counter it has slowed. A heightened need to maintain the effectiveness of currently available agents exists. Healthcare-associated infections (HAIs) are a significant cause of poor treatment outcomes and elevated healthcare and societal costs worldwide. At the beginning of 2024, we started a prospective, interventional, interrupted time-series study, based on Prospective Audit and Feedback in the Intensive Care Unit (ICU) and in the internal medicine ward of our hospital. The primary outcomes will be the difference in the antibiotic consumption, and the incidence of bloodstream infections (BSI) caused by multidrug-resistant (MDR) organisms. The secondary outcomes will include the hospital mortality rate, the mean length of stay and the antibiotic expense. We conducted a snapshot analysis of the first three months to assess the efficacy our program. In the first three months we registered a global reduction in antibiotic expense (almost by half in comparison of 2023 first quarter) and consumption, particularly in the use of carbapenems: (change in level, CL: -51,26 DDD/1000 PD,) and third-generation cephalosporins (CL: -6 DDD/1000 PD). We registered a reduction in the use of hydroalcoholic gel, probably due to the reducted perception after the waning of risk perception towards Covid-19, although no big difference was observed in BSI incidence due to MDR Gram-negative organisms (CL: +1,2 events/1000 PD). Albeit partial, once again these findings demonstrated that implementation of an antimicrobial stewardship program, no matter the level of healthcare, is critical for fighting the AMR and to lessen the burden on Public Health; in particular our program induced a significant reduction in antibiotic consumption that lead to more funds at disposal to improve our clinical practice.

Key messages:

- Once again our findings demonstrated that implementation of an antimicrobial stewardship, no matter the level of healthcare, is critical for fighting the AMR.
- Our program induced a significant reduction in antibiotic consumption.

Background: This systematic review assesses the current available evidence across the WHO European region on the effectiveness and cost-effectiveness of the different approaches used for TB screening and also explores the facilitators and barriers that migrants face during screening programs.

Methods: We conducted an extensive, comprehensive, and systematic literature search across multiple databases, including MEDLINE, Cochrane, Scopus, and ISI Web of Knowledge, without any restrictions on publication date or language. In addition, we reviewed grey literature and reports from WHO. The data were meticulously analyzed using RStudio, with a focus on screening effectiveness indicators, such as infection and disease detection rates, uptake, coverage, and cost-effectiveness economic analyses.

Results: Our review included 43 studies covering over 8 million migrants from 11 countries. The findings demonstrate that while screening uptake was high, coverage varied, and completion rates for preventive treatments were low. Economic analyses supported the high cost-effectiveness of the screening programs, particularly when integrating both active TB and LTBI screening strategies.

Conclusions: The implementation of uniform screening protocols could potentially streamline efforts, reduce TB transmission, and offer substantial public health and economic benefits, making this research highly relevant for policymakers and healthcare providers.

Key messages:

- An important strength of this study lies in its pioneering approach of current recommendations regarding screening for latent tuberculosis infection and active TB within the WHO European region.
- This is the first study that provides a comprehensive overview of screening interventions across 11 countries and incorporates studies with large sample sizes (n > 8 million migrants).

A systematic review of practices against healthcare associated infections and antibiotic resistance

Antonella Agodi

A Agodi[1]*, M Barchitta*[1]*, E Campisi*[1]*, E Di Liberto*[1]*, A Maugeri*[1]*, R Magnano San Lio*[1]*, G Favara*[1]*, E Vecchi*[2]*, F D'Ancona*[3]
[1]University of Catania, Catania, Italy
[2]Department of Public Health, Emilia-Romagna Region, Bologna, Italy
[3]Department of Infectious Diseases, ISS, Rome, Italy
Contact: agodia@unict.it

Introduction: Antimicrobial Resistance (AMR) and Healthcare-Associated Infections (HAIs) can be preventable by promoting Infection Prevention and Control (IPC) practices. Despite the available evidence, there are still significant gaps regarding the combined and cumulative effects of AMR drivers, IPC practices and HAIs. To address this issue, we conducted a Systematic Review to evaluate the impact of AMR drivers and the effect of IPC practices on epidemiological variation of HAIs.

Materials and methods: After designing the protocol, the systematic literature search has been performed on PubMed, Scopus, and Web of Science. After obtaining the relevant articles, citations were imported into the Rayyan Systematic Review Software. Subsequently, basing on the predetermined inclusion criteria, articles screening process was conducted firstly evaluating the title and abstract of each article and then by full text reading. The predesigned data extraction template included first author's last name, year of publication, location, study title, study design, aims of research, involved wards, population groups, type of Multidrug Resistant (MDR) pathogens, interventions, and outcomes.

Results: Literature search strategies identified 3,637 records in the databases consulted. After de-duplication, 2,881 titles and abstracts remained for screening, and 435 full-text articles were assessed for eligibility. Preliminary results show that among the eligible studies 4% had a pre-post study design, 25% focused on Intensive Care Units, 33% investigated antibiotic usage and antimicrobial stewardship, 17% investigated hand hygiene adherence and 10% analysed the compliance to IPC practices.

Conclusions: The knowledge gained from this comprehensive approach will be used to harmonize the AMR drivers explored to improve the general IPC measures. Moreover, this evidence will improve national awareness and will be important in identifying potential interventions on Governance and IPC measures to contrast AMR.

Key messages:

- In the battle against AMR, it is crucial to recognize the impacts of its drivers and the effect of IPC practices.
- AMR and HAIs can be prevented through comprehensive IPC programs.

Abstract citation ID: ckae144.1921
COVID-19 premature mortality in Serbia: Does the place of death matter?

Aleksandar Stevanović

A Stevanović[1,2]*, M Šantrić-Milićević*[1,2]*, J Todorović*[1,2]*, N Rajović*[3]*,*
N Rosić[4]*, G Bjelobrk*[5]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Center - School of Public Health, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[3]Institute for Medical Statistics, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[4]City Institute of Public Health Belgrade, Belgrade, Serbia
[5]Statistical Office of the Republic of Serbia, Belgrade, Serbia
Contact: aleksandar.stevanovic@med.bg.ac.rs

Background: The COVID-19 pandemic has significantly impacted healthcare services provision in Serbia and globally. Many people did not seek or reach healthcare due to various reasons, and a significant number of COVID-19 deaths were not confirmed by laboratory testing. Within the project of the Laboratory for Strengthening Capacity and Performance of Health System and Workforce for Health Equity, we assessed the differences in years of life lost (YLL) of COVID-19 death cases according to the place of death.

Methods: The Statistical Office of the Republic of Serbia provided average life expectancy and anonymous individual mortality data of the Serbian population in 2020, 2021, and 2022, where COVID-19 was the underlying cause of death (ICD-X codes: laboratory confirmed - U07.1 and clinically diagnosed - U07.2), also disaggregated by the place of death (at home or in a hospital). Analytical statistics and nonparametric tests were used to assess the differences in premature mortality by place of death with a significance level set at $p < 0.05$.

Results: In all observed years, a total of 45,632 death cases due to COVID-19 occurred (94.3% in hospital and 5.7% at home). Most COVID-19 deaths were coded as U07.1 (93.8% in hospital, 91.3% at home). An average of 12.12±7.50 YLLs was estimated per death, with a median of 11.50. There was a significant difference ($p < 0.001$) in the median number of YLLs between those who died in the hospital (11.50) and those who died at home (6.78). Furthermore, deaths occurring at home had fewer YLLs but were more frequently coded as U07.2 ($p < 0.001$).

Conclusions: The place of death is relevant when assessing the impact of COVID-19 on premature mortality in Serbia. On average, persons who died at home due to COVID-19 had a lower number of YLLs compared to those who died in a hospital. More research is necessary on the other factors contributing to premature mortality and inequalities in the COVID-19 burden in Serbia.

Key messages:

- During the first three years of the COVID-19 pandemic in Serbia, 5.7% of COVID-19 deaths occurred at home, resulting in an average of 9.89 years of life lost.
- The COVID-19 pandemic highlights the need to investigate deaths that occur at home and improve pandemic preparedness.

Abstract citation ID: ckae144.1922
Scoping Review of Pre-Exposure Prophylaxis and Post-Exposure Prophylaxis in HIV Prevention in Türkiye

Sabanur Cavdar

S Cavdar[1,2]
[1]Public Health Services, Istanbul Eyupsultan District Health Directorate, Istanbul, Türkiye
[2]Health Management Doctorate Program, Uskudar University, Istanbul, Türkiye
Contact: sabanur.cavdar@gmail.com

Background: Pre-Exposure Prophylaxis (PrEP) is a medical -anti-retroviral- prevention method that reduces the risk of HIV transmission during sexual intercourse or injection drug use. Post-exposure prophylaxis (PEP) refers to taking medicine after risky exposure. The European Centre for Disease Prevention and Control (ECDC) has recommended the integration of PrEP into the existing HIV prevention packages since 2015. In Türkiye, first PrEP Guideline was published in 2022. The aim of this study is to evaluate the literature gap on the PrEP and PEP for HIV prevention research in Türkiye.

Methods: This study was conducted in October 2023. Searches were performed using the keywords ‘HIV, AIDS’ and ‘Pre-exposure prophylaxis, PrEP, Post-exposure prophylaxis, PEP’ in PubMed, Web of Science, Scopus, TRDizin, and Dergipark for all years. ‘Türkiye, Turkey, Turkish’ were added into the keywords in international indexes, without using country filters. Inclusion criteria were research on PrEP or PEP for HIV, research conducted in or using data from Türkiye, publications in English/Turkish. Exclusion criteria were non-HIV topics, non-Turkish data, non-English/Turkish publications. Lists were merged, duplicates were removed. Inclusion-exclusion criteria were conducted at title and abstract level. Full texts of the included articles examined for bibliometric characteristics, study types, and key results.

Results: 1014 publications yielded, 993 evaluated, and 17 fully reviewed. Four discussed Türkiye’s PrEP practices (2018-2023); three analyzed PEP regimens; three were reviews on PrEP/PEP in Türkiye (2016-2022). Two original research articles explored PrEP awareness among Türkiye’s men having sex with men (2022) and infectious disease physicians’ attitudes toward PrEP (2020). Studies showed gaps in PrEP information and service access.

Conclusions: There are limited studies published on PrEP and PEP in HIV prevention in Türkiye. This study highlights the need for local research on the topic.

Key messages:

- Evaluation of Pre-Exposure Prophylaxis (PrEP) and Post-Exposure Prophylaxis (PEP) publications highlights gaps in HIV prevention research.
- Limited literature on PrEP and PEP in HIV prevention emphasizing the need for further studies and improved access to PrEP information.

Estimating the impact of the COVID-19 vaccination programme in Ireland: December 2021-March 2023

Louise Marron

L Marron[1,2]*, A Mateo-Urdiales*[3]*, J O’Donnell*[1]*, E Robinson*[1]*, L Domegan*[1]
[1]Health Protection Surveillance Centre, Dublin, Ireland
[2]2ECDC Fellowship Programme, EPIET, ECDC, Stockholm, Sweden
[3]ISS, Rome, Italy
Contact: marronl@tcd.ie

Background: In Autumn 2023, COVID-19 booster vaccines were offered to all those aged ≥50 years in Ireland. There was concern that vaccine fatigue would impact uptake. We aimed to quantify the direct impact of the COVID-19 vaccination programme on averted outcomes in individuals aged ≥50 years, during a period of Omicron variant dominance, to inform vaccination strategy and public health communication.

Methods: We conducted a retrospective observational study from December 2021 to March 2023 in Ireland. We considered as averted outcomes symptomatic SARS-CoV-2 presentations to primary care, emergency department (ED) presentations, hospitalisations, intensive care unit (ICU) admissions and deaths due to COVID-19. We used an adapted formula from other vaccine impact published studies, including national data on notified outcomes, vaccine coverage data and vaccine effectiveness (VE) estimates, sourced from the WHO’s live systematic VE review, to estimate the count and prevented fraction of outcomes in ≥ 50-year-olds averted by the COVID-19 vaccination programme. The number of expected outcomes in the absence of vaccination was calculated by summing the counts of outcomes observed and outcomes averted.

Results: Between December 2021 and March 2023, the COVID-19 vaccination programme averted 48,551 symptomatic presentations to primary care (36% of expected), 9,517 ED presentations (53% of expected), 102,160 hospitalisations (81% of expected), 3,303 ICU admissions (89% of expected) and 15,985 deaths (87% of expected).

Conclusions: During Omicron dominance, the COVID-19 vaccination programme averted symptomatic and severe outcomes, including deaths due to COVID-19, underscoring the benefits of COVID-19 vaccination. In the context of vaccine fatigue emerging as an important public health issue in Ireland and internationally, these findings can inform future COVID-19 booster vaccination programmes and communication about the reason for and importance of COVID-19 vaccination.

Key messages:

- The COVID-19 vaccination programme in Ireland prevented illness and death in people aged ≥50-years. Vaccination therefore protected population health and the healthcare system.
- These findings can be used to inform future COVID-19 vaccination policies, planning for winter, pandemic preparedness and communisation about the importance of ongoing COVID-19 vaccination programmes.

Abstract citation ID: ckae144.1924
Influenza vaccine effectiveness in Ireland during two influenza seasons, 2022/23 and 2023/24

Louise Marron

L Marron[1,2]*, A McKenna*[1]*, J O’Donnell*[1]*, L Domegan*[1]
[1]Health Protection Surveillance Centre, Dublin, Ireland
[2]ECDC Fellowship Programme, EPIET, ECDC, Stockholm, Sweden
Contact: marronl@tcd.ie

Background: Live Attenuated Influenza Vaccine (LAIV) is recommended in Ireland for all children aged 2-17 years. Quadrivalent influenza vaccine is recommended for all others eligible for vaccination, including those aged ≥18 years with underlying medical conditions and all aged ≥65 years. We aimed to estimate influenza vaccine effectiveness (IVE) against Acute Respiratory Infection (ARI) presentations to primary care due to influenza over two influenza seasons in Ireland, to inform vaccination recommendations and communication campaigns.

Methods: We undertook a test-negative design case control study within the national sentinel surveillance General Practice network, as part of the European Vaccine Effectiveness Burden and Impact Studies (VEBIS) network. We compared influenza vaccination status among influenza Polymerase Chain Reaction (PCR) positive cases with influenza PCR negative controls, amongst patients consulting with ARI. We verified vaccination status using the national influenza vaccination database. We estimated end of season IVE for

2022/23, and mid-season IVE (up to 7th April 2024) for 2023/24, using multivariable logistic regression and adjusting for age, onset time, medical condition, and sex.

Results: In 2022/23, there were 288 cases and 765 controls. In 2023/24 there were 515 cases and 1,482 controls. Overall vaccination coverage was 23% in both seasons. Coverage in 2-17 year-olds was 10% in 2022/23 and 12% in 2023/24. In 2022/23, overall IVE was 42% (95%CI 9-54) and 50% (95%CI -30-83) in 2-17 year-olds. Overall IVE in 2023/24 was 37% (95%CI 16-54) and was 67% (95%CI 28-87) in 2-17 year-olds.

Conclusions: Influenza vaccination reduced medical attendance to primary care with ARI due to influenza, demonstrating benefits of vaccination, particularly among children. Influenza vaccination should continue to be offered and promoted to recommended groups, including children.

Key messages:

- This study suggests that influenza vaccination protected population health and the health service from medical attendance to primary care with acute respiratory infection due to influenza.
- Higher influenza vaccine effectiveness was observed in children aged 2-17 years. These findings can inform influenza vaccination programmes with LAIV for children in Ireland and internationally.

Abstract citation ID: ckae144.1925
Organizational barrier to herpes zoster vaccination uptake in Europe: a systematic review

Michele Sorrentino

C Fiorilla[1], M Sorrentino[1,2], A Belpiede[1], I Stilo[1], M Mercogliano[1], M Triassi[1], R Palladino[1,3]
[1]Dipartimento di Sanità Pubblica, Università degli Studi di Napoli, Naples, Italy
[2]Department of Public Health, University of Pavia, Pavia, Italy
[3]Department of Primary Care and Public Health, School of Public Health, Imperial College, London, UK
Contact: sorrentinoemme@gmail.com

Background: The Herpes Zoster virus represents a significant public health threat for unvaccinated frail individuals and older adults, aged 50 or older. Globally, 95% of elderly and frail individuals are susceptible to develop Herpes Zoster as already being exposed to Varicella Zoster Virus. Organizational and logistical barriers, such as cost management, vaccine storage requirements, supply limitation, logistic difficulties, absence of a streamlined collection system, and healthcare system deficiencies might reduce vaccination uptake.

Methods: A systematic review was conducted to identify studies published in the last 10 years, and focused on logistic and organizational barriers for Herpes Zoster vaccination uptake among frail and participants aged 50+ in Europe. Prisma guidelines were followed, and AXIS tool was used to evaluate the risk of bias.

Results: After a thorough analysis, 4 studies were selected from a total of 863 for detailed review. The analysis revealed several barriers to vaccination uptake, including challenges involving healthcare professionals, participant-related obstacles concerning perceptions and knowledge, accessibility issues, structural deficiencies, and social dynamics. A significant barrier identified is the perception among participants that general practitioners either do not support the vaccination or that participants themselves underestimate the risk of developing Herpes Zoster. Additionally, current communication strategies have proven inadequate, indicating a need for more effective and updated approaches to increase public awareness. These factors contribute to hesitancy regarding vaccination.

Conclusions: This study provides a comprehensive examination of the organizational and logistical barriers to the Herpes Zoster vaccination uptake. Tailored interventions are essential to overcome these barriers. Successfully addressing these challenges might enhance vaccination rate and reduce the public health burden associated with Herpes Zoster.

Key messages:

- Several logistic and organizational barriers reduce the Herpes Zoster vaccination uptake.
- Further literature is required to understand how to overcome those barriers, and increase vaccination uptake.

Abstract citation ID: ckae144.1926
Factors associated with mosquito-borne disease protective behaviour in metropolitan France

Juan Carlos Ocampo-Alvarado

J Ocampo-Alvarado[1], J Dussault[1], J Mueller[1]
[1]Epidémiologie des Maladies Emergentes, Institut Pasteur, Paris, France
Contact: juan-carlos.ocampo@pasteur.fr

Background: Mosquito-borne diseases (MBD) are increasing and expanding their range throughout metropolitan France. Promoting individual protective behaviour is imperative, but research on its determinants is limited to southern regions. This study examines factors influencing MBD protective behaviour in the metropolitan French population.

Methods: 2,087 subjects responded to a self-administered online questionnaire in November 2023. The analysis plan was pre-registered. We fitted two mixed effects models to estimate the frequency and count of protective behaviours across sociodemographic groups and to identify which factors predict protective behaviour.

Results: Frequency of protective behaviour is significantly positively associated with getting bitten by mosquitoes often ($\beta = 3.39$; 95% CI: 3.10, 3.69) and sometimes ($\beta = 1.54$; 95% CI: 1.31, 1.76) compared to almost never, perceived MBD threat ($\beta = 0.11$; 95% CI: 0.06, 0.15), and having financial difficulties ($\beta = 0.23$; 95% CI: 0.02, 0.43). Count of protective behaviours is associated with getting bitten by mosquitoes often ($\beta = 0.39$; 95% CI: 0.30, 0.49) and sometimes ($\beta = 0.14$; 95% CI: 0.05, 0.23), perceived MBD threat ($\beta = 0.02$; 95% CI: 0.00, 0.03), MBD knowledge ($\beta = 0.06$; 95% CI: 0.04, 0.08), and having a chronic disease ($\beta = 0.08$; 95% CI: 0.02, 0.14). Models were adjusted for place of residence, education, and age. No associations were found between sex, having experienced an MBD, or confidence in public authorities to manage health crises.

Conclusions: This study provides the first insights into MBD protective behaviour and its associated factors considering all metropolitan French regions. Our results highlight several factors which may inform MBD prevention communication and policies focused on increasing individual protective behaviour.

Key messages:

- People often bitten by mosquitoes are more likely to engage in more frequent and a higher number of mosquito-borne disease protective behaviour than people almost never bitten by mosquitoes.
- Higher perceived mosquito-borne diseases threat is associated with more frequent and a higher number of mosquito-borne disease protective behaviour.

Hand hygiene intervention in the prevention of healthcare associated infections

Asma Ben Cheikh

A Ben Cheikh[1], H Ghali[1], S Bhiri[1], S Balhi[1], S Khefacha[1], M Ben Rejeb[1], H Said Laatiri[1]
[1]Prevention and Security of Care Department, University of Sousse, Faculty of Medicine of Sousse, Sousse, Tunisia
Contact: asmasmams@yahoo.fr

Background: Healthcare associated infections are a major cause of morbidity and mortality in intensive care units. Observance hand hygiene is singled out as a key element in interruption of these infections. The present study aimed to assess whether hand hygiene intervention program in intensive care unit at the Sahloul University Hospital of Sousse is able to decrease healthcare associated infections.

Methods: We carried out a pre-experimental study among patients hospitalized in seven intensive care units at the Sahloul University Hospital of Sousse during two distinct periods of 3 months, the first in 2019 and the second in 2021. During these two periods, we monitored only patients hospitalized in the ICU for more than 48 hours and incidence of healthcare associated infections was compared. Healthcare associted infections were defined as infections occurred at least 48 hours after admission to the intensive care units. The hand hygiene promotion intervention, done during the year 2020, was based on 3 axes (training sessions, procedures writing and professional practicesevaluation).

Results: Incidence of healthcare associated infections decreased significantly in post-intervention ($p = 0.000$). The decrease of Ventilator-associated pneumonia was significantly higher than other types of infections($p = 0.042$). Extended Spectrum B-Lactamase Producing Enterobacteriaceae infections and Ceftazidim resistant Pseudomonas Aeruginosa infections decreased significantly in after intervention ($p = 0.000$).

Conclusions: The results of our study showed that improved hand hygiene resulted in a reduction in healthcare associated infections.

Key messages:

- Observance hand hygiene is singled out as a key element in interruption of healthcare associated infections.
- Improved hand hygiene resulted in a reduction in healthcare associated infections.

Abstract citation ID: ckae144.1928
Determinants of crimean-congo hemorrhagic fever (cchf) outbreaks: a retrospective analysis

Muhammad Gul Sartaj

MG Sartaj[1], *MR Tahir, M Ali*[2]
[1]Health, Government, Peshawar, Pakistan
[2]National Institute of Health, Ministry of NHSR&C, Islamabad, Pakistan
Contact: drmgsartaj1@gmail.com

Introduction: Crimean-Congo Hemorrhagic Fever (CCHF), a viral tick-borne zoonotic disease with high mortality rates, poses a particular threat in Pakistan during religious event of Eid-ul-Azha as increased livestock contact. This study aims to analyze CCHF cases from three outbreaks, to identify transmission and disease patterns. Understanding these patterns can inform targeted interventions for future outbreaks.

Methods: A retrospective cross-sectional study was conducted to examine three CCHF outbreak investigations between July 2nd and August 12th, 2023 in Khyber Pakhtunkhwa, Pakistan. Multisectoral teams, including human and animal health departments, investigated these outbreaks. Data was collected through semi-structured case investigation tools. The healthcare providers, patients and family were subjects. During active case surveillance, 41 probable contacts were traced.

Results: Among positive cases, male predominance (71.4%) was observed. The highest proportion of cases occurred in the 15-29 year age group (42.9%, $n = 6$). Individuals involved in animal handling professions had the highest prevalence (50%, $n = 7$), followed by students (21.4%, $n = 3$). Common clinical manifestations included high-grade fever (100%), muscle pain (92.9%), and bleeding symptoms (85.7%), with 64.3% of cases reporting vomiting blood. The average recovery time was 7.1 days, while fatal cases had an average of 6.8 days from symptom onset to death. Recovery was observed in 64.3% of cases, with a mortality rate of 35.7%. Chi-square analysis showed significant associations between gender, occupation, and disease outcome ($p < 0.05$).

Conclusions: This study identified a higher risk of CCHF in males, young adults, and individuals involved in animal handling during outbreaks. Public health interventions targeting occupations, demographics, particularly education and protective measures for animal handlers during Eid-ul-Azha days, are crucial to mitigate future outbreaks

Key messages:

- Young male adults, and individuals involved in animal handling are on greater risk of higher risk of CCHF infections in Khyber Pakhtunkhwa, Pakistan.
- One Health community can leverage these findings to develop better prevention and control strategies through collaboration between human and animal health sectors.

[4]Athena Institute, Vrije Universiteit Amsterdam University, Utrecht, Netherlands
[5]Health Connect Partners, London, Netherlands
Contact: t.cesuroglu@erasmusmc.nl

Introduction: Health systems in the EU operate at the national level, granting Member States autonomy for outbreak preparedness and response within their territories whilst coordinating at EU level to combat serious cross-border threats. The EU's Early Warning and Response System (EWRS) provides the platform to exchange personal data for contact tracing across 30/EEA countries and was extensively utilized during COVID-19. This study examines insights from EU/EEA countries and assesses the feasibility of integrating national digital systems with EWRS to increase its effectiveness.

Methods: A comparative case study surveyed representatives from 24 countries and interviewed nine, analyzing contact tracing processes, actors, digital technologies, and challenges/facilitators during COVID-19. Thematic analysis was complemented by two webinars engaging EU/EEA countries to validate findings and gather additional perspectives.

Results: EWRS was valued for safety and efficiency but faced challenges during peak pandemic periods due to the heavy manual workload. Integrating national digital systems with EWRS could enhance data quality, timeliness, and coordination between countries. However, countries have varied and incompatible digital contact tracing systems, limiting the feasibility of their integration with EWRS. Moreover, most countries organize contact tracing at the subnational level, with regional entities developing and managing their own digital technologies under national guidance. Smaller countries excluded, subnational contact tracing case management systems were often not integrated with each other to exchange personal data in an automated way at a national level.

Conclusions: While integrating national digital systems with EWRS could bolster efficiency of contact tracing across EU/EEA, the presence of diverse technologies and decentralized governance poses feasibility challenges. Other improvements are needed to enhance cross-border contact tracing during outbreaks.

Key messages:

- Integrating national digital systems with EWRS promises enhanced efficiency for contact tracing across EU/EEA in line with Regulation (EU) 2022/2371 on serious cross-border threats to health.
- Diverse technologies and decentralized governance pose feasibility challenges, underscoring the need for further enhancements in cross-border contact tracing in EU/EEA during large outbreaks.

Abstract citation ID: ckae144.1930
Social determinants and drivers of use of SARS-CoV-2 self-tests in a French national cohort study

Salomé Garnier

S Garnier[1,2], J Warszawski[1], the EpiCov study group[1]
[1]Centre for Epidemiology and Population Health, INSERM, Paris, France
[2]EHESP French School of Public Health, Paris, France
Contact: salomegarnier99@gmail.com

Background: Self-tests for SARS-CoV-2 became quickly available after the onset of the epidemic. They were especially recommended for high-risk and hard-to-reach populations. This study examines whether self-tests successfully reached vulnerable groups during first months of availability in France.

Methods: The EpiCov study is a national population-based cohort study conducted in France during the Covid-19 pandemic. Primary outcome variable was use of self-test at last SARS-CoV-2 test, among those who reported testing at least once between May-July 2021. Univariate and multivariate binomial weighted logistic regressions were run, stratified by age group (16-24 yrs, 25-59, 60+), to identify social determinants and drivers of use of self-tests.

Results: Overall, 11% of the population who tested for SARS-CoV-2 between May-July 2021 reported using a self-test as last test. Demographic factors were highly predictive of use of self-tests among 25-59 y/o, but not among younger and older age groups. Use of self-tests was highest among 16-24 y/o, people with higher education, lowest population density areas, and people with high overall frequency of testing. Use was lowest among 60+ y/o, unemployed and retired people, and first-generation immigrants. When stratifying by age, 16-24 y/o with high perceived Covid-19 risk were more likely to use self-tests (aOR 1.99, 95% CI 1.10-3.59). Among 25-59 y/o, in-person workers were more likely to use self-tests than remote workers (aOR 1.91 [1.20-3.05]). Among 60+ y/o, employed people were more likely than retired people (aOR 3.97 [2.30-6.85]).

Conclusions: With higher utilization in low population density areas and among frequent testers, convenience may be a primary driver of use of self-tests. Additional drivers include perceived risk among younger people and exposure at work for those $\geq$25 yrs. Inequities in use were observed, with lower use among people with low education, older age, and immigrants.

Key messages:

- Use of self-tests in France during the Covid-19 pandemic was low among vulnerable population groups, including people with lower education, immigrants, and older individuals.
- Drivers of use included geographical access to healthcare services, perception of risk among younger respondents, and exposure at work among adults aged $\geq$25 years.

Factors influencing washing hands during the COVID-19 pandemic in the Ukraine population

Kim Young-Jin

YJ Kim[1], JW Lee[1], KB Kim[2], JW Noh[3]
[1]Health Administration, Yonsei University Graduate School, Wonju City, South Korea
[2]International Healthcare Administration, Catholic University of Daegu, Daegu, South Korea
[3]Health Administration, Yonsei University, Wonju City, South Korea
Contact: qnsghd610@gmail.com

Background: Washing hands is recommended as one of the key preventive measures for reducing the transmission of COVID-19 and other infectious agents. The World Health Organization (WHO) consistently emphasized that handwashing is one of the most effective methods to prevent COVID-19. However, research on Ukraine handwashing has been limited. This study aims to investigate factors influencing the practice of regular handwashing in Ukraine during the COVID-19 pandemic.

Methods: This study analyzed 800 households from the 2020 Ukraine Multi-Sector Needs Assessment (MSNA) survey data. The survey, conducted from January to February 2020, was administered by the REACH Initiative. The data was analyzed using Stata/MP version 16.1.

Results: As the number of household members increases, especially when the head of the household is female, the likelihood in adoption of washing hands more regularly increases significantly. People who take between 30 to 59 minutes to arrive at healthcare facility by walking, compared to those who take less than 15 minutes showed significantly decreased likelihood in washing hands more regularly.

Conclusions: While social distancing measures and travel restrictions have reduced contact possibilities with friends and colleagues, families represent the smallest social unit, making complete isolation within them difficult. Hence, the number of household members increases, there may be a higher tendency to wash hands more frequently due to the virus. Given that women exhibit higher levels of concern and fear regarding the pandemic, it is interpreted that they are more likely to wash their hands more frequently. Also households living more than 5km from the nearest health facility face higher barriers in accessing health care. They are more likely to wash their hands less due to low access to medical information.

Key messages:

- The number of household members, the gender of the head of the household, and access to health facilities can affect COVID-19 prevention behaviors, such as hand washing.
- Hand washing can prevent infectious diseases as well as various germs, so it is required to implement policies that can make them a habit.

Abstract citation ID: ckae144.1932
Uncovering Prognostic Clinical Phenotypes in Children and Adolescents with SARS-CoV-2 Infection

Yanyan Shi

Y Shi[1], R Strobl[1,2], R Berner[3], J Armann[3], S Scheithauer[4], E Grill[1,2]

Contact: sally_shi@foxmail.com

Background: Characterizing clinical phenotypes is important for classifying patients, predicting disease outcomes, and adapting treatment. We aimed to identify distinct clinical phenotypes among hospitalized children and adolescents with SARS-CoV-2 infection and to evaluate variations in prognosis across these phenotypes.

Methods: The DGPI (German Society of Pediatric Infectious Diseases) registry serves as a nationwide, prospective registry for children and adolescents hospitalized with a SARS-CoV-2 infection in Germany. We applied hierarchical clustering and integrated variables such as sex, SARS-CoV-2-related symptoms, pre-existing comorbidities, clinically relevant coinfection, and SARS-CoV-2 risk factors to describe distinct clinical phenotypes. Subsequently, we applied a multinomial logistic regression model to examine the association between these phenotypes and discharge status.

Results: The DGPI registry encompassed 6983 patients and facilitated the identification of six distinct phenotypes for children and adolescents with SARS-CoV-2. Phenotype A had a similar symptom pattern as the total sample. Predominant symptoms of patients with other phenotypes were gastrointestinal (95.9%, B), asymptomatic (95.9%, C), lower respiratory tract (49.8%, D), lower respiratory tract and ear, nose and throat (86.2% and 41.7%, E), and neurological (99.2%, F). Patients with phenotype C had lower odds of residual symptoms (OR: 0.10 [0.06, 0.15]) than those with phenotype A, whereas patients with phenotype D and E had higher odds of residual symptoms (OR: 1.33 [1.11, 1.59] and 1.91 [1.65, 2.21], respectively) than those with phenotype A. Patients with phenotype D were significantly more likely (OR: 4.00 [1.95, 8.19]) to have an unfavorable outcome, compared to patients with phenotype A.

Conclusions: We could show that the identified phenotypes could facilitate early risk assessment and aid in tailoring individualized patient management strategies.

Key messages:

- Six distinct clinical phenotypes existed in children and adolescents with SARS-CoV-2 infection.
- Phenotypes could assist in risk evaluation and help personalize patient care.

Abstract citation ID: ckae144.1933

Preventive interventions on vector-borne diseases related to climate change: an Umbrella review

Gianluca Fevola

G Fevola[1], A Valz Gris[1], W Ricciardi[1,2], MR Gualano[2,3]
[1]Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Leadership in Medicine Research Centre, Università Cattolica del Sacro Cuore, Rome, Italy
[3]UniCamillus-Saint Camillus International University of Health Sciences, Rome, Italy
Contact: gianlucaf.jk@gmail.com

Background: Vector-borne diseases (VBDs) are a global challenge to public health, being influenced by ecological factors and climate change. Despite the several preventive public health interventions that can be implemented, the evidence of their impact is still fragmented. An organic overview of the current evidence can provide relevant information on the effectiveness of these actions.

Methods: We conducted an umbrella review following the PRIOR checklist. Relevant reviews were searched using PubMed and Cochrane databases. We considered eligible all systematic reviews published in English between 2013 and 2023, containing meta-analysis on public health interventions aimed at reducing incidence, prevalence, or the burden of disease of VBDs, without demographic restrictions.

Results: We screened 1971 records. 51 reviews were included. 38 reported outcomes targeting Malaria, 9 Dengue, 2 Yellow Fever, 1 Leishmaniasis,1 Zika, 1 Chikungunya, 1 Crimean-Congo haemorrhagic fever, 1 Lyme disease and 1 Schistosomiasis. Several interventions were assessed worldwide. 18 reviews considered chemoprophylaxis, 9 net/curtains, 8 vaccines, 6 repellents, 3 housing interventions, 2 community participation, 2 MTaT and 2 oral supplementations. Authors stated conclusions are favourable to the interventions assessed for the 73%, but the certainty level is mostly considered low.

Conclusions: Public health preventive interventions are fundamental in responding to the threat of VBDs, but their impact may vary depending on several factors. Further research must provide more effective interventions and strategies, with a cohesive presentation of their evidence.

Key messages:

- Effective reduction of VBDs burden requires a combination of interventions that must be tailored to local ecological, social, and epidemiological factors.
- Evidence presented in this umbrella review can inform evidence-based policies and programs aimed at combating VBDs at local, national, and global levels.

Abstract citation ID: ckae144.1934

Risk perception survey for healthcare-associated infections in a large teaching hospital in Rome

Riccardo Paolini

R Paolini[1], G Fei[1], L Carlomagno[1], A De Santis[1], S Orlandi[1], M De Giusti[1,2]
[1]Sanità Pubblica e Malattie Infettive, La Sapienza, Rome, Italy
[2]OUC Igiene Ospedaliera, AOU Policlinico Umberto I, Rome, Italy
Contact: riccardo.paolini@uniroma1.it

Background: Healthcare-associated infections (HAIs) are the main complications of hospitalization. The goal of the study was to enhance awareness, improve risk perception, and facilitate measures to reduce the outcomes of HAIs. A bottom-up approach, in which the healthcare workers involved play a key role, can be adopted to decrease the spread of HAIs. Therefore, a survey was conducted in a large teaching hospital in Rome from 2019 to 2023, excluding 2020 due to COVID-19.

Methods: A longitudinal study was conducted in all integrated care departments with beds. The data was collected using a standardized, anonymous, self-administered questionnaire for healthcare workers. The questionnaire consisted of 61 items assessing socio-professional features, knowledge of HAIs, attitudes and barriers to hygiene compliance, self-analysis of professional behavior and advice for new interventions. The study lasted 21 days between November and December, which is considered a period of normal care activity. A multivariable logistic regression model was built. Statistical analyses were performed with STATA 18.0.

Results: There were 384 health workers respondents: female (67.7%) and nurses (56.5%). The most represented areas were internal medicine (37.9%) and surgery (27.3%). The correct frequency of perception of HAIs increased from 33.3% in 2019 to 36.3% in 2023. From 2022 to 2023, the multivariable model showed that physicians (OR 0.48, CI 95% 0.24-0.93, p-value 0.03) and elder staff (OR 1.02, CI 95%, 1.0-1.1, p-value 0.04) seemed to be more aware of the prevalence of HAIs in their ward.

Conclusions: Targeted training days were organized after the study to discuss the data collected. Staff awareness of the prevalence of HAIs in their ward is improving, even if it is complicated to quantify it by attending HAIs training events. The survey has been included as a corporate goal for 2024 as a useful tool to improve awareness of HAIs and to evaluate the effectiveness of ongoing training.

Key messages:

- A bottom-up approach, in which healthcare workers assume a pivotal role, can be employed to reduce the spread of HAIs as it serves as a valuable tool to evaluate the efficacy of targeted training.
- The results indicate that the education of healthcare workers is a crucial factor in enhancing awareness of HAIs. Therefore, there is a need to improve the education of younger and non-medical staff.

Abstract citation ID: ckae144.1935
Enhancing port preparedness in Germany in the event of infectious diseases – a best practice study

Johannes Neumann

M Frese[1], *J Neumann*[1], *M Boldt*[2], *L Ehlers*[2], *M Dirksen-Fischer*[2], *S Gueye*[1], *J Bäßler*[1], *V Harth*[1], *J Heidrich*[1]
[1]Institute for Occupational and Maritime Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany
[2]Hamburg Port Health Center, Institute for Hygiene and Environment, Hamburg, Germany
Contact: joh.neumann@uke.de

Background: The maritime sector is exposed to specific risks in the area of communicable diseases. In Germany, five ports are designated to enforce the International Health Regulations (IHR) and must have certain core capacities to respond immediately to cross-border health threats. A joint external evaluation conducted by the World Health Organization (WHO) revealed a need to reinforce central structures in Germany. The overarching objective of the study is to harmonize and consolidate the requisite capacities for maritime health security.

Methods: Qualitative interviews ($n = 35$) at baseline were conducted with various stakeholders, including port medical services, port authorities and other stakeholders. The parameters to be analysed included specific activities and interfaces during infectious incidents, experience with past infection incidents, training and exercise, and the need for action. Furthermore, a document analysis was conducted, during which the existing contingency plans and standard operating procedures were reviewed.

Results: In essence, the initial challenges posed by the COVID-19 pandemic have led to the establishment of well-defined procedures and interfaces between the various stakeholders involved. There is a necessity for enhanced interpersonal communication between the various stakeholders and the implementation of sustainable training practices. Furthermore, greater transparency and standardisation of regulations in international health emergencies is desired.

Conclusions: Given the infrequency of cross-border infection incidents on board ships, targeted preparation within stakeholders is often given a lower priority than other work priorities. The participatory study design is intended to develop comprehensive concepts in collaboration with the IHR ports in the ongoing project. Subsequently, these concepts will be tested in tabletop exercises and incorporated into training formats for public health actors.

Key messages:

- The qualitative interview study at baseline revealed a substantial need for sustained communication and training practices among stakeholders for infectious disease preparedness in German IHR ports.
- The document analysis revealed relevant differences in the extent and scope of contingency plans of German ports designated under the International Health Regulations.

Abstract citation ID: ckae144.1936
Tackling Pertussis in Schools: A Public Health Unit's Approach

Luciana dos Reis Gomes

D Roque Carvalho[1], *LR Gomes*[1], *V Veríssimo*[1], *D Vital Brito*[1]
[1]Public Health Unit Cascais, Western Lisbon Local Health Unit, Lisbon, Portugal
Contact: gomes.lr@gmail.com

Issue: Pertussis is a highly infectious bacterial respiratory disease, easily transmitted in closed settings, such as schools. In Portugal, 2019 was the last year with a significant number of cases (83). As pertussis usually follows epidemic cycles from 3 to 5 years, another wave is expected in 2024. Children aged 1-5 years are particularly vulnerable as they no longer benefit from maternal vaccination and have not yet received the 5-year boost recommended in the national schedule.

Description of the problem: In April 2024, the Cascais Public Health Unit (PHU) addressed two possible pertussis cases in preschools. A streamlined response protocol was drafted, including an online contact tracing form and task distribution among response team members, along with templates and a scripted guide for standardized communication.

Results: We were provided a list of close contacts for the children and staff and shared an online form. In the first case, 34 in 35 identified contacts responded to the form, while in the second case, 38 in 55. When comparing both scenarios, the average scripted call duration decreased from 10 to 6 minutes. The PHU response to the first index case took 6 hours, involving 4 physicians and 5 nurses, whereas to the second took 4 hours, involving 3 physicians and 3 nurses. However, implementation requires at least one team member with basic information technology skills to set up the system.

Lessons: Clear communication channels between schools and public health authorities are vital for effective outbreak management. Streamlining communication processes with online forms and scripted conversation guides improved efficiency. Centralised data collection reduced response time and resource requirements in each outbreak.

Key messages:

- Established communication channel, standardized data collection, and streamlined protocol allow more effective outbreak management.
- Centralized data collection via digital tools is particularly useful in limited human resources settings.

Abstract citation ID: ckae144.1937
STI/HIV care in times of COVID-19 according to Dutch healthcare professionals: A mixed methods study

Jenneke van Ditzhuijzen

J van Ditzhuijzen[1,2], *AYAM Reilingh*[1,2], *TJA Albers*[1], *H Bos*[3], *JBF de Wit*[1]
[1]Interdisciplinary Social Science, Utrecht University, Utrecht, Netherlands
[2]Department of Obstetrics & Gynecology, Amsterdam UMC, Amsterdam, Netherlands
[3]SOA AIDS Nederland, Amsterdam, Netherlands
Contact: j.m.vanditzhuijzen@uu.nl

Background: Surveillance data from the Netherlands show that STI/HIV testing decreased at the start of the COVID-19 pandemic, suggesting barriers in access to STI/HIV care. However, the impact of the pandemic on STI/HIV care may be more complex, and key populations could be differentially affected. The aim of this study was to gain more insight into the impact of COVID-19 on STI/HIV care in the Netherlands from the perspective of STI/HIV care providers.

Methods: We investigated whether professionals in STI/HIV care experienced changes compared to pre-COVID in access to care, demand and provision of care, shifts online care, and quality of care. An online survey was completed by 192 STI/HIV care professionals. Additionally, semi-structured interviews were held with 23 STI/HIV care professionals.

Results: According to participants, specific subgroups of priority populations may have had difficulties accessing STI/HIV care during the pandemic especially during lockdowns and at public sexual health services. Professionals were concerned to have lost sight of subpopulations in vulnerable circumstances and that the pandemic may have magnified inequalities in access to STI/HIV care, which may be related to different levels of health and digital literacy required for telephone and video consultations. Furthermore, participants found online care provision was not up to standards and were concerned about follow-up care for patients using private online providers of remote tests.

Conclusions: Professionals experienced that COVID-19 measures may have compounded existing disparities. To minimize inequalities in access to STI/HIV care during a pandemic, it is recommended to prioritize services for people in vulnerable circumstances such as recent migrants and people with low health or digital literacy. More collaboration between and within sectors may help in better organizing healthcare and prevent overburdening of specific sectors.

Key messages:

- According to STI/HIV care providers, the COVID-19 pandemic differentially impacted different STI/HIV care sectors, but also increased existing inequalities in access to care for vulnerable groups.
- Professionals experienced that COVID-19 measures impacted the provision of STI/HIV care, access to care for vulnerable populations, and quality of care.

Abstract citation ID: ckae144.1938
Emergency Department admissions for Acute Respiratory Infections: a retrospective analysis

Francesca Di Serafino

F Di Serafino[1], N Zotti[1], L Carmisciano[1], L Baglietto[1], AD Porretta[1,2], M Cristofano[2], F Foltran[2], M Pistello[2], C Rizzo[1]
[1]University of Pisa, Pisa, Italy
[2]Pisa University Hospital, Pisa, Italy
Contact: francesca.diserafino@gmail.com

Background: Acute Respiratory Infections (ARIs) have a relevant impact on public health in terms of prevalence and costs associated with the diseases. The COVID-19 pandemic highlighted the need to adopt accurate surveillance systems to respond to new emergencies and meet the demand for access to care. The aim of our work is to describe the accesses at the Emergency Departement (ED) of the Pisa University Hospital (AOUP), Italy, for ARIs, from 2017 to 2021.

Methods: A retrospective analysis of electronic medical records from the AOUP was conducted from January 2017 to December 2021. The analysis focused on ED admissions and positive lab test results, examining their correlation with ED visits caused by ARI. Multiple linear regression models were used to understand the influence of viral laboratory results on ARI-related ED admissions, adjusting the results for age. The study also assessed the contribution of each virus incausing ARI within different age groups.

Results: 33,101 (annual average 5,520) ARI admissions in ED were registered, resulting in 7,426 hospital admissions (22.8%, annual average 1,163) with a seasonal pattern between week 42 of each year and week 17 of the following year. The reduction in emergency room admissions in 2020 (weekly average of 78.2, compared to 144.3 in 2017-2019) may be due to the restrictions implemented for the COVID-19 pandemic. Nevertheless, the average weekly rate of ED admissions caused by ARI was 30.8% in 2020, as compared with 21.7% in 2017-2019. Analysis by age group showed a peak of accesses in the last weeks of 2021 for the <1 and 1-4 years old age groups.

Conclusions: Data on ARI-related admissions provide valuable insights into the dynamic patterns of seasonal air-borne infections and age-related vulnerabilities. This could be useful in directing health policies to identify indicators of future epidemic waves, contributing to the ongoing efforts to enhance preparedness and response strategies for respiratory infections.

Key messages:

- It is important to create an integrated surveillance system to monitor and respond to ARIs.
- Strategies should prioritise vaccination campaigns, particularly for RSV and influenza.

Abstract citation ID: ckae144.1939
Whooping cough – a recurrent epidemic

Maria Manuel Dantas

P Coelho[1], C Torres[1], J Gonçalo[1], E Cordeiro[1], MM Dantas[2], JP Pimentel[1]
[1]Public Health Department, Regional Health Administration of Central Portugal, Coimbra, Portugal
[2]Public Health Unit, Unidade Local de Saúde de Coimbra, Coimbra, Portugal
Contact: mmdgcf@gmail.com

Background: Whooping cough (WC), or Pertussis, is a vaccine-preventable and highly contagious infectious disease. Although it has a relatively low fatality rate, approximately 13% of reported cases develop secondary bacterial pneumonia. This was because of several recurrent epidemics across Europe in the last decades, with the latest beginning in mid-2023 and still ongoing. The Central Region of Portugal is currently being affected, and this study aims to describe the current epidemic at the regional level.

Methods: Data from epidemiological inquiries of confirmed and probable cases of WC pertaining to the Central Region of Portugal from January 2020 till April 2024 was gathered from the mandatory report national epidemiological surveillance system (SINAVE). Both a temporal comparison of number of cases and a statistical space-time scan with permutation were conducted (software SaTScan v10.)

Results: A comparison by month of reported cases shows an increase in cases from September 2023 until December 2023 followed by an exponential increase from January 2024 until April 2024 denoting an ongoing epidemic. In the statistical space-time analysis of 107 reported cases between September 2023 and April 2024, 8 nonsignificant clusters were identified with different locations involved in non-overlapping periods.

Conclusions: The finding of several unrelated clusters, even though nonsignificant, during a short time period indicates that Pertussis transmission is ongoing at the local level probably through asymptomatic or barely symptomatic cases that act as reservoirs. Clinicians must hold a high clinical suspicion for a timely diagnosis, treatment and report and health authorities must reinforce control measures to limit the spread of this disease.

Key messages:

- Pertussis remains a disease of significant concern recurrent outbreaks across Europe show that public health local authorities have an important role in timely management of cases and outbreaks.
- Local level transmission and intervention may play a pivotal role in the epidemiologic dynamic of Pertussis.

Abstract citation ID: ckae144.1940
Understanding Hand Hygiene Knowledge Gaps: Insights from Primary Healthcare in Portugal

Afonso Herdeiro Cachim

A Cachim[1], A Luz Fortes[1], I Fernandes[1], MT Antunes[1], P Pereira[1], SM Canto[1], MM Paixão[1]
[1]USP Francisco George, ULS Santa Maria, Lisbon, Portugal
Contact: afonsocachim@gmail.com

Background: Healthcare-associated infections cause a significant burden of disease globally. Hand hygiene is crucial for preventing these infections but despite recommendations, compliance with hand hygiene protocols among healthcare professionals is often inadequate. In Portugal, there have been several initiatives aiming to increase awareness on the importance of hand hygiene practices amongst healthcare professionals including in primary healthcare facilities. Nationally, there are two models of organization of primary healthcare facilities with differences in funding and allocation of resources.

Methods: In this study, the World Health Organization's Hand Hygiene Knowledge Assessment Questionnaire for Healthcare

Professionals was translated into Portuguese and validated with infection control specialists. It was then distributed to primary healthcare professionals in the Northern Lisbon area, in March 2024 to assess knowledge on hand hygiene practices and highlight potential training needs. The responses were analyzed, with the Kruskal-Wallis test carried out, followed by the Mann-Whitney U test when required.

Results: A response rate of 21,5% (65/302) was obtained, with most participants being nurses (58%), followed by physicians (34%). There was a statistically significant difference depending on the model of organization of the primary healthcare unit to which the participant belonged ($\chi 2 = 8.428$, $p = 0.014$, $df = 2$)., There was no significant difference between the score and the professional category of the participant ($\chi 2 = 5.76$, $p = 0.12$, $df = 3$).

Conclusions: The findings of this study show that the model of organization of a primary healthcare unit can impact the knowledge of professionals and not just practices. This study also underscores the significance of comprehensive assessments of the context before interventions and the need for further studies to understand how we can better inform future training initiatives.

Key messages:

- Organizational differences in primary healthcare units impact hand hygiene knowledge among professionals, emphasizing the need for tailored training initiatives.
- Comprehensive assessments of healthcare contexts, coupled with validated linguistic tools, are crucial for reliable intervention strategies in infection control.

Abstract citation ID: ckae144.1941
Experiences of treating people with persisting symptoms after COVID-19: a focus group study

Ana Goes

A Goes[1], *M Santos*[2], *J Silva*[1], *M Moniz*[1], *P Soares*[1,3], *A Leite*[1,3]
[1]NOVA National School of Public Health, Lisbon, Portugal
[2]ISCTE Instituto Universitário de Lisboa, Cent, ISCTE, Lisbon, Portugal
[3]National Institute of Health Dr. Ricardo Jorge, INSA, Lisbon, Portugal
Contact: ana.goes@ensp.unl.pt

Background: A proportion of people who had COVID-19 infection continue to suffer with persistent symptoms. The long-term effects of COVID-19 are recognised as heterogeneous and complex, challenging health services. This study aims to explore the experiences of healthcare professionals dealing with patients suffering from persisting symptoms following COVID-19 infection and their views on the healthcare services response.

Methods: We held 4 focus groups ($n = 19$) with healthcare professionals by video-call. Healthcare professionals were recruited using a snowball strategy, taking level of care, healthcare area, and nature of function as diversification criteria. Participants were invited to tell their experiences regarding the following topics: experiences and challenges in providing care to patients with persisting symptoms following COVID-19 infection; usual care pathways; models of care. Data were recorded, transcribed, and anonymized. The qualitative data were submitted to thematic analysis following an inductive approach. A computer-assisted qualitative data analysis software (MaxQDA) was used.

Results: Based on thematic analysis, 4 core themes emerged: uncertainty; new condition, usual challenges; variable standards implementation; personalized and multilevel care. This new condition challenged health services and health professionals to keep adjusting and updating responses in a context of uncertainty, but at the same time revealed the usual challenges and needs for providing timely and integrated care. Health services burden challenges the implementation of care standards. This heterogeneous condition demands a multi-level response, including general information and advice, enabling self-management, and providing rehabilitation.

Conclusions: Healthcare professionals envision an heterogenous condition, bringing uncertainty to healthcare services. More research, training, and information to the population is required for an appropriate response.

Key messages:

- Persisting symptoms following COVID-19 challenged an already overwhelmed health system, bringing barriers to healthcare standards implementation.
- The heterogeneous nature of the condition and the healthcare services burden may leave some people to chance, demanding a diverse set of care.

Abstract citation ID: ckae144.1942
Investigation of a Norovirus GII outbreak in a primary school in Portugal,2023

Filipa Cristovão

F Cristovão[1], *R Marques*[1], *V Peixoto*[1], *M Ourique*[1], *N Rodrigues*[1], *D Martins Correia*[1]
[1]Public Health Unit of ACES South West, Regional Health Administration of Lisbon and Tagus Valley, Lisbon, Portugal
Contact: filipa.cristovao@gmail.com

Background: The onset of acute gastroenteritis cases among students in a primary school class on September 19, 2023, prompted an immediate response from the local Public Health unit. A collaborative effort was initiated to investigate and contain the outbreak.

Methods: Epidemiological questionnaires were distributed to 166 students and 8 staff members, defining cases as individuals exhibiting symptoms including diarrhoea, vomiting, or nausea between September 19th and September 24th, 2023. Additionally, stool samples were collected from three individuals.

Results: Out of 166 students and 8 staff members, 39 individuals met the case definition, resulting in attack rates of 22% (37/166) and 25% (2/8) among students and staff, respectively. Laboratory analysis confirmed two cases of Norovirus GII among the tested specimens, with five students requiring medical attention.

Conclusions: Our investigation underscores the significance of continuous epidemiological surveillance and swift implementation of infection control measures in school settings. The detection of Norovirus transmission emphasizes the necessity for rigorous adherence to infection control best practices. Our findings advocate for sustained technical support from public health authorities to prevent and manage similar outbreaks effectively.

Key messages:

- Study on Norovirus outbreak in a primary school highlights the imperative of infection control measures, emphasizing the importance of ongoing support from public health authorities.
- The Norovirus outbreak investigation underscores the vital role of surveillance and swift response in containing infectious diseases within educational settings safeguarding all.

Abstract citation ID: ckae144.1943
Monitoring violence in healthcare. A lesson from the pandemic

Giacomo Viti

N Magnavita[1], *I Meraglia*[1], *G Viti*[1]
[1]Occupational Health, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: giacomo.viti.med@gmail.com

Introduction: Violence against healthcare workers is a serious, underreported, and underestimated problem. Only a few healthcare companies have efficient violence monitoring systems and risk assessment is often entrusted to non-validated algorithms. The monitoring system implemented in 2005 in a public health company allowed for an accurate analysis of the phenomenon.

Methods: For the entire observation period (2005-2023), the one-year prevalence of violent incidents (physical assaults, threats, and harassment) has been reported by all during the periodic medical examination in the workplace. Furthermore, after each periodical inspection of workplaces, the occupational doctor requested a detailed description of violent events that occurred in the department, using the Violent Incident Form distributed online anonymously.

Results: In 2005/6 the one-year prevalence of physical assaults was 8.2%. Prevention efforts led to a moderate reduction in the rate (7.8% in 2011/12). A collapse in rates was observed in 2021 (3.2%). In 2022, physical violence rose again to 5.6%. Harassment affected 19.6% of workers in 2005/6, falling to 7.2% in 2021 and rising again to 21.6% in 2022. Physical violence perpetrated by patients was more frequent in psychiatric services (OR 25.7, CI95% 11.1; 59.6) and violence perpetrated by visitors in emergency and urgence services (OR 8.8, CI95% 3.8; 20.5) than in general services. Workers attributed the drop in attacks primarily to the filtering of access to work areas, which limited the presence of visitors and relatives. The lower demand for services had also resulted in an optimal ratio between staff and patients, improving the quality of care. Furthermore, in the very first pandemic phase, health workers enjoyed a very favorable consideration from the population, which had further reduced the causes of conflict.

Conclusions: The pandemic has shown that better relationships between patients/visitors and staff are effective in reducing violence.

Key messages:

- Monitoring of violence against healthcare workers shows that it has decreased during the pandemic.
- HCWs believe that (i) limiting visitor access (ii) better balancing demand for services and (iii) better opinion towards HCWs were the causes of the reduced rate of violence.

Abstract citation ID: ckae144.1944
Unplanned emergency department attendances due to home and leisure accidents in the elderly Portugal

Tatiana Alves

T Alves[1], *S Silva*[1], *P Braz*[1], *M Papadakaki*[2], *R Mexia*[1], *C Aniceto*[1], *C Matias-Dias*[1]
[1]Epidemiology, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
[2]Department of Social Work, Hellenic Mediterranean University, Heraklion, Greece
Contact: tatiana.alves@insa.min-saude.pt

Home and Leisure Accidents (HLA) have been identified as a relevant public health issue with individual, societal and economic consequences. So, common cause of injury-related morbidity and mortality, especially among older people. Evidence shows that most of HLA among the older ones are associated with identifiable and modifiable risk factors. However, more detailed information about the context and characteristics of such events is needed. This study aimed to characterize the occurrence of HLA in victims aged 65 and over related to hospital Emergency Department (ED) of the National Health Service in Portugal based on hospital records, through EVITA system. A descriptive analysis of the data was performed. Bivariate comparisons were performed using Pearson's chi-square test with a significance level of 5%. In this analysis, the statistical program SPSS V.27 was used. During the 2022 year the older people aged 65 and over represented 25% of the total of attendances in the emergency department. In the 2022 year there were 70 452 HLA in people victims aged 65+, constituting 32% of hospital ED attendances by HLA (preliminary data). The results show that 65,9% of the attendances were amongst the age group of 75 years and beyond. More frequently reported in females (64,3%) than in males (35,6%), being these differences statistically significant ($p < 0{,}01$). The summer season for both age groups had higher proportion of HLA. In both age groups 65-74 years and 75 years and over most of HLA occurred at home (65,2%; 68,8%), followed by outdoor spaces (12,2%; 6,7%), public area (3,4%; 13,6%) and transport area (9,2%; 5,5%), these differences were statistically significant ($p < 0{,}01$). Regarding to the products/agents most involved in the HLA the "floor" was the leading category in age group 65-74 years (27,1%) and in the oldest 75 years and over (43,0%). Considering that globally HLA can be prevented, this information reinforces the importance of this problem and its magnitude.

Key messages:

- The older people represented 25% of the total of attendances in the emergency department in the year in analysis. 13% of ED attendances occurred due to HLA.
- The National Injury Surveillance System provides information that allows to know the characteristics and circumstances of HLA that occur in older people.

Abstract citation ID: ckae144.1945
Preventing unintentional injuries in children: the parents' beliefs matters (CHILD Vigilance)

Tatiana Alves

T Alves[1], *M Papadakaki*[2], *B Strukcinskiene*[3], *S Silva*[1], *P Braz*[1], *C Aniceto*[1], *K Vagionaki*[2], *J Chliaoutakis*[2], *C Matias-Dias*[1]

Contact: tatiana.alves@insa.min-saude.pt

The CHILD Vigilance project is a European study supported by the Injury Prevention & Safety Promotion Section of the European Public Health Association (EUPHA INJ) and aims at assessing parenting knowledge and attitudes that are relevant to supervision and risk taking in children. For children the majority of these injuries occur in or around the home when their safety is the responsibility of a parent or other caregiver. The study aims contribute to the epidemiological knowledge of injuries through the study of the perceptions of parents and caregivers of children and adolescents. A descriptive, observational, cross-sectional study was developed under the CHILD Vigilance project, developed at European level within the scope of the Injury Prevention & Safety Promotion Section of the European Public Health Association. The information was collected by survey, from parents' associations and schools in the EU countries represented in the EUPHA INJ Section. A total of 916 valid responses were obtained, involving 1229 children (51,4% male; mean age 7,8 years). Falls were perceived as the most common type of unintentional injuries in pre-schoolers and school-age children (47,8% in Greece; 63,5% in Portugal; 74,8% in Lithuania). However it was found differences in these countries as to the most common type of injury in adolescents, pointing out road traffic crashes (41.2% in Greece vs 39.5% in Portugal) and poisonings in Lithuania (38,1%). Some differences were also observed between these countries as to the most common causes of death. In Greece and Lithuania diseases were reported the main cause in the pre-schoolers (62,5%; 35,1%) and in primary education (55,1%; 29,7%), being injuries pointed as the most frequent cause only in the oldest. The study emphasizes the need to invest in the identification of appropriate determinants of child unintentional injuries and harmonised injury outcomes across global initiatives.

Key messages:

- The lack of data regarding to parents' knowledge on injury prevention involving children highlight the need to conduct this type of studies.
- The need for adequate epidemiological data on the burden of child injuries and validated tools to accurately measure injuries.

Background: Poor sleep is common among adolescents and associated with unintentional injuries. The current evidence base is limited by differences in measures of sleep and injury implemented across studies. We examined the potential universality of the relationship between poor sleep and injury cross-nationally using self-reports from 229,589 adolescents in 46 countries that were collected using common procedures and measures.

Methods: A cross-sectional study was conducted using records from the 2017/18 Health Behaviour in School-aged Children (HBSC): World Health Organization cross-national study. The prevalence of sleep indicators (difficulties in falling asleep, insufficient sleep, social jet lag) and medically treated injuries (overall, multiple) were described across countries and by gender. Multivariable modified Poisson regression analyses were conducted within and across countries to test the consistency of the association between poor adolescent sleep and injuries.

Results: Overall, indicators of poor sleep were reported by nearly half of adolescents, and varied by gender and across countries. Country-level analyses found consistently positive associations between indicators of poor sleep and injuries. Pooled (multi-country) analyses further demonstrated a universality of these relationships across sleep indicators and injury outcomes. The strength of relationships varied by gender, with more robust associations detected among girls compared to boys.

Conclusions: Poor sleep is a robust and mainly consistent risk factor for injury among adolescents across countries and regions. Public health officials and policymakers should therefore recognize adolescent sleep as a health priority. The promotion of sleep hygiene may represent a novel target for injury prevention at regional and national levels.

Key messages:

- Poor sleep, in the form of sleep difficulties, insufficient sleep, and social jet lag, were robust and mainly consistent injury risk factors among adolescents across 46 countries.
- Public health officials should recognize sleep hygiene as a novel focus for adolescent injury prevention.

Mapping barriers and bottlenecks for personalized preventive approaches in health systems worldwide

Nicolò Scarsi

N Scarsi[1], A Taha[1], S Farina[1], T Osti[1], L Russo[1], C Savoia[1], A Maio[1], L Villani[1], R Pastorino[1,2], S Boccia[1,2]

[2]Department of Woman and Child Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: nicolo.scarsi@unicatt.it

Over the past decades, the growing prevalence of chronic disease globally raised the public health need to plan tailored personalized preventive approaches, mainly through big data and -omic sciences. However, a conspicuous body of literature highlighted the existence of many barriers and bottlenecks hindering their actual implementation in real-word settings. From here, this scoping review of reviews aims to map all known barriers and bottlenecks to the implementation of personalized preventive approaches in European health systems and beyond. PubMed, Web of Science, Scopus and gray literature sources were consulted from 2017 to January 2023, identified barriers and bottlenecks were analyzed against the Consolidated Framework for Implementation Research (CFIR). Out of 11,602 records, 220 were deemed eligible for full-text screening, and a final sample of 34 review studies were extracted. Studies were mainly performed in USA 15 (44%) and UK 3 (9%), followed by Canada 2 (6%), India 2 (6%) and Italy 2 (6%). From our results, the lack of evidence on clinical utility, guidelines, specialized professionals, citizen trust and cultural issues are the most frequently reported barriers to the implementation of personalized preventive approaches worldwide. These in turn affect country specific policies and the applicability of such innovations across different populations, raising the risk of increasing health inequalities and discrimination concerns. Findings confirmed that most translational challenges pertain to primary and secondary prevention levels across several chronic diseases, with particular concerns for non-European ancestry individuals.

Key messages:

- The identification of bottlenecks are informative of future precision public health interventions.
- Barriers reported in most of the studies suggest the need to establish a targeted agenda.

Abstract citation ID: ckae144.1948
Economic evaluation of Polygenic Risk Scores in healthcare interventions: a systematic review

Leonardo Maria Siena

LM Siena[1], M Riccio[1], A Rosso[2], V Baccolini[1], G Migliara[1], C Isonne[1], I Leone[1], C Marzuillo[1], P Villari[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Department of Environmental and Prevention Sciences, University of Ferrara, Ferrara, Italy
Contact: leonardo.siena@uniroma1.it

Background: Polygenic Risk Scores (PRS) quantify genetic susceptibility to diseases, promising personalized healthcare. This review explores current evidence regarding the economic evaluation of strategies based on PRS or other polygenic risk stratification approaches, scrutinizing their methodologies.
Methods: The study protocol was registered in PROSPERO (CRD42023442780). A systematic search in PubMed, Scopus, and Web of Science identified full economic evaluations of intervention based on polygenic risk stratification strategies. The quality of the included articles was assessed using the Drummond checklist. This study was supported by the EC and MUR under PNRR - M4C2-I1.3 Project PE_00000019 'HEAL ITALIA".
Results: Nineteen articles were included in the analysis, with oncological conditions being the most frequently investigated (13), followed by cardiovascular conditions (3). In nearly 80% of the studies, PRS was employed for screening interventions, with the general population being the primary target in 14 out of the 19 studies. All the economic analysis models investigated cost-utility in terms of QALYs, with Markov models and microsimulations being the most common structures. The majority of these models were based on simulated cohorts derived mostly from North American or European data, with 9 adopting a healthcare system perspective and 6 a societal perspective. Although delivery strategies for PRS testing were rarely addressed, PRS costs were included in nearly all studies. Indirect costs were examined in fewer than half of the studies. In 12 out of 19 studies, the conclusions claimed the cost utility of PRS involving strategies.
Conclusions: Despite the technique's potential, evaluations of various strategies based on PRS approaches yield heterogeneous conclusions regarding cost-utility. Our study highlights the factors contributing to this heterogeneity and underscores the need for further exploration, ideally prioritizing real-world data.
Key messages:

- PRS strategies evaluations vary in cost-utility conclusions, highlighting the need for further investigation.
- Real-world data and practical implications should be prioritised in PRS research.

Abstract citation ID: ckae144.1949
Health impact of the Serious Accidents Punishment Act in Korean occupational settings

Jian Lee

J Lee[1], B Yoon[2,3], J Oh[1], H Park[1], J Sim[2], J Yoon[2,3,4]

[3]Occupational Health, Yonsei University, Seoul, South Korea
[4]Innovation in Digital Healthcare, Yonsei University Health System, Seoul, South Korea
Contact: leejian83@yuhs.ac

Background: Interrupted time series analysis serves as a valuable study design for assessing the efficacy of public health interventions implemented at a specific moment in time at the population level. We aim to elucidate the effects of the Serious Accidents Punishment Act implemented in February 2021 in Korea by analyzing changes in the incidence rates of occupational diseases.
Methods: The monthly data from patients with occupational diseases was extracted from the National Health Insurance Service Cohort database from 2011 to 2023. An Interrupted time series analysis with Poisson segmented regression was used to compare the rates before and after the Serious Accidents Punishment Act introduction in both outpatients and inpatients. Adjustments or stratification variables included sex, age, company size, and injury-related international classification of diseases codes (Injury, poisoning, and certain other consequences of external causes, S00-T88).
Results: Based on injury rates, men's inpatient injury rates remained stable, but outpatient rates decreased after the act implementation, while women's injury rates consistently declined in both inpatient and outpatient settings. The Interrupted time series regression analysis indicates that the Serious Accidents Punishment Act led to a significant reduction in both outpatient and inpatient injury rates for men and women, with a marked decline in outpatient rates and hospital admissions among women post-intervention.
Conclusions: The Interrupted time series regression results suggest that the Serious Accidents Punishment Act has been effective in reducing injury-related healthcare usage, highlighting the necessity of gender-specific interventions and the potential impact on lowering inpatient visits, although causality remains uncertain without further analysis.
Key messages:

- The Serious Accidents Punishment Act significantly reduced occupational injury rates in Korea, especially among women, demonstrating effective public health intervention.
- Interrupted time series analysis reveals Serious Accidents Punishment Act's impact on reducing healthcare usage for occupational injuries, highlighting the need for gender-specific approaches.

Abstract citation ID: ckae144.1950
Evaluating Genetic Testing: A Systematic Review of Assessment Frameworks

Valentina Baccolini

V Baccolini[1], G Migliara[2], A Sciurti[1], AE Kaminska[1], A Anniballo[1], A Pistollato[1], E Pitini[3], C Marzuillo[1], G La Torre[1], P Villari[1]
[1]Sapienza University of Rome, Department of Public Health and Infectious Diseases, Rome, Italy
[2]Link Campus University, Department of Life Sciences, Health, and Health Professions, Rome, Italy
[3]Ministry of Health, General Directorate for Health Prevention, Rome, Italy
Contact: valentina.baccolini@uniroma1.it

Introduction: The assessment of the risks and benefits of genetic/genomic tests has long been addressed using various frameworks. They are mostly ACCE-based, focus on technical aspects, but often overlook economic and organizational considerations. The few HTA-based approaches, though more comprehensive, lack validation and implementation. This review's purpose is to identify all evaluation frameworks for genetic/genomic tests and synthesize their key aspects.
Methods: PubMed, Scopus, Web of Science, and Google Scholar were searched. Inclusion criteria were documents describing evaluation frameworks for genetic/genomic tests, that were original, specifically created, and covering at least three assessment domains. This study was supported by the EC and MUR under PNRR - M4C2-I1.3 Project PE_00000019 'HEAL ITALIA'.
Results: Overall, 12546 unique records were screened, of which 67 documents were assessed for eligibility. A total of 29 studies were included, reporting 24 different frameworks. These frameworks were published between 2000 and 2019, mostly from USA (50%),

Canada (13%) and UK (13%). There was substantial interest in the economic facets of the technology (92%), albeit without extensive detail, and high attention was given to its technical accuracy (70-90%). The clinical value was also consistently mentioned (70-90%), similarly to legal, ethical, and social considerations (70-80%). However, there was minimal emphasis on non-health outcomes (20-50%), and insufficient attention to organizational, educational, and implementation barriers (20-50%).

Discussion: A pressing need exists for a universally accepted evaluation framework for genetic/genomic tests. Applying a general HTA methodology, potentially based on the EUnetHTA core model, that can integrate solid theoretical and methodological principles, and result in a validated, comprehensive, and widely shared tool for genetic test evaluation, is a viable option to foster the implementation of these technologies.

Key messages:

- Genetic/genomic test evaluations focus on technical accuracy and clinical value, often missing economic and organizational aspects.
- A universal, validated, HTA-based evaluation framework for genetic/genomic tests is needed to enhance their implementation in clinical practice.

Contact: vagia.ts@gmail.com

Introduction: Benzodiazepine and sedative hypnotics (BSH) may have significant adverse effects and associated costs, especially in older adults: increased risk of falls, fractures, hospitalisations, impaired functioning, delirium, cognitive impairment and mortality. Addressing BSH overuse is therefore an urgent priority to improve patient safety in Europe.

Objectives: To present the 5-year research project BE-SAFE, funded by the European Commission (HORIZON Europe) and by the Swiss State Secretariat for Education, Research, and Innovation. BE-SAFE aims to improve patient safety by addressing knowledge and practice gaps related to the reduction of BSH used by older adults for sleep problems.

Methods: BE-SAFE involves seven inter-related work packages and six European countries (Belgium, Greece, Norway, Poland, Spain and Switzerland) as well as experts from Canada; it proposes an interdisciplinary and inter-sectorial approach with experts in guidelines, implementation, dissemination, case studies, geriatrics and sleep. BE-SAFE will develop an intervention comprising trustworthy clinical guidelines, implementation recommendations and patient-centred material. This intervention will be tested in a cluster randomized controlled trial; 470 patients (65 years old and above) and 62 prescribing physicians in hospital and outpatient settings.

Results: BE-SAFE is expected to result in reduction of BSH use. Its toolkit, encompassing setting-specific implementation recommendations, will enable healthcare professionals (HCPs) to identify, evaluate and prevent risks of BSH use. The BE-SAFE approach could also be expanded to cover reduction of use of other medications.

Conclusions: Through BE-SAFE, patient safety is expected to improve; BE-SAFE project will reach a wide-ranging audience, including general population, informal carers, older adults, HCPs, healthcare system leaders and decision makers. Authors acknowledge the significant input of J. Grimshaw and W. Levinson, Canada.

Key messages:

- Deprescription of benzodiazepine and sedative hypnotics, especially in older adults, is a priority due to their side effects, particularly in this age group.
- The European project BE-SAFE aspires to create easy-to-use guidelines to this aim, improving thus patient safety and healthcare.

Administrating first aid in road traffic accidents in Bulgaria: a cross-sectional study

Nikolina Radeva

N Radeva[1], M Rohova[2], A Bakhova[3], H Romanova[1]
[1]Disaster Medicine and Maritime Medicine, Medical University, Varna, Bulgaria
[2]Health Economics and Management, Medical University, Varna, Bulgaria
[3]Social Medicine and Healthcare Organisation, Medical University, Varna, Bulgaria
Contact: rnikolina@gmail.com

Background: Bulgaria had the highest road mortality rate among European Union members in 2023, having previously ranked second after Romania. Research has consistently demonstrated that prompt pre-hospital care can significantly reduce the adverse effects of road traffic accidents. Thus, we conducted a cross-sectional study to explore the involvement of trained road traffic casualties and bystanders in administering first aid.

Methods: The study, carried out between April and December 2021, collected data via an online survey administered to members of the Scientific and Academic Cooperation Council by the State Agency Road Safety. The survey encompassed a range of topics, including first aid training, involvement in traffic accidents, behaviour of bystanders, administration of first aid, and sociodemographics.

Results: Among the 292 respondents, a sizeable proportion (90%) reported having received first aid training. Of these, 35.1% (95% CI 29.2-41.1%; $p < 0.001$) had personally experienced a road traffic accident, and 64.5% (95% CI 58.1-70.1%; $p < 0.001$) had witnessed one. It is noteworthy that a fifth of those involved in accidents had employed the skills acquired from first aid training, which included applying a dressing to a wound, bleeding control, and immobilising a fracture. Correspondingly, an equivalent percentage of bystanders administrated aid, with the majority of them performing basic airway management. However, the findings revealed that a significant proportion of participants (79.3%) did not engage in providing first aid. The primary rationale stated was the assessment that it was nonessential.

Conclusions: Despite the growing road safety challenges and many respondents witnessing or being involved in accidents, only a quarter of those trained in first aid actually provided assistance. Considering the increasing number of deaths and severe injuries, it is crucial to assess the need for frequent first aid training and the population's proficiency in first aid.

Key messages:

- Bystanders' competence in administrating first aid can mitigate the adverse effects of road traffic accidents.

- Among other road safety measures, investments in first aid training can be beneficial in reducing fatalities and severe injuries.

Abstract citation ID: ckae144.1953
Loneliness and the prevalence of injuries, falls and fractures in older people

Aleksandra Ciochoń

A Ciochoń[1,2,3], M Kozela[1], A Pająk[1]
[1]Department of Epidemiology and Population Studies, Jagiellonian University Medical College, Cracow, Poland
[2]Doctoral School of Medical and Health Science, Jagiellonian University Medical College, Cracow, Poland
[3]Department of Environmental Health, Jagiellonian University Medical College, Cracow, Poland
Contact: aleksandra.ciochon@doctoral.uj.edu.pl

The feeling of being alone (loneliness) experienced by older people contributes to deterioration of health, reduced physical and mental fitness, or inability to continue life roles. Loneliness may lead to behaviors that increase the risk of accidents, falls, and fractures, which are particularly dangerous in old age. The aim of this study was to assess the relationship between loneliness and the prevalence of injuries, falls, and fractures in older people. The studied group consisted of 464 people (48% men), aged 62-86 years (mean: 71.6, SD: 6.3), who participated in the Polish part of the HAPIEE Study (Health Alcohol and Psychosocial Factors in Eastern Europe); random subsample examined in 2019-2020. Trained nurses interviewed respondents in their homes. The 3-item UCLA scale (range 3-9, cutoff point$\geq$6) was used to assess loneliness. Data on injuries or accidents in previous 10 years, falls in previous 12 months, history of wrist, hip fracture or undergoing joint surgery/alloplastic was recorded. Multivariable logistic regression analysis was used. There were 460 participants included in the analysis. In 34 participants (7.3%) UCLA score was $\geq$6. In the previous 10 years, 95 respondents (20.5%) reported an injury or accident, 77 (16.6%) fell in previous 12 months. There were 6 (1.3%) respondents with history of hip fracture, 48 (10.3%) with history of wrist fracture, and 35 (7.5%) with history of joint surgery/alloplastic. No statistically significant relationship between loneliness and the prevalence of injuries, falls and fractures in older residents was found neither in the crude models nor after adjustment for covariates (age, sex, BMI, marital status, having offspring). Loneliness did not predict injuries, falls, and fractures in older urban residents. It seems that perception of being alone is weaker determinant of health as a measure not fully reflecting objective social isolation, which may actually have a greater impact on falls and injuries.

Key messages:

- 1/5 of older people have experienced any injury or accident and 17% reported to have fallen in the previous year.
- Loneliness did not predict injuries, falls, and fractures in older urban residents.

Abstract citation ID: ckae144.1954
Concept of a medical and public health cancer genomics platform

Maria Lucia Specchia

ML Specchia[1,2], MR Cozzolino[3], MG Cacciuttolo[1], A Ammendolia[2], R Pastorino[1,2], S Boccia[1,2]
[1]Department of Life Sciences and Public Health, Catholic University of the Sacred Heart, Rome, Italy
[2]Hospital Foundation A. Gemelli IRCCS, Rome, Italy
[3]Regional Health Emergency Service 118, Rome, Italy
Contact: marialucia.specchia@unicatt.it

Background: This study aims to produce the concept of an open-access medical and public health cancer genomics platform aimed at aggregating and sharing documentation of ongoing initiatives and data resulting from the CAN.HEAL project, available for EU researchers, healthcare professionals, policy makers, citizens and patients.

Methods: The context (reference sector, stakeholders and research evidences), feasibility (privacy management and data processing), and platform's end users were analysed; the CAN.HEAL project deliverables were listed and clustered; aspects related to the definition of the overall platform architecture and modules integration were studied.

Results: The project deliverables were catalogued into 8 categories which could be the platform's cloud interface main labels: results from events, policy papers, newsletters, mapping results and reports, datasets, recommendations and guidelines, use cases, courses and training activities. To define the overall system architecture, the following key activities should be implemented: content management system choice, hosting configuration and setup of the development domain, content management system installation, development of HTML web pages, data entry, data visualisation and graphic layout, and test and debug. To the modules integration purposes the following items should be addressed: creation of a server analytics account; social network integration; activation of additional system for sending newsletters.

Conclusions: Cloud-based data platform allows to securely manage, integrate, analyse and share large datasets. Establishing an infrastructure to help researchers access, store and analyse large amounts of biological data is of paramount importance both to enable advances in research and support health policy making processes. The CAN.HEAL platform could help aligning clinical and population-based interventions for integrating the genome of Europe biobanking initiative into public health genomics for cancer.

Key messages:

- Connecting healthcare data can support the challenge of accessing the relevant information needed for the policy and decision making processes to effectively promote population health and wellbeing.
- The set-up of a medical and public health cancer genomics platform promotes the effective translation of genome-based knowledge and technologies into public policy and health services.

Preventing battery ingestion in children: public health strategies and technological innovations

Dario Gregori

D Gregori[1], S Baldas[2], G Lorenzoni[1]
[1]Biostatistics, Epidemiology and Public Health, University of Padova, Padua, Italy
[2]Prochild, Protecting Children Association, NPO, Trieste, Italy
Contact: dario.gregori@ubep.unipd.it

Background: Accidental ingestion of button batteries can cause severe and sometimes fatal injuries, such as chemical burns, esophageal perforations, and long-term complications. In response to this challenge, prevention strategies have evolved. A recent example of safety-targeted technological innovation includes new coin lithium batteries with more secure packaging, a non-toxic bitter coating to deter ingestion, and a 'color alert technology' that activates a blue dye upon contact with saliva. These features are designed to discourage ingestion and facilitate the rapid identification of an injury, allowing for timely medical intervention.

Methods: This abstract reviews the public health strategies proposed or implemented to prevent this serious type of injury, augmented by an analysis of data from the Susy Safe registry, which identified

1,115 cases of battery ingestion in children, and an additional 94 cases from the literature, totaling 1,209 injuries.

Results: The review of existing prevention strategies highlights various approaches, including public awareness campaigns, enhanced product regulations, and the implementation of stricter safety standards for batteries and devices. Analysis of Susy Safe data helps characterize the issue, underscoring the frequency and circumstances of battery ingestions and provides an empirical basis to assess the effectiveness of existing prevention strategies and to guide the development of new policies. The combination of technological improvements and legislative initiatives could represent a significant breakthrough in preventing these dangerous injuries.

Conclusions: While technological innovations are promising, effective prevention of battery ingestion will require a multifaceted approach that integrates technology, education, public policy, and regulatory oversight. Collaboration among manufacturers, lawmakers, health professionals, and the community is essential to reduce the incidence of these medical emergencies.

Key messages:

- Accidental ingestion of button batteries can cause severe and sometimes fatal injuries.
- The combination of technological improvements and legislative initiatives could represent a significant breakthrough in preventing button batteries in children.

Funded by the European Commission under the Digital Europe Programme and through co-funding from participating Member States, the European Genomic Data Infrastructure (GDI) aims to support the 1+Million Genome initiative for establishing an effective data infrastructure for genomic data. GDI has the potential to fill the gap between genomic research and clinical practice, promoting the implementation of data-driven precision medicine in Europe with the harmonisation of genomic and related phenotypic and clinical data across adhering countries. Launched in November 2022, the GDI project is a collaborative effort involving partners from 20 European countries, divided into 8 Work Packages across three Pillars. GDI is structured with the development of a framework (Pillar I Long-term sustainability) and the necessary tools (Pillar II 1+MG infrastructure deployment), with the implementations of use cases (Pillar III Application and innovation solution) to support research and innovation, integrate findings into the clinic and healthcare, and improve public health measures. In the first 2 years, we completed the starter kit which we are currently testing with real data. Over the subsequent years, the GDI project aims to provide a federated and sustainable infrastructure for facilitating research that use genomic data. Through authorized secure access, clinicians and researchers can leverage genomic insights for faster and more precise clinical decision-making, diagnosis, and treatments. The GDI project represents a significant opportunity to improve healthcare outcomes and public health measures by leveraging the potential of genomics. By providing secure access to extensive genomic datasets combined with phenotyped data, the infrastructure sets the foundation for international partnerships in personalized medicine. Ultimately, this initiative holds the promise of advancing medical understanding, enhancing patient care, and fostering economic growth across Europe.

Key messages:

- GDI drives personalised medicine via international collaboration, building a sustainable infrastructure. Harmonizing data accelerates innovation, improving outcomes and fostering growth in Europe.
- GDI aims to revolutionize healthcare by collecting and harmonizing genomic and clinical data in Europe. It facilitates faster and more precise decisions and treatments, improving healthcare outcomes.

GRADE evidence to decision framework in genomics guidelines: systematic review & appraisal

Abdelrahman Mahmoud Ahmed Abdelsamad Taha

A Taha[1], *L Russo*[1], *AM Pezzullo*[1], *S Boccia*[1,2]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Woman and Child Health, Fondazione Policlinico Universitario A. Gemelli, Rome, Italy
Contact: bedoabdelsamad94@gmail.com

Background: Transparent development of clinical practice guidelines (CPGs) is important for genomic medicine, as this field promises to partially challenge the traditional hierarchies of evidence. The GRADE Evidence to Decision (EtD) framework has recently emerged as a transparent and rigorous tool to produce recommendations. Our aim was to survey the genomic CPGs that used the GRADE EtD and appraise the applicability of its criteria and the quality of produced CPGs.

Methods: We systematically searched PubMed, Scopus, Web of Science and the gray literature till 2023 for relevant CPGs. From each eligible CPG, we extracted the reporting of the GRADE EtD criteria: benefits, harms, resource use, cost-effectiveness, acceptability, feasibility, equity and values. The quality of the CPGs were appraised across various domains using the (AGREE) II instrument.

Results: Among 1,144 records, 15 CPGs met inclusion criteria between 2018 and 2023, comprising 66 recommendations. Reporting of GRADE EtD criteria varied. Benefits, harms and their balance were addressed in approximately half of the recommendations 48% and 52% respectively. Feasibility, acceptability and values were also 52%, 47% and 40% respectively, resource use 39%, cost-effectiveness 23%. Equity was addressed in 36% of the recommendations. Quality appraisal of the CPGs also varied, domains were reported as follows: scope and purpose, clarity of presentation, editorial independence 86%, 85% and 84% respectively, rigor of development 77%, stakeholder involvement 72%, while applicability was 59%.

Conclusions: GRADE EtD is applied heterogeneously in genomic medicine CPGs, with difficulty in applying all of its criteria, including benefits and harms. Quality varied across domains with applicability of the CPGs less demonstrated.

Key messages:

- Transparent approaches are needed in developing CPGs for genomic medicine.
- Current genomic CPGs fail to address crucial aspects for producing recommendations, including benefits and harms.

Abstract citation ID: ckae144.1958

Insights from a hospital database: injuries among children under 6 years old due to falls

Nato Pitskhelauri

N Pitskhelauri[1]*, K Akhobadze*[1]*, N Chikhladze*[1]
[1]Public Health, Faculty of Medicine, TSU, Tbilisi, Georgia
Contact: n_a_t_o_nato@yahoo.com

Background: Pediatric injuries represent a significant public health concern globally, contributing to substantial morbidity and mortality among children. In Georgia, limited data exists regarding pediatric injuries. The aim of the study was to analyze epidemiological characteristics and trends of pediatric injuries among children aged under 6 years who received treatment in hospitals across whole country.

Methods: NCDC hospitalization database for 2015-2022 was used for the study.

Results: Over the study period, a total of 5979 children under the age of 6 received treatment in all hospitals across Georgia. The highest number of hospital admissions were registered in 2019. 60% were boys and 40% were girls of the hospitalized patients. Boys were predominant across all age groups, with the highest proportion among children aged 5 years old. There was a significant variation in hospital admissions according to the seasons, with the highest admissions occurrence in summer. As for the cause of admission, 37% resulted from falls on the same level, 10% from falls between different levels, 7% involved falling from a bed, 4% from falling out or through a building, and 4% from falling down stairs. The cause of falls was unspecified in 23%. In 72% of cases, the injured body part was the head, 17% were upper extremity injuries, and 7% were lower extremity injuries. Of the patients, 90% recovered, 2% discontinued treatment, 8% were transferred, and the outcome was fatal for 0.23% of patients. Among the fatal cases, 36% resulted from falls from, out of, or through a building, 29% from falls between different levels, 14% from falling or jumping, 7% from falls involving a bed, and 7% from falls on the same level.

Conclusions: These findings underscore the importance of preventive measures, especially regarding fall prevention, to reduce the incidence of pediatric injuries in Georgia.

Key messages:

- There was a significant variation in hospital admissions according to the seasons, with the highest admissions occurrence in summer.
- These findings underscore the importance of preventive measures, especially regarding fall prevention, to reduce the incidence of pediatric injuries in Georgia.

Abstract citation ID: ckae144.1959

Risk perceptions and risk behavior among children attending a road safety education program in Greece

Kyriaki Vagionaki

K Vagionaki[1]*, S Lioliou*[1]*, E Galathri*[1]*, I Koutsodimitropoulou*[1]*, T Tsitakis*[1]*, S Poimenidou*[1]*, G Markakis*[1]*, CH Gnardellis*[2]*, J Chliaoutakis*[1]*, M Papadakaki*[1]
[1]Social Work, Hellenic Mediterranean University, LaHeRS, Heraklion, Greece
[2]University of Patras, Patra, Greece
Contact: kikivagionakis@gmail.com

Background: Road Traffic Injuries (RTI's) are a significant public health concern for children, placing a considerable burden on their well-being. Greece has consistently recorded high numbers of RTI's among adolescents.

Methods: A university lab (LaHeRS, HMU) offers a road safety education program for primary and secondary students in Heraklion, Greece. The program consists of two parallel sessions (practical training using a driving simulator and activity-based risk-perception training) aimed at enhancing competencies in resilience to peer influence, empowering children to engage in informed decision-making and fostering hazard perceptions skills. The current presentation reports on 800 students who attended the program between October 2023 and April 2024. A structured questionnaire was used to collect data on student's beliefs, attitudes and practices on road safety.

Results: A total of 800 students attended the program from the broader Crete Region. 50.5% were girls with a mean age of 12.6 (SD = 2.3) years, 60.9% secondary education students, 58% resided in rural areas. 33.9% reported using a motorcycle and 33.8% a car without a driving license. 23.3% reported experiencing a road traffic incident while commuting. 57.1% identified road safety as a problem in their place of residence, only 26.5% felt safe on local streets and only 9.1% considered other road users as watchful. Additionally, 66.8% highly valued helmet use as a precaution in short distances. 71.6% reported always wearing seatbelt in front seats and 68.9% thought seatbelts are important at back seats. 52.1% did not identify themselves as risk takers on the street, and only 22.5% felt competent in avoiding road risks. 32.9% admitted experiencing peer pressure while commuting.

Conclusions: Risk taking behaviors and low use of protective measures are prevalent among school aged children and need to be addressed through targeted road safety education programs and interventions.

Key messages:

- Promoting safe behaviors and enhancing risk perception is critical among children and young adolescents.
- Road safety education should be integrated into school curricula, starting from pre-school education.

Abstract citation ID: ckae144.1960

Association between frailty and fear of falling among the elderly in Latvia

Aija Bukova-Zideluna

A Bukova-Zideluna[1,2]*, A Villerusa*[1,2]*, L Springe*[1,2]*, D Baltmane*[3]
[1]Institute of Public Health, Riga Stradins University, Riga, Latvia
[2]Department of Public Health and Epidemiology, Riga Stradins University, Riga, Latvia
[3]Statistics Unit, Riga Stradins University, Riga, Latvia
Contact: aija.bukova@rsu.lv

Background: Frailty and fear of falling in the ageing population represent notable public health challenges. Fear of falling among the elderly population is a significant concern, as it can lead to decreased mobility, loss of independence, and increased risk of injury. Frailty intensifies this fear, as frail individuals often have reduced strength, balance, and coordination, making them more susceptible to falls.

Methods: Data from the population-based survey SHARE with respondents aged 50+ in Latvia of Wave 9 (collected 2022) was analysed. Frailty was assessed using the SHARE-Frailty Instrument. Fatigue, appetite, walking difficulties, and physical activity were self-reported and grip strength was measured using a hand grip dynamometer. Fear of falling was evaluated using visual material.

Financed by the project RSU internal and RSU with LSPA external consolidation No.5.2.1.1.i.0/2/24/I/CFLA/005, Postdoctoral Grant Associated factors of frailty and fall-related mortality in the older population in Latvia No.RSU-PG-2024/1-0005.

Results: The sample comprised 1439 older adults from Latvia (60.4 % female) with a mean age of 67.9 (95% CI 67.5 - 68.4). Based on SHARE-FI, frailty and pre-frailty prevalence were 7.2% and 44.5% respectively. In the study, 11.3% of females and 6.5% of males interviewed reported experiencing fear of falling. Frailty was correlated with fear of falling in 43.7% of frail individuals and 11.5% of pre-frail individuals. After adjusting for age and gender, those with pre-frailty and frailty had greater odds of fear of falling.

Conclusions: Understanding the interaction between the fear of falling and frailty in older adults can guide the development of public health policies and initiatives that aim to mitigate the fear of falling and, consequently, reduce the prevalence of frailty. Promoting healthy ageing behaviours, such as regular exercise, balanced nutrition, and social engagement, can help prevent frailty and its associated risks.

Key messages:

- Fear of falling results in limitation of activities, intensification of physical decline, and increased susceptibility to frailty.
- Encouraging healthy ageing underscores the significance of early recognition of frailty symptoms and accessing suitable support.

[4]Department of Medical, Surgical Science, University of Catania, Catania, Italy
[5]Department of Medicine and Surgery, University of Perugia, Perugia, Italy
[6]Department of Cardiovascular Sciences, Università Cattolica School of Medicine, Rome, Italy
Contact: luca.proto@unicatt.it

Background: Cardiovascular diseases (CVD) represent a major global health concern, requiring innovative primary prevention strategies. Personalized prevention, through the use of digital technologies and genetic risk scores (PRS), holds promise but requires further investigation to assess clinical efficacy. Consequently, the INNOPREV trial aims to investigate the efficacy of PRS and/ or digital technologies in the uptake of CV preventive behaviors uptakes.

Methods: The INNOPREV trial is a multicenter randomized controlled trial conducted in Italy across three hospital centers in Rome, Catania, and Palermo. It aims to recruit 1020 participants aged 40-69 with a high 10-year CVD risk. Participants are allocated to traditional CVD risk assessment, or genetic testing, or digital interventions, or a combination of both. The study involves comprehensive CV risk assessments at baseline and follow-up visits at one, five, and twelve months. Data analysis will utilize mixed-effects models to analyze longitudinally collected data and explore potential moderators and mediators of behavior change.

Results: Preliminary results indicate good progress in recruitment, which currently stands at 250 participants (25% of expected). Recruited females have a mean age of 59 ± 6 years, while males have a mean age of 58 ± 6 years. Currently, PRS analyses indicate that 77% of participants have intermediate scores, and 23% have low scores. Follow-up will be essential to evaluate the efficacy of the proposed interventions.

Conclusions: We expect that the INNOPREV trial will provide evidence towards integration of innovative approaches based on PRS and digital devices, in the traditional preventive approaches for CVDs. Expectations are high based on the limited effectiveness of the current approaches in CV risk reduction based on lifestyle advice.

Key messages:

- INNOPREV trial examines PRS and digital technology for CVD prevention, aiming to enhance preventive efficacy. Initial findings suggest promising potential for innovative CVD prevention strategies.
- The INNOPREV trial aims to investigate the efficacy of personalized prevention strategies, including PRS and digital technologies, in improving cardiovascular preventive behaviors.

[3]Stanford Prevention Research Center, Stanford University School of Medicine, Stanford, USA
[4]Epidemiology and Population Health Department, Stanford University School of Medicine, Stanford, USA
[5]Department of Biomedical Data Science, Stanford University School of Medicine, Stanford, USA
Contact: luigi.russo12@icatt.it

Background: Polygenic Risk Score (PRS) represents a promising advancement in personalized medicine, enabling the inherited risk assessment for disease outcomes based on the effect of various common genetic variants. The utilization of PRS information to promote the adoption of healthier behaviors has witnessed an increase interest in recent years, but its full potential still needs to be fully addressed.

Methods: This systematic review aims to assess the efficacy of disclosing PRS information on individuals' engagement in risk-reducing interventions. CENTRAL database has been searched up to December 2023 to identify randomized controlled trials (RCTs) comparing the disclosure of PRS results, with scenarios where other or no information is provided. We performed a preliminary meta-analysis on the mean difference of clinical and psychological outcomes between the two arms.

Results: Out of 4419 results, we included 12 studies. Trials focused on primary (83%), secondary (8%) and tertiary (8%) preventive interventions. As for the possible diseases predicted by the PRS, cardiovascular diseases (33%) were the most common ($n = 4$), along with cancers (33%), diabetes (25%) and metabolic disease (8%). PRS result disclosure was compared to standard care ($n = 7$), no information provided ($n = 4$), and family risk ($n = 1$). By pooling data from four comparable studies, we report a reduction in the mean difference for LDL cholesterol in the intervention group of -6.39mg/dL (95%CI -10.09, -2.70, I^2=0%, $p < 0.001$). No significant changes were observed for systolic and diastolic blood pressure, and weight, in 3 studies and 4 analyzed studies, respectively. An increase in anxiety levels was observed towards the PRS group in 4 studies (SMD 0.24, 95%CI 0.02, 0.46, $I^2 = 66\%$, $p = 0.03$).

Conclusions: Preliminary analysis show small or no effects of PRS disclosure on intermediate health or psychological outcomes. Larger trials assessing the potentiality of PRS disclosure are still needed.

Key messages:

- From the analysis of twelve preventive trials on the efficacy of PRS on behavior change, we report a positive effect on LDL cholesterol reduction.
- Larger well conducted trials are needed to integrate PRS-based information into future preventive strategies.

Genetic and other omics-based information in the most-cited recent clinical trials

Luigi Russo

L Russo[1], S Farina[1], LM Siena[3], R Pastorino[1,2], S Boccia[1,2], JPA Ioannidis[4,5,6]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Woman and Child Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

[5]Epidemiology and Population Health Department, Stanford University School of Medicine, Stanford, USA
[6]Department of Biomedical Data Science, Stanford University School of Medicine, Stanford, USA
Contact: luigi.russo12@icatt.it

Introduction: Since the genomic revolution, the utilization of genetic and omics technologies has undergone considerable expansion within clinical studies, employed in design, analysis, and interpretation.

Methods: A recent study of Siena et al. developed a database containing the 600 most cited clinical trials published from 2019 to 2022. Building on this database, the aim of our study is to assess how frequently genetic and other omics-based information has been used in the design, analysis, results or conclusion of these recent influential trials.

Results: 132 out 600 (22%) trials used genetic or other omics. These trials were more likely to be oncology trials (76%vs34%), having industry funding (59%vs47%), and having industry authors (75%vs54%) than others. Overall, genetics and genomics were present in 75% of the trials (100/132), and oncology was the predominant medical field (76%, n = 101). The prevailing use was detection of specific mutations (n = 99), often (n = 60) used as eligibility criterion. These mutations were mostly somatic (n = 85), while 14 were germline. Other applications included transcriptomics (20.4%), proteomics (10.6%), metabolomics (8.3%) and metagenomics (8.3%). 36 studies (27%) employed multiple applications. Genetics or other omics were used in 10% of the studies (14/132) for randomization stratification and in 63% (83/132) to conduct subgroup analysis. Among the latter, in 48% (40/83) the presence of a somatic mutation was significantly associated with the investigated health outcomes, while germline mutation or other omics only in the 12% (10/83). In the trials conclusions, authors addressed the relevance of the genetic or omics information in 62.1% (82/132) of the trials.

Conclusions: A sizeable proportion of the most-cited clinical trials use genetics or omics-based information, but the large majority pertains to cancer mutations in oncology trials. Use of genetics and omics needs to become more common in other clinical trial fields.

Key messages:

- Genetic profiling and omics applications should be incorporated into trial design.
- Genomic research is mostly oncology related and it needs to be expanded to other medical fields.

Abstract citation ID: ckae144.1964
Cost of fall injuries in traffic are for pedestrians and bicyclists - municipal respons needed

Jens Martin Lauritsen

J Lauritsen[1,2]
[1]Ortopedic Department, Odense University Hospital, Odense M, Denmark
[2]Clinical Medicine, University of Southern Denmark, Odense M, Denmark
Contact: jel@rsyd.dk

Motivation: Pedestrians and bicyclists have been posting in news and social media with reflections on municipal efforts to clean bicycle paths and sidewalks in icy and wet conditions. The municipality have lowered budgets for these cleaning efforts in recent years.

Methods: Analysis of A&E department registration data with the Nomesco core dataset allows for separation of location, age, sex, time of day and date of injury. Injury severity is classified according to diagnosis of treatment (minor/major). Cost calculations are based on national scales from the Ministry of Transport (ambulance/police/treatment/rehabilitation). Cold weather was defined as lowest day temperature < 5 degree C (Danish Metereological service DMI).

Results: During 2023 all pedestrians or bicyclists (n = 2516) treated at the A&E following an incident on sidewalks, streets or bicyclepaths (population 225.000) were included. Non-serious were (total/cold weather): sidewalks (699/266), bicyclepaths (414/117), streets (762/277). Serious: sidewalks (290/130), bicyclepaths (123/32), streets (228/100). Assessment of economical costs was DKK: Non-serious were (total/cold weather): sidewalks (20.8/7.9), bicyclepaths (12.4/3.5), streets (22.7/8.3). Serious: sidewalks (42.2/18.9), bicyclepaths (17.9/4.7), streets (33.2/14.6).

Discussion and conclusions: The economic burden for the population and municipality far exceeds the costs for cleaning the streets, bicyclepaths and sidewalks in icy and wet conditions. With appropriate injury surveillance and communication to municipal authorities revised cleaning principles was decided at the political level

Key messages:

- Appropriate and focused injury registration is needed for targeted political level decision.
- Standardized and targeted economic calculations are persuasive in the political arena at the local level.

Abstract citation ID: ckae144.1965
A university-based counseling program for perpetrators of family violence in Greece: initial evidence

Maria Papadakaki

M Papadakaki[1], V Kounali[1], K Vagionaki[1], E Megge[2], TH Manioti[2], MG Morfovasili[2], M Dimitraki[1], M Toraki[1], SG Mavridou[1], E Vasilaki[1]
[1]Department of Social Work, LaHeRS & PHC-HMU, Hellenic Mediterranean University, Heraklion, Greece
[2]First Instance Prosecutor's Office of Heraklion, Heraklion, Greece
Contact: mpapadakaki@hmu.gr

Penal mediation is defined in Greek Law 3500/2006 and aims at repairing the harm caused to the victim of family violence and rebuild family relationships. Mediation process starts upon victims' unreserved consent and perpetrators' willingness to stop further acts of violence, attend a counseling program and restore any harm/damage caused to the victim. Then the prosecutor ceases the case for 3 years and refers the perpetrator to counseling. If any of the previous conditions are violated during this period the criminal procedure continues at the stage before mediation. A university lab in Crete, Greece (LaHeRS, HMU) offers one of the few in Greece perpetrators' behavior change programs in collaboration with the Prosecutor's Office. LaHeRS counseling program consists of a minimum of 24 sessions per offender based on an individual or group approach. Emphasis is placed on perceptions of power and control, anger management, trauma management, emotional expression, and social/communication skills. Each perpetrator is offered 2 sessions (intake/violence documentation and assessment of individual/couples' needs), 2-3 sessions for psychiatric and risk assessment, 12-15 individual or group counseling sessions (combined with couples' sessions, as necessary), 2-4 individual social support sessions. Sessions are conducted by trained psychologists and social workers. The current presentation reports on the Intimate partner violence (IPV) cases referred between February

2022 and December 2023. A total of 70 IPV cases attended the program (male n = 65; mean age 43.4; Greek n = 56; urban residence n = 49; children average=1.92). Physical violence was reported in 54 cases and verbal aggression in 43 cases. Four perpetrators had mental health problems and 6 were identified with some form of drug and alcohol misuse. Lack of communication and emotional skills, lack of parent emotional support, gender roles stereotypes and patriarchal attitudes were common among perpetrators.

Key messages:

- It is important for perpetrators' programs to address the underlying causes of criminal behavior to promote positive changes in perpetrators' lives.
- Effective penal mediation programs require collaboration and partnership between justice agencies, academia and community organizations.

Abstract citation ID: ckae144.1966

The profile and aberrant driving behavior of juvenile traffic law violators in Greece

Kyriaki Vagionaki

K Vagionaki[1], *S Lioliou*[1], *V Kounali*[1], *A Stefanakis*[2], *G Stefanakis*[2], *M Toraki*[1], *CH Gnardellis*[3], *J Chliaoutakis*[1], *M Papadakaki*[1]
[1]Social Work, Hellenic Mediterranean University, LaHeRS, Heraklion, Greece
[2]Educational Experiental Road Safety Center, EERSC, Agios Nikolaos, Greece
[3]University of Patras, Patra, Greece
Contact: kikivagionakis@gmail.com

The majority of juvenile offenses in Greece are related to road traffic violations. Juveniles in Crete region are required to attend an educational program offered by LaHeRS lab (HMU), in collaboration with the Prosecutor's Office as part of reformative measures. The current presentation reports on the profile and aberrant driving behavior of juvenile offenders who attended the program between 2023-2024. The Driver Behavior Questionnaire (DBQ) was administered to 181 juvenile offenders. Participants were males (97.8), with a mean age 18.6 (SD = 1.2), resided in rural settings (51.8%) and secondary students 60.7%. The mean age of the first offence was 15.8 (SD = 1.1, min 13 - max 18). Participants scored low in all DBQ scales (covered violations mean=6.1, sd = 7.5; unintentional violations mean=0.9, sd = 1.6; lapses mean=8.9, sd = 10.5). No statistically significant difference was found in DBQ scores between those who had and did not have a driver's license, as well as between those from urban or rural areas. The three DBQ subscales significant correlated ($p < .001$). Among other risky behaviors, 54.9% reported exceeding the legal speed limit, 66.3% reported aggression feelings when driving behind a slow vehicle, 34.5% used mobile phones while driving, 17.7% reported alcohol use while driving. Surprisingly, 85.5% stated high confidence addressing risks on the roads.

Key messages:

- Early interventions on aberrant driving behavior among adolescents is crucial.
- Educational programs should be tailored to address the unique needs of juvenile traffic law violators.

[5]CNRS, EHESS, INSERM, Institut de Recherche Interdisciplinaire sur les Enjeux Sociaux, Aubervilliers, France
Contact: pauline.brugailleres@u-bordeaux.fr

Background: The European Region exhibits the world's lowest exclusive breastfeeding rate at 6 months. Addressing work-related breastfeeding challenges is crucial, particularly for women navigating precarious work situations, compounding their adversity. This scoping review surveys research on maternal employment characteristics facilitating breastfeeding continuation post-return to work in the European Region.

Methods: Studies from 2013 to 2023 were gathered from Scopus, PubMed, and PsycInfo. Inclusion criteria comprised English or French quantitative/qualitative studies exploring links between maternal employment characteristics and breastfeeding status, duration, or experience. Participants were employed mothers of healthy children sustaining breastfeeding post-resumption of work. Key determinants included work-related factors contributing to socially diverse working conditions, encompassing type of employment, working conditions, and work environment. Geographic scope included World Health Organization European Region countries.

Results: Among 693 hits, 13 studies met criteria. Eight focused on work and breastfeeding, others explored broader breastfeeding determinants. Represented countries: Spain (n = 4), France (n = 4), UK (n = 2), Ireland (n = 2), Netherlands (n = 1). Findings highlighted methodological heterogeneity, indicating a lack of conceptual framework linking work, breastfeeding, and social health inequalities. Nonetheless, self-employment, non-manual professions with time flexibility, workplace breastfeeding facilities, coworker support, and breastfeeding workplace policies emerged as pivotal factors supporting working mothers' breastfeeding.

Conclusions: Backing breastfeeding choices for working mothers is crucial amid adversities faced by mothers and children. These results underscore the need for targeted workplace interventions, including time flexibility, breastfeeding facilities, and promotion of breastfeeding-friendly policies.

Key messages:

- Self-employment, non-manual occupations, time flexibility, breastfeeding facilities, support of co-workers and breastfeeding workplace policies promote continuation of breastfeeding.
- Policy directives targeting low skilled or precarious jobs are needed to reduce social health inequalities broadly, and in particular, in relation to breastfeeding practices.

Abstract citation ID: ckae144.1968
Children eight to twelve years of age have clear opinions about Positive Health

Cindy De Bot

C De Bot[1], J Dierx[1]
[1]Center of Expertice Perspective in Health, Avans University of Applied Sciences, Breda, Netherlands
Contact: cma.debot@avans.nl

Introduction: Positive Health (PH) focuses on the ability to maintain control over one's own health, also for children. This study explores how primary school children eight to twelve years of age think about the concept of PH and the dimensions of PH as described in the child tool.

Methods: A qualitative research method was applied, in which 25 semi-structured interviews consisting of eight questions were conducted.

Results: Children mainly think of nutrition, exercise and 'feeling good' when asked what PG means. More specifically on the different dimensions, for 'My body' they mainly think about sleeping, healthy eating and exercise. For 'My feelings and thoughts', they mainly mention being happy, sad or angry and also for 'feeling good about yourself' they mainly talk about emotions and feeling good where appearance is important. The dimension 'Now and later' is mainly about occupation later, according to the children. Friends and bullying are terms mentioned in the dimension 'Participation' and being able to do what they feel like is most important in the dimension 'Daily life'. For children, the dimensions 'Feeling good about yourself' and 'My feelings and thoughts' are most important. In addition, 'Participating' is important where having fun with friends is particularly mentioned by all children.

Conclusions: Children aged eight to twelve years of age perceive PH more than just the physical component and recognise all the dimensions of PH be it in their own words. Where children of all ages value the dimensions 'Feeling good about yourself', 'My feelings and thoughts' and 'Participating' most, these dimensions become even more important with increasing age. For teachers, youth health professionals and parents/carers this might imply, first, that the concept of Positive Health could be used as a tool when talking about being and staying healthy. Second, interventions might be more effective when aligned to children's perceptions and language.

Key messages:

- The concept of Positive Health could be used as a tool when talking about being and staying healthy.
- Interventions might be more effective when aligned to children's perceptions and language.

Abstract citation ID: ckae144.1969
Factors associated with the consumption of ultra-processed among Brazilian and Portuguese pregnant

Sara Rodrigues

MC de Lima[1], DS Sartorelli[2], SSP Rodrigues[3]
[1]Postgraduate Program in Public Health, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil
[2]Department of Social Medicine, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil
[3]Faculty of Nutrition and Food Science, University of Porto, Porto, Portugal
Contact: saraspr@fcna.up.pt

Considering the recent evidence about the negative effect of the consumption of ultra-processed foods (UPF) on current and future generations, and pointing to the development of public food policies adapted to the needs of pregnant women, it is important to identify the factors associated with high consumption of UPF. Cross-sectional comparative study that used data from: 1) a randomized controlled clinical trial conducted with pregnant women treated at Health Units in a city in São Paulo ($n = 350$), Brazil; and 2) the National Dietary and Physical Activity Survey 2015-2016, Portuguese pregnant women ($n = 226$). Two 24-hour recall surveys were collected. The UPF were classified according to the Nova. Usual consumption was estimated using the Multiple Source Method software. The percentage of energy coming from UPF was calculated using the mean (±SD) and 95%CI. Adjusted and crude linear regression models were used. The analysis were conducted in SPSS (version 21), considering $p < 0.05$ as significant. The average age of the total sample was 29.4(±6.3) years and the BMI corresponded to 27.8(±3.4)kg/m^2. The average daily energy consumption from UPF among Brazilian pregnant women was 449.6(±207.6) kcal, representing 24.2(±8.8)% of the total energy consumed on a usual day; among Portuguese women the average corresponded to 484.2(± 242.4)kcal and 22.3(9.3)%, respectively. In crude and adjusted linear regression models, the participation of UPF in total energy was higher among single Brazilian pregnant women compared to married women (3.2[0.8-5.5]p=0.009); Among Portuguese women, an inverse relationship was observed between weekly physical activity (PA) $\geq$150 minutes and UPF energy consumption (-3.2[-6.0 - -0.3] p= 0, 03). In the studied pregnant women, results showed that being single and practicing less than 150 minutes of PA weekly were factors associated with greater consumption of UPF, characterizing a priority group to receive nutritional interventions during prenatal care.

Key messages:

- Public policies and strategies to reduce the consumption of ultra-processed foods during pregnancy.
- Promotion of healthy lifestyle habits and impact on current and future health.

Abstract citation ID: ckae144.1970
Addressing deficits in malnutrition care in northern Sierra Leone; an educational intervention

Laura Gabbott

L Gabbott[1]
[1]Bristol Royal Hospital for Children, University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, UK
Contact: laura.gabbott@gmail.com

The 2017 Sierra Leone National Nutrition Survey reported poor practice regarding the medical management of severe acute malnutrition and the provision of emergency food to patients, particularly in the northern city of Makeni. We developed a training package for paediatric nurses, aiming to design an easily reproducible format which could be utilised nationally. Our aims were to empower and educate staff to provide more consistent care by challenging the negative cultural perception of malnourished patients and increasing knowledge of key guidelines. A two-day course based around UNICEF guidance on malnutrition was developed with the financial support of the Sierra Leonean office of the World Health Organisation. We sought the advice of local staff on issues impacting the quality of malnutrition care, including cultural barriers, educational limitations and supply issues. Lectures and practical sessions were devised covering recognition, assessment and management. Communication skills were taught using role play, focussing on the key role of nurses in parental education, and nursing skills were reinforced using practical tasks. Local staff identified for their strong teaching and leadership were recruited as instructors and to provide feedback on session design and content. 21 candidates attended from across the region, with the majority based in inpatient feeding units. Candidates completed a pre- and post-course written examination and a qualitative feedback form. Pre-course exam results ranged from 35%-85% with an average of 65%;

post-course results showed improvement with a range of 55%-100% and an average of 88%. Candidates rated the course on average 9.7 out of 10 and the written feedback was positive. We subsequently observed positive changes in clinical practice in the inpatient feeding units across the region. Based on these assessments the course achieved its aims. Further study is needed to know if noted clinical improvements were sustained.

Key messages:

- Challenging local cultural perceptions of malnourished patients is crucial to establishing improvement in medical care for this group.
- Sustainable educational intervention requires local instructors who can independently deliver teaching, and establishing this cohort at the course inception is critical to its ongoing success.

[2]Department of Interdisciplinary Sciences, Faculty of Dental Medicine and Health Osijek, University of Osijek, Osijek, Croatia
Contact: ivan.miskulin@mefos.hr

Background: Gambling has become a routine form of entertainment for many young people studying in universities. This study aimed to investigate the prevalence and characteristics of gambling disorder among Croatian university students.

Methods: A cross-sectional study using an anonymous self-administered questionnaire with sociodemographic and socioeconomic questions along with the Croatian version of the South Oaks Gambling Screen questionnaire (SOGS-CRO) was conducted in a representative sample of Croatian university students from Osijek, Eastern Croatia during January, and February 2020.

Results: A total of 844 students participated in the study, 45.6% males and 54.4% females, with a median age of 19.00 years (interquartile range 19.00-23.00 years). Gambling activities were performed by 66.2% of the students, most commonly lotteries, sports bets, and bingo. The final scores of the SOGS-CRO suggested that 21.1% of students may have a gambling disorder, with 16.4% being "probable pathological gamblers" and 4.7% being "problem gamblers". Playing cards for money, animal bets, stocks bets, slot machines bets, pull-tabs, and other gambling activities such as online or videogames or mobile games present a higher risk of gambling disorder ($p < 0.001$, $p < 0.001$, $p < 0.001$, $p < 0.001$, $p < 0.001$, $p < 0.001$, respectively). Being male, repeating the year of study, being a student in interdisciplinary or technical field of study, and having a mother with gambling disorder ($p < 0.001$, $p = 0.029$, $p < 0.001$, $p < 0.001$, respectively) were the revealed contributing factors to the development of gambling disorder in study participants.

Conclusions: The study points to the fact that gambling disorder is quite a prevalent public health issue in the Croatian university student population. Specific public health preventive programs need to be designed and implemented in the study population to successfully prevent the development of investigated behavioral addiction.

Key messages:

- Public health interventions directed toward the prevention of gambling must involve younger population subgroups, such as university students.
- When designing the preventive programs for the successful prevention of gambling within the university student population selected sociodemographic variables should be considered.

Abstract citation ID: ckae144.1972
Cannabis use, mental health and suicide attempts among adolescents in Puerto Rico

Juan Reyes

J Reyes[1]
[1]Biostatistics and Epidemiology, University of Puerto Rico, Canovanas, USA
Contact: juan.reyes5@upr.edu

Cannabis is the most widely used illicit substance worldwide, with recent reports estimating an 11.6% annual prevalence of use in North America. Mental health, suicidal ideation, suicide attempts and completed suicides, has been the focus of several studies exploring its association with frequent cannabis use. The purpose of this study is to evaluate the association between cannabis use, mental health symptoms and suicide attempts among adolescent students in Puerto Rico. Consulta Juvenil X is a monitoring program that aims to study the prevalence of substance use, mental health and violent behavior as well as the risk factors associated with those practices. The survey was conducted during the 2018-20 academic year. The study utilizes a self-administered questionnaire. The sample included 4,668 (54%) females and 3,977 (46%) males. Half of the sample was between seventh and ninth grade with a median age of 15 years old. The majority of the sample was recruited from the public school system in Puerto Rico (70.3%). The prevalence of marihuana use in the public and private schools participating in the study was 9.4% and the suicide attempts was 7.6%. Multiple logistic regression analyses revealed that students who use marihuana during the last year were significantly more likely to report depressive and anxiety symptoms after controlling for sociodemographic variables. Moreover, adolescents who use marihuana were significantly more likely to report suicide attempts after controlling for depression symptoms (OR = 3.07; 95%CI: 2.53-3.72). Findings of this study suggest that adolescents who report marihuana use seem to be at higher risk for mental health problems and suicide attempts. Understanding who is most likely to report marihuana use is important in developing interventions to prevent mental health problems and suicidal behaviors.

Key messages:

- Findings of this study suggest that adolescents who report marihuana use seem to be at higher risk for mental health problems and suicide attempts.
- Understanding who is most likely to report marihuana use is important in developing interventions to prevent mental health problems and suicidal behaviors.

Abstract citation ID: ckae144.1973
Breast milk sharing practices in emergency settings

Carolina Tannenbaum-Baruchi

C Tannenbaum-Baruchi[1], *H Harari*[1]
[1]School of Nursing Science, The Academic College of Tel Aviv–Yaffo, Yaffo, Israel
Contact: carolinata@mta.ac.il

Background: In emergencies, breast milk sharing becomes essential to sustain infant nutrition when access to maternal breastfeeding is disrupted. This study examines donor motivations and assesses the impact of such initiatives on infant health outcomes during wartime.

Methods: This qualitative study investigated a community of breast milk donors on a Facebook platform for the month following the start of the war on October 7, 2023. We investigated two main groups participating in breast milk sharing through reflective thematic analysis of social media messages.

Results: A count of posts one month before and after October 7 revealed a doubling in post frequency post-7/10, emphasizing the surge in war-related posts. Two main themes emerged concerning the war:

1. Infant needs: Posts addressed various infant needs, including general necessities and those specific to war-related situations. Requests for milk sharing emerged from the second day of the war, particularly for infants whose mothers were missing or injured. Government information from the National Human Milk Bank was shared within these Facebook groups, encouraging donations for these infants.
2. Donor Motivation: Posts reflected both non-war-related and war-related motivations, with a notable emphasis on the latter. Authors, including both women and men, actively promoted the donation of human milk to conflict-affected areas. Suggestions included pumping milk specifically for war-affected infants or offering frozen human milk. Some posts also offered to collect and deliver human milk to needy infants within the affected regions.

Conclusions: Post frequency doubled in both Facebook groups compared to the previous month, mainly focusing on war-related topics, indicating an increased drive to share human milk with those affected by the conflict.

Key messages:

- Breast milk sharing, crucial in emergencies, analyzed via social media, sheds light on donor motivations and impacts on infant health during conflicts.
- This qualitative study investigated a community of breast milk donors on a Facebook platform for the month following the start of the war on October 7, 2023.

Abstract citation ID: ckae144.1974
Heterogeneity of postpartum bonding and maternity blues among mothers three days after delivery

Slavica Kozina

S Kozina[1], *N Tomić*[2], *M Šunj*[3,4], *M Kaliterna*[5], *T Boraska Marasović*[5], *T Mastelić*[5], *T Kozina*[6], *SM Pranić*[7]

[6]Department of Professional Studies, University of Split, Split, Croatia
[7]Department of Public Health, University of Split School of Medicine, Split, Croatia
Contact: sjkozina@gmail.com

Background: Findings about risk factors for postpartum depression (PPD) are often inconsistent. The variability could be due to the heterogeneity of characteristics of mothers at risk for PPD in certain populations, which has important mental health implications. We examined the heterogeneity of sociodemographic, pregnancy and labor characteristics in postpartum women referred to follow-up care on the third day after delivery.

Methods: We performed a nested cross-sectional latent profile analysis (LPA) on a convenience sample of women in a tertiary community hospital in Split, Croatia in 2020. Participants completed the first subscales of Postpartum Bonding and Maternity Blues questionnaires, as well as five subscales of the Questionnaire of Family Functioning According to Parents and 12 sociodemographic, pregnancy and childbirth-related variables. LPA identified profiles of mother-infant bonding and postnatal blues, and multinomial regression analysis was used to determine the influence of different profiles.

Results: Of the 318 participants, the best-fitting model had three latent profiles. First ($n = 76$, 24% of participants) and second ($n = 216$, 68% of participants) latent profiles showed good postpartum bonding, while second profile showed higher primary blues. Third profile ($n = 80$, 25% of participants) was characterized by poorer postpartum bonding and elevated primary blues. Only good youth experiences of mothers with their parents (relative risk [RR] 0.26; 95% CI 0.12-0.57; $p = 0.001$) and good present-day relationships with partners (RR 0.26; 95% CI 0.13-0.52; $p < 0.001$), significantly decreased the risk for third latent profile classification.

Conclusions: Postpartum bonding and primary blues of women who gave birth three days prior were heterogeneous. This heterogeneity could result in the well-documented heterogeneity of postpartum depression in women, and therefore, be the focus of mental health interventions in similar settings.

Key messages:

- We found heterogeneity of sociodemographic, pregnancy, and labor characteristics in postpartum women after delivery, highlighting the variability in risk factors for postpartum depression.
- This heterogeneity could result in the well-documented heterogeneity of postpartum depression in women, and therefore, be the focus of mental health interventions in similar settings.

Abstract citation ID: ckae144.1975
Risk Factors for Unplanned Readmissions in Paediatric Neurosurgery: A Systematic Review

Lance Vincent Sese

LV Sese[1,2,4], *MC Guillermo*[3,4]
[1]Nuffield Department of Primary Care, University of Oxford, Oxford, UK
[2]Neurology, National Hospital for Neurology and Neurosurgery, London, UK
[3]Neonatal Medicine, Luton and Dunstable University Hospital, Luton, UK
[4]Ateneo School of Medicine and Public Health, Ateneo de Manila University, Metro Manila, Philippines
Contact: l.sese@nhs.net

Background: Unplanned hospital readmission (UHR) after paediatric neurosurgery is an important indicator of surgical outcomes. As this field deals with complex cases, there is an increased likelihood of potential complications and the subsequent need for readmission. Hence, the study aims to identify factors contributing to 30-day and 90-day UHR rates in children undergoing neurosurgical procedures.

Methods: A systematic review (Prospero CRD 42023455779) was conducted, which included studies from Embase, Medline, CINAHL, and Global Index Medicus databases that reported unplanned readmissions within 30-/90-days of an index neurosurgical procedure. Quality and risk of bias assessment was done using the Newcastle-Ottawa scale. Data extraction and narrative synthesis were performed to identify significant factors associated with UHR.

Results: 2593 titles were identified following the search strategy. 52 studies were included after screening and quality appraisal. Most studies were from the United States and are retrospective cohort in nature. Majority were cranial procedures ($n = 30$), with common ones being shunt procedures for hydrocephalus and cranial tumour resections. Aetiology-related, procedural complexities, and age emerged as the three most common significant risk factors. Age is a significant predictor (9/52), with younger children facing higher odds compared to their older counterparts across different procedures. While early readmissions can be due to disease progression, some are linked to preventable causes. The included studies also exhibited significant heterogeneity. Variations in definitions and examined variables, as well as the inclusion of studies from both national databases and single institutions, contributed to this heterogeneity.

Conclusions: Overall, findings from this study contribute to a collective understanding of factors affecting unplanned readmissions in paediatric neurosurgery.

Key messages:

- Identified risk factors can help guide creating and refining surgical protocols for post-operative monitoring and follow-up.
- UHRs reflect the interplay among surgical complexity, patient characteristics such as age, and disease aetiology.

Abstract citation ID: ckae144.1976
Professionals' perspectives on barriers for timely antenatal care for ethnic minority women

Shuby Puthussery

S Puthussery[1], *A Verstraeten*[1,2], *O Ilozumba*[3]
[1]Maternal and Child Health Research Centre, University of Bedfordshire, Luton, UK
[2]Health and Life Sciences, Vrije Universiteit, Amsterdam, Netherlands
[3]Institute of Applied Health Research, University of Birmingham, Birmingham, UK
Contact: shuby.puthussery@beds.ac.uk

Background: Antenatal care (ANC) is important to promote health and well-being of women and babies. Women from ethnic minority backgrounds are likely to start ANC later and to attend fewer appointments than recommended compared to white women. These women and their babies are more likely to experience negative health outcomes. This study explored the perspectives of maternity care professionals on barriers for timely ANC initiation for ethnic minority women in the UK (UK) and The Netherlands.

Methods: We conducted qualitative semi structured in-depth interviews with 19 healthcare professionals (eight and eleven from the UK and The Netherlands respectively) including nurses, midwives, general practitioners and obstetricians. All interviews were conducted virtually on Teams or Zoom and were recorded, transcribed and analysed using a thematic approach using ATLAS.ti version 9 software.

Results: Maternity care professionals in the UK and The Netherlands perceived more or less similar barriers for ethnic minority women for timely ANC initiation. As reflected in the accounts, these barriers operated at individual and health system levels, and included negative interactions with antenatal care providers, women's and community's lack of trust in the health system, differences in spoken language between women and professionals, cultural differences, role of family and wider networks, and difficulties in reaching care. Perceived measures to facilitate access included skill development of healthcare professionals; educating women and building awareness in the community about how to navigate the healthcare system; integration of preventative psychosocial care into maternity services and continuity of care.

Conclusions: Similarity in perceived barriers and mitigation measures indicated the potential for developing and implementing targeted cross-country interventions to facilitate timely ANC initiation for ethnic minority women in high-income European countries.

Key messages:
- Maternity care professionals in the UK and The Netherlands perceived similar barriers for ethnic minority women for timely ANC initiation.
- There is potential for developing targeted cross-country programmes and services to support mothers from ethnic minority backgrounds to start antenatal care on time.

Abstract citation ID: ckae144.1977
Cross-sectional study of bystander roles in school bullying incidents in the United Arab Emirates

Ismail Elkonaisi

I Elkonaisi[1], *A AlKetbi*[1], *AS Abdullahi*[1], *B AbuHamada*[1], *I Elbarazi*[1], *M Grivna*[1,2]
[1]Institute of Public Health, College of Medicine & Health Sciences, UAE University, Al Ain, UAE
[2]Department of Public Health & Preventive Medicine, Second Faculty of Medicine, Charles University, Prague, Czechia
Contact: i.konaisi@uaeu.ac.ae

Background: School bullying is a widespread public health issue with far-reaching consequences on the psychological well-being and academic performance of students. This study focuses on the perspective of bystanders to better understand their role in the dynamics of bullying in school environments in the United Arab Emirates.

Methods: We employed a multi-stage random sampling approach to collect data from students in grades 6 to 9 at the sample of public and private schools in Al Ain, using a validated self-report questionnaire. IBM SPSS software version 28.0 was used for the analysis using appropriate statistical tests.

Results: Out of 728 surveyed students, 290 (40%) were from private and 438 (60%) from public schools. A total of 425 (58%) of students were bystanders observing bullying incidents across all schools, with 65% of males versus 45% of females witnessing such events. Physical bullying was the most frequent type of bullying observed by 67% of students. The classroom was most often location, 75% in private schools and 61% in public schools. Verbal abuses such as making fun and name-calling were commonly reported. Bullying targeting physical appearance was particularly noted, with 31% of bystanders stating that bullying was due to perceptions of a student's face being 'funny' and 21% due to beliefs about weight. 59% felt sad, and 29% didn't go to school as a result of the bullying. Reporting to teachers was limited (25%).

Conclusions: The high prevalence of bystanders in school bullying incidents in Al Ain was observed, especially among male students. The results emphasize the critical need for comprehensive anti-bullying programs that include bystander intervention strategies to promote a supportive and inclusive educational environment.

Key messages:
- Many of students are witnessing bullying, highlighting the need for effective intervention programs.
- Empowering bystanders is crucial in preventing bullying and enhancing the safety at schools.

Abstract citation ID: ckae144.1978
Can a mindfulness programme in schools for students with ADHD symptoms improve emotional well-being?

Marianne Holopainen

M Holopainen[1,2], *M Hintsanen*[3], *J Lahti*[1], *T Vahlberg*[4], *S-M Volanen*[2,5]
[1]Psychology, University of Helsinki, Helsinki, Finland
[2]Folkhälsan Research Center, Helsinki, Finland
[3]Psychology, University of Oulu, Oulu, Finland
[4]Biostatistics, University of Turku, Turku, Finland
[5]Public Health, University of Helsinki, Helsinki, Finland
Contact: marianne.holopainen@helsinki.fi

Background: This study employs a cluster randomized controlled trial to investigate the effectiveness of a universal mindfulness-based intervention (MBI) in classrooms in improving emotional well-being and emotion regulation among adolescents with elevated ADHD symptoms.

Methods: The study comprised 342 students: 164 in an MBI group, 128 in a relaxation control group, and 47 in an inactive control group. Positive and negative emotional states and the emotion regulation strategies of rumination, acceptance, catastrophizing, positive reappraisal, and self-kindness were measured at the pre- (T0) and post-intervention (T9) and the 26-week follow-up (T26). Linear mixed models were used to analyze the intervention effects among all participants and separately by gender and ADHD symptom type.

Results: The results showed that compared to the controls, there was a beneficial effect on the MBI group concerning acceptance at T9; acceptance remained at the baseline level in the MBI group but decreased in the inactive control group. In contrast, in the inactive control group, rumination decreased at T9, and positive reappraisal increased at T26 compared to the MBI group. The MBI had no detectable effects on self-kindness, catastrophizing, or positive/negative emotional states. Findings on the emotion regulation strategies varied by gender. In boys, the MBI increased acceptance at T9 compared to the inactive control group, whereas in girls, the programme reduced catastrophizing at T9 and T26 compared to the active control group. Contrary in boys, MBI group exhibited less reduction in catastrophizing at T9 compared to the inactive control group.

Conclusions: Universal MBIs may have some beneficial effects on emotion regulation in adolescents with elevated ADHD symptoms. Both girls and boys might be responsive to universal MBIs as part of the school curriculum, however not all consequences are positive (especially in boys).

Key messages:

- Universal MBIs in classrooms may have some beneficial effects on emotion regulation among adolescent with elevated ADHD symptoms; however, the results are contradictory and more research is needed.
- Even though, universal MBIs may have some benefits, they may require modifications to lead to more beneficial effects on emotional well-being when used with this subgroup of students.

Abstract citation ID: ckae144.1979
Social support for women undergoing induced abortions in Belgrade, Serbia

Tatjana Gazibara

T Gazibara[1], *J Dotlic*[2,3], *N Maksimovic*[1], *J Maksimovic*[1], *J Bila*[2,3], *L Tulic*[2,3], *J Stojnic*[2,3], *M Miloradovic*[4], *D Plavsa*[5]

[2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[3]Clinic for Obstetric and Gynecology, University Clinical Center of Serbia, Belgrade, Serbia
[4]Institute of Hygiene and Medical Ecology, University of Belgrade, Belgrade, Serbia
[5]Department of Prevention, Institute of Public Health of Serbia, Belgrade, Serbia
Contact: tatjanagazibara@yahoo.com

Background: Having an unwanted pregnancy requires social support to help women ease the stress and stigma of having an induced abortion. The study aimed to investigate the main providers of social support to women having induced abortions.

Methods: Women undergoing induced abortions from 2022 to 2024 in a University clinic in Belgrade were invited to participate. Data were collected using an anonymous questionnaire examining socio-demographic data of women and sources of social support.

Results: This study included 433 women out of which 50.1% informed their mothers about the abortion, 23.1% their fathers, 87.3% their partners, 42.3% their friends, and 1.6% women told no one about the abortion. A total of 40% of women were supported to undergo the abortion by their parents, 80.1% by their partner, 34.9% by friends, and there were 2.1% of women who did not get any support to perform abortion. There were significantly more ($p = 0.001$) mothers (163 vs. 54), fathers (87 vs. 13), partners (331 vs. 47), and friends (136 vs. 47) who were informed about the abortion and also supported women compared to those who did not provide support. Getting support for the abortion by the parents was associated with younger age, not being in a relationship, and not having children. Support of the partner was linked to older age, higher education, being unemployed, being married with more children, and having abortions previously. Being supported by friends or not being supported at all did not correlate with socio-demographic data of the investigated women.

Conclusions: Women are generally supported by their family and friends in their decision to have induced abortions. This study identified socio-demographic factors that impact the choice of principal supporting person when undergoing induced abortion.

Key messages:

- Partners are the main source of social support for married women who had induced abortion.
- Parents are principal social supporters for single younger women undergoing induced abortion.

Abstract citation ID: ckae144.1980
Is confidence in knowledge related to childbirth fear and mode of birth among Polish women?

Patrycja Surma

P Surma[1,5], *A Micek*[2], *M Bednarek-Chałuda*[3], *K Stoll*[4], *I Nenko*[1]

[3]Department of Disaster and Emergency Medicine, Jagiellonian University Medical College, Cracow, Poland
[4]Department of Family Practice, University of British Columbia, Vancouver, Canada
[5]Doctoral School of Medical & Health Sciences, Jagiellonian University Medical College, Cracow, Poland
Contact: patrycjasurma@doctoral.uj.edu.pl

Background: In Poland, cesarean section (CS) rate is 48% what means that it is one of the highest rate among OECD countries and the highest in the European Union. WHO has considered that CS rates higher than 15% at the population level are not associated with reductions in maternal and newborn mortality rates. Fear and attitudes towards childbirth are shaped years before the first pregnancy. Yet, little is understood about how young people's knowledge, attitudes and fears concerning the birth process shape their healthcare preferences around birth. Thus, the aim of the study was to examine whether confidence in knowledge was associated with childbirth fear prior to pregnancy and preference for CS.

Methods: We recruited 782 women aged 18 - 35 (mean 24.7, $sd = 3.19$) who had never been pregnant but wished to have at least one child in the future. The women answered questions about: (i) socio-economic situation, (ii) confidence in knowledge and educational needs related to pregnancy and childbirth; (iii) fear of childbirth prior to pregnancy; (iv) preferred mode of birth in the hypothetical pregnancy in which there are no medical indications for cesarean section.

Results: Almost one in four women (22.1%) preferred CS in a hypothetical low-risk pregnancy. In addition, most often young women gained knowledge on pregnancy and birth from experiences and stories of family members (62.3%). Women with moderate and high level of confidence in knowledge had respectively lower odds of high level of childbirth fear prior to pregnancy comparing to women with low level of confidence in knowledge ($OR = 0.57$, 95% CI: 0.39-0.83 and $OR = 0.54$, 95% CI: 0.33-0.88, respectively).

Conclusions: Increasing knowledge about pregnancy and childbirth among young women might lower childbirth fear and thus, indirectly, lower rates of CS in the future.

Key messages:

- The results of this study may solve very important public health problem i.e. the growing rates of cesarean section.
- Confidence in knowledge may be an important factor associated with the level of childbirth fear.

Abstract citation ID: ckae144.1981
Association of childhood mental health and cardiovascular risk in adolescence and young adulthood

[6]Institute of Epidemiology and Social Medicine, University of Münster, Münster, Germany
Contact: bueschgesj@rki.de

Introduction: Mental health (MH), and in particular depression, is linked bi-directionally to cardiovascular disease through biological as well as behavioral pathways. Low MH has been associated with behaviors associated closely with cardiovascular risk (CVR) factors, such as reduced physical activity and sleep disturbances. It is not clear at what age the relation between MH and CVR begins to manifest and if MH in the young is also associated with vascular remodeling, operationalized as carotid-intima media thickness (CIMT).

Methods: We investigated the longitudinal association between childhood MH problems (age 3 to 17) and CVR factors as well as CIMT from carotid sonography in 4,361 14 to 28-year-olds of the KiGGS cohort. Using linear regression analyses adjusted for socioeconomic status, we analyzed the association of the Strength and Difficulties Questionnaire (SDQ) score with systolic blood pressure (SBP), body mass index (BMI), total cholesterol (TC), and CIMT in z-scores by sex and age. Additional cross-sectional analyses included scores of the Mental Health Inventory (MHI-5) and Patient Health Questionnaire (PHQ-9) in young adulthood.

Results: Childhood SDQ scores were significantly associated with SBP, BMI and TC one decade later ($-0.03 \leq ß \geq 0.02$). Cross-sectionally, no association of MHI-5 scores in young adults with CVR factors was found. PHQ-9 scores in young adults were associated significantly with SBP and BMI ($-0.26 \leq ß \geq 0.01$). The investigated MH problems from childhood to young adulthood were not linked to CIMT.

Conclusions: Our results confirm an early association of MH with the examined CVR factors. However, we could not find evidence for an association between MH and vascular remodeling in this population-based sample of adolescents and young adults. Our results emphasize the importance of prevention strategies focusing on both, physical and MH of the young, in order to prevent vascular damage later in life.

Key messages:

- Our results show an early association of childhood mental health with the examined cardiovascular risk factors systolic blood pressure, body mass index and total cholesterol one decade later.
- Our results confirm the importance of prevention strategies focusing on both, physical and mental health of the young.

Abstract citation ID: ckae144.1982
Prescribing contraceptives to minors without parental knowledge and consent

Maya Peled-Raz

M Peled-Raz[1], *O Goldstick*[2]
[1]School of Public, University of Haifa, Haifa, Israel
[2]Haifa and Western Galilee District, Clalit Health Services, Haifa, Israel
Contact: meraz@netvision.net.il

Background: Sexually active adolescents may seek oral contraceptives without parental consent, posing challenges due to minors' confidentiality and consent regulations. This is especially the case under the un-nuanced Israeli legal scheme regarding adolescents' care.

Methods: Israeli OBGYNs were contacted through mailing lists and social media groups and asked to fill an online questionnaire regarding their experience and protocols concerning prescription of contraceptives to minors. They were also asked about their comprehension of the relevant legal obligations, the importance they ascribe to different ethical interests and considerations, as well as their training.

Results: Of the 177 responding gynecologists, 75% consulted minors about contraceptives during the past year, most of them without any training on providing care to adolescents. More than a third of respondents believed that parental involvement wasn't legally required, while only 8% thought it mandatory for all minors under the age of 18. Most (75%) would 'almost always' prescribe contraceptives without parental knowledge upon request, while 20% never would. No correlation was found between respondents' practices and their perception of the legal obligations. Participants agreed that the risk to the health of the minor due to having sex without contraceptives is of utmost importance. Those willing to prescribe gave greater weight to minor's autonomy consideration, while those who do not prescribe were more concerned with the acts legal ramifications. The majority set the age of 15 as the threshold for consistently prescribing contraceptives to minors without parental involvement.

Conclusions: Access to contraceptives for mature minors without parental involvement is vital. There is great need for education and training for healthcare providers on providing medical treatment to adolescents, as well as for the development of policies and guidelines, addressing adolescents' health disparities.

Key messages:

- Israeli legal requirements challenge and hinder adolescents' care as well contradict OBGYNs ethical and professional beliefs.
- There is great need for education and training, as well as for the development of policies and guidelines, addressing adolescents' health disparities.

Background: Accumulating evidence suggests that phthalate exposure affects neurodevelopment, including emotional and behavioral outcomes. Our aim was to investigate if prenatal phthalate exposure affects the developmental course of internalizing and externalizing symptoms from early childhood to adolescence.

Methods: Concentrations of seven phthalate metabolites were measured in first-trimester maternal spot urine samples, and DEHP, and high and low molecular weight phthalate concentrations were calculated (HMW and LMW, respectively). Mothers reported internalizing and externalizing symptoms via the Strengths and Difficulties Questionnaire at 4 years and the Child Behavior Checklist at 6, 11 and 15 years. Group-Based Trajectory Modeling was used to classify 546 participants of the Rhea Cohort (Crete, Greece) into 4 distinct groups (Stable low, Stable high, Low-Increasing, and High-Decreasing symptoms). We evaluated the association of prenatal phthalate exposure with the odds of an adverse (Stable high, Low-Increasing, and High-Decreasing) internalizing and externalizing symptom trajectory in 150 children using multivariable-adjusted logistic regression (reference group: stable low).

Results: Only for girls, exposure to DEHP and HMW phthalates was associated with higher odds of being grouped in an adverse internalizing symptoms trajectory (OR [95%CI]: 1.52 [1.03, 2.25] and 1.57 [1.03, 2.39], respectively). Regarding externalizing symptoms, interactions with gender emerged for DEHP ($p = 0.024$) and HMW ($p = 0.028$) phthalates, and increased odds of being grouped into an adverse trajectory were observed in girls, whereas boys showed the opposite trend, albeit none reached statistical significance.

Conclusions: The findings suggest programming effects of prenatal phthalate exposure on the developmental course of emotional symptoms in girls. Further research is needed to clarify the association between in utero phthalate exposure and behavioral symptoms.

Key messages:

- Phthalate exposure is linked to adverse trajectories of emotional symptoms, emerging from preschool age and up to adolescence.
- Phthalate effect on internalizing and externalizing symptoms varies by gender.

Youth insights on a digital crowdsourcing intervention to reduce HIV stigma in Kazakhstan

Yi Yihang Sun

Y Sun[1], SE Landers[1], S Yang[1], G Mergenova[2], L Sarsembayeva[2], O Balabekova[2], A Davis[1]
[1]School of Social Work, Columbia University in the City of New York, New York, USA
[2]Global Health Research Center of Central Asia, Almaty, Kazakhstan
Contact: ys3514@columbia.edu

Background: In Kazakhstan, nearly a quarter of new HIV infections occur among adolescents and young adults (AYA). Testing can reduce the spread of HIV, yet AYA have low testing rates in Kazakhstan, due in part to HIV-related stigma. This qualitative paper explores participants' perceptions of digital crowdsourcing content designed to reduce HIV stigma and promote HIV self-testing among AYA in Kazakhstan.

Methods: We conducted semi-structured interviews with 20 AYA who participated in a digital crowdsourcing intervention. Questions focused on AYA's perceptions of the crowdsourced content they viewed for the intervention, namely their likes, dislikes, the perceived impact of the content, and areas for improvement. Qualitative data analysis was conducted using a thematic approach.

Results: Findings revealed a perceived need for more youth-developed digital interventions. AYA favored artistic, interactive content featuring health specialists, youth characters, or real-life stories. Short videos and images were AYA's favorite content formats. Many AYA showed less interest in longer videos and text-heavy content, finding them hard to understand. Most participants reported improved knowledge of HIV, reduced stereotypes related to HIV, heightened interests in HIV topics, more willingness to get tested, and changes of attitudes towards people living with HIV. Recommendations for future interventions include tailoring content to different AYA age groups and creating more engaging and easily digestible content.

Conclusions: This study highlights the potential of crowdsourced digital interventions in promoting HIV knowledge and awareness of HIV-related stigma among AYA in Kazakhstan. AYA appreciated youth-developed, interactive content that included real-life stories and artistic visual presentations.

Key messages:

- This study highlights the potential of crowdsourced digital interventions in promoting HIV knowledge and awareness of HIV-related stigma among AYA in Kazakhstan.
- AYA appreciated youth-developed, interactive content that included real-life stories and artistic visual presentations.

Abstract citation ID: ckae144.1985
Anemia in pregnancy and adverse maternal health outcomes - birth-registry based study from Georgia

Natia Skhvitaridze

N Skhvitaridze[1,2,3], A Gamkrelidze[1], T Manjavidze[1,2,3], T Brenn[2], E Anda[2], C Rylander[2]
[1]Global and European Health Education and Study, The University of Georgia, Tbilisi, Georgia
[2]Department of Community Medicine, UiT The Arctic University of Norway, Tromso, Norway
[3]National Center for Disease Control and Public Health, Tbilisi, Georgia
Contact: natiaskh@yahoo.com

Anemia in pregnancy is an important public health challenge; however, it has not been thoroughly studied in Georgia. We assessed the prevalence of anemia during pregnancy across Georgia and the association between anemia in the third trimester of pregnancy and adverse maternal outcomes. We used data from the Georgian Birth Registry and included pregnant women who delivered between January 1, 2019, and August 31, 2022 ($n = 158{,}668$). The prevalence of anemia (hemoglobin (Hb) < 110 g/L) at any time during pregnancy was calculated per region. Women in the third trimester were classified into three groups, based on their lowest measured Hb value: no (Hb ≥ 110 g/L, reference group); mild (Hb 100-109 g/L); and moderate to severe anemia (Hb < 99 g/L). Adjusted odds ratios (aOR) with 95% confidence intervals (CIs) were calculated for the associations between anemia status and post-delivery intensive care unit (ICU) admission and preterm delivery. The prevalence of anemia occurring at least once during pregnancy was 40.6%, with large regional differences in anemia prevalence (25.1%-47.0%). Of 105,811 pregnant women with Hb measurements in the third trimester, 71.0% had no anemia; 20.9%, mild anemia; and 8.1%, moderate or severe anemia. The odds of post-delivery ICU admission did not increase linearly with decreasing Hb value (P for trend .13), and the relationship was inverse for preterm delivery (P for trend .01).

Key messages:

- A considerable proportion of pregnant women in Georgia have anemia during pregnancy, and the prevalence and quality of reporting differ across regions.
- To accelerate national progress toward the SDGs and mitigate the consequences of anemia, equal countrywide access to high-quality ANC programs and complete registration of Hb values should be ensured.

Abstract citation ID: ckae144.1986
Professional support for children or adolescents whose mental well-being is at risk

Tiina Putkuri

T Putkuri[1,2], I Latva-Korpela[1], M Häkkinen[1]
[1]Laurea University of Applied Sciences, Vantaa, Finland
[2]Department of Nursing Science, University of Turku, Turku, Finland
Contact: tiina.putkuri@laurea.fi

Background: Children and adolescents' mental health issues are globally among the most significant concerns. Research on the topic often focuses on already manifested mental health problems, and research concerning mental well-being and the preferences of service users regarding early-stage support is scarce. This study aimed to define what professional support experts-by-experience hope for a child or adolescent in situations where mental well-being is threatened.

Methods: The qualitative study with focus group interviews was conducted in Finland during the autumn of 2022. Participants ($n = 26$) were experts-by-experience who had experienced threats to mental well-being either during their own childhood (before the age of eighteen years) ($n = 19$) or through the perspective of being a parent (n = 3), or both (n = 4). The data was analyzed using inductive content analysis.

Results: In situations where the mental well-being of children or adolescents is at risk, professionals working with families were expected to 1) demonstrate an appreciative and compassionate attitude, 2) provide a daycare environment or school environment that supports mental well-being, 3) support the participation of children and adolescents, 4) involve and support family, 5) organize peer support, and 6) provide services that are seamless and need-adapted.

Conclusions: The results help to develop services supporting mental well-being, considering the perspective and preferences of service users. During the study, one model identified to meet the participants' desires was the Open Dialogue Approach originally developed in Finland.

Key messages:

- In services supporting mental well-being, ensuring the child's or adolescent's participation and involving parents is important.
- In addition to the support provided by professionals, the significance of peer support was highlighted. Professionals should actively refer service users to peer support.

Abstract citation ID: ckae144.1987
Maternal health in conflict-affected settings: a case study from a frozen conflict zone

Anya Agopian

A Agopian[1], L Musheghyan[1], Z Sargsyan[1], D Abrahamian[2], A Dorian[2]
[1]College of Health Sciences, American University of Armenia, Yerevan, Armenia
[2]Fielding School of Public Health, University of California, Los Angeles, USA
Contact: aagopian@aua.am

Background: Reproductive, maternal, newborn and child health are negatively impacted in conflict-affected settings, and may be acutely affected in frozen conflicts due to fragile health systems and uncertain geopolitical contexts. To better understand maternal health in a frozen conflict zone, we examined maternal health outcomes in Nagorno-Karabakh during a ceasefire period prior to the forced displacement of the entire population.

Methods: Multistage cluster sampling was used to sample 1023 households in Nagorno-Karabakh during the summer of 2022. From each household, one woman, age 18 to 49, participated in an interviewer-administered survey. Maternal health outcomes were assessed among all married women who had ever given birth. Women with at least one child under 5 years were also asked about their most recent pregnancy.

Results: Among all married women, 85.5% had ever given birth, 19.0% ever had a miscarriage, and 2.8% ever had a stillbirth. Of the 299 women with at least one child under 5, 97.7% received antenatal care, of which 90.4% had at least 4 visits. Over half experienced toxicosis (51.8%), 16.4% high blood pressure, 13.0% anemia, and 6.4% hemorrhage during their most recent pregnancy. The most common delivery complications were uterine scarring (19.7%), breached birth (7.0%), prolonged labor (6.4%) and hemorrhage (5.7%). Age was found to be a significant factor, with the odds of toxicosis ($p = 0.039$) and breached birth ($p = 0.009$) decreasing, yet the odds of miscarriage ($p = 0.001$) and hypertension ($p = 0.007$) increasing with age.

Conclusions: Almost all women reported adequate antenatal care with birth outcomes comparable to global statistics, demonstrating the ability of Nagorno-Karabakh to provide sufficient maternal healthcare while in a frozen conflict. Fortifying and ensuring access to maternal and reproductive healthcare, particularly antenatal care, is vital for ensuring the health and wellbeing of women and children in conflict-affected settings.

Key messages:

- Women in Nagorno-Karabakh received antenatal care and experienced birth outcomes similar to global rates, demonstrating the value of access to reproductive healthcare in conflict-affected settings.
- Future studies should examine the impact of forced displacement on the women of Nagorno-Karabakh to better understand the effect of conflict on reproductive and maternal health.

Abstract citation ID: ckae144.1988
Harming the innocent: estimating the number of children affected by parental problem gambling

Andreas Bickl

A Bickl[1], N Stefan[1,2,3], S Buth[4], L Schwarzkopf[1,2,3]
[1]Bavarian Coordination Centre for Gambling Issues, IFT - Mental Health & Addiction Research, Munich, Germany
[2]IBE - LMU, Institute for Medical Information Processing, Biometry, and Epidemiology, Munich, Germany
[3]Pettenkofer School of Public Health, Munich, Germany
[4]ISD, Institute for Interdisciplinary Addiction and Drug Research, Hamburg, Germany
Contact: bickl@ift.de

Background: The impact of parental problem gambling on children and adolescents encompasses negative outcomes in psychological, financial, behavioral, physical health, and family relationship domains. For Germany, estimates on the number of co-affected minors are lacking.

Methods: Within the population-representative Germany-wide "Glücksspielsurvey 2023" (i.e., "Gambling Survey 2023"), we assessed parenthood in survey participants with gambling disorder (GD; according to DSM-5) as well as the number of minors (age <18 years) living a) together with a person with gambling disorder (shared household) or b) apart from a parent with gambling disorder (separate household). Using a "minimum maximum approach," we performed a weighted extrapolation to estimate the number of co-affected minors in the German resident population (range 18 to 70 years of age) and the prevalence of parental GD among Germany-residing minors.

Results: 46.8% (n = 132) of survey participants with GD report shared households with minors and 16.3% (n = 46) separate households. The average number of minors concerned was 1.55 (SD = 0.07) in shared and 1.51 (SD = 0.13) in separate households. This translates into 480,294 to 701,766 co-affected children in shared households (3.4% to 4.9% of Germany-residing minors) and 91,742 to 124,618 co-affected children in separate households (0.6% to 0.9% of Germany-residing minors).

Discussion and conclusions: Taking shared and separate households into account, one in 20 Germany-residing minors is co-affected by parental GD. Acknowledging that impaired psychosocial wellbeing in the context of parental GD could persist into adulthood of co-affected minors, this issue ought to be recognized as a major public health concern. To reduce related harm, children of people with GD should be best possibly integrated into the care process by offering additional help and support strategies explicitly addressed at this vulnerable population.

Key messages:

- Parental problem gambling significantly impacts a substantial portion of German minors, with approximately one in 20 being affected, highlighting the urgent need for attention to this issue.
- Recognizing parental gambling's long-term impact on minors, it's crucial to implement support strategies in care to address their needs effectively.

Abstract citation ID: ckae144.1989
Longitudinal analyses (2018-2022) of the COVID-19 impact on Swiss pediatric healthcare utilization

Julia Dratva

M Dey[1], *M von Rhein*[2], *T Volken*[1], *A Chaouch*[3], *U Laasner*[4], *M Seiler*[2], *J Dratva*[1,5]

[4]Professional Association of Swiss Pediatricians in Private Practice, Dietikon, Switzerland
[5]Medical Faculty, University of Basel, Basel, Switzerland
Contact: julia.dratva@zhaw.ch

Background: The impact of COVID-19 on healthcare utilization in the early pandemic is well documented. However, studies on changes in both primary and tertiary pediatric healthcare utilization that considered data beyond the first pandemic year is lacking.

Methods: National health insurance data (primary care) and pediatric emergency department data (tertiary care) from Jan. 2018 - June 2022 and on 0-18-year-olds were analyzed with interrupted time series. The first lockdown was used to differentiate between pre-pandemic and pandemic periods.

Results: Several healthcare services yielded significantly lower average utilization rates during the pandemic vs. the pre-pandemic period, particularly in the youngest age groups. In primary care, the relative utilization, compared to the pre-pandemic mean, dropped in regards to regular (0-5y: 0.760 [0.644-0.896]; 6-10y: 0.850 [0.742-0.974]), well-child (0-5y: 0.871 [0.765-0.992]), and urgent visits (0-5y: 0.638 [0.500-0.813]; 6-10y: 0.810 [0.665-0.985]), and for the vaccination against measles/mumps/rubella (MMR; 0-5y: 0.841 [0.729-0.971]). Similarly, in tertiary care, this pattern emerged for non-urgent (Zurich: 0.55 [0.482-0.627]; Geneva: 0.526 [0.435-0.636]; Ticino: 0.502 [0.436-0.578]) and urgent visits (Zurich: 0.573 [0.498-0.659]; Geneva: 0.487 [0.375-0.632]; Ticino: 0.676 [0.57-0.802]). The utilization rates of most services dropped markedly after the lockdown and recovered to some extent over the pandemic phase. However, no recovery was found for the MMR-vaccination. In primary care, higher average utilization rates during the pandemic were identified for telephone consultations (0-5y: 1.394 [1.218-1.594]; 6-10y: 1.547 [1.387-1.726]; 11-15y: 1.578 [1.430-1.741]; 16-18y: 1.831 [1.614-2.076]).

Conclusions: The pandemic's effect on utilization seemed to have occurred temporarily, but it cannot be ruled out that some children have not fully caught up on preventative measures (well-child visits and MMR-vaccinations).

Key messages:

- Pediatric healthcare utilization dropped considerably immediately after the lockdown, with the most pronounced decrease observed in the youngest children.
- The heterogenous recovery over the pandemic period points to the necessity to continue to monitor utilization rates, catch-up visits, and vaccination statistics.

Abstract citation ID: ckae144.1990
Generalised and visceral obesity metrics and ankle-brachial systolic blood pressures during pregnancy

Konstantinos Giannakou

K Giannakou[1], *G Fakonti*[2], *M Kyprianidou*[1], *H Viswambharan*[2], *K Kain*[3]
[1]Department of Health Sciences, European University Cyprus, Nicosia, Cyprus
[2]LICAMM, University of Leeds, Leeds, UK
[3]NHS England, NHS Improvement, Leeds, UK
Contact: K.Giannakou@euc.ac.cy

Background: Increased body mass index (BMI) (generalised obesity) and waist-to-height ratio (WHtR) (visceral obesity) are associated differently with brachial and ankle blood pressures in the general population. Ankle blood pressures are associated with blood glucose in pregnancy. This study investigates the relationship between BMI and WHtR with the brachial and ankle blood pressures separately during pregnancy.

Methods: Pregnant women were recruited during antenatal visits at an antenatal clinic in Bradford Royal Infirmary, UK, and their BMI, waist circumference, systolic, and diastolic blood pressure were clinically measured by staff in the second trimester. Additionally, blood pressure readings from both arms (left and right brachial arteries) and ankles [dorsalis pedis artery (DP) and posterior tibial artery (PT) on both sides] were obtained using Doppler by research staff.

Results: A total of 179 women participated, with an average BMI of 28.5 Kg/m2 (SD = 4.97) and average WHtR of 0.61 (SD = 0.08). BMI exhibited a positive correlation with all blood pressure measurements ($r = 0.165$ to 0.419, $p < 0.05$), while WHtR demonstrated significant correlations only with the right brachial, left PT, systolic and diastolic blood pressures (r: 0.170 to 0.271, $p < 0.05$). Moreover, BMI significantly associated with all blood pressure measurements in linear regression models, after adjusting for various sociodemographic and other factors, whereas WHtR significantly predicted only right brachial and left PT and some of the other blood pressure measurements.

Conclusions: BMI, and to a lesser extent WHtR, are associated with both brachial and ankle blood pressure measurements during pregnancy. These findings underscore the importance of recognizing the varying impacts of cardiometabolic risk factors for early detection and management of potential complications in pregnancy and the postpartum period.

Key messages:

- BMI & WHtR are associated differently with brachial and ankle blood pressures in pregnancy.
- Further exploration of combined non-invasive measurements like BMI, WHtR, brachial, and ankle blood pressures in early pregnancy for gestational diabetes mellitus and other co-morbidities is needed.

Abstract citation ID: ckae144.1991
Long-term effects of unintended pregnancies carried to term on mothers and children

Wieke Beumer

WY Beumer[1,2], *MH Koot*[1,2], *T Vrijkotte*[3], *TJ Roseboom*[2], *J van Ditzhuijzen*[1,4]
[1]Obstetrics & Gynecology, Amsterdam UMC, Amsterdam, Netherlands
[2]Epidemiology & Data Science, Amsterdam UMC, Amsterdam, Netherlands
[3]Public & Occupational Health, Amsterdam UMC, Amsterdam, Netherlands
[4]Interdisciplinary Social Science, Utrecht University, Utrecht, Netherlands
Contact: w.beumer@amsterdamumc.nl

Background: Research on psychological effects of unintended pregnancies that are carried to term presents mixed results, and evidence on long-term associations is scarce. The aim of the current study was to examine effects of unintended pregnancies carried to term on both mothers and children, up to 16 years postpartum.

Methods: This study is based on the Dutch population-based birth cohort study 'Amsterdam Born Children and their Development' (ABCD-study), which included pregnant people in 2003 (n = 7784) and is still following these mothers and their children. Structural Equation Models were analyzed per time-point, examining associations between unintended pregnancy and maternal psychosocial distress, and children's internalizing- and externalizing problems, while controlling for co-occurring risks. Further, mediating effects via maternal mental health and bonding on children were assessed.

Results: Around 5 years postpartum, pregnancy mistiming was positively associated to maternal psychological distress. Antenatal psychological distress was a much stronger predictor of maternal psychological distress than unintended pregnancy. Pregnancy mistiming was a significant predictor of internalizing and externalizing problems and unwanted pregnancy of internalizing problems in the children from these pregnancies, around 5 years postpartum. These associations were mostly mediated by maternal mental health and poorer maternal bonding. All associations were no longer present at 12 and 16 years postpartum.

Conclusions: Unintended pregnancies often coincide with maternal mental health problems, and results showed that associations between unintended pregnancy and both mother's and children's psychosocial problems are strongly influenced by maternal mental health. Therefore it is important to improve maternal mental health for the benefit of both mother and child, rather than on the isolated effect of unintended pregnancy.

Key messages:

- Carrying an unintended pregnancy to term impacts psychological health in both mothers and their children up to 5 years but no longer at 12 or 16 years postpartum.
- The effects of unintended pregnancy on psychological health in mothers and children are mostly explained by maternal mental health and bonding, so the focus should be on improving these.

Abstract citation ID: ckae144.1992
Mixed-method study of women's experiences of Respectful-Disrespectful Maternity Care in Cyprus

Nicos Middleton

N Middleton[1,2], *I Papairaklidiou*[1], *M Kapsou*[1,3], *E Hadjigeorgiou*[1], *P Kinni*[1], *M Karanikola*[1], *C Nicolaou*[1], *O Kolokontroni*[1,2], *& RESPECT project team*[4]
[1]Department Nursing & Cyprus International Institute, Cyprus University of Technology, Limassol, Cyprus
[2]Birth Forward, Scientific Advisory Board, Nicosia, Cyprus
[3]Birth Forward, Nicosia, Cyprus
[4]RESPECT, EU CERV-Daphne Programme, Limassol, Cyprus
Contact: nicos.middleton@cut.ac.cy

Background: Since the WHO reports on Disrespect and Abuse (D&A) in childbirth, there was an increase in studies across Europe exploring women's experiences. Even though contentious, a 2024 EU Committee report adopts the term obstetric violence. With the highest caesarean section (C/S) in the EU, the birth environment in Cyprus raises questions about informed choices.

Methods: The RESPECT mixed-method study gained insights into the experiences of women in Cyprus with focus groups ($N = 6$, 28 women) and survey (online and in-person) tapping on Rights for Respectful Maternity Care (RMC), as measured by Person-Centred Maternity Care scale (PCMC), autonomy in decision making (MADM), dignity and respect (MoRi) and mistreatment (MIST).

Results: Among 516 responses (61% first childbirth, 38.5% vaginal, 15% public sector, consistent with official statistics), the 35-item PCMC (range 0-100%) represents a continuum of quality standards deviations (Med=81, IQR=61-92). Lowest scores were recorded for "Communication & Autonomy", with 28.5% reporting 'feeling pushed into a decision', with associations observed with younger age, first-time birth, mode and place of birth, highlighting social inequity. Based on MADM, 23.8%, 14.1% and 14.7% women were classified as having moderate, low or very low autonomy. For mistreatment, 32.0% reported at least one of 11 indicators, most commonly privacy violations and no freedom of movement. Formula feeding against wishes (13.6%), vaginal examinations (11.6%) and episiotomy (7.8%) where most common among 33.7% reporting procedures without consent. Deductive content analysis of narratives according to RMC triangulate findings of weak shared decision-making processes.

Conclusions: Given that C/S reduction was identified as a national priority in Cyprus, the RESPECT findings can widen the conversation about quality improvement and form the basis to engage with local stakeholders in an open-dialogue about RMC, guided by participatory action research principles.

Key messages:

- In the medicalized birth environment of Cyprus, women report a range of sub-optimal practices, with ethical implications, primarily affecting the right to autonomy.
- Adopting the Respectful Maternity Care framework, the findings can stimulate and shape quality improvement efforts in a participatory and inclusive process with local stakeholders.

Abstract citation ID: ckae144.1993
Impact of Adverse Childhood Experiences on Child Development in South America: A Systematic Review

Sara Cooklin Urbano

S Cooklin Urbano[1], *L Hurt*[1], *L Copeland*[2]
[1]Cardiff University, School of Medicine, Cardiff, UK
[2]Cardiff Metropolitan University, Cardiff School of Sport & Health Sciences, Cardiff, UK
Contact: sara.cooklin@gmail.com

Background: Adverse Childhood Experiences (ACEs) have garnered attention globally for their detrimental effects on children's development, such as lower communication, gross and fine motor, and personal-social domains. While extensively studied in high-income countries, there remains a gap in understanding their prevalence and impact in low- and middle-income countries (LMICs). This review aimed to identify, evaluate, and summarize the findings of an association between ACEs and children's developmental and mental health outcomes in South America

Methods: A systematic review was conducted to investigate the association between ACEs and childhood development in South America. Databases MEDLINE, PsycINFO, Web of Science, Applied Social Sciences Index and Abstracts, Literatura Latino Americana em Ciências da Saúde, IBECS and CINAHL were searched. Selection criteria encompassed studies from Brazil, Colombia, Argentina, Peru, Venezuela, Chile, Ecuador, Bolivia, Paraguay, Uruguay, Guyana and Suriname examining the effects of ACEs on developmental outcomes and mental health disorders in children under 18 years old. Quality assessment aligned with World Health Organization standards was employed.

Results: Twenty-four studies met the inclusion criteria, with most categorized as low or very low quality. While the majority demonstrated a significant association between ACEs and developmental or mental health outcomes, a few studies reported null findings. Challenges in study quality, such as small sample sizes and selection bias, were identified.

Conclusions: Despite limitations in study quality, findings underscore the impact of ACEs on child development and mental health in South America. Because of the low quality of the existent studies the next steps should be to grasp a greater understanding of the issue. This review also highlights the urgency for further research and targeted interventions to mitigate the long-term consequences of ACEs in this region.

Key messages:

- ACEs profoundly affect child development and mental health in South America, necessitating urgent attention and intervention.
- Addressing the impact of ACEs in South America is critical for fostering healthier developmental trajectories and enhancing public health outcomes.

Using diversity, equity and inclusion school practices to mitigate child health inequities in Canada

Camila Honorato Albuquerque Torres

C Honorato Albuquerque Torres[1,2]*, J Dabravolskaj*[2,3]*, PJ Veugelers*[1]*, K Maximova*[2,3]
[1]School of Public Health, University of Alberta, Edmonton, Canada
[2]MAP Centre for Urban Health Solutions, Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada
[3]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada
Contact: honorato@ualberta.ca

Background: The burden of unhealthy lifestyle behaviours and mental disorders disproportionately affects children in deprived neighbourhoods. In Canada, school practices addressing diversity, equity and inclusion (DEI) are promoted to address such inequities. We aimed to assess whether DEI school practices can help mitigate the impact of neighbourhood deprivation on children's lifestyle behaviours and mental health.

Methods: In 2023 we gathered survey data from 1497 grade 4-6 children (aged 9-12) in 22 elementary schools located in deprived neighbourhoods in Alberta, Canada. Children reported their diet, screen time, physical activity, and mental health. Principals reported on the implementation of DEI practices in schools (full vs. partial). School postal codes were used to derive tertiles of the Canadian Index of Multiple Deprivation, comprised of four dimensions that capture: 1) residential instability; 2) economic dependency; 3) ethno-cultural composition and 4) situational vulnerability of neighbourhoods.

Results: Overall, 45% of schools had fully implemented DEI practices. These schools were located in more deprived neighbourhoods for residential instability (55%), economic dependency (71%), ethno-cultural composition (60%), and situational vulnerability (64%). Children in more deprived neighbourhoods reported more sugar consumption, more screen time, and poorer mental health, compared to children in less deprived neighbourhoods. However, in those neighbourhoods where DEI practices were fully implemented, the adverse effects of neighbourhood deprivation were alleviated, whereby children reported less sugar consumption, less screen time, and better mental health.

Conclusions: The implementation of DEI school practices can help mitigate the adverse effects of neighbourhood deprivation on children's physical and mental health, particularly in deprived neighbourhoods.

Key messages:

- School practices targeting diversity, equity, and inclusion are more commonly implemented in schools located in deprived neighbourhoods.
- Diversity, equity, and inclusion school practices mitigate the adverse effects of neighbourhood deprivation on children's lifestyle behaviours and mental health.

[2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy
Contact: vincenza.gianfredi@unimi.it

Background: The COVID-19 pandemic led to widespread disruptions in educational systems globally, forcing a transition to remote learning modalities. This systemic change raised concerns about its potential impact on the academic performance of students in developmental ages. This systematic review and meta-analysis aimed to evaluate the association between the COVID-19 pandemic and academic performance among developmental-age students, quantifying the effect size using Cohen's d.

Methods: We searched PubMed/MEDLINE, Scopus, and Embase for studies published up to December 2023 that assessed the impact of the COVID-19 pandemic on academic performance. The review was performed following the PRISMA 2020 guidelines. The quality of the included studies was evaluated using the Newcastle-Ottawa Scale. The pooled effect size was calculated using Cohen's d, with its 95% confidence interval. The protocol has been registered in PROSPERO.

Results: Out of 3671 retrieved articles, 30 studies met the inclusion criteria, and 13 were suitable for meta-analysis, involving a combined total of 4,893,499 students. The Cohen's d was -0.07 (95% CI = -0.10 to -0.03; $p < 0.001$), indicating a small but statistically significant decline in academic performance associated with the pandemic. Subgroup analyses revealed that mathematics suffered the most significant impact, with a Cohen's d of -0.14 (95% CI = -0.18 to -0.10; $p < 0.001$). All the included studies were judged as moderate-high quality.

Conclusions: The COVID-19 pandemic has had a negative effect on the academic performance of students of developmental ages, particularly in mathematics. These findings highlight the need for targeted interventions to mitigate the educational setbacks caused by the pandemic, especially in core subjects where the decline in performance was most pronounced.

Key messages:

- The COVID-19 pandemic has significantly disrupted educational systems worldwide, resulting in a small but statistically significant decline in academic performance among students of developmental ages.
- The shift in educational delivery during the pandemic particularly affected learning outcomes in mathematics more than in other subjects.

Abstract citation ID: ckae144.1996
The influence of education on antenatal care and nutrition of newborns in Croatia

Maja Maric-Bajs

M Maric-Bajs[1]*, A Puljak*[1]*, D Bajs*[2]
[1]Public Health Service, Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia
[2]School of Medicine, University of Zagreb, Zagreb, Croatia
Contact: maja.maric-bajs@stampar.hr

Background: Previous studies indicate differences in the nutrition of newborns. Great efforts are invests in public health education of expectant mothers in order to improve the health of their offspring.

Methods: An analytical study of data on the influence of social factors and the level of education of mothers on the nutrition of newborns, habits of pregnant women and antenatal care in the City of Zagreb was conduct in 2022. The paper shows analytical results expressed in percentages of the prevalence and 95% confidence interval (CI).

Results: The survey covered 6,358 women giving birth in the City of Zagreb in 2022. Most mothers fed their newborns in the hospital with breast milk (48.6%) or a combination of breast milk and artificial nutrition (45.8%), and only 1.4% with artificial nutrition. The share of mothers who fed their newborns exclusively with breast milk is slightly higher among highly educated women (52.4%). The majority of women had their newborn's first feeding within one hour (81.4%), also more often in highly educated women. The first breastfeeding is most often ten (10.1%) or 15 minutes after birth (8.2%). Only 1.1% of pregnant women smoked during pregnancy, of which the largest share was women with a high school diploma (62.1%). With the increase in education, the share of women with 5 or less antenatal checks decreases (completed college 3.3%, higher school 4.6%, secondary school 6.6%, primary school 12.7%). The largest share of pregnant women who had their first antenatal examination only after 10 weeks of pregnancy is among women with a high school diploma (11.3%).

Conclusions: The education of pregnant women influenced their adoption of positive lifestyle habits, the need for timely and regular antenatal care and the benefits of feeding newborns with breast milk. Additional education through public health campaigns aimed at pregnant women and future parents as well as breastfeeding support groups need to be continuously implement.

Key messages:

- The education of pregnant women influenced their adoption of positive lifestyle habits, the need for timely and regular antenatal care and the benefits of feeding newborns with breast milk.
- Additional education through public health campaigns aimed at pregnant women and future parents as well as breastfeeding support groups need to be continuously implement.

Abstract citation ID: ckae144.1997
It must not be dangerous to talk about it! Parents views of communication with schoolnurses on weight

Caroline Skantze

C Skantze[1], *G Almqvist-Tangen*[2], *M Nyholm*[1], *S Karlsson*[1,3]
[1]School of Health and Welfare, Halmstad University, Halmstad, Sweden
[2]Department of Paediatrics, University of Gothenburg, Gothenburg, Sweden
[3]Faculty of Health Science, Kristianstad University, Kristianstad, Sweden
Contact: caroline.skantze@hh.se

Background: The study aimed to describe parents' experiences of communication with school nurses concerning the growth data and weight development of their children aged 8 and 10 years old in Sweden.

Methods: The design was descriptive and qualitative. 15 women and 3 men in south Sweden were included, with children who had performed health visits in the School Health Service (SHS). Data were collected through in - person semi structured interviews. Qualitative content analysis was used.

Results: The results illustrated the health visit's purpose as unclear with need for improved dialogue and lacking feedback from the SHS. "To be able to get guidelines of what is the normal growth and what is a normal deviation and maybe a bit more about diet and lifestyle and movement." The need for an improved channel for receiving information from SHS, and access to their child's growth data. "Couldn't they have a school nurse site or information page, where you get information about your child from the day they enroll in school until they leave." Parents experienced a lack of a child-centered perspective, described the child's context as not in focus, and desired collaboration. "I think that it is very important that children feel good in their bodies, and that is a really important task for health care."

Conclusions: (a) Initiating a discussion regarding the preventive health work of school nurses and the main assignment of SHS. (b) Development of a child-centered perspective towards parents and children with focus on the child's entire social context. (c) Implementation of evidence-based methods for communicating growth data and weight development between SHS and parents.

Key messages:

- An increased dialogue between parents and SHS was requested, with a reachable way of communication via a digital platform.
- A holistic view of the child, with positive professional attitudes seem essential to meet the needs of the child.

Abstract citation ID: ckae144.1998
Influence of socio-economic factors on obstetric morbidity in Eastern India: A study based on NFHS 5

Nilanjana Gupta

N Gupta[1], *P Raj*[1]
[1]Department of Humanities and Social Sciences, Indian Institute of Technology Patna, Patna, India
Contact: guptanilanjana123@gmail.com

Background: Obstetric morbidity encompasses health issues related to pregnancy or childbirth, excluding accidental causes. The whole process of childbearing is not just a biological phenomenon, rather it is governed by personal, social, cultural, and institutional factors. The entire eastern region of India including the four provinces of Bihar, Jharkhand, Odisha, and West Bengal is susceptible to high maternal mortality and morbidity. It presents a strong background to further envisage the factors responsible for such situation. Thus, the study aims to explore regional variations and socio-economic factors associated with obstetric morbidity among women in eastern India.

Methods: This study uses data from the 2019-2021 National Family and Health Survey (NFHS 5). The explanatory variable, obstetric morbidity, includes issues during pregnancy and delivery- vision difficulties, bleeding, swelling, convulsions, fever, breech presentation, and prolonged labor. Predictor variables include age, age at marriage and first birth, wealth index, residence, toilet facility, caste, working status, media exposure, religion, birth order, and education level. Bivariate and binary logistic regression analyses have been used as a methodological tool.

Results: In the eastern region, 53.76% women experience obstetric issues. Women belonging to 15-24 years with higher educational attainment increases the prevalence of obstetric morbidity. The probable reason is, with education, awareness about reproductive morbidity increases and in turn the reporting for morbidity increases. Therefore, the findings showed age, educational attainment, wealth quintile, media exposure, residence, work status, birth order and toilet facilities are highly associated with obstetric morbidity among women.

Conclusions: Implementing of targeted interventions, and awareness campaigns are crucial to reducing obstetric complications and maternal mortality in the eastern region of India

Key messages:

- Socioeconomic correlates impact obstetric morbidity in eastern India in manifolds especially education, age, and wealth quintile of women in eastern India.
- Obstetric morbidity is a growing concern in eastern India, thus implementing targeted interventions and awareness campaigns are much needed.

Abstract citation ID: ckae144.1999
Factors associated with tobacco consumption during pregnancy in Portugal: a cross-sectional study

Filipa Gomes

F Gomes[1], *A Leite*[2,3,4], *A Machado*[2,3,4]
[1]Public Health Unit, Local Health Unit of Loures-Odivelas, Loures, Portugal
[2]Department of Epidemiology, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
[3]NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[4]Comprehensive Health Research Center, NOVA University Lisbon, Lisbon, Portugal
Contact: filipagomes291@gmail.com

Background: Tobacco consumption during pregnancy hinders mother and foetus health. Previous studies in Portugal have attempted to assess tobacco consumption and its associated factors; but none have studied representative samples.

Objectives: We aimed to estimate the prevalence of tobacco consumption during pregnancy in Portugal, and to determine sociodemographic, economic and healthcare access associated factors.

Methods: We performed a cross-sectional study using 2019 National Health Survey data. Women reporting a pregnancy between 2010 and 2019 were included. The outcome was daily or occasional tobacco consumption during pregnancy. Exposure variables were age group, nationality, marital status, region of residence, educational level, occupation/professional area, social support, net monthly income, and pregnancy trimester in the first surveillance appointment. Populational prevalence of tobacco consumption, and crude (PR) and adjusted prevalence ratios (aPR) with 95% confidence intervals (95%CI) were obtained using Poisson regression.

Results: Prevalence was 8.1% (95%CI: 5.6-11.4) (n = 744). PR was higher in young (PR: 1.4, 95%CI: 0.7-2.8), Portuguese (PR: 4.2, 95%CI: 1.1-16.4), single (PR: 1.6, 95%CI: 0.7-4.0) pregnant women, living in Azores (PR: 2.9, 95%CI: 1.0-7.9), with the 9th grade (PR: 4.9, 95%CI: 1.8-13.9), manual job (PR: 4.2, 95%CI: 1.2-14.2), weak social support (PR: 3.3, 95%CI: 1.3-8.7), 3rd income quintile (PR: 4.5, 95%CI: 1.0-19.9), 2nd or 3rd trimester appointment (PR: 2.1, 95%CI: 0.8-6.0). aPR was higher in pregnant women with the 9th grade (aPR: 4.7, 95%CI: 1.7-13.4) or high school (aPR: 4.0, 95%CI: 1.5-10.8) and weak social support (aPR: 2.9, 95%CI: 1.2-6.6).

Conclusions: The prevalence of tobacco consumption during pregnancy in Portugal was comparable to the European Region. Portuguese pregnant women, with less than tertiary education, and weak social support showed higher prevalences.

Key messages:

- The prevalence of tobacco consumption during pregnancy in Portugal was 8.1%. Pregnant women with less than tertiary education, and weak social support showed higher prevalences of tobacco consumption.
- Overall, smoking is more prevalent in socioeconomically disadvantaged pregnant women thus contributing to increased health inequities.

Abstract citation ID: ckae144.2000

Inequalities in preterm birth by deprivation and ethnicity: A national cohort study in England

Iona Hindes

I Hindes[1], *D Zenner*[1], *B Ibrahim*[2], *J Jardine*[1,2], *S Iliodromiti*[1,2]
[1]Women's Health Research Unit, Queen Mary University of London, London, UK
[2]Royal College of Obstetricians and Gynecologists, London, UK
Contact: i.hindes@qmul.ac.uk

Background: Preterm birth has decreased in the UK; however, the extent of inequalities remains unclear. This study aimed to quantify socioeconomic and ethnic inequalities in preterm birth rates using routinely collected maternity data in England.

Methods: Retrospective analysis of cohort data from the NHS England Hospital Episode Statistics (HES). All women aged 13-55 with a singleton livebirth (April 2018 to March 2021) at 24-42 weeks were included. Multivariate Poisson regression was used to estimate the rate of preterm birth (livebirth between 24 + 0 and 36 + 6 weeks') for each ethnic and deprivation postcode group, these were compared to white women from the least deprived 20% of areas. We iteratively developed the model, adjusting for covariates associated with preterm birth. A post-hoc calculation identified the rate of preterm birth for each ethnic group at each level of deprivation.

Results: We identified 1,111,045 livebirths between April 2018 and March 2021. The rate of preterm birth increased with socioeconomic deprivation and was highest at 7.1% per 100 livebirths (95%CI:7.00-7.20) in women living in the 20% most deprived areas, compared to 5.6% (95%CI:5.50-5.74) in women in the 20% least deprived areas. White women had the lowest preterm birth rate at 6.5% (95%CI:6.47-6.58) and South Asian women had the highest rate at 6.9% (95%CI:6.76-7.04) (Table 2). The rate of preterm birth increased according to increased area-level deprivation across all ethnic groups. In areas of high deprivation, the preterm birth rate was similar across ethnic groups. Whereas in less deprived areas, there were marked inequalities between ethnic groups.

Conclusions: Inequalities in preterm birth remain, despite overall decreases in preterm birth. We found area deprivation and individual ethnicity interact to increase the risk of preterm birth in marginalized communities. Interventions need to holistically consider the structural and socioenvironmental determinants of preterm birth.

Key messages:

- Area deprivation and ethnicity remain key drivers of inequalities in preterm birth, despite overall decreases in preterm birth.
- To reduce inequalities tailored prevention strategies are needed to address socioenvironmental and structural determinants of preterm birth in high deprivation areas and minoritized ethnicity groups.

Abstract citation ID: ckae144.2002

Correlation between vaccine hesitancy, vaccine reliability and perceptions of infectious diseases

Medīha Bal

M Bal[1], E Yücel[1], E Salış[1], M Dinleyici[2], D Arslantaş[1], A Ünsal[1]
[1]Public Health Department, Eskisehir Osmangazi University, Eskişehir, Türkiye
[2]Pediatrics, Eskisehir Osmangazi University, Eskişehir, Türkiye
Contact: balmediha@gmail.com

Background: Vaccine hesitancy is a delay in vaccine acceptance or refusal despite the availability of vaccination services. In recent years, the rise in vaccine hesitancy has attracted attention. This study aimed to evaluate the perception of vaccine hesitancy, vaccine safety, and infectious diseases among parents.

Methods: This cross-sectional study was conducted with 503 parents who applied to the pediatrics outpatient clinic of a university hospital. The questionnaire used in the study included questions on sociodemographic characteristics, factors related to vaccine hesitancy, The Vaccine Hesitancy Scale (VAS), the Vaccine Safety Scale (VSS), and the Perception Scale for Infectious Diseases (PPSID). Multivariate Linear Regression Analysis was used to find the variables associated with vaccine hesitancy.

Results: The mean age of the parents was 37.6±7.6 years. Parents' scores on the ATS ranged from 17-85, with a mean score of 20.1±6.6 points. A moderate negative correlation was found between parents' VAS and VSS scores, and between VAS and PPSID scores ($r=-0.412$, $p < 0.001$; $r=-0.409$, $p < 0.001$, respectively). According to the multivariate linear regression analysis the variables found to be associated with vaccine hesitancy, income status, maternal education level, child's age group, having information about childhood vaccination schedule, child's immunization status, the necessity of childhood vaccines, having sufficient information about the safety of vaccines, vaccine safety level, and infectious disease perception level were found to be significant predictors of vaccine hesitancy (F: 12,844, $p \leq 0.001$, R2: 0.334).

Conclusions: This study determined that vaccine hesitancy was higher in families with lower income, who have not completed the schedule nor been vaccinated, doubt the necessity of vaccines to prevent infectious diseases, lack of knowledge about the reliability of vaccines, and whose children are still in primary school.

Key messages:

- Health professionals have a critical role in reducing vaccine hesitancy.
- It would be appropriate to plan face-to-face or online programs with parents.

[7]Department of Nutritional, Food and Consumer, Fulda University of Applied Sciences, Fulda, Germany
[8]Institute of Medical Psychology, University Heidelberg, Heidelberg, Germany
Contact: helena.ludwig-walz@bib.bund.de

Background: Restrictions during the COVID-19 pandemic induced changes in the fitness behavior of children and adolescents, which may be associated with long-term public health challenges. This systematic review analyses how physical fitness has changed during the pandemic and to what extent the changes remain in the aftermath of the pandemic.

Methods: We conducted a systematic search in seven databases with a peer-reviewed search string for studies until Dec 2023. Our inclusion criteria encompassed studies with children and adolescents ≤ 19 years living in the WHO European Region and in which validated measurements were used (single measurements or test batteries). Eligibility screening, data extraction and risk of bias assessment (using ROBINS-E instrument) were all carried out independently by two reviewers. We published an a priori protocol in a peer-review journal and conducted reporting in accordance with the PRISMA 2020 statement. Trial registration: PROSPERO: CRD42023395871.

Results: Our search retrieved 28 studies from 15 WHO European Region countries with an age range from 5 to 19 years. Physical fitness was reported in 21 validated single measurements (e.g. 20 m shuttle run, handgrip strength, standing long jump) and 9 validated test batteries (e.g. Alpha-Fitness Battery, German Motor Test, International Physical Performance Test Profile). The preliminary analyses pointed to a sharp decline in youth physical fitness during the COVID-19 pandemic. After restrictions were eased, physical fitness improved, but remained under pre-pandemic levels, particularly in boys.

Conclusions: The findings indicate a potential suboptimal behavioral adaptation of children and adolescents after the COVID-19 pandemic. Medium and long-term programs to change passive behavior and improve physical fitness are urgently needed. In addition to individual prevention programs, stronger consideration should also be given to schools and sport clubs regarding activities promoting physical fitness.

Key messages:

- Physical fitness in children and adolescents remains below pre-pandemic levels after restrictions removal.
- Initiating immediate public health action to increase physical fitness is urgently needed.

Abstract citation ID: ckae144.2004

Socioeconomic inequalities in substance use among Norwegian adolescents between 2014 and 2022

Arnhild Myhr

A Myhr[1], RK Vesterbekkmo[2], ER Sund[3,4,5]
[1]Digital, SINTEF, Steinkjer, Norway
[2]Regional Drug and Alcohol Competence Centre, St. Olavs University Hospital, Trondheim, Norway
[3]HUNT Research Centre, Norwegian University of Science and Technology, Levanger, Norway
[4]Faculty of Nursing and Health Sciences, Nord University, Levanger, Norway
[5]Levanger Hospital, Nord-Trøndelag Hospital Trust, Levanger, Norway
Contact: arnmy@tkmidt.no

Background: Increasing use of substances is observed among adolescents in recent years. Early onset of substance use dramatically increases the risk of substance use disorder, dependence, and poorer psychological, social, and physical health, and is thus a public health concern. We explore trends in socioeconomic inequalities in past year use of cannabis and other illicit drugs between 2014 and 2022 among Norwegian adolescents.

Methods: This study is based on data retrieved from five waves of the nationwide Norwegian Ungdata survey (2014-2022) among adolescents attending upper secondary education (N = 282,259; 51 % girls). Trends in socioeconomic inequalities were assessed using the Slope Index of Inequality (SII) and the Relative Index of Inequality (RII).

Results: The use of cannabis and other illicit drugs increased among boys (from 13% to 19%, and from 2% to 5%, respectively) and girls (from 8% to 14%, and from 1% to 3%, respectively) between 2014 and 2022. Higher prevalence's was observed among the least affluence girls between 2020 and 2022, both in absolute and relative terms (SII: 0.01 to 0.06, RII: 0.97 to 1.52, $p < 0.001$). No inequalities were observed among boys during this time. While relative and absolute inequalities in use of other illicit drugs decreased in boys, absolute inequalities increased in girls. Boys were more likely than girls to have used cannabis and other illicit drugs, although the gender gap in cannabis use narrowed slightly during the study period.

Conclusions: Our data suggest increasing use of cannabis and other illicit drugs among Norwegian adolescent boys and girls between 2014 and 2022. Future studies should examine the potential causes of increasing substance use as a basis for understanding, and distinguishing between, the many intertwining factors that influence adolescent drug use behaviors.

Key messages:

- The use of cannabis and other illicit drugs increased between 2014 and 2022 among Norwegian boys and girls.
- While inequalities in the use of cannabis and ither illicit drug use increased in girls, small or no inequalities was observed among boys.

Abstract citation ID: ckae144.2005
Is there a maximum transfer time for safe planned home births? Building evidence to

Ciara Carroll

C Carroll[1], *ISL Campillo*[2], *J Keane*[2], *P Corcoran*[2], *R Greene*[2], *P Kavanagh*[3]
[1]Public Health HSE Dublin and North East, Health Service Executive, Dublin, Ireland
[2]National Perinatal Epidemiology Centre, University College Cork, Cork, Ireland
[3]National Health Intelligence Unit, Health Service Executive, Dublin, Ireland
Contact: ciara.carroll2@hse.ie

Evidence-based assessment of suitability for planned home birth (PHB) is a critical component of safe, effective home birth services. This study aimed to build an evidence base to inform transfer time recommendations for the Health Service Executive (HSE) Home Birth Service in Ireland. Transfer rates, time and distance were described for women who began labour at home with the HSE Home Birth Service between 2012 and 2021. Binary logistic regression was used to identify factors associated with intrapartum transfer and to examine the relationship between transfer time and outcomes. A survey on home birth policy and practice was issued to informants in countries offering comparable services to the HSE. Of 2,000 women initiating labour at home, 376 (18.9%) required intrapartum transfer, with transfer rates of 48.2% and 10.1% for primiparous and multiparous women, respectively. Primiparity (aOR: 8.95, 95% CI 6.89-11.7, $p < 0.001$) and maternal body mass index ≥ 30 (aOR: 1.93, 95% CI 1.14-3.20, $p = 0.013$) significantly increased the odds of intrapartum transfer. Serious adverse outcomes were rare in those requiring intrapartum transfer. No statistically significant increase in poor outcomes was detected with increasing transfer time; however, statistical power to detect small but important effects was limited. In other home birth services, transfer time is explicitly considered when assessing suitability; information provided to women includes details on transfer rates and times. While this study did not find a threshold time associated with increased risk of adverse outcomes for PHB, it has highlighted the significance of transfer time in shared decision-making on birthplace. Women considering PHB should receive parity-specific information on outcomes including transfer rates. This work highlights the pivotal role of Public Health in ensuring that evidence is combined with expert judgement and womens' preferences to provide high quality, accessible, person-centred services.

Key messages:

- Transfer time plays a key role in supporting shared decision-making for women considering a home birth.
- This study identified opportunities to extend the comprehensiveness of assessment of suitability for planned home births using local and international evidence.

Abstract citation ID: ckae144.2006
Online Forum Conversations on Abortion in Poland: Navigating Medical, Emotional, and Legal Challenges

Krzysztof Klimiuk

KB Klimiuk[1], *A Kot*[1], *Ł Balwicki*[1]
[1]Department of Public Health and Social Medicine, Medical University of Gdańsk, Gdańsk, Poland
Contact: krzysztof_klimiuk@gumed.edu.pl

Background: Abortion is a common medical procedure worldwide, but access is restricted in Poland, forcing many women to seek abortions without medical supervision. This can lead to health risks and reflects broader challenges regarding reproductive rights and healthcare.

Methods: We conducted a qualitative and quantitative analysis of online forums discussing abortion to understand the challenges faced by women in Poland. Data was gathered from popular abortion forums identified through Google searches, with a pilot study refining the research focus.

Results: A total of 13,397 responses from 370 threads across 4 forums were analyzed. The most prevalent theme was the 'Abortion Process Progression,' indicating a strong need for information and support. Discussions on 'Emotional and Psychological Aspects' and 'Medical and Pharmacological Aspects' highlighted the need for holistic care. This suggests that legal restrictions and fear of repercussions hinder women's access to professional assistance, exacerbating health disparities and inequalities.

Conclusions: This study offers a general look at the abortion experiences of Polish women, revealing challenges that often go unnoticed by policymakers and healthcare professionals. By analyzing online forums, it uncovers nuanced issues such as the lack of access to medical supervision, information gaps, and emotional support, highlighting discrepancies between policy and needs. The findings call for decriminalizing abortion, launching educational campaigns to combat misinformation, and strengthening support systems, aligning Poland's reproductive health services with European Union standards, ensuring women's access to safe and supportive healthcare.

Key messages:

- This study shows how Poland's restrictive abortion laws push women to online forums, revealing medical, emotional, and logistical challenges, emphasizing the need for care and accurate information.
- The research highlights the need for decriminalizing abortion, addressing misinformation, and support Poland's reproductive health services with EU standards, ensuring safer care for women.

Abstract citation ID: ckae144.2007
Inequalities in education in the COVID-19 pandemic: health and education professionals' perspectives

Nicola J Gray

NJ Gray[1], IL Backhaus[2], S Manandhar[3], M Beck[2], C Chabot[4], J Jourdan[4], TA Eikemo[2]

[4]UNESCO Chair 'Global Health & Education', Université Clermont Auvergne, Paris, France
Contact: N.J.Gray@hud.ac.uk

Background: Cycles of school closure and reopening during the COVID-19 pandemic, coupled with remote learning, led to concerns about increasing inequality in education that persist in 2024. The aim of this abstract, within a wider study of safe school reopening, is to explore health and education professionals' perceptions of inequalities among students during the pandemic.

Methods: In 2021, online semi-structured interviews were conducted in 6 languages with education and health professionals. They explored the: 1-effect of the pandemic on schools/pupils/teachers; 2-reorganisation of schools; 3-experience of implementing infection control measures in schools; 4-intersectoral working; 5-important resources for keeping schools open. Interviews were transcribed verbatim and translated into English where needed. A deductive qualitative analysis was undertaken using the conceptual framework developed by the United Nations H6+ Technical Working Group on Adolescent Health and Well-Being. Domain 3 (safety and supportive environment) includes consideration of equality.

Results: 62 interviews were included in the analysis (22 health and 40 education professionals from 28 countries). Professionals perceived greater negative impact on education for specific groups of students. Those with chronic illness stayed out of school for longer than others. Good access to distance learning was difficult for students from rural areas (lack of internet/electricity), disadvantaged families (lack of electronic equipment) or larger families (less learning space at home).

Conclusions: Professionals perceived that school closures intensified the disadvantage experienced by certain groups of students, exacerbating inequalities in education. Targeted catch-up strategies are still needed.

Key messages:

- School closure during the COVID-19 pandemic have exacerbated inequalities in education.
- In future health crisis impacting schooling, targeted catch-up strategies would be needed for certain groups of students.

Abstract citation ID: ckae144.2008
National survey to estimate seroprevalence for toxoplasmosis among pregnant women in France, 2021

Sara Mazzilli

S Mazzilli[1,2], M Tourdjman[1], ENP study group[1,3,4]
[1]French National Public Health Agency, Sante Publique France, Saint-Maurice, France
[2]EPIET, ECDC, Stockholm, Sweden
[3]Institut National de la Santé et de la Recherche Médicale, Paris, France
[4]DREES, Paris, France
Contact: sara.mazzilli@santepubliquefrance.fr

Background: Toxoplasmosis during pregnancy can result in congenital malformations and fetal death. In France, universal antenatal screening and monthly re-testing of seronegative pregnant women has been established since the 1970s. However, decreasing Toxoplasma gondii seroprevalence among pregnant women and lower incidence of congenital toxoplasmosis may challenge the cost-effectiveness of such programs. The aim of this study was to estimate the current seroprevalence among pregnant women participating in the 2021 national perinatal survey (ENP).

Methods: All adult women giving birth in France between 15-21 March 2021 were invited to participate in the ENP. Data collected included demographic information, nationality, socio-economic status, education level and Toxoplasma gondii serology. We classified a woman as seropositive if she had IgG antibodies prior to pregnancy or seroconverted during it. Univariable and multivariable regression analyses using Poisson model were conducted to estimate prevalence ratios (PRs) and identify significant factors associated with seropositivity.

Results: Among the 15,605 participating women, 0.22% seroconverted during pregnancy. The overall seroprevalence was 25.95%. Seropositivity was higher with increasing age (~5% per 5 years), among residents of French overseas territories Guadeloupe/Saint Martin (PRs:1.07; 95%-CI: 1.03-1.10), La Réunion (PRs:1.10; 95%-CI: 1.08-1.13) and Mayotte (PRs:1.27; 95%-CI: 1.23-1.31), with lower education (PRs:1.22; 95%-CI: 1.04-1.42) and African nationality (PRs:1.11; 95%-CI: 1.02-1.20).

Conclusions: High seroprevalence for Toxoplasma gondii was found in older women, which may reflect their higher risk of past exposure. The observed geographical differences in seroprevalence may mirror dietary and environmental diversity. Declining seroprevalence among pregnant women in France can affect screening effectiveness and warrants a comprehensive review to determine appropriate future prevention strategies.

Key messages:

- Older women and residents of French overseas territories show higher toxoplasmosis seroprevalence, possibly due to past exposure risks and diverse diets/environments.
- Declining toxoplasmosis seroprevalence among pregnant women in France can affect screening effectiveness and warrants a comprehensive review to determine appropriate future prevention strategies.

Background: Excessive use of digital devices, including smartphones and tablets, has been shown to increase the risk of myopia in children. Gaps persist in understanding parental attitudes towards handheld screen use and effective interventions guiding eye health policies. This study examined the associations between parental behavior related to myopia and children's handheld screen use.

Methods: Data obtained from 395 parents of pre-adolescents (Mean age 10.63; SD 1.09) were used, collected from an online community panel. Parents reported on various behavioral determinants related to myopia and their child's screen time: knowledge, attitude, risk perception and self-efficacy. They reported on their child's frequency and amount of screen use. Logistic regression analysis was used to assess associations between variables, using parental efforts to reduce screens as outcome measure.

Results: Of the 395 participating 9-12 year-olds, 73.4% of the children spent up to two hours a day on recreational handheld screens, 26% more than two hours. Of the parents surveyed, 28.1% perceived the risk of screen-induced myopia as significant, prompting 62.6% of them to take active measures to minimize screen time. The more knowledge parents had on child myopia the more they attempted to reduce screen time (OR = 2.57; 95% CI [1.57-4.19], p = <.001). Moreover, a more negative attitude towards screens was significantly related to attempting to reduce screen time (OR = 1.26; 95% CI [1.17-1.35],p = <.001).

Key messages:

- These findings emphasize a need to address parental knowledge and attitude towards myopia and screen time reduction.
- We recommend increasing knowledge, influencing attitude and searching for alternatives as a part of behavioral change strategies.

The association between screen use, psychological distress and sleep among adolescents in Norway

Anne Mari Steigen

AM Steigen[1], T Bonsaksen[1], TH Stea[2], M Leonhardt[3], L Lien[1], AL Kleppang[1]
[1]Inland Norway University of Applied Sciences, Elverum, Norway
[2]University of Agder, Kristiansand, Norway
[3]VID Specialized University, Oslo, Norway
Contact: anne.steigen@inn.no

Background: Today's adolescents dedicate a significant portion of their time to screens. Concerns have arisen regarding the lasting impact of screen use on adolescent health, making it a crucial public health topic. Previous studies have presented both positive and negative outcomes associated with screen use. Further insight is required into various forms of screen use and the influence on adolescent health. The objective of this study is to examine the relationship between gaming, social media use, psychological distress, and sleep among adolescents.

Methods: This study is based on cross-sectional data from the Ung-HUNT4-study, a health study conducted among adolescents 13-19 years old in Trøndelag municipality in Norway from 2017-2019 (n = 8066). Binomial logistic regression was used to analyse the association between gaming, social media, psychological distress and sleep. Analysis was controlled for gender, age, family economy and having friends.

Results: Preliminary results showed that the odds for having psychological distress were higher for those who spent more than 3 hours on social media after school (OR: 1.31, 95% CI: 1.10-1.57), and on weekends (OR: 1.45, 95% Cl: 1.22 - 1.73), and on gaming in weekends (OR:1.30 Cl: 1.08-1.55) compared to those who spent 3 hours and less. The odds for sleeping < 8 hours per day on weekdays were higher for those who spent more than 3 hours on gaming after school (OR: 1.27 Cl:1.07-1.52), and more than 3 hours on social media after school, (OR:1.41 Cl:1.20-1.67) or on weekends (OR:1.39 Cl: 1.19-1.62), compared to those who spent 3 hours or less.

Conclusions: More than 3 hours spent on social media after school and on weekends was associated with significantly higher odds for psychological distress and less sleep on weekdays. More knowledge about the impact of different types of screen use on adolescents' health is needed, and new public health strategies to secure safe screen use should be developed.

Key messages:

- Screen use is associated with psychological distress and less sleep.
- Awareness on various types of screen use and its influence on health in adolescence, is important in public health policy and practice.

Abstract citation ID: ckae144.2011
Antibiotic use in the first 1000 days and maternal-infant outcomes: results from the MAMI-MED cohort

Martina Barchitta

M Barchitta[1], A Maugeri[1], R Magnano San Lio[1], G Favara[1], E Campisi[1], E Di Liberto[1], C Ojeda-Granados[1], C La Mastra[1], MC La Rosa[1], A Agodi[1]
[1]Department GF Ingrassia, University of Catania, Catania, Italy
Contact: mbarchitta@unict.it

Introduction: Antibiotic use within the initial thousand days of life could potentially lead to a range of negative health outcomes for both mothers and infants. This study seeks to identify the primary factors influencing antibiotic use and examine the associations with adverse neonatal outcomes, specifically focusing on neonatal intensive care unit (NICU) admissions.

Methods: Data were gathered from pregnant women and their offspring enrolled in the 'MAMI-MED' study at ARNAS Garibaldi Nesima in Catania (Italy), from December 2020 to January 2024. Information regarding antibiotic exposure and maternal-infant health outcomes was collected through follow-up questionnaires administered at birth, one year, and two years postpartum.

Results: Among 1492 women (average age: 31 years) included in the study, 20.4% reported using antibiotics during pregnancy. The mean age of antibiotic users during pregnancy was significantly higher compared to non-users (p = 0.008). Among the 304 women who used antibiotics during pregnancy, 45.5% did so during the third trimester, 41.4% during the second trimester, and 13.1% during the first trimester. Furthermore, 47.1% of women reported antibiotic use at delivery or postpartum. Of the 904 children studied, 63% were administered at least one antibiotic between birth and the first year of age. A greater proportion of newborns admitted to the NICU were born to mothers who used antibiotics during the second trimester of pregnancy compared to those who used antibiotics during other trimesters (p = 0.013).

Conclusions: Comprehensive research is needed to delve deeper into the intricate factors influencing maternal antibiotic use. This should thoroughly explore socio-demographic variables, such as income level, education, and access to healthcare. Understanding these multifaceted influences can provide valuable insights into designing tailored public health interventions aimed at promoting prudent antibiotic use during pregnancy.

Key messages:

- Different factors influence maternal antibiotic use.
- Tailored public health interventions aimed at promoting prudent antibiotic use during pregnancy are needed.

[4]UCD Centre for Human Reproduction, The Coombe Hospital, Dublin, Ireland
[5]School of Public Health, University College Cork, Cork, Ireland
Contact: peter.naughton3@hse.ie

Background: Obesity during pregnancy poses inter-generational health risks and places added burden on healthcare systems. Characterising levels of obesity during pregnancy is necessary to guide future research, policy and practice.

Methods: The systematic review was performed according to PRISMA guidelines. PubMed, Embase and Web of Science were searched. Studies published between 2009 and 2023 that report the prevalence of obesity during pregnancy in countries in the World Health Organization (WHO) European region were eligible. The Joanna Briggs Institute Prevalence Critical Appraisal tool was used. Two reviewers screened studies independently. A single reviewer completed data extraction and quality assessments, a second checked 20% of extractions and a third resolved disagreements. Narrative synthesis was completed.

Results: 100 studies reporting the prevalence of obesity during pregnancy in the WHO European region were identified. 59% from Western Europe, 36% Northern, 4% Southern and 1% Eastern. Data within the studies was collected between 1950 and 2019. 35% of studies reported national estimates, 65% regional. 39% studies had measured height and weight, 34% did not report how either were ascertained, 6% used self-report for both, 17% had self-reported height but measured weight, 4% a mixture of self-report and measurement. The smallest sample was 157 while the largest was 1,891,097. Estimated prevalence of obesity during pregnancy ranged from 2.3% (Sweden, data collected 1982-1989) to 28.3% (England, 2007).

Conclusions: This review identifies variation in the prevalence of obesity during pregnancy in the WHO European region. This may reflect diverse sociocultural contexts, different methodological approaches and temporal trends. There was limited evidence available for Southern and Eastern Europe.

Key messages:

- There are high levels of obesity during pregnancy within the WHO European region.
- Enhanced primary prevention and resourcing of obstetric services is needed.

Abstract citation ID: ckae144.2013
Influenza and COVID-19 vaccines in pregnancy: investigation on associated factors and HAPA theory

Alessandra Fallucca

[3]Kore University, Faculty of Medicine and Surgery, Enna, Italy
Contact: alex.fallucca@gmail.com

Background: Infections caused by influenza and COVID-19 during pregnancy represent a current public health problem as there are multiple populations at risk of complications: pregnant women, fetus, and future unborn children. The anatomical and physiological remodulation characteristic of pregnancy is responsible for the high pathological burden related to respiratory infections. Co-administration of influenza and COVID-19 vaccines may be beneficial because these two respiratory viruses cocirculate during cold weather. The need to explore pregnant women's attitudes toward co-administration of influenza and COVID-19 vaccines and to evaluate factors associated with vaccine decision-making led to the conduct of this study.

Methods: In Palermo, Italy, during the 2021-2022 influenza season, a cross-sectional study was conducted to evaluate pregnant women's intention to adhere to co-administration of influenza and COVID-19 vaccines. The determinants of vaccination attitudes were investigated through the administration of a questionnaire. The Health Action Process Approach theory (HAPA) was adopted to explore the cognitive behavioral aspects.

Results: Overall, 120 pregnant women were enrolled; average age 32 years, 98.2% ($n = 118$) of Italian nationality and 25.2% ($n = 30$) with obstetric or pathological conditions of pregnancy at risk. Factors significantly associated with attitudes toward co-administration of influenza and COVID-19 vaccines among pregnant women were: high level of education ($OR = 13.96$; $p < 0.001$), expectations of a positive outcome ($OR = 2.84$; $p < 0.001$) and self-efficacy ($OR = 3.1$; $p < 0.001$).

Conclusions: Vaccines co-administration could represent an advantageous preventive practice to facilitate vaccination logistics and allow full adherence to vaccinations recommended to pregnant women. Effective strategies to promote co-administration of influenza and COVID-19 vaccines could be focused on counselling about the expectation of positive outcomes of vaccine co-administration.

Key messages:

- The need to explore pregnant women's attitudes toward co-administration of influenza and COVID-19 vaccines and to evaluate determinants of vaccine decision-making led to the conduct of this study.
- Vaccines co-administration could represent an advantageous preventive practice to facilitate vaccination logistics and allow full adherence to vaccinations recommended to pregnant women.

Contact: rita.ochili@ukhsa.gov.uk

Introduction: COVID-19 highlighted the importance of infection prevention and control (IPC) across all settings. As children are important transmitters of infection, teachers and schools play an important role in infection prevention. The aim of this study is to understand attitudes towards, and knowledge of IPC in schools post-Covid, and highlight any gaps in the training and resources needed.

Methods: An online survey of 1000 primary and secondary school teachers was carried out across England. Pearson's chi-squared test, corrected for survey design, was used to test for differences in proportions across levels of categorical variables. Two qualitative workshops with eight head teachers were carried out to gather more in-depth information.

Results: 1000 teachers completed the survey across a range of teaching roles. Respondents reported that IPC measures are now less frequently implemented than during the pandemic. 71% of respondents say their role has changed since the pandemic, now having more responsibility for pupil health and hygiene; higher in primary versus secondary school teachers (31% v 25%; $p < 0.05$). 1/3 felt this change was permanent; 84% had no IPC training. Knowledge gaps were identified in the areas of IPC roles within schools, and IPC measures. 72% teachers claim they feel better prepared to deal with a public health outbreak compared to pre-pandemic, although 22% do not have an updated IPC policy; 35% had unmet needs.

Conclusions: Schools and teachers play a pivotal role in preventing the spread of communicable disease, highlighted during the COVID-19 pandemic. Teachers need, and more importantly want, more IPC training. Training and updated policies would support the educational workforce who feel their needs are not being met. Providing more streamlined, consistent, clear and concise information from trusted sources is required.

Key messages:

- It is imperative to understand educators' role in IPC in schools as they are key players in supporting local and national efforts to reduce the spread of infections.

- Teachers desire further training with comprehensive information, and up-to-date policies to support their infection prevention and control efforts in educational settings.

Risk factors for the gambling, smoking and alcohol consumption triad in Portuguese adolescents

Pedro Ramos

P Ramos[1,2], *J Alves*[2,3]
[1]Public Health Unit, São José Local Health Unit, Lisbon, Portugal
[2]NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[3]Comprehensive Health Research Center, NOVA University Lisbon, Lisbon, Portugal
Contact: pedroeduardoramos@gmail.com

Background: Addiction to gambling, tobacco, and alcohol poses significant risks to mental, social, and physical health, particularly during adolescence, a critical period for habit formation. This study investigates risk factors linked to these habits among Portuguese adolescents.

Methods: This cross-sectional study used the 2019 ESPAD questionnaire, targeting 16-year-old adolescents. The sample comprised 4,365 responses. Descriptive analysis determined the prevalence of gambling, smoking, and alcohol use, as well as social, economic, and behavioral factors. Bivariate associations were assessed using the Exact Fisher test, and multiple logistic regression identified key predictors for the outcome of interest (cumulative presence of gambling, smoking and alcohol consumption). Statistical analysis was conducted with SPSS version 29.0, with a significance level of $p < 0.05$.

Results: Among adolescents, 6.2% presented probable problematic gambling according to the Lie/Bet test, with 3.7% spending at least 30 minutes a day gambling. In the past 30 days, 14.3% smoked, 42.7% drank alcohol, and 10.5% engaged in binge drinking. The behavioral triad was observed in 56 individuals. Male gender (OR = 2.024; 95% CI: 1.097-3.734; p = 0.024), problematic online gaming behavior (OR = 2.041; 95% CI: 1.005-4.144; p = 0.048) and going out at night at least once a week (OR = 1.439; 95% CI: 1.242-1.669; $p < 0.001$) significantly increased the risk of the behavioral triad. In contrast, parental control (parents knowing where the adolescent is on Saturday night) had a significant protective effect (OR = 0.162; 95% CI: 0.086-0.303; $p < 0.001$).

Conclusions: The study underscores the importance of parental supervision to curb risky behaviors in adolescents. It suggests implementing public health programs in schools, leveraging gaming for early screening, and tightening online gambling regulations to mitigate future health risks associated with gambling, smoking, and alcohol use.

Key messages:

- Absence of parental supervision, male gender, problematic online gaming and frequently going out at night are risk factors for this behavioral triad.
- Public health strategies are needed to prevent gambling addiction, emphasizing parental awareness, identification of at-risk students, and comprehensive school-based approaches.

Abstract citation ID: ckae144.2016
Sociodemographic and lifestyle correlates of energy drinks consumption in Serbian adolescents

Jelena Gudelj-Rakic

J Gudelj-Rakic[1], *B Kilibarda*[1], *M Vasic*[1], *V Jovanovic*[1]
[1]Institute of Public Health of Serbia, Belgrade, Serbia
Contact: jelena_gudelj@batut.org.rs

Background and aim: Energy drinks (EDs) are non-alcoholic beverages that typically contain high levels of caffeine and sugar in combination with other ingredients known to have stimulant properties. Although there is growing evidence of the harmful physiological and psychological effects of energy drinks their popularity has increased during the past decade. While researchers point out variety of health consequences, data on prevalence and correlates of EDs consumption are scarce. Aim of the study was to determine prevalence of EDs consumption and to investigate sociodemographic and lifestyle correlates of EDs consumption among adolescents in Serbia.

Study design: Secondary analysis of data obtained from 2022 Health Behaviour in School-aged Children Study (HBSC) in Serbia. Study included 3962 students aged 11, 13 and 15 years. Students with missing values for one or more study variables were excluded from the analyses.

Methods: Multiple logistic analyses stratified by age and sex were performed to estimate the associations between consuming EDs and sociodemographic and lifestyle characteristics.

Results: Overall, 15.6% of students consumed EDs more than once a week (16.2% of boys and 15.5% of girls) with highest percentage among 15-year-old students (20.3%). For both genders, the percentage of adolescents consuming ED more than once a week was higher among adolescents with lowest family affluence (21.9%), those consuming soft drinks daily (39.5%) and alcohol weekly (47.6%). In boys only, consuming ED several times a week was more frequent among adolescents having at least 60 min moderate-to-vigorous physical activity (MVPA) daily than among those with lower levels of MVPA.

Conclusions: Different patterns of ED consumption were identified suggesting need for tailored interventions aimed at reducing ED consumption in adolescents.

Key messages:

- Every fifth h 15-year-old student in Serbia consume EDs more than once a week.
- Higher EDs consumption among physically active boys indicate need for targeting interventions that will address this issue.

Abstract citation ID: ckae144.2017
Mental health benefit uptake of women before and during the perinatal period in Austria

Julia Kern

J Kern[1], *I Zechmeister-Koss*[1], *M Edlinger*[2], *C Hörtnagl*[2], *J Paul*[2], *A Lampe*[3]
[1]Austrian Institute of Health Technology Assessment, Vienna, Austria
[2]Medizinische Universität Innsbruck, Innsbruck, Austria
[3]Ludwig Boltzmann Institute for Rehabilitation Research, Vienna, Austria
Contact: Julia.Kern@aihta.at

One in five women may experience a perinatal mental illness (PMI) during pregnancy and up to one year after giving birth, during the so-called perinatal period. Although there is strong evidence that this can have a negative effect on the children's future health, many mothers do not receive any treatment. To determine whether and what type of mental health services women in Austria claim during the perinatal period, the uptake of five key mental health insurance benefits was analysed using pseudonymised health insurance data from Austria's largest insurance, ÖGK. In 2017 and 2018, 131,025 ÖGK insured women gave birth, representing 80% of all births in Austria in the two years. Of these women, almost 20% claimed at least one benefit during the perinatal period. Including the year before pregnancy this number increased to 25%. Most often, only one benefit was claimed in only one of the analysed periods (the year before pregnancy, pregnancy, and the year after birth). Psychotherapy was claimed most often, while hospital admissions occurred the least. Further, the youngest ($\leq$ 20 years) and the oldest ($\geq$ 41 years) women claimed benefits more frequently than at other ages. After adjustment for the shorter pregnancy period, benefit uptake was generally highest during pregnancy and lowest after giving birth. Considering the shortage of specialised perinatal mental health services in Austria, the uptake of the five analysed types of services was high and corresponds to international prevalence figures on PMI. The actual number may be even higher, considering the services and the women not covered in the available data. As there is a lack of a perinatal mental health infrastructure and specialised healthcare staff in Austria, this warrants further investigations into the quality of care provided to the women and more training and education concerning mental problems occurring during the perinatal period.

Key messages:

- Around a quarter of women claim mental health benefits during the perinatal period, most often psychotherapy services.
- Substantial demand for mental health services during the perinatal period calls for comprehensive infrastructure and quality assessments of available options.

Abstract citation ID: ckae144.2018
An evaluation over time: Dipsalut's "Program for families"

Elena Soler

E Soler[1], *M Estrada*[1]
[1]Health Promotion, Dipsalut, Girona, Spain
Contact: esoler@dipsalut.cat

Issue: Dipsalut's "Program for Families" is a parental skills and positive parenting program aimed at all fathers, mothers, and other adult caregivers of children aged 3 to 12 in the province of Girona, Spain. The Program is based on the Convention on the Rights of the Child (1989), which recommends that states promote programs that develop parenting styles that respect children's rights to be heard and recognized. Research supports that offering parenting skills to parents contributes to the child's well-being throughout the growth stage.

Description: The program began in 2018 in a pilot phase that lasted until 2019, when the first evaluation was done to compare different methodologies. After selecting a definitive one (based on the method of Adele Faber and Elaine Mazlish), in 2023, an external evaluation was done, with a follow-up of participants from previous editions. In this evaluation process, we considered the durability of the contents over time, evolutions of assistance, and comparison of the modalities of 4 and 6 sessions. A quantitative methodology has been used through a self-administered questionnaire addressed to the participants (387 responses).

Results: Impact of the program: 78% of parents value the program as having a positive impact on their parenting skills. Durability: there are differences in how the passage of time affects content retention. Impact of attendance: the parenting skills of those who have attended all program sessions last longer. The attendance percentage at all sessions was higher (61.4%) in the four-session modality.

Lessons: Although families do not remember all the tools learned, their confidence, the improvement in the family atmosphere, and the fact that they feel more skilled are maintained over time. Main messages: Families have improved their parenting skills since the program gives them more tools to manage family conflicts, to promote their children's self-esteem and to encourage their autonomy.

Key messages:

- With the positive parenting program, parents increase their self-confidence to manage the challenges of parenting, especially in intra-family communication and conflict management.
- It is essential to promote positive parenting programs with an experiential methodology and maintained over time.

Abstract citation ID: ckae144.2019
"Friendships fizzled out": Trajectories and risk factors of youth loneliness following COVID-19

Imme Rahmon

I Rahmon[1,2], *MA Mol*[3], *L van Leersum-Bekebrede*[1], *M Dückers*[2,4,5], *E Marra*[1]
[1]RIVM, Bilthoven, Netherlands
[2]Faculty of Behavioral and Social Sciences, University of Groningen, Groningen, Netherlands
[3]Department of Social Sciences, Wageningen University and Research, Wageningen, Netherlands
[4]ARQ National Psychotrauma Center, Diemen, Netherlands
[5]NIVEL, Utrecht, Netherlands
Contact: imme.rahmon@rivm.nl

Background: Social distancing and isolation during the COVID-19 pandemic left a mark on the social, emotional and cognitive development of youth. We aimed to identify the course of Dutch youth loneliness and its predictors since the Omicron lockdown in December 2021.

Methods: Data were obtained from a repeated cross-sectional panel study between March 2022 and September 2023, in which loneliness was assessed using the 6-item De Jong Gierveld Loneliness Scale. Youth (12-25 years) participating in at least three timepoints were included. A latent class growth analysis (LCGA) was performed to identify trajectories of loneliness. Themes identified in qualitative data (open-ended questions halfway 2022) were recoded into binary quantitative variables to be included in regression analyses. Two-step multivariable multinomial logistic regression was used to determine risk factors per trajectory class. Goodness of fit was assessed using the likelihood-ratio test.

Results: Identified trajectories were: 1) very lonely ($n = 140$), 2) moderate lonely ($n = 373$), 3) recovering ($n = 511$), and 4) not lonely ($n = 384$; reference). Compared to the other trajectories, youngsters following a moderate or very lonely trajectory had more often little to no trust in the future and more often experienced non-specific symptoms and stress due to various causes. Including perceptions showed that youth in these trajectories experienced a greater impact of the pandemic on their social relationships. The inclusion of perception also improved the model's goodness of fit ($p < 0.001$).

Conclusions: Up to 18 months after the COVID-19 pandemic, youngsters that reported loneliness continue to endure its consequences on their social lives. Despite the apparent association between the Omicron lockdown and continuing loneliness, claims about causality should be made with caution. However, findings implicate the importance of political and social recognition of the pandemic's ongoing impact on vulnerable youth.

Key messages:

- Lonely youth experienced a greater impact of the COVID-19 pandemic on their social lives.
- Political and social recognition of the pandemic's ongoing impact on vulnerable youth is wanted.

Abstract citation ID: ckae144.2020
Maternal pre-pregnancy weight and infant spontaneous movement: is there an association?

Lisa De Pasquale

L De Pasquale[1], *L Palandri*[1], *L Marrozzini*[2], *V Trevisani*[2], *MR Scasserra*[1], *N Bertoncelli*[2], *F Facchinetti*[2], *L Iughetti*[2], *L Lucaccioni*[2], *E Righi*[1]
[1]Biomedical, Metabolic, and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy
[2]Medical & Surgical Science of Mothers, Children and Adults, University of Modena and Reggio Emilia, Modena, Italy
Contact: lisadepa93@gmail.com

Introduction: Maternal pre-pregnancy overweight status might create a chronic systemic inflammatory environment for the foetus, impairing neurons development. The Motor Optimality Score-Revised (MOS-R) is an established tool to assess infant spontaneous movement at 3-5 months helping predict later neurodevelopmental outcomes in infants, including language, minor neurological dysfunction or learning difficulties at school age. The aim of our study was to investigate if maternal BMI together with other characteristics were potentially associated with MOS-R score at 3-5 months in a sample of newborns representative of physiologic full-term pregnancies.

Methods: 128 mother-children couples were enrolled in the Hospital of Modena, Italy. Mothers' socio-demographic characteristics and BMI pre and during pregnancy were collected. MOS-R was assessed in infants within 9-18 weeks post term age (Median 13, IQR 12-14). Descriptive statistics, bivariate associations and multivariate analysis were performed.

Results: In our sample, 94.5% of infants (44% females) had a MOS-R$\geq$25 (optimal score), 3.9% a MOS-R between 23-24 and 1.6% a MOS-R<23. In bivariate analyses pre-pregnancy BMI$\geq$25 and weight gain higher than recommended during pregnancy were associated with MOS-R<25 ($p < 0.05$); being unemployed before and during pregnancy and having pregnancy during COVID lockdown were associated with reduced "age adequate movement repertoire" subcategory ($p < 0.05$). In multivariate analysis, pre-pregnancy BMI$\geq$25 remained the only factor significantly associated with lower scores ($p < 0.05$).

Discussion: Our sample of healthy infants showed a typical range of spontaneous movements reflecting neural integrity. However, lower MOS-R scores were associated with pre-pregnancy overweight. This finding reinforce the importance of enhancing public health actions targeted at keeping a weight in the normal range to protect from a large number of unhealthy conditions both the mother and the offspring.

Key messages:

- Pre-pregnancy weight appears associated with infant spontaneous movement in 3-5 months infants.
- Public health actions targeted at keeping female weight in the normal range must be strengthen.

Abstract citation ID: ckae144.2021
Electromagnetic fields exposure and neuropsychological effects in young people

Kinga Polanska

K Polanska[1], A Jankowska[1], M Scieszko[1], P Politanski[1]
[1]Nofer Institute of Occupational Medicine, Łódź, Poland
Contact: kinga.polanska@imp.lodz.pl

Background: In recent years, there has been a large increase in the use of communication/connected devices and technologies. This raises a question about radiofrequency electromagnetic fields (RF-EMF) exposure levels and neuropsychological effects of RF-EMF in young people. The aim of this study was to assess the pattern of use of communication/connected devices and technologies and its impact on cognition and mental health of early school age children in Poland.

Methods: The study population consists of 293 children from Polish Mother and Child Cohort (REPRO_PL). The study was based on questionnaire data covering type and duration of usage of communication/connected devices and technologies by mothers during pregnancy and children at age of 7 years. The environmental exposure to RF-EMF was also taken into account. Based on such data RF-EMF exposure was assessed. Child emotional and behavioral assessment was done by Strengths and Difficulties Questionnaire whereas IQ and psychomotor development of children was performed by psychologist using Intelligence and Development Scales.

Results: About 75% of young people used smartphones (2% for voice calls and 7% for Internet browsing at least one hour per day). Tablet or laptop use was declared by 59% and 56% of respondents, respectively. More than 10% declared that they use these devices at least one hour a day. The main factors determining the use of new technology devices were parental age and education ($p < 0.05$) and the age at which youth started school education ($p = 0.06$). In multivariable regression model higher level of RF-EMF was associated with total difficulties and emotional problems ($p < 0.05$).

Conclusions: This study presents the pattern of use of new technology devices by early school age children in Poland and the association between the exposure to RF-EMF and child mental health.

Key messages:

- The use of communication/connected devices and technologies is common among young people in Poland.
- The exposure to RF-EMF can increase mental health problems among young people.

Abstract citation ID: ckae144.2022
"If-then"-scenarios in the care of pregnant women with diabetes in socially vulnerable positions

Mette Mørup Schlütter

Background: Pregnant women with diabetes in socially vulnerable positions face a multiplicity of medical, social, and psychological risks during pregnancy and birth and are susceptible to health inequities. This presentation explores the tentative nature of care provided to these women.

Methods: We base our findings on ethnographic fieldwork among health professionals at an obstetric outpatient clinic in Denmark.

Results: The unpredictability of diabetes during pregnancy calls for a flexible approach to treatment, placing significant demands on health professionals, pregnant women, and their partners and their ability to adjust to new scenarios. Our initial findings underscore that care is not static; it is dynamically adjusted to meet the medical, social, and psychological needs of the women. The adjustments in care encompass the negotiation and monitoring of insulin dosages, fetal weight, appointment frequencies, and additional consultations and impromptu phone consultations to follow up. An example of the tentativeness in care could be that if there is a sudden decrease in insulin requirements close to the due date then the birth might be induced. Beyond medical monitoring and treatment, the care extends to social initiatives that the health professionals must coordinate with various municipalities, depending on where the pregnant women live. This could include a joint meeting after the delivery between the woman, her partner, a health professional from the obstetric ward, and a social worker from the municipality. Often, this meeting is mentioned during consultations and intersectional meetings before the birth but is not formally arranged. Instead, it is tentative - if the pregnant woman would like a meeting upon discharge, then the health professional will set up a meeting.

Conclusions: Medical, social, and psychological care practices for women with diabetes in socially vulnerable positions are replete with "if-then" scenarios.

Key messages:

- Care for pregnant women with diabetes in socially vulnerable positions is characterized by its fluidity and flexibility adjusting to the interplay of medical, social, and psychological needs.

- The "if-then" scenarios that characterize the care for pregnant women with diabetes in socially vulnerable positions put high demands on the ability to adapt and adjust continuously.

TOPSE for babies in Norwegian: Examining the reliability of a tool to measure parenting self-efficacy

Marit Burkeland-Lie

M Burkeland-Lie[1,2], *JS Skogen*[1], *M Hysing*[2], *A Dovran*[3]
[1]Department of Health Promotion, Norwegian Institute of Public Health, Bergen, Norway
[2]Department of Psychosocial Science, University of Bergen, Bergen, Norway
[3]Stine Sofie Centre, Stine Sofies Foundation, Grimstad, Norway
Contact: Marit.Burkeland-Lie@fhi.no

Background: Parents' confidence in their parenting abilities and self-efficacy (PSE) is an important factor for parenting practices. The Tool to measure Parenting Self-Efficacy (TOPSE) is a questionnaire created to evaluate parenting programs by measuring PSE. Initially, it was designed for parents with children between 0-6 years old. A modified version specifically for parents of infants aged 0-6 months (TOPSE for babies) is currently being piloted. In this study, we have investigated the reliability of the Norwegian version.

Methods: The study included 123 parents of children aged 0-18 months who completed a digital version of the TOPSE questionnaire. Professional translators performed the translation from English to Norwegian and a back translation in collaboration with the author group. Mean and standard deviation were calculated for each of the questionnaire's six domains, and a reliability analysis was conducted using a Bayesian framework for the total sample (parents of children aged 0-18 months) and specifically for the parents of the youngest group of children (0-6 months).

Results: The overall Bayesian alpha coefficient for the six domains ranged from 0.54 to 0.83 for the entire sample, and from 0.63 to 0.86 for parents with children aged 0-6 months. For two of the domains, one item in each proved to primarily contribute to the low alpha coefficients and removing them improved the reliability, especially for parents of the youngest group of children.

Conclusions: Reliable tools to assess PSE and evaluate parenting programs is important. The Norwegian version of TOPSE for babies seems to be a reliable tool for measuring PSE, although there are variations across the children's age groups and domains.

Key messages:

- The findings from this study indicate that TOPSE in Norwegian is a reliable tool for assessing PSE.
- While our findings are promising, further research is warranted to establish a more robust evaluation, across both mothers and fathers, parental age and socioeconomic groups.

Abstract citation ID: ckae144.2024
Resilience and mental and physical health of higher and lower educated youth during COVID-19

Jelena Kollmann

J Kollmann[1], *MHL Hollaar*[1], *G Servant-Miklos*[1], *PL Kocken*[1], *S Denktas*[1]
[1]ESSB, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: kollmann@essb.eur.nl

Background: COVID-19 had a considerable impact on the mental and physical health of youth. To limit the impact of this crisis on their health, resilience was required. This study aims to discover how resilient, in terms of mastery, emotional reactivity and social support, groups of youth with different SES were during COVID-19, and what risk and protective factors they experienced.

Methods: Two qualitative datasets were analyzed. One dataset included 10 interviews of university students during April-May 2020, and the other dataset included 8 interviews with pre-vocational secondary education adolescents during October 2021 to March 2022. Interviews were held in person or online. Data were analyzed with thematic analysis in Atlas.ti.

Results: In general, university students displayed resilience despite the tumultuous beginning of the pandemic, and their mental and physical health was positive. Protective factors that helped them during COVID-19 were spending time with friends and family, being healthy and having a healthy lifestyle, and being able to avoid stressful situations. Risk factors that impacted their resilience were loneliness, COVID-19 anxiety, and missing stability and routine. Adolescents receiving pre-vocational secondary education showed mixed resilience later in the COVID-19 period, and they made negative observations about their health. Protective factors that helped them were achieving good results in school, hobbies, and avoiding stressful situations. Risk factors they experienced were lack of motivation and having difficulties at school. They experienced worry about school progress during COVID-19.

Conclusions: University students and lower educated adolescents seemed to have differing resilience during the impactful stages of COVID-19, possibly due to differences in their psychological development. To protect their well-being, it is important that policy makers consider the protective and risk factors that impact the health of youth during crises.

Key messages:

- Resilience differs among the two different age groups and education levels.
- Policy makers should consider the protective and risk factors that impact the health of youth during crises.

Abstract citation ID: ckae144.2025
Stakeholder perspectives on supplemental milk for infants under six months with growth faltering

Shuby Puthussery

S Puthussery[1], *C Okeke*[1], *A Gavine*[2], *A McFadden*[2], *P Tseng*[1]
[1]Maternal and Child Health Research Centre, University of Bedfordshire, Luton, UK
[2]School of Health Sciences, University of Dundee, Dundee, UK
Contact: shuby.puthussery@beds.ac.uk

Background: Growth faltering is a significant public health issue among infants aged <6 months (m). Supplemental milk is commonly used for infants with growth faltering, with variations in type and duration. We synthesized qualitative evidence on stakeholder perspectives about equity, feasibility, and acceptability of the type and duration of supplemental milk for infants aged <6m with growth faltering.

Methods: We conducted a comprehensive search of six electronic databases in addition to manual searches to identify all qualitative studies published during January 2000-June 2022. Identified articles were screened in two stages against an inclusion criteria with titles and abstract screened first followed by full-text screening. Included studies were quality appraised using the Critical Appraisal Skills Programme checklist. The primary outcome was equity, feasibility, and acceptability of various supplemental milk for infants <6mwith growth faltering.

Results: Eighteen studies, reporting perspectives of mothers, fathers, grandmothers and healthcare providers were included. Studies were conducted in North America (9), Africa (5) and Asia (3) and South Australia (1). Donor human milk (DHM) (13) and infant formula(9) were the main supplementary milk reported followed by cow/goat milk (2). Key sub-themes derived were: education/awareness, socioeconomic status (SES), race and religion, practicality, availability of resources, sustainability, cost, affective attitude, perceived effectiveness and ethicality. Maternal/caregiver SES was a key sub-theme across all three supplemental milk feeds, acting either as a barrier or facilitator for uptake.

Conclusions: DHM and infant formula were the most commonly reported supplemental feed for infants aged <6m with growth faltering. Maternal/care giver factors were perceived as key to ensure equity, feasibility, and acceptability with respect to type and duration of supplemental milk for infants aged <6m with growth faltering.

Key messages:

- Stakeholders perceived donor human milk and infant formula as main supplemental milk for infants aged <6 months with growth faltering.
- Maternal/care giver factors are key to ensure equity, feasibility, and acceptability of supplemental milk for infants aged <6 months with growth faltering.

Abstract citation ID: ckae144.2026
Association between infant feeding behavior and maternal choice of breastfeeding type

Samantha Denise Chávez Castillo

KA Abonce Bautista[1], P Cordero Garcia[1], F Ruiz Garcia[1], MC Ceballos Vela[1], JC Viñas Dozal[1], JE Villegas-Dominguez[1], F Lopez Hernandez[1], K Vázquez Hernández[1]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
Contact: samc80543@gmail.com

Introduction: Feeding in infants is a fundamental process influenced by the mother-child relationship during the early months of life. The regulation of feeding behavior, and hunger and satiety cues may be interpreted by the mother, potentially relating to the type of feeding chosen.

Objectives: To determine the association between infant feeding behavior and the type of breastfeeding chosen by the mother.

Methods: A cross-sectional and prospective study was conducted, including mothers with children aged between 6 and 18 months. Those with medical contraindications for immediate postpartum breastfeeding or with suspension of exclusive breastfeeding during the first 6 months of life due to medical prescription were excluded. The Baby Eating Behavior Questionnaire was used to evaluate the baby's enjoyment of food, appetite response, eating speed, and satiety response.

Results: 108 mothers were included, with 87% in agreement with exclusive breastfeeding (EBF), 43.3% using breastfeeding as the primary feeding method, and only 33.3% practicing EBF during the first 6 months. Food response (FR) scored 19.6 (±4.3), enjoyment of food (EF) 17.6 (±2.1), satiety response (SR) 7.1 (±2.0), eating speed (ES) 8.8 (±2.3), and appetite (AP) 4.2 (±0.7). Comparing FR, EF, SR, ES, and AP scores between those who practiced EBF and those who did not showed $p > 0.05$. sociodemographic characteristics, perinatal factors, stance on EBF, number of hours per day with the child, feeding location, poor technique, breastfeeding pain and lack of medical guidance, all showed $p > 0.05$ when comparing between those who practiced EBF and those who did not; in contrast to perceiving that the baby wanted to breastfeed (2.5/1.0-6.2), having time to feed (3/1.2-7.2) and having no health problems (10/1.2-78.7) all with p-value <0.05.

Conclusions: The mother's perception identifying the baby's desire to breastfeed, having time to feed the baby and not having health problems favor exclusive breastfeeding.

Key messages:

- Maternal perception plays an important role in deciding to give SCI, so it is the physician's job to educate the mother so that she has additional arguments for choosing SCI.
- The infant's feeding behavior does not have a significant impact on the mother's behavior in choosing SCI feeding.

Abstract citation ID: ckae144.2027
Predictors of social withdrawal among early adolescents in Korea: a latent growth class analysis

Heeyoung Kim

J Lee[1], E Kim[2], H Kim[1]
[1]Social Welfare, Ewha Womans University, Seoul, South Korea
[2]Medicine, Yonsei University, Seoul, South Korea
Contact: 8khy@naver.com

Background: This study examines the trajectory of social withdrawal from the fourth grade of elementary school to the first grade of middle school in Korea. By classifying them, we identify individual differences such as individual, family, and school factors.

Methods: This study uses data from the Korean Youth Panel Survey (KYCPS) conducted by the Korea Youth Policy Research Institute, which includes data from the 1st-4th waves of KYCPS 2018, with a total of 2,607 participants (1,313 boys and 1,294 girls). A latent class growth analysis verifies the trajectory of youth social withdrawal, classifies latent classes, and identifies predictive. SPSS 24.0 was used to analyze the main variables' characteristics, descriptive analysis, and reliability. Mplus 8.9 was used to test the research model.

Results: First, results indicated that three was the optimum number of latent classes. We identified three latent classes 'high level of withdrawal continued (HL)', 'medium level of withdrawal increased (ML)', and 'low level of withdrawal increased (LL)'. Second, when compared the 'LL' and 'HL' groups, the higher the self-esteem, the higher the friendship, and the higher the dependence on smartphones, the more likely it was to be in the 'HL' group. Third, when comparing 'LL' and 'ML' groups, the more negative the parenting attitude, the more likely it was to be in the 'ML' group. On the other hand, higher self-esteem and more positive friend and teacher relationships were associated with a higher likelihood of being in the 'LL' group.

Conclusions: It is necessary to seek differentiated interventions to prevent social withdrawal among early adolescents. Parental education to understand the adolescent period and practical approaches to intervene in the negative psycho-emotional aspects of adolescents continuously are needed to enhance the healthy psychological development of early adolescents.

Key messages:

- The higher the self-esteem, the higher the friendship, and the higher the dependence on smartphones, the more likely it was to be in the 'high level of withdrawal continued' group.
- Higher self-esteem and more positive friend and teacher relationships were associated with a higher likelihood of being in the 'low level of withdrawal increased' group.

Nicotine use in Polish adolescents and sociodemographic factors correlations - PolNicoYouth study

Marta Miller

M Miller[1], A Tyrańska-Fobke[2], Ł Balwicki[2]
[1]Faculty of Medicine, Medical University of Gdańsk, Gdańsk, Poland
[2]Department of Public Health & Social Medicine, Medical University of Gdańsk, Gdańsk, Poland
Contact: mmiller@gumed.edu.pl

Background & aim: Almost 36% of Polish smokers started their addiction before the age of 17. Polish youth exhibit a higher prevalence of e-cigarette use (29.5%) than traditional cigarettes (26.2%). This study aimed to outline the prevalence of tobacco and nicotine product use based on usage frequency, poly-product use patterns among ever/former/naive users.

Methods: In the 2020 cross-sectional study, secondary school students from 200 schools, were selected nationwide using a stratified and random approach, making the sample representative of the entire Polish population. Data were collected through Computer-Assisted Web Interviews, using a questionnaire based on the Global Youth Tobacco Survey. Bayesian linear regression was used to assess correlations.

Results: The study consisted of 16,712 pupils aged 15-18. Almost 30% of participants admitted to current e-cigarette usage. Questions on parental smoking habits showed that 45.95% of parents smoke traditional cigarettes, 13.89% use e-cigarettes, and 13.80% use heated tobacco products (HTP). There was a very strong positive correlation between the female gender and the initiation of smoking with regular cigarettes (log[BF]=10.76). A very strong positive correlation between those studying in vocational schools and with initiation with regular cigarettes during initiation (log[BF]=18.13), while high school students had a greater association with e-cigarettes (log[BF]=11.08). There was also a very strong positive correlation between adolescents initiating smoking with regular cigarettes when their parents are also regular cigarette smokers (log[BF]=8.11) - no corresponding correlations were observed for e-cigarettes and HTP. There is a moderate positive correlation indicating a relationship between younger age (15 vs 18) and initiation by e-cigarette (log[BF]=1.8).

Key messages:

- The type of nicotine product used by adolescents for nicotine initiation correlates differently with various socio-demographic factors and the type of nicotine product used by parents.
- Taking these relationships into consideration enables the development of tailored nicotine prevention.

An evaluation of the first ten years of Newborn Screening for cystic fibrosis in Ireland

Fiona McGuire

F McGuire[1], B Linnane[2], A Collins[3], P Marsden[3]
[1]Public Health, Health Service Executive, Tullamore, Ireland
[2]Paediatric Respiratory Consultant, University Hospital Limerick, Limerick, Ireland
[3]Child Health Public Health, Health Service Executive, Tullamore, Ireland
Contact: fiona.mcguire@hse.ie

Ireland has the world's highest incidence of cystic fibrosis (CF). Newborn screening for CF (NBSCF) improves outcomes but identifies carriers and may yield false positive/inconclusive results. This study aimed to evaluate the performance of the first 10 years of the Irish NBSCF programme. Data collected by the programme between 01st July 2011 and 30th June 2021 were analysed, including cases of CF, CF carriers and Cystic Fibrosis Screen Positive Inconclusive Diagnosis (CFSPID). Microsoft Excel was used to calculate sensitivity, specificity and positive predictive value (PPV). Results were compared to European Cystic Fibrosis Society (ECFS) standards. Overall 650,809 neonates were screened, with 290 cases of CF, 533 CF carriers and 21 CFSPIDs reported. NBSCF identified 284 (98%) of the children with CF, sensitivity was 97.93% (95% CI 96.29-99.57), specificity was 99.91% (95% CI 99.91-99.92%), PPV was 0.34 (95% CI 0.31-0.37). The observed incidence of CF was 1 in 2,203, still Europe's highest. Of the six undetected cases, most were of Asian ethnicity, suggesting panel limitations for diverse ethnicities.The Irish NBSCF programme exceeded ECFS standards. Most false negatives were caused by CFTR mutations undetected by the genetic panel. Increasing the size of the genetic panel increases detection of CFSPID and carriers and is not currently recommended. Ongoing validity monitoring is vital as the Irish population diversifies.

Key messages:

- The Irish Newborn Screening Programme for Cystic Fibrosis is effective.
- Ongoing validity monitoring is vital as the Irish population diversifies.

Abstract citation ID: ckae144.2030
The relationship between perceived parental phubbing and smartphone addiction in adolescents

Özge Tonbuloğlu Altıner

Ö Tonbuloğlu Altıner[1], N Mutlu Karakaş[2], C Özbaş[1], A Uğraş Dikmen[1], S Özkan[1]
[1]Public Health, Gazi University, Ankara, Türkiye
[2]General Pediatric, Gazi University, Ankara, Türkiye
Contact: ozgealtiner@gmail.com

Background: Parental phubbing refers to the degree to which parents reduce or ignore their interactions with their children while taking care of their smartphones. Today, it has become important to conduct studies to understand the effects of parental phubbing on adolescents, which is increasing globally. This study aims to evaluate the relationship between perceived parental phubbing and smartphone addiction as well as depression in adolescents.

Methods: In this cross-sectional study, 314 adolescents aged 10-18 years who applied to the general pediatrics outpatient clinics of a university hospital in Ankara, the capital of Türkiye, were included. The questionnaire form used for data collection consisted of questions about the sociodemographic information of the participants, 'Perceived Parental Phubbing Scale', 'Kutcher Adolescent Depression Scale Short Form', and 'Smartphone Addiction Short Form for Adolescents' items. Descriptive statistics, Mann Whitney U, Kruskal Wallis H test and Spearman correlation analysis were used to analyse the data. A value of $p < 0.05$ was considered statistically significant.

Results: Depression and smartphone addiction levels were found to be significantly lower in adolescents who did not smoke, engaged in regular physical activity and had a close group of friends ($p < 0.05$). It was also found that the level of perceived parental phubbing was significantly higher in adolescents whose parents' education level was above high school and who felt lonely ($p < 0.05$). Low level positive correlations was found between perceived parental phubbing and both depression ($r = 0.116$, $p = 0.041$) and smartphone addiction ($r = 0.128$, $p = 0.023$).

Conclusions: As the level of parental phubbing perceived by adolescents increased, the levels of depression and smartphone addiction in adolescents increased. These negative effects of parental phubbing on adolescents should be taken into consideration by mental health professionals.

Key messages:

- It is important to consider and question parental phubbing as one of the related factors in adolescents with high levels of smartphone addiction and depression.
- There is a need for studies to increase the awareness of parents, who are important role models for adolescents, about the concept of phubbing and its effects on adolescents' mental health.

Abstract citation ID: ckae144.2031
Income inequality and risky health behaviors of affluent adolescents in the post-Communist Europe

Armen Torchyan

A Torchyan[1,2], I Houkes[1], H Bosma[1]
[1]Department of Social Medicine, Maastricht University, Maastricht, Netherlands
[2]Department of Family and Community Medicine, King Saud University, Riyadh, Saudi Arabia
Contact: a.torchyan@maastrichtuniversity.nl

Background: We aim to study the "golden youth" hypothesis and examine the risky behaviors of adolescents with high socioeconomic position (SEP) in post-Communist countries of Europe (PCCE) in relation to income inequality.

Methods: Adolescents aged 11-15 years from 14 PCCE participating in the Health Behavior in School-aged Children survey 2017/18 were included. A K-means cluster analysis was conducted to group adolescents based on tobacco smoking, alcohol use, binge drinking, and bullying perpetration. Generalized linear mixed models were fitted.

Results: Four clusters of adolescents were identified. The percentage of high-SEP adolescents in Cluster 1 (low risky behaviors) was slightly less compared to middle and low-SEP groups (70.9% vs 73.1% vs 73.9%, respectively). High-SEP adolescents were more likely to be in Cluster 2, characterized by frequent alcohol consumption but moderate binge drinking (14.3% vs 12.6% vs 10.7%). The prevalence of risky behaviors was similar between high and low-SEP adolescents in Cluster 3 (high smoking, frequent alcohol use, binge drinking, and moderate bullying) (8.0% vs 7.7% vs 8.2%) and Cluster 4 (high levels of bullying perpetration) (6.7% vs 6.5% vs 7.2%). Countries with higher Gini index were at a greater risk of reporting risky behaviors. High-SEP adolescents were more likely to engage in risky behaviors in countries with high income inequality. The odds ratios comparing high- vs. low-SEP adolescents ranged from 0.89 in the least unequal to 1.67 in the most unequal countries for multiple risky behaviors (Cluster 3: P-interaction = 0.042) and from 0.61 to 1.19 for bullying perpetration (Cluster 4: P-interaction = 0.030).

Conclusions: High-SEP adolescents in PCCE might be at an increased risk for unhealthy and vicious behaviors, especially in countries with high income inequality. This study highlights the need for policies that address income inequality to ensure the well-being of adolescents across socioeconomic strata in PCCE.

Key messages:

- High-SEP adolescents might be at an increased risk for unhealthy behavior in PCCE.
- Wide income inequality might contribute to risky behaviors among high-SEP adolescents.

Abstract citation ID: ckae144.2032
Pleasure-inclusive sex education, sexual agency and sexual wellbeing in youth: A scoping review

Jenneke van Ditzhuijzen

J van Ditzhuijzen[1,2], *A Overeem*[1,3]
[1]Interdisciplinary Social Science, Utrecht University, Utrecht, Netherlands
[2]Obstetrics and Gynecology, Amsterdam UMC, Amsterdam, Netherlands
[3]Sexual Wellbeing Netherlands, Utrecht, Netherlands
Contact: j.m.vanditzhuijzen@uu.nl

Background: A recent review study showed that pleasure-inclusive sex education can contribute to reducing sexual health risks such as unwanted pregnancy and STIs (Zaneva et al., 2022). Pleasure-inclusive sex education could also contribute to other measures of sexual wellbeing. In this study, we review the literature on associations between pleasure-incorporating sex education and sexual agency (including related concepts such as autonomy) and sexual wellbeing (part 1), and between sexual agency and sexual wellbeing (part 2).

Methods: We searched in 5 scientific databases using a wide scope of variables related to pleasure inclusive sex education, sexual agency, and various outcomes of sexual wellbeing, focusing on the last 2 decades. Forty-six articles were selected.

Results: In part 1 of the review we found that all studies reported associations between pleasure-based sex education and sexual agency or sexual wellbeing, but the literature is characterized by limitations and did not permit conclusions about the role of an added benefit of the pleasure component. In part 2 of the review study, we found positive associations between sexual agency (and related variables) and sexual wellbeing (including decreased levels of (re-)victimization).

Conclusions: Sexual agency may be related to increased sexual wellbeing, but it is still largely unclear whether pleasure-inclusive sex education can significantly contribute to this. There is a great need for high quality research, using innovative evaluation designs, taking into account the role of other important sources of sex education and other contextual factors.

Key messages:

- A lot of work has been done, but the evidence that pleasure in sex ed 'works' for sexual wellbeing, is limited and indirect.
- Great need for high quality research using novel and more realistic evaluation approaches.

Abstract citation ID: ckae144.2033
Prevention of sexual exploitation of children in sport clubs and social work in Switzerland

Julia Dratva

F Wieber[1,2], *M Deforth*[1], *D Winogradow*[2], *S Marti*[1], *J Dratva*[1,3]
[1]School of Health Sciences, Zurich University of Applied Science, Winterthur, Switzerland

[3]Medical Faculty, University of Basel, Basel, Switzerland
Contact: julia.dratva@zhaw.ch

The Convention on the Rights of the Child, ratified in 1989, provides a clear normative basis for the protection of children from violence, abuse and exploitation. Despite efforts to protect children, many children and young people are victims of sexual violence. In the extracurricular sector, clubs offer great potential for preventing sexual exploitation. However, obstacles such as the taboo nature of the topic and the clubs' limited resources make it difficult to develop and independently implement specific prevention offers. The aim of the project was to record the activities and competencies of sports clubs, youth associations and other youth organizations in the area of prevention of sexual assault among children and adolescents in the leisure sector and to determine the need for prevention services in the canton of Zurich in Switzerland. In addition, information was obtained on the impact of existing prevention services as well as information on their further development in terms of content and organization. Together, 979 participants from sports clubs, youth associations and youth organizations (e.g. board members, coaches, leaders) as well as the parents of children who are members of these clubs were surveyed. An impact model was developed for systematic modeling, as proposed by "Health Promotion Switzerland". The prevention of sexualized violence is seen as a very relevant topic by sports clubs, youth associations, open child and youth work and parents. However, the current implementation of prevention measures also shows that there are still barriers to implementation and room for improvement in prevention work. Participants from all areas would particularly like support with advice on how to deal with suspected cases/incidents, the provision of information materials and the creation of a protection concept. Specific ideas for the further development of prevention work were also generated and will be discussed.

Key messages:

- The prevention of sexualized violence is seen as a very relevant topic by sports clubs, youth associations, open child and youth work and parents.
- The study reveals that prevention measures are only partially implemented and identifies barriers and facilitators for improvement.

[3]Santé Publique France, Paris, France
[4]Social Epidemiology, Institut Pierre Louis d'épidémiologie et de Santé Publique, Paris, France
[5]Agence Régionale de Santé, Bordeaux, France
Contact: aude.mondeilh@inserm.fr

Background: The poor health status of underserved populations is compounded by low vaccination uptake, leading to a greater risk of epidemics. On October 2017, a measles outbreak started in the southwest of France among under-vaccinated social groups, including Travellers. We aimed to describe the health status, healthcare use and child measles-mumps-rubella (MMR) vaccination coverage in Travellers according to their environmental and living conditions.

Methods: A cross-sectional study with a three-stage random sample design was conducted between October 2019 and March 2022 in the Nouvelle-Aquitaine region in France. Trained social workers administered face-to-face questionnaires to collect data on adults and children. Anthropometric measurements, vaccination records, and data using an environmental exposure questionnaire were also collected.

Results: The participation rate was high (73.6%), with 1030 adults and 337 children included. Concerning the adults, 36.6% had obesity, 14.4% reported diabetes, 24.7% hypertension, and 14.4% major depression. The prevalence of major depression was significantly higher in adults living in precarious and unauthorized housing than in those with adequate housing (19.8 vs. 14.7%, $p = 0.03$). The unmet health care needs in the last 12 months was 48.4%. With regard to children, 45.3% had full (i.e., 2-dose) MMR vaccination coverage at 24 months and 17.9% had obesity. Finally, 74.5% of the households experienced housing insecurity, and 22.2% did not have a supply of drinking water.

Conclusions: Traveller children and adults faced deleterious environmental and living conditions potentially affecting their health, healthcare use, and vaccination coverage. These results demonstrate the need for urgent interventions for underserved populations which take into account their difficult living conditions.

Key messages:

- Travellers have a greater burden of chronic diseases than the general French population and measles-mumps-rubella vaccination coverage among Traveller children is lower than in the general population.
- The more precarious the housing, the more likely Travellers are to report having a chronic disease (social exclusion gradient).

Abstract citation ID: ckae144.2035
Acculturation and self-management abilities of well-being among older Moroccans in the Netherlands

Hager Hussein

H Hussein[1], JM Cramm[1], AP Nieboer[1]
[1]Department of Socio-Medial Sciences, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: hussein@eshpm.eur.nl

Background: Migration involves a variety of stressors. Their accumulation over time may negatively impact migrants' well-being. The extent that older migrants can integrate into a host society may determine their readiness to adopt behaviors such as self-management of well-being. Research regarding this relation among older Moroccans, one of the largest migrant groups in the Netherlands, has not been examined. This study aimed to investigate the relationship between acculturation and self-management abilities of well-being among older Moroccans and to examine differences in subgroups.

Methods: This cross-sectional study included 290 older Moroccans (≥ 65) living in Rotterdam, the Netherlands. Linear regression was applied to explore associations between acculturation (attachment to Moroccan and Dutch cultures) and self-management abilities of well-being. Independent samples t-tests were used to test differences between subgroups.

Results: Older Moroccans who received low education were found to be less attached to the Dutch culture [3.24 (0.72) vs. 3.54 (0.73); $p = 0.016$]. They were also poorer self-managers of their well-being [2.60 (0.59) vs. 2.86 (0.58); $p = 0.012$], along with those with multimorbidity [2.55 (0.60) vs. 2.77 (0.54); $p = 0.006$] and those lacking comprehension of Dutch [2.46 (0.56) vs. 2.69 (0.59); $p = 0.011$]. Self-management abilities of well-being had a negative association with multi-morbidity ($\beta = -0.18$, $p = 0.007$) and lack of Dutch comprehension ($\beta = -0.16$, $p = 0.031$), and a positive association with attachment to Moroccan ($\beta = 0.17$, $p = 0.012$) and Dutch ($\beta = 0.18$, $p = 0.010$) cultures.

Conclusions: Findings indicate that attachment to Moroccan and Dutch cultures is beneficial for older Moroccans' self-management of well-being. Efforts need to support older migrants' integration for them to adequately function and feel at home. Interventions promoting integration and self-management need to consider the characteristics of older migrant populations

Key messages:

- Attachment to origin and host cultures benefits older migrants' self-management of well-being. The cultural context of older migrants needs to be considered when promoting values of self-management.
- Differences in acculturation and self-management of well-being existed between older migrant subgroups. Interventions promoting these values should account for the diversity that exists among migrants.

Vaccine awareness and hesitancy among Ukrainian refugee mothers in Bulgaria

Milena Karcheva

M Karcheva[1], V Nedkova-Milanova[2], M Stoynovska[3]
[1]Department of Epidemiology, Medical University-Pleven, Faculty of Public Health, Pleven, Bulgaria
[2]Department of General Medicine, Medical University-Pleven, Faculty of Public Health, Pleven, Bulgaria
[3]Department of Hygiene, Medical University-Pleven, Faculty of Public Health, Pleven, Bulgaria
Contact: milena_karcheva@abv.bg

Issue: Migration carry out risk of disrupting the epidemiological well-being among refugees and host populations. Since the beginning of Ukraine crisis over 50 000 refugees remain in Bulgaria; 92% are women and children. There is suboptimal childhood immunization coverage among Ukrainian refugee community prior to arrival in Bulgaria.

Description of the problem: Childhood vaccination is mandatory in Bulgaria for TB, hepatitis B, diphtheria, tetanus, pertussis, poliomyelitis, rubella, measles, mumps, Haemophilus influenzae B and pneumococci. Refugees with uncertain immunization status are vaccinated according to the national immunization schedule and receive personal immunization card. As of March 2024, we conducted cross-sectional study to assess knowledge and attitudes of Ukrainian mothers through an interview.

Results: Of 105 mothers interviewed, 72.38% were with higher education. Arrived women were not familiar with Bulgarian health system and especially with vaccination. Absence of language barrier and presence of doctors among them facilitated our study.56.19% believe that migration has disrupted their children's vaccinations. 56.19% consider that migration has disrupted their children's vaccination. Aware of benefits of vaccines were 91,43%, they mainly trust doctors-84.76%, they pay attention to the positive discussion in the media-55.77%.Mothers realize the importance of herd immunity, considering that vaccinated children protect the others-68.57%. Leading reasons for mistrust of vaccines, mothers indicate - doubt in favor of vaccine-24.76%, medical contraindications for child-21.90% and doubts about quality of the vaccine-19.05%.They pay attention to positive discussion in the media-55.77% and have confidence in Bulgaria's institutions.

Lessons: The Government of Bulgaria provided significant support and medical care for the prevention of vaccinepreventable diseases among Ukrainian children. Institutions and volunteers work for successful integration of refugees.

Key messages:

- Need to know the immunization status of Ukrainian children admitted to Bulgaria.
- Increasing trust in vaccines and the health system in general in Bulgaria requires additional explanatory campaigns among refugees.

[3]General Medicine, Medical University, Pleven, Bulgaria
Contact: mariela_kamburova@yahoo.com

Introduction: Persons of Roma origin often face serious inequities concerning their state of health and their access to good quality health services. The aim of the study is to analyze the health services consumption and barriers in the health care of persons of Roma origin in Bulgaria.

Methods: The cross-sectional study was conducted and a semi-structured face to face interview were applied in 2022. Adult citizens of Roma origin were covered as follows: residents of Knezha - a total of 59 people and households from the towns of Knezha and Kotel - 18 families (50 persons). The cities are representative of settlements of medium size with separate neighborhoods of Roma origin. Data processing was performed by SPSS v.24.

Results: Over two thirds of the covered persons of Roma origin do not have health insurance. In each household an average of 1.8 uninsured people was found, but in some of the families almost all of the elderly members are not insured. Due to lack of health insurance in 14% of the households were reported a refusal to provide health care by general practitioners (GPs) and specialists in out-hospital care. 82.1% of Roma women have never had a mammography and 71.4% a smear test. In 83.3% of the households required direct payment for the provision of health services, which corresponds to the high share of informal payments in health care in Bulgaria (34 % in 2023), but among the Roma population this share is significantly higher. The households have to pay for specialized out-hospital care (66.6%), GPs (22.2%), and for emergency assistance (5,6%). 44.4% of the families have used the services of emergency care in the last one year. While in one third of the families an adult member was hospitalized in 27.8% of them there is a need for hospital treatment, which is unrealized.

Conclusions: The Roma population in Bulgaria is characterized by an unfavorable health profile and the health services provided to the persons of Roma origin are inadequate to their needs.

Key messages:

- Persons of Roma origin in Bulgaria often face serious inequities concerning their state of health and their access to good quality health services.
- Improving the socioeconomic status of people of Roma origin will increase their opportunities for health insurance and going to improve their access to health services.

Institutional Discrimination in Health Security Policies against Immigrants in South Korea

Sun-Seog Kweon

S Kweon[1,2,3], M Baek[2], Y Choi[2], J Kim[2]
[1]Department of Preventive Medicine, Chonnam National University Medical School, Hwasun-gun, South Korea
[2]Gwangju Institute for Public Health and Equity, Gwangju, South Korea
[3]Gwangju-Jeonnam Regional Cancer Center, Chonnam National University Hwasun Hospital, Hwasun-gun, South Korea
Contact: ujingogo@paran.com

Background: South Korea is poised to become Asia's first multiethnic society with over 5% of its population, totaling more than 2.5 million, being immigrants. This demographic shift presents significant public health challenges linked to widespread, and even intensifying, institutional discrimination in healthcare services.

Methods: This study reviews discriminatory practices across ten essential health security programs, including National Health Insurance (NHI) system, disability assistance, occupational health services, maternal and child care services, national immunization program, health screening program, and assistance for catastrophic medical expenses. Government data and personal narratives were also reviewed to identify the discriminatory elements that can have significant consequences, including increased disease prevalence, higher incidence of occupational injuries, and broader socio-economic instability among migrants.

Results: Discriminatory elements were found in most programs, with the exception of emergency medical services. These programs commonly provide fewer benefits or impose stricter eligibility criteria for migrants compared to nationals. In particular, the Korean NHI system demands migrants to pay higher premiums and more rigorous maintenance requirements.

Conclusions: The findings emphasize the need for urgent reforms to equalize health insurance costs, simplify eligibility criteria for migrants, and broaden the scope of benefits to encompass all residency statuses. Implementing these changes will enhance public health infrastructure, improve occupational safety, and foster better integration of the diverse population, ultimately promoting social cohesion and a fairer health system for all.

Key messages:

- A number of discriminatory elements against migrants have been identified in South Korea's social security policies that can exacerbate health disparities.
- Reforms are needed to expand benefits and relax eligibility criteria for migrants in key healthcare policies, including the National Health Insurance system.

Abstract citation ID: ckae144.2039
Health-related quality of life among refugees from Nagorno Karabagh resided in Kotayk, Armenia

Diana Muradyan

A Giloyan[1], *T Harutyunyan*[1], *V Petrosyan*[1]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
Contact: dmuradyan@aua.am

Background: In September 2023, more than 100,000 ethnic Armenians were displaced from Nagorno Karabakh (NK). This study assessed the health-related quality of life (HRQoL) and associated factors among NK refugees who settled in Kotayk province of Armenia.

Methods: We surveyed 197 refugees using a structured interviewer-administered questionnaire, which collected information about socio-demographics, chronic diseases, smoking status, HRQoL, utilization of healthcare services, living conditions and food access. The SF-36 Health Survey assessed HRQoL. Ophthalmic examination was conducted. Eyeglasses and medications were provided at no cost to those requiring them.

Results: The participants' mean age was 64.8 years and 59.4% were retired. The most commonly reported chronic diseases were bone/ joint diseases (67.5%), hypertension (55.3%) and heart diseases (24.9%). Around 48.7% of participants experienced sleeping disorders often/ very often. The mean total SF-36 score was 57.42±23.12; the mean physical (PHC) and mental health component (MHC) scores were 63.57±26.28 and 59.37±20.04, respectively. Only 28% of the participants utilized healthcare services after displacement. Most participants had consistent access to an adequate food supply. In the adjusted analysis age (B/PHC=-0.94, $p < 0.001$; B/MHC=-0.61, $p < 0.001$), sleeping disorder (B/PHC=-21.86, $p = 0.011$; B/MHC=-17.44, $p = 0.001$), use of medical service (B/PHC=-8.63, $p = 0.022$; B/MHC=-6.95; $p = 0.015$) and having more than one chronic disease (B/PHC=-17.35, $p < 0.001$; B/MHC=-10.90, $p = 0.001$) were associated with both PHC and MHC.

Conclusions: This study marks the first assessment of HRQoL among NK refugees. Governmental support and interventions targeting individuals with ophthalmic, sleeping, and chronic diseases might be beneficial. Follow-up assessments should track changes in both physical and mental health scores in this population, as they may fluctuate over time in response to displacement challenges.

Key messages:

- Age, sleeping disorder, use of medical service, and the number of chronic diseases were significantly associated with decreased PHC and MHC of HRQoL
- Interventions targeting individuals with restricted access to healthcare services, as well as those affected by eye diseases and chronic health issues might be beneficial.

Abstract citation ID: ckae144.2040
Vaccination in the post pandemic era - a qualitative study of the experiences of Somali immigrants

Thea Steen Skogheim

RN Gleditsch[1,2], *TS Ofitserova*[1], *BA Winje*[3], *NS Sheikh*[4], *TS Skogheim*[5], *BT Hansen*[1]
[1]Division of Infection Control, Norwegian Institute of Public Health, Oslo, Norway
[2]FAFO, Oslo, Norway
[3]Faculty of Health Sciences, Oslo Metropolitan University, Oslo, Norway
[4]Faculty of Landscape and Society, Norwegian University of Life Sciences, Ås, Norway
[5]Division of Health Services, Norwegian Institute of Public Health, Oslo, Norway
Contact: thea.skogheim@fhi.no

Background: The Somali population is the largest non-European immigrant group in Norway and past studies have indicated lower coverage for both childhood vaccines and COVID-19. However, little is known about views and experiences of vaccination among this group and how their experiences might impact their vaccination decision-making process. This study explored views and experiences with vaccination among Somali immigrants in Norway.

Methods: We conducted semi-structured interviews with 15 participants in the fall of 2022. To better understand the participants' perceptions of vaccine information, the data was inductively analyzed using a reflexive thematic analysis.

Results: Based on the thematic analysis, we focused on four sub themes: 1) the impact of COVID-19 on views of vaccines; 2) new versus old vaccines; 3) childhood vaccination; 4) trust in vaccines. The study found that the participants' experiences during the pandemic have impacted their views on vaccination in general. Many of the participants expressed positive views and high levels of trust in the Norwegian health authorities and their vaccination recommendations. It was found that having sufficient information and trust in vaccination recommendations contributed to higher vaccine readiness. Viewing vaccines as new and insufficiently tested or researched, as well as lacking information about potential side-effects, increased participants' hesitancy when faced with vaccination decisions. Among the parents in this study, postponing the measles-mumps-rubella-vaccine due to fear of autism was a common occurrence.

Conclusions: The current study fills an important gap in knowledge about views, experiences, and vaccination decisions among the Somali population in Norway. Knowledge from this study can help adapt better vaccine information and further improve the prevention of infectious diseases in Norway in general and for under-vaccinated groups in particular.

Key messages:

- Having sufficient information and trust in vaccination recommendations contributed to higher vaccine readiness.
- Viewing vaccines as new and insufficiently tested/researched, as well as lacking information about potential side-effects, increased participants' vaccine hesitancy.

Abstract citation ID: ckae144.2041
A Qualitative Study of Implementation Outcomes of a Group-Based Intervention for Immigrant Parents

Pauliina Sibbie

P Sibbie[1,2], *R Lämsä*[1], *N Skogberg*[3], *K Peltonen*[4], *T Laajasalo*[2]
[1]Department of Public Health, University of Helsinki, Helsinki, Finland
[2]Special Services Unit, THL, Helsinki, Finland
[3]Department of Public Health and Welfare, THL, Helsinki, Finland
[4]INVEST Research Flagship Centre, University of Turku, Turku, Finland
Contact: pauliina.sibbie@helsinki.fi

Background: Inequities in service utilization between immigrant families and native populations have emerged within the Nordic welfare countries, highlighting the need for culturally sensitive parenting support. Despite the proven efficacy of parenting interventions, their implementation phases have not been adequately addressed in extant implementation research, particularly regarding structural racism and inequities. This study aims to contribute to the literature from an implementation perspective by describing a pilot of 'Being a Parent in Finland,' a culturally sensitive group-based intervention for migrant parents. Its specific focus is on investigating barriers to and facilitators of implementation outcomes from the perspectives of service providers.

Methods: The qualitative data consisted of thematic interviews ($N = 6$) with service providers ($N = 9$) compiled at distinct phases of the pilot from 2021 to 2023. In addition, data triangulation was utilized through document analysis of 125 pages of various documents regarding the pilot as a supplementary data collection method. Content analysis was conducted on the data using Atlas. ti 23.

Results: The findings stress the alignment of the target group, service placement, and preventive measures for enhancing parenting intervention's acceptability, appropriateness, and feasibility. Implicit objectives, such as perceiving the target group as 'at-risk,' can impede intervention success and exacerbate stigmatization of the target group. Culture- and context-specific adaptations, and community engagement foster parental trust and intervention accessibility.
Conclusions: The findings underscore the significance of congruent objectives, community engagement, and adaptive iterations in preventive parenting interventions. Advocating for these elements in implementation strategies is crucial for reducing stigmatization and enhancing equity and efficacy in services tailored to minority parents.
Key messages:

- Acknowledging equity in both implementation research and strategies is paramount.
- Implementing trust-building is crucial for culturally sensitive parenting interventions.

Abstract citation ID: ckae144.2042

Satisfaction with maternity care among immigrant women compared to non-immigrant women

Vera Seidel

V Seidel[1], L Teschemacher[2], J Breckenkamp[3], T Borde[4], M David[5], M Abou-Dakn[6], W Henrich[1]

[5]Gynecology, Charité - Universitätsmedizin Berlin, Berlin, Germany
[6]Obstetrics and Gynecology, St. Joseph Hospital, Berlin, Germany
Contact: vera.seidel@charite.de

Introduction: Migration is a worldwide phenomenon leading to challenges for the health care system. There is conflicting evidence on the effect of migration on the satisfaction with obstetric care. Our hypothesis was that satisfaction with obstetric care was lower in immigrant women with and without self-defined (sd) refugee status than in non-immigrant women.
Methods: In the Pregnancy and Obstetric Care for Refugees (PROREF)-study between June 2020 and April 2022 in Berlin women were interviewed 1-3 days after giving birth with the Migrant Friendly Maternity Care Questionnaire (MFMCQ). The interview data was linked to the routine perinatal data of the hospital charts. Descriptive analysis and logistic regression analysis were performed to identify factors influencing satisfaction with obstetric care.
Results: A total of 3420 women (Frauen (247 with sd refugee status, 1356 immigrant women und 1817 non-immigrant women) could be included in the study, with an overall response rate of 77.5%. Satisfaction measured generally high with over 80% of women being satisfied with obstetric care at all three time points: during pregnancy, during labor and birth and after giving birth. We identified two factors associated with an increased chance of being satisfied with obstetric care: sd refugee status (OR 2.57, 95% Cl 1.48 - 4.44, p-value 0.0008) and being multipara (OR 1.40, 95% Ci 1.18 - 1.67, p-value 0.000).
Conclusions: Efforts on improving birth experience should focus on primipara. Among the reasons for non-immigrant women being less satisfied with care than women with sd refugee status might be different expectations and the timing of data collection.
Key messages:

- Refugee women might have different expectations regarding birth experience than other immigrant women and non-immigrant women.
- Satisfaction with obstetric care in Berlin is generally high among immigrant women and non-immigrant women.

Abstract citation ID: ckae144.2043

Dialogue between researchers and older immigrant women in Norway post COVID-19: A qualitative study

Prabhjot Kour

P Kour[1], GK Agata[1], E Diaz[1,2]
[1]Pandemic Centre, University of Bergen, Bergen, Norway
[2]Department for Health and Function, Western Norway University of Applied Sciences, Bergen, Norway
Contact: Prabhjot.Kour@uib.no

Background: In the wake of the COVID-19 pandemic, marginalized groups, particularly older immigrant women, have faced new challenges, prompting an urgent need for research to understand their post-pandemic needs and foster inclusive healthcare systems. In view of this, older immigrant women and researchers developed a project based on dialogue, holding monthly meetings for a year, with the aim of improving health literacy for the women, and enlightening the researchers on the women's challenges. This study has sought to understand the experiences of the dialogue between older immigrant women and researchers.
Methods: We utilized participant observation in five dialogical meetings between older immigrant women and researchers, followed by semi-structured interviews with 8 older immigrant women and 7 researchers in Bergen. Data was analyzed using thematic analysis, supported by audio-recorded and transcribed interviews, alongside notes from participant observations.
Results: Analysis yielded three main themes of health knowledge, collaboration, and power dynamics. The dialogue was seen as a positive experience by both older immigrant women and researchers, with a view to establishing collaboration and trust. It also encouraged user participation in research, for the women, and carrying out research that was relevant to this otherwise 'invisible' population to the health system, for researchers, whilst empowering the women with knowledge to improve and maintain their own health.
Conclusions: This study sheds light on the crucial role of dialogue between older immigrant women and researchers in understanding post-COVID-19 needs. The findings underscore the importance of fostering collaboration, trust, and user participation in research, empowering marginalized populations while addressing gaps in the healthcare system. By amplifying the older immigrant women voices' and promoting inclusive research practices, we can foster responsive and equitable healthcare systems.
Key messages:

- Dialogue between older immigrant women and researchers is essential for understanding post-COVID-19 needs, fostering collaboration and trust.
- User participation empowers marginalized groups, while relevant research improves healthcare inclusivity and outcomes for all.

Co-designed study with the Traveller Community in Ireland to determine cancer awareness & attitudes

Patricia Fitzpatrick

P Fox[1], R Jalal[1], P Fitzpatrick[2], K Frazer[1], L Kavanagh[3], MB Collins[3], U Kennedy[4], T McCarthy[4], B Quirke[5], R Joye[1]
[1]School of Nursing, Midwifery & Health Systems, University College Dublin, Dublin, Ireland
[2]School of Public Health, University College Dublin, Dublin, Ireland
[3]Pavee Point, Traveller Centre & Roma Centre, Dublin, Ireland
[4]National Cancer Control Programme, HSE, Dublin, Ireland
[5]Social Inclusion, HSE, Dublin, Ireland
Contact: patricia.fitzpatrick@ucd.ie

Background: Irish Travellers are a distinct ethnic minority group (formal recognition March 2017). They experience higher mortality than the general population at all ages for all causes of death.

Study Aim: To determine cancer awareness and attitudes among the Traveller Community in Ireland, and to identify barriers/enablers to cancer risk reduction behaviours and early diagnosis of cancer.

Methods: A co-designed multi-method study was developed in collaboration with Pavee Point, a national NGO for Travellers, the National Social Inclusion Office (NSIO) and the National Cancer Control Programme (NCCP) including: 1. Consultation with Pavee Point and NSIO representatives to inform the study proposal and methodology. 2. Co-design of methodology for ethics applications and subsequent data collection plan including interview topic guides and the development of a culturally appropriate version of the NCCP's 2022 National Survey on Cancer Awareness, adding questions on social determinants of health and screening participation. 3. Collaboration with 12 peer-led Primary Health Care for Travellers Projects (PHCTPs), to provide in-person training for Traveller Community Health Workers to undertake a cross-sectional survey of 380 adult Travellers. 4. Collaboration with PHCTPs to undertake 20 semi-structured interviews with Travellers. 5. Conduct of semi-structured interviews with healthcare professionals to explore perceptions of barriers/enablers for Travellers engaging with the health system.

Lessons Learned: Working closely and collaboratively with our study partners, we gained valuable insights which enabled effective and efficient data collection across 8 counties, while exceeding our survey target sample size. Implications for Research: Collaborative, trusting, and respectful relationships are critical for all studies, but particularly when working with minority groups.

Conclusions: The study findings will inform policy for improved cancer outcomes among Travellers in Ireland.

Key messages:

- Formation of a collaborative and respectful relationship with the Traveller community has facilitated successful research.
- Traveller Community Health Workers (peer researchers) were key to the success of data collection.

Abstract citation ID: ckae144.2045
Comparison of hospital treatments of the Roma settlements' inhabitants in Slovenia

Tatjana Krajnc Nikolic

T Krajnc Nikolic[1], *M Ranfl*[1], *K Rostohar*[1]
[1]NIJZ, Murska Sobota, Slovenia
Contact: tatjana.krajnc-nikolic@nijz.si

Background: Roma ethnic minority in Slovenia was recognized as a vulnerable group with worse health indicators and significantly shorter life expectancy. The vast majority of Roma population in Slovenia have health insurance. We were investigating the use of hospital services in Roma population according to their age and comparing it with the rest of the population.

Methods: We determined the inhabitants of Roma settlements from the Slovenian register on residents. The data on hospital treatments used were from Slovenian national register on hospital treatments for the period 2018 to 2022. We compared different ratios according to certain hospital treatments within age categories of patients and co-pared those two groups. The frequency statistics, ANOVA and comparison of column proportion tests were used (p-value$<$0.005, 95% CI).

Results: Inhabitants of Roma settlements were more often treating in hospitals that rest of population. If comparing the frequency of hospital treatments between age groups only in Roma population, the percentage of hospital treatments steeply declines with age as well as the number of persons in age groups. The highest percentages and numbers of services are in the youngest age group of 0-15 years, and the lowest in the oldest group (75+). Therefore, significantly higher ratios of hospital treatments were detected in younger then in older age groups.

Conclusions: Roma children and youngsters (0-15 years old) had the highest rate of hospital treatments and it declined with the age. It was consistent with age pyramid of Roma as young population as well as emphasized care for children in culture. The steady decline rate of hospital treatments with age could be explain with delayed seeking of health care services in adult age and higher premature mortality that leads to smaller adult population. Additional and in-depth research is necessary to explain the root causes of higher premature mortality and use of primary and preventive health services.

Key messages:

- Higher use of hospital treatments was caused by higher morbidity. It is necessary to explore the leading causes of hospital treatments and premature mortality.
- It is necessary to explore the use of primary health care service, preventive service and level of health literacy of inhabitants of Roma settlements.

Abstract citation ID: ckae144.2046
Self-help groups for people with migration experience

Marion Weigl

M Weigl[1], *Sandra Ecker*[1]
[1]Austrian National Public Health Institute, Vienna, Austria
Contact: marion.weigl@goeg.at

Background: Self-help groups as voluntary associations of people to jointly cope with illnesses or psychological problems are sometimes regarded as the fourth pillar of the health care system. Still, so far people with migration experience do not resp. less participate in self-help groups in Austria. The project aimed therefore on identifying related obstacles and solutions.

Methods: A mixed-methods approach was chosen: a systematic literature search; interviews, focus groups and workshops; including people with migration experience and experts. A concept for self-help groups was delevoped in a participatory way, piloted in Vienna and evaluated.

Results: The study confirmed, that the concept of self-help groups as they are usually implemented in Austria is not known among people with migration experience. But there is a great need for exchange among those with a chronic illness or their relatives. Success factors and obstacles are mainly related to the access to people with a migration experience and the way how such self-help groups are set up. Much time needs to be invested in developing a common understanding of the concept of a self-help group and in maintaining contacts. However, despite the of the personal benefit, the often stressful life situation of people with migration experience is an obstacle for continuous participation or even initiating a self-help group oneself.

Conclusions: The project showed, that, although the concept of self-help groups is often not known, people with a migration experience can benefit from it. But more support is needed than is usually provided by the established self-help organisations. A change in the understanding of self-help groups on the one hand and integrating such activities in services/associations working with migrants on the other hand could improve the access for people with migration experience to this important pillar of the health care system.

Key messages:

- Several obstacles hinder people with migration experience in participating in self-help groups in Austria, e.g. the concept itself is unknown to them.
- Implementing a specific concept for self-help groups with support by professionals can facilitate the access of this population group to an important part of the health care system.

Abstract citation ID: ckae144.2047
Heterogeneity in health and lifestyle among preschool children with migrant background in Sweden

Faustine Kyungu Nkulu Kalengayi

S Alseddig[1], *FK Nkulu Kalengayi*[1], *M Vaezghasemi*[1], *L Lundahl*[2], *M Lindkvist*[1], *K Lindvall*[1], *SA Silfverdal*[3], *A Ivarsson*[1]
[1]Department of Epidemiology and Global Health, Umea University, Umea, Sweden
[2]Department of Applied Educational Science, Umea University, Umea, Sweden
[3]Department of Clinical Sciences, Pediatrics, Umea University, Umea, Sweden
Contact: faustine.nkulu@umu.se

Background: Parental country of birth and socioeconomic status affect children's health, lifestyle, and access to care. But inequality patterns may vary depending on the outcome and indicator being studied. While prior studies have focused on single health outcomes, this study assessed the relationship between parental migrant status and a range of health and lifestyle indicators among 3-year-old children.

Methods: Using an outcome-wide approach, we analyzed data from cross-sectional population-based surveys of 3-year-old (2014-2018) in Northern Sweden, which included 9,099 children aged 33-42 months. The surveys were administered to parents. Logistic and linear regressions were performed to examine the association between parents' place of birth and outcome indicators. Additionally, we controlled for parents' income and education using multiple regression models.

Results: Children with at least one migrant parent were perceived by their parents to have poorer health (OR:1.5, CI:1.01-2.36) and more socio-emotional problems (OR: 2.8, CI: 2.20-3.59) compared to those with two Swedish parents. While there were no significant differences in estimated BMI, lifestyle indicators showed that these children consumed more sweets (OR:4.5, CI: 3.02-6.58), less milk (OR: 1.3, CI: 1.09-1.55), fewer vegetables (OR:1.6; CI: 1.22-2.05) and brushed their teeth less frequently (OR: 2.8, CI: 2.17-3.53). However, they spent more time playing outdoors on weekdays (OR:1.6, CI:1.22-2.00) and weekends (OR: 1.5, CI: 1.18-1.94), but screen time remained consistent between weekdays and weekends.

Conclusions: Parental migrant status has varying impacts on children's health and lifestyle, with some indicators showing worse outcomes for children with migrant parents compared to those with Swedish parents, while others do not. An outcome-wide approach is crucial for targeted actions to strengthen protective factors and mitigate risk factors, and ultimately reduce inequalities in early childhood.

Key messages:

- The link between parental migrant status and children's well-being is complex. Not all indicators show worse outcomes, inequality patterns vary based on the specific outcome and indicator measured.
- An outcome-wide approach is crucial to identify action areas for targeted interventions to reinforce protective factors and mitigate risk factors, and ultimately reduce inequalities during childhood.

Conversation circles – an inventive way to talk about and address migratory related mental health

Maissa Al-Adhami

M Al-Adhami[1], *J Wångdahl*[2], *C Tomsfelt*[3], *K Carlzén*[3], *P Svensson*[4]
[1]Department of Public Health Sciences, Uppsala University, Uppsala, Sweden
[2]ARC, Karolinska Institutet & Stockholm University, Stockholm, Sweden
[3]County Administrative Board, Skåne, Malmö, Sweden
[4]Department of Clinical Sciences, Lund University, Lund, Sweden
Contact: maissa.aladhami@uu.se

Refugees in European countries face psychological stressors stemming from pre-, peri- and post-migration experiences. In Sweden, a mental health promotion program for newly settled refugees "Ways Forward - After the escape", was tried out to mitigate the consequences of negative migratory experiences. The program included training of course leaders and implementation of conversation circles for participants, i.e., short in-depth courses for smaller groups led by a trained leader. The objective of the program was to equip civic communicators working within the Introduction program for refugees with the necessary skills to lead conversation circles on mental health in cities in the south of Sweden. During 2020-2023, 43 course leaders were trained and 55 refugees participated in conversation circles. The course leader training included 50 hours of training on themes of the program "Ways Forward"; health and well-being, loss and identity, grief and forgiveness, reconciliation and acceptance, stress and stress management, trauma and trauma-conscious care. The conversation circles for participants were given in 3-hour modules x 10 occasions.

1. How did the course leaser perceive the utility of the training for their work with the target group? 2. In what ways has the intervention assisted the participants in navigating their mental and well-being in Sweden? The results showed that course leaders acquired new knowledge and practical skills and tools to lead reflective conversations about mental health related to migration. Participants reported a higher awareness of mental health issues, less stigma, trying out new coping techniques and increased motivation to seek help. Short training courses for civic communicators on migratory mental health increased knowledge and gave new skills and tools to lead conversation circles. Newly settled refugees reported higher awareness, new tools and less stigma to talk about mental health following participation in conversation circles.

Key messages:

- Short training courses on mental health related to migration increased knowledge and gave new skills and tools to lead conversation circles.
- Newly settled refugees reported higher awareness, new tools and less stigma to talk about mental health following participation in conversation circles.

Abstract citation ID: ckae144.2049
Discrimination against migrants: does social capital moderate harmful effects on mental health?

Louise Biddle

L Biddle[1], *B Stacherl*[1], *E Heidinger*[1]
[1]Socioeconomic Panel, DIW Berlin, Berlin, Germany
Contact: lbiddle@diw.de

The harmful mental health effects of perceived discrimination are well established. Yet, the role of regional-level social capital in mitigating these effects remains underexplored. Using data from the German Socioeconomic Panel (SOEP; 2010-2021) we apply random effects models to assess the effect of perceived discrimination on mental health (mcs subscale of the SF-12) adjusting for individual socio-demographic factors and regional-level socioeconomic deprivation. We assess interaction with general social capital (civic organisations, electoral turnout, generalised trust) and migrant-specific resources (proportion of non-nationals and share of far-right votes). We juxtapose non-refugee migrants ($n = 13478$) with refugees subject to mobility restrictions ($n = 5558$) to assess for bias introduced by selective mobility into regions. In the non-refugee sample, we confirm negative effects of frequent discrimination experiences on mcs (ß: -3.74; 95%CI: -4.39, -3.08). Moderation analyses show insignificant results for general social capital, but a negative interaction effect of proportion of non-nationals (ß: -0.71; 95%CI: -1.34, -0.08). Analyses among refugees confirm the negative effect of discrimination on mcs (ß: -6.29; 95%CI: -7.49, -5.08) and the moderating effect of the proportion of non-nationals (ß: -1.63; 95%CI: -2.78, -0.48), as well as showing a positive moderation effect for generalised trust (ß: 0.84; 95%CI: 0.11-1.57). Results demonstrate the negative implications of living in areas with a high proportion of non-nationals for migrants experiencing discrimination, which may be explained by the higher marginalisation of migrants in these areas and increased service access barriers. The absence of a moderation effect of general social capital appears to be the result of selection bias, with positive effects of generalised trust seen for refugee migrants.

Key messages:

- Ethnic discrimination affects mental health of refugee and non-refugee migrants.
- The effect of discrimination on mental health are stronger in areas with higher proportion of non-nationals.

Abstract citation ID: ckae144.2050
Shifting focus - the need to prioritise an inclusive public health approach to trauma

Joanne Hopkins

J Hopkins[1,2]
[1]Policy and International Health, Public Health Wales, Cardiff, UK
[2]Faculty of Social and Life Sciences, Wrexham University, Wrexham, UK
Contact: joanne.hopkins2@wales.nhs.uk

Since 2017, the Welsh government has prioritised the development of a Public Health Approach to understanding the impact of Adverse Childhood Experiences. Taking the work of Bellis et al, and the population level research to understand the prevalence of ACEs, and associated risks (Bellis etc al, 2015), the ACE Hub Wales was established to coordinate a multi-agency, cross sector approach to preventing, tackling and mitigating the impact of adversity in childhood. The Hub developed its approach to advocate for more public awareness of the life course risks to health if the right support was not accessed or available to children, such as poor mental health and chronic conditions such as type 2 diabetes and heart disease in adulthood. From 2021 there has been a dramatic shift to attempting to understand the experiences, and unmet needs, of children and people who have come to Wales to seek sanctuary, migrant women who have no recourse to public funds, and people experiencing racism and discrimination. In 2021, the ACE Hub Wales co-produced a Wales national trauma-informed practice framework including a set of principles placing inclusion at the heart of the approach in Wales; shining a light on the need to have a cultural, intergenerational and gender-based understanding of adversity and trauma which links directly to, informs and supports the government's ambitions to be a nation of sanctuary and to be anti racist by 2030. To continue to ignore the experiences of adversity and trauma by people of colour, and Gypsy, Roma and Traveller people; is to perpetuate the health inequity experienced in healthcare, and justice systems. Wales has committed to developing wisdom, not just knowledge, that means that a public health approach is inclusive of all of our communities in Wales.

Key messages:

- The experiences of racialised ad minoritised communities from population studies of adversity and trauma is traumatizing.
- Understanding the life course impact of adversity and trauma must include the experiences of racism and discrimination to be inclusive and trauma-informed.

Abstract citation ID: ckae144.2051
Experiences of discrimination in Finnish healthcare services

Katri-Leena Klemettilä

K-L Klemettilä[1,2]*, R García Velázquez*[1]*, N Skogberg*[1]*, AE Castaneda*[1]*,*
M Eid[1]*, H Kuusio*[1]
[1]THL, Helsinki, Finland
[2]University of Eastern Finland, Kuopio, Finland
Contact: katri-leena.klemettila@thl.fi

Background: It has been found that foreign-born people report more discrimination than the general population. This study examines experiences of discrimination in Finnish healthcare, with a focus on individuals with a foreign background.

Methods: Two nationally representative cross-sectional data sets were used: MoniSuomi ($n = 7838$; response rate 44.1%) and Healthy Finland Surveys ($n = 28154$; response rate 46.3%). The outcome variable, experiences of discrimination, was predicted by means of stepwise logistic regression models covering (1) socioeconomic factors, (2) factors related to healthcare service need and use, and (3) migration-related factors.

Results: In healthcare services, migrants experienced discrimination more than twice as frequently as the general population (8.9% versus 3.6%, 95% CI = 8.0-9.8, 3.2-4.1). According to regression models, relevant factors were insufficient income, being female, studying as the main occupation and poor mental and physical health. Foreign background was not independently associated with discrimination. However, higher educational attainment, chronic disease, and use of occupational healthcare services increased the likelihood of experiencing discrimination only among those of foreign background and showed the opposite trend for the general population. All migration-related factors increased the risk of discrimination.

Conclusions: The findings underline the need for training on explaining the service system, overcoming language barriers, and working with forced migrants. The occupational healthcare workforce would particularly benefit from these interventions. The results inform the development of professionals' training.

Key messages:

- Migrants experience higher levels of discrimination in healthcare compared to the general population. Multiple factors explain this difference.
- Healthcare professionals require training to better inform patients about the service system, to improve communication and to address the situation of forced migrants.

Contact: p.paudyal@keele.ac.uk

Background: Effective communication of relevant health information is challenging in elderly minority ethnic groups due to language barriers and cultural differences. During the COVID-19 pandemic, much of the public health guidance around COVID-19 was in dominant languages, lacking cultural nuance. This study aimed to co-produce culturally, linguistically, and age-appropriate health education resources in COVID-19, tailored to the needs of older adults from ethnic minority backgrounds.

Methods: This study involved three stages: 1) Semi-structured interviews with Indian and Nepalese older adults (≥ 65 years), their families (≥ 18 years) and healthcare professionals (HCPs) (≥ 18 years) engaging with these communities; 2) Co-production of COVID-19

information resource, and c) Implementation of co-produced resources among the communities.

Results: 24 participants took part in the study. There was wide variation in participants' knowledge of COVID-19; some were knowledgeable, while others had limited information. Participants highlighted the need for information in multiple formats and languages and discussed the importance of culturally avenues for information dissemination. Drawing on these findings and two co-production workshops held with the stakeholders, culturally sensitive information leaflets (electronic and paper) were co-prodcued in Hindi and Nepalese using age-appropriate images and infographics. The leaflets were distributed widely to the Nepalese and Indian communities, healthcare trusts and local authorities using the networks of community members, HCPs, and religious leaders.

Conclusions: The project highlights the significance of participatory methods in the development of culturally relevant public health interventions applicable to the cultural practices of ethnic minority groups. The co-production approach in this study could influence information provision for future public health campaigns for other marginalised groups.

Key messages:

- Health information should be co-produced with a representative sample of the community members and relevant stakeholders.
- There is a need on an ongoing basis to identify and fill the information gaps, address misinformation and develop targeted messages.

Abstract citation ID: ckae144.2053

Young North African migrants in Europe: exploring their health and the adequacy of health services

Yves Jackson

Y Jackson[1,2], E Rocilla Arachega[1,2], B Broers[2], C Chamay Weber[3], O Rigumye[1], M Pinon[1,4]

[2]University of Geneva, Geneva, Switzerland
[3]Division of Paediatrics, Geneva University Hospitals, Geneva, Switzerland
[4]School of Health Sciences, Western Switzerland University of Applied Sciences, Geneva, Switzerland
Contact: yves.jackson@hcuge.ch

Background: Over five million people from North Africa (NA) lived in Europe in 2019, including youth characterized by intense transborder mobility, precarious living conditions and high-risk behaviours such as prostitution and illegal activities. This population challenges health professionals and institutions ability to deliver medical care and health information remains scarce. This scoping review aims to better understand NA adolescents and young adult (aged 12-25) health status, access to and use of healthcare.

Methods: Following the Arksey and ÓMalley process and based on the Population-Concept-Context framework, we searched the CINAHL, Cochrane, Embase, PubMed, PsycINFO and Web of Science databases for peer-reviewed articles and non-index reports. We systematically tracked references.

Results: Initial search returned 5319 articles of which we included 13 (2 Spanish, 2 French, 3 German). All reported about observational studies. Nine of 13 papers included males only and 11 focused exclusively on unaccompanied minors. They reported about physical health conditions related to poverty such as dental caries, iron deficiency and dermatological conditions (n = 5) or infectious diseases, notably tuberculosis (n = 7). Trauma-related mental health conditions were frequently reported (n = 7), including post-traumatic stress disorder and alcohol, cannabis or benzodiazepines harmful use with frequent overlapping presentations. Three studies discussed multi-pronged barriers to healthcare, emphasizing the importance of transcultural approaches and attention to social factors.

Conclusions: Embedded into multiple factors of vulnerability, poor physical and mental health is commonly associated with young NA migrants. Evidence is limited in scope and quality notably about females and young adults. There is an important gap about optimal strategies to deliver tailored health services, notably to respond to complex mental health needs.

Key messages:

- The complex health needs and barriers to care of young NA migrants in Europe are not adequately documented, understood, and addressed.
- Particular attention should be paid to trauma-related mental health conditions.

Changes in integration and wellbeing by educational background among migrants in Kristiansand

Khadra Yasien Ahmed

K Ahmed[1], YT Sima[1], A Lunde[1], LT Fadnes[1,2], B Kumar[3], E Diaz[1,4]
[1]Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway
[2]Bergen Addiction Research, Department of Addiction Medicine, Bergen, Norway
[3]Norwegian Institute of Public Health, Oslo, Norway
[4]Department of Health and Functioning, Western Norway University of Applied Sciences, Bergen, Norway
Contact: khadra.ahmed@uib.no

Background: Integration levels and wellbeing of newly arrived migrants change according to their everyday activities in their new home country. Although migrants have very different educational backgrounds and expectations regarding work in Norway, the compulsory educational activities are the same for all, disregarding their educational background.

Aims: To examine the changes in integration and wellbeing among newly arrived migrants participating in a compulsory integration program in Norway, according to their educational background.

Methods: As part of the Integration for Health project (I4H) we collected information from participants in Kristiansand municipality through a self-filled questionnaire in 2023 (N = 102) repeated six months apart, including questions from the Immigrant Policy Lab Index and the WHO-5 Well Being Index. For both screening tools, higher scores indicate better integration and wellbeing. Information on educational background was dichotomized into either health or non-health (natural and technical) sciences, using health sciences as the reference. We used generalized estimating equations to calculate relative risks (RR) with 95% confidence intervals (CI) adjusted for age and gender.

Results: The mean age was 34 years (SD 8.3) and 59% were women. Mean residency time was 3 years (SD 0.14). In terms of education, 14% had health sciences, and 86% had other educational backgrounds. We did not find change in wellbeing over the six-month period (RR 1.0 (95% CI 0.9-1.1), and this trend was similar for both educational groups (RR 0.9 (95% CI 0.8-1.1). Integration score slightly increased after six months (RR 1.0 (95% CI 1.0-1.1). However, there was no difference by educational background (RR 1.0 (95% CI 0.9-1.0).

Conclusions: Changes in wellbeing and integration among participants in the compulsory introductory program with short residency time, do not seem to vary by educational background in a six-month period.

Key messages:

- Schools and introductory programs in the host country can be used as a arena to enhance both the integration and wellbeing of newly arrived migrants.

- Strengthening migrants' educational opportunities in the new host country is also of importance.

Mental health trajectories among Syrian refugees in Norway: A longitudinal cohort study

Yeneabeba Tilahun Sima

YT Sima[1], EM Strømme[1], E Diaz[1,2]
[1]Global Public Health and Primary Care, University of Bergen, Bergen, Norway
[2]Department of Health and Functioning, Western Norway University of Applied Sciences, Bergen, Norway
Contact: Yeneabeba.Sima@uib.no

Background: Refugees encounter various risk factors that can affect their mental health throughout the migration process. However, while most studies focus on mental health challenges at the time of resettlement, only a few explore these changes over an extended period. This study aims to explore changes in mental health among Syrian refugees in Norway and to identify influencing factors.

Methods: This is a prospective cohort study using data from CHART and Integration for Health studies, which followed Syrian refugees granted settlement in Norway. Data collection took place in Lebanon between 2017-2018 (baseline), and at one- and four-years post-arrival in Norway. Assessments for anxiety/depression and post-traumatic stress disorder (PTSD) were conducted using the Hopkins Symptom Checklist (HSCL-10) and the Harvard Trauma Questionnaire, respectively. Mixed-effects logistic regression analyzed temporal changes, with results presented as odds ratio (OR) with 95% confidence intervals (CI). The study also explored the effect modification of outcomes by the following baseline factors: age, gender, education.

Results: A total of 132 participants were included in all three data collection points. There was a decrease in the proportion of participants reporting anxiety/depression (from 30% to 28%, OR 0.1, 95% CI 0.1 - 0.2) four years post-settlement. The proportion of participants reporting PTSD symptoms decreased one year after settlement (from 4% to 3%, OR 0.3, 95% CI 0.1 - 0.7), but increased to 4% four years after arrival, showing no improvement from baseline (OR 0.8, 95% CI 0.4 - 2.0). No interactions were observed between changes over time and baseline variables.

Conclusions: After four years in Norway, Syrian refugees reported improvement in anxiety/depression, but PTSD symptoms worsened. This highlights the need for ongoing support that extends beyond the initial phases of resettlement.

Key messages:
- Refugees face various risk factors that affect their mental health throughout the migration process.
- Ongoing mental health support for refugees is essential, beyond the initial resettlement phase.

An observational study in Roma women in Greece: measuring health factors in an understudied group

Konstantina/Dina Zota

K Zota[1], A Dalma[1], S Tzirita[1], M Kouvari[1], K Katsas[1], E Zioga[1], N Drougos[1], P Karnaki[1], A Veloudaki[1]
[1]Institute of Preventive Medicine, Environmental & Occupational Health, Marousi, Greece
Contact: d.zota@prolepsis.gr

Background: The Roma have always been one of the most vulnerable and at the same time understudied minority groups in Europe, living under difficult conditions and experiencing discrimination. The aim of the present work was to summarize the health and lifestyle profile of Roma women living in various regions of Greece.

Methods: A multi-center, observational study was implemented in April-June 2022, in the context of a national program entitled "Empowering Young Roma Women in matters of health, prevention and human rights: a new methodological approach". Roma women, living in 5 areas of Greece, and health professionals working with Roma groups were considered as eligible to participate. A two-step, methodological approach was followed: a. qualitative study with Focus Groups and b. questionnaire-based survey.

Results: In total, n = 41 participants in FGs, and n = 99 responders in survey were recorded. 40% of participants were smokers (>10-15 cigarettes/day). Main quitting reasons, were "to set a good example and cost'. Increased consumption of ultra-processed foods and beverages, low plant-based foods intake, frequent breakfast omission and eating-out were reported by the vast majority of participants. Only 15% of responders had undergone typical, gynecological, screening tests while 1 in 5 responders used contraception. Regarding vaccinations, even if about 8 in 10 women seemed to comply with the obligatory vaccines for their children, a high vaccination reluctancy in 70% of the study sample was recorded in case of vaccination in adulthood.

Conclusions: This study stands one of the very few that underscore the vulnerability of Roma women in terms of poor health literacy, unhealthy lifestyle behaviours and low motivation to typical preventive measures. Improving access to primary health care services and tailored, culturally sensitive training is crucial.

Key messages:
- Social inclusion of the increasing population of Roma women is crucial.
- Health promotion, taking into consideration Roma women's special needs, shall be a decisive factor of this process.

Abstract citation ID: ckae144.2057
Health status by time of arrival among Ukrainian refugees in Norway

Angela Labberton

AS Labberton[1], L Ozeryansky[2], Y Helland[1], TS Skogheim[1], TM Hansen[1,3]
[1]Division for Health Services, Norwegian Institute of Public Health, Oslo, Norway
[2]The Graduate School, University of Washington, Seattle, USA
[3]Quality Indicators and User Surveys, The Norwegian Directorate of Public Health, Oslo, Norway
Contact: AngelaSusan.Labberton@fhi.no

Background: Over 75000 refugees from Ukraine have come to Norway since February 2022. Previous studies show that the refugees have poor health for several domains, and reports suggest that those fleeing Ukraine at later stages have even poorer health. However, more systematic knowledge is lacking. This study aimed to measure self-reported health in a sample of adult refugees from Ukraine according to month of arrival to Norway in 2022.

Methods: Data were collected via an online, digital questionnaire, in a cross-sectional study design between 28.10.22 - 31.01.23. Recruitment was via multiple potential physical and social media contact points, including asylum reception centres, municipalities, non-profit organisations, and Facebook groups for refugees in Norway. The survey included self-reported health outcomes: overall health, oral health, presence of long-term illnesses or disabilities, and a short version of Hopkins Symptom Checklist (HSCL-5).

Results: Among 727 respondents, 82% were female, 65% aged 30-49 years, 69% had higher education and 53% responsibility for children in Norway. 383 arrived February-April (T1), 200 May-August (T2) and 144 September-December (T3). Compared to T1, later periods had higher proportions of males, a younger age distribution and lower proportions with higher education. Proportions reporting poor/very poor overall health, presence of long-term illness, and long-term disability were highest in T3. Oral health and HSCL-5 showed an opposite trend, with lower proportions reporting poorer health in both later periods. Respondents in T3 were still more likely to report poor health and long-term illnesses after adjusting for sex, age and education.

Conclusions: Respondents arriving later in 2022 generally reported poorer long-term health, but less psychological distress than those arriving earlier. These findings may help to inform planning of health services to refugees from Ukraine, especially in areas receiving large numbers of refugees.

Key messages:

- Refugees from Ukraine arriving earlier to host countries appear to have generally better health compared to those arriving later.
- Refugee health services should plan and scale accordingly when large numbers of refugees are expected as a result of international crises.

Abstract citation ID: ckae144.2058

Toolkit for Translating Health Information: A Resource for Crisis Health Communication and beyond

Charlott Nordstrøm

C Nordstrøm[1], *E Tidemann*[2]
[1]Social Determinants of Health, The Norwegian Directorate of Health, Oslo, Norway
[2]Communication, The Norwegian Directorate of Health, Oslo, Norway
Contact: charlott.nordstrom@helsedir.no

Issue/Problem: Translating health information accurately and effectively presented a critical challenge in crisis communication during the pandemic. In linguistically diverse contexts, ensuring access to vital health information is essential for promoting public health outcomes. Addressing this issue, we summarized our experience in a comprehensive toolkit for translating health information, aiming to enhance accessibility, reliability, and relevance across various settings and countries.

Description of the Problem: Our initiative responds to the need for standardized translation practices in the dissemination of health information in Norway. Translation practices in the health sector often lack standardization, leading to inconsistencies, inaccuracies, and risk of less comprehension. Questions guiding our project included: How can lessons learned from the extensive translation work done during the pandemic improve the accuracy and consistency of health information translation in general?

Results: We have developed a practical toolkit tailored to diverse linguistic and cultural contexts. Our toolkit summarizes lessons learned from extensive translation work during the pandemic, supported by validation from experts in the field of translation. The toolkit has been welcomed by other organizations, which underscores the potential of standardized translation tools to mitigate barriers to health communication in multilingual settings.

Lessons: Lessons gleaned from translating information during the pandemic highlight the importance of evidence-based translation practices, knowledge of the target demographic and the integration of cultural considerations into translation workflows. Furthermore, our experience underscores the value of inclusive approaches in development, promotion and distribution of the translated materials.

Key messages:

- Standardized translation tools can increase access to vital health information, fostering equitable health outcomes.
- Collaboration and inclusive approaches are key drivers in advancing standardized translation practices for effective health communication.

Abstract citation ID: ckae144.2059

Empowering Young Roma Women in matters of health and primary care: an innovative training program

Konstantina/Dina Zota

K Zota[1], *M Balta*[1], *E Zioga*[1], *N Drougos*[1], *M Kouvari*[1], *D Pinotsi*[1], *P Karnaki*[1], *A Veloudaki*[1]
[1]Institute of Preventive Medicine, Environmental & Occupational Health, Marousi, Greece
Contact: d.zota@prolepsis.gr

Background: Roma communities are rather diverse groups with different level of knowledge, beliefs and motivations in relation to their health. Raising awareness and self-efficacy of these individuals is a challenging field in the EU public health agenda.

Objectives: To address this challenge, the program entitled "Empowering Young Roma Women in matters of health, prevention and human rights: a new methodological approach" was developed with the aim to empower Roma women in terms of health and prevention topics pilot testing different educational methods. A two-step co-design approach was performed to determine the training content, tools, methods. The training was implemented in 5 areas throughout Greece (Volos, Chalkida, Thiva, Agia Varvara, Zefyri) in Jan-Oct 2023, including 3 phases: a. Train-the-trainers, b. Training the Roma women and c. Training evaluation.

Results: The educational material developed for health and prevention included 4 units (gynaecological health issues, vaccinations, smoking and nutrition). Each unit consisted of a theoretical background to develop the material, a presentation for future trainers, a presentation for trainees, a brochure, and a poster. For the training a new methodological approach was tested i.e. a health professional or Roma women (after being trained) to deliver the training. In total, 548 pre-post questionnaires were collected. Most trainees, understood the content of the training, acquired new knowledge and found the information interesting and possible to include in their daily life. 80% trainees expressed their satisfaction with the overall presentation. Regarding knowledge improvement based on the type of trainer only a slightly greater degree of improvement was observed for Roma trainers.

Conclusions: It is crucial to develop culturally appropriate health interventions by directly working with communities, to understand their particular needs, and to ensure they receive the information needed to make informed decisions.

Key messages:

- Maintaining and promoting health is a decisive factor of social inclusion.
- Tailor-made training of ethnic minorities shall be an integral part of the EU public health agenda.

Abstract citation ID: ckae144.2060

Use of specialist health care among Norwegian-born children with one immigrant parent

Naima Said Sheikh

M Kjøllesdal[1], *Y Helland*[2], *N Sheikh*[1], *T Indseth*[2]
[1]Department of Public Health Sciences, Norwegian University of Lifesciences, Ås, Norway
[2]Health Research Services, Norwegian Institute of Public Health, Oslo, Norway
Contact: naima.said.sheikh@nmbu.no

Background: An increasing number of children grow up with one immigrant and one native born parent. We know little about health in this group. Our aim was to compare the risk of receiving diagnoses of physical health conditions in specialist health care among Norwegian-born children with one immigrant parent compared to Norwegian background children.

Methods: Data from Medical Birth Registry of Norway were linked to data from the Norwegian Patient Registry (diagnoses in specialist health care), and Statistics Norway (parental country of origin, education, and household income). We estimated hazard ratios (HR) with Cox proportional hazard regressions, with Norwegian background children as reference category, adjusted for sex, birth year, parental education, and household income.

Results: Children with an immigrant parent had lower hazards than Norwegian background children of diagnoses of most types of infections, but higher hazards of some, including tuberculosis, and skin infections. They also had higher hazards than Norwegian background children of receiving diagnoses of obesity and other nutritional deficiencies, and skin diseases, but lower hazards for other conditions, including chronic lower respiratory disease, disease of the digestive system, and visual or hearing impairment. The hazards of diagnoses of any neurological condition, sleeping disorders and epilepsy were lower among children with an immigrant mother, but higher among those with an immigrant father. Differences between children with one immigrant parent and Norwegian background could not be explained by differences in parental education or household income.

Conclusions: Children of one immigrant parent do not overall use specialist health care for physical health issues more than other children.

Key messages:

- Awareness of diagnoses given most frequently to children of one immigrant parent can help promote timely diagnoses and adequate use of services, which is important for prevention of later illness.
- Barriers to health care use among children of immigrants should be further researched.

Abstract citation ID: ckae144.2061

Impacts of an interpretation fee on immigrants' access to healthcare: A Danish survey study

Maj Rørdam Nielsen

MR Nielsen[1], *SS Jervelund*[2]
[1]Centre for Private Governance, Faculty of Law, University of Copenhagen, Copenhagen, Denmark
[2]Section for Health Services Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark
Contact: mrn@jur.ku.dk

Background: In 2018, a fee for healthcare interpretation was introduced for immigrants living in Denmark for more than 3 years to incentivize learning Danish faster. The fee entails out-of-pocket costs ranging from 26-225 EUR per consultation, outpatient visit, or hospital admission. Little evidence is available on how immigrants experience impacts of the fee on their access to healthcare. The study aims to address this gap.

Methods: Using survey data collected among newly arrived immigrants ($n = 486$) at 26 cluster-randomly selected language schools in 2021, we analysed prevalence and socio-demographic background of immigrants reporting interpretation needs, and self-reports about whether the fee had caused immigrants to refrain from seeking healthcare, using ad hoc interpreters, and trying to learn Danish faster.

Results: In the study population, 19% (95% C.I. 14-26%, $n = 95$) reported interpretation needs. Refugees and their families (OR: 10.2, 95% C.I. 5.3-19.7) more often reported interpretation need compared with EU/EEA immigrants, as did immigrants with low education (OR: 1.9, C.I. 1.2-2.8), low income (OR: 2.6, C.I. 1.6-4.5) or poor self-perceived health (OR: 3.2, C.I. 1.1-9.2), adjusted for gender, age, region of residence, and length of stay. Among immigrants needing interpretation, 42% (C.I. 32-53%, $n = 69$) reported having refrained from seeking healthcare due to the fee, 73% (C.I. 55-86%, $n = 119$) using ad hoc interpreters, and 77% (C.I. 59-89%, $n = 126$) trying to learn Danish faster.

Conclusions: Findings suggest that the policy aim of incentivizing resettlement country language acquisition is partly met, but that the fee has unintended consequences in terms of hampered access to healthcare and increased use of ad hoc interpreters, raising concerns about unmet health needs and poorer quality of care, especially for vulnerable immigrants. Potential benefits of the policy should be carefully evaluated against severe negative impacts on immigrants' access to healthcare.

Key messages:

- Healthcare interpretation fees appear to be incentivizing acquisition of the resettlement language, but at the same time severely hamper access to care.
- The fee appears to disproportionately affect vulnerable immigrants, including refugees and their families and immigrants with low education, low income, and poor health.

Abstract citation ID: ckae144.2062

Risk of eating disorders and body image in adolescents in Belgium: is migration status a modifier?

Morgane Eggen

M Eggen[1], *G Yalman*[1], *E Holmberg*[1], *W Assakali*[1], *C Mertens*[1], *K Castetbon*[1]
[1]RC in Epidemiology, Biostatistics and Clinical Research, Université Libre de Bruxelles, Brussels, Belgium
Contact: morgane.eggen@ulb.be

Background: The risk of eating disorders (ED) has been linked to body image (BI) dissatisfaction in adolescents. In addition, the origin and host country culture may influence BI dissatisfaction. Our objective was to assess the modifying effect of migratory status on the association between BI and risk of ED in Belgium, a setting characterized by a large proportion of migrant adolescents.

Methods: In the 2022 cross-sectional "Health Behaviour in School-aged Children" (HBSC) study in French-speaking schools, 7,267 adolescents aged 12 to 20 self-completed questionnaires. Risk of ED was determined by an Eating Attitude Test (EAT-7), score ≥ 5. BI was categorised into 3 groups: "too thin", "about the right size" and "too fat". Migratory status was divided into "native", "2nd generation" and "1st generation" migrants. The association between BI and ED was estimated using logistic regressions adjusted for socioeconomic and psychosocial characteristics. After the inclusion of the "migration*BI" interaction term, migration-stratified logistic regressions were conducted.

Results: Overall, 13.0% of students were at risk of ED. Percentages of ED were 15.7% among those who perceived themselves as "too fat" (vs. "about the right size": aOR=1.67 [95%CI: 1.34-2.08]) and 19.4% in the "too thin" group (aOR=3.36 [2.54-4.45]). Despite non-significant interaction terms, perceiving themselves as "too fat" (vs. "about the right size") was not associated with the risk of ED in 1st generation migrants (aOR: 1.24 [0.67-2.29]). Compared with the overall estimation, it was lower in 2nd generation migrants (aOR: 1.43 [1.00-2.03]) while it was slightly higher in natives (aOR: 1.95 [1.45-2.62]).

Conclusions: These findings suggest complex interrelations between BI and risk of ED according to migratory status in adolescents with potential underlying mechanisms involving cultural norms. Promoting positive BI as a possible way for preventing the development of eating disorders need to be further investigated.

Key messages:

- This study shows differences of body image dissatisfaction according to the migratory status in adolescents, inducing potential impacts on the risk of eating disorders.

- Better understanding differences in body perception related to cultural background could help prevent risk of eating disorders in adolescents, by promoting positive body image for example.

Abstract citation ID: ckae144.2063
Immigrants and nurses' perspectives on the barriers in using health promotion services in Finland

Maliheh Nekouei ML

M Nekouei ML[1], *J Lindström*[2], *H Turunen*[1,3]
[1]Department of Nursing Science, University of Eastern Finland, Kuopio, Finland
[2]Department of Public Health and Welfare, THL, Helsinki, Finland
[3]Kuopio University Hospital, Kuopio, Finland
Contact: maliheh.nekouei@uef.fi

Background: The incidence of chronic diseases and health disparities is high among immigrants. Lack of access to health promotion services targeting the needs of the immigrant population was reported. This study aimed to explore the perspectives of immigrants and nurses on the barriers to using health promotion services in Finland.

Methods: A qualitative study with 12 focus group interviews was conducted in various cities across Finland. A total of 69 participants, including 46 adult immigrants and 23 registered nurses, were selected through purposive sampling. A semi-structured interview was used. Interviews were transcribed verbatim and analyzed using content analysis.

Results: The analysis generated four themes: insufficient individual factors (i.e., knowledge, skills), restraining cultural norms (i.e., unhealthy cultural habits, gender disparities), inadequate health promotion services (i.e., lack of resources, structural limitations), and negative environmental impacts on health behavior (i.e., sweet foods and beverages, cold weather).

Conclusions: The findings suggest reinforcing health promotion services to prevent chronic diseases among the immigrant community. Providing health education resources that are culturally tailored helps improve immigrants' knowledge to make healthier decisions in their own lives after migration. Moreover, it is recommended to introduce the health care system of the host country and healthy habits during the integration process, along with language training.

Key messages:
- Improving equity in using health promotion services for immigrants requires reforms.
- More strategies are needed to prevent chronic diseases among immigrants in Finland.

Abstract citation ID: ckae144.2064
Understanding and addressing the needs of refugee and asylum-seeking children and young people

Amy Stevens

A Stevens[1,2]
[1]Bevan CIC, Bradford, UK
[2]The Yorkshire and Humber School of Public Health, Leeds, UK
Contact: amyjanestevens@doctors.org.uk

Issue/problem: Europe is home to an increasing number of refugee and asylum-seeking children at risk of health and wellbeing needs due to their life experiences. They are frequently marginalised, impoverished, and face barriers accessing the healthcare and support they need. Bevan, an English social enterprise providing health and wellbeing services to Inclusion Health populations, carried out a needs assessment of migrant children registered at one of its General Practices to determine challenges and opportunities to ensuring their right to health. The knowledge and learning generated is relevant across sectors; organisations and geographical boundaries.

Description of the problem: The assessment included a literature review, audit of child new patient health checks, service mapping, multi-agency stakeholder interviews and a consultation event with unaccompanied minors. Findings informed Bevan's Migrant Children and Young People (CYP) Strategy, local service development and system-wide recommendations.

Results: Key areas of concern identified included mental health; safeguarding; development; nutrition; and inter agency working. Challenges to meeting needs were complex and included national policies, poor provider understanding of rights and entitlements, language and cultural barriers, health service waiting lists, housing and silo-working.

Lessons: Responding to findings Bevan invested in an in-house CYP mental health service and CYP social prescriber, opened a drop-in clinic and wellbeing service for unaccompanied minors, and initiated orientation and health information sessions for new arrivals with peer advocate support. Bevan now hosts a city-wide cross-sector Migrant CYP stakeholder group and collaborates with regional and national partners to develop resources to promote the health of migrant CYP.

Key messages:
- The needs assessment enabled development of a responsive integrated service for migrant CYP that meets their health needs and addresses their social determinants of health.
- The Migrant CYP stakeholder group has improved inter-agency working, helped identify service gaps, increased advocacy opportunities, and facilitated co-creation of solutions to meet population needs.

Abstract citation ID: ckae144.2065
Multidisciplinary approach to asylum seekers health assessment: a 5-year experience in Modena, Italy

Stefania Paduano

S Paduano[1], *M La Torre*[1], *L Borsari*[2], *Z Kahfian*[2], *F Incerti*[2], *A Carlei*[2], *A Liguori*[2], *A Bargellini*[1], *T Filippini*[1,3]
[1]Department Biomedical, Metabolic & Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy
[2]Department Public Health - Public Hygiene Service, Local Health Authority of Modena, Modena, Italy
[3]School of Public Health, University of California Berkeley, Berkeley, USA
Contact: stef.paduano@gmail.com

Background: Asylum seekers' well-being represents a global health issue. They face significant challenges to their physical and mental health due to their migratory path. In the Modena province (Northern Italy), a multidisciplinary approach has been applied to the care of asylum seekers by Department of Public Health (DPH), with a team of specialists in infectious diseases, dermatology, gynaecology, obstetrics, psychology and preventive medicine. Asylum seekers receive a first visit, including medical and psychological assessment and screening for infectious diseases. Ad hoc pathways are also active for asylum seekers who need secondary-level care. This study aims to investigate the health status of asylum seekers referred to Modena Centre.

Methods: This cohort study enrolled asylum seekers hosted in Modena between November 2018 and May 2023. During the first visit, personal and anamnestic data were collected aided by cultural mediators, along with clinical assessment. Furthermore, Tuberculin-Skin-Test (TST) and blood tests for HBV-HCV-HIV-Syphilis were performed.

Results: A total of 646 migrants were included, 94% were males with a median age of 26 years (range: 15-50), the majority from Bangladesh (39%). Females were mostly from Ivory Coast (36%), median age of 30 years (range: 17-45). Most conditions were treated at the primary care level and were related to cutaneous disease (22%), only 11% of subjects required second-level diagnostics. Positive TSTs were 41% (N = 265). Of them, 55.5% (N = 147) also tested positive for QuantiFERON-TB. Screening for infectious diseases revealed positivity rates of 4% for HBsAg, 1% for HCVAb, 0.8% for HIV and 1.4% for TPPA+RPR.

Conclusions: The multidisciplinary approach is the innovative and strength point of this protocol for asylum seekers' health ensuring prompt management of pathologies after their arrival. Moreover, data collection is useful for improving intake services and implementing public health programs for vulnerable individuals.

Key messages:

- The innovation of this protocol for asylum seekers' health lies in its multidisciplinary approach.
- Clinical data collection will support health policies' choices to protect vulnerable individuals.

Abstract citation ID: ckae144.2066
Determinants of health among Ukrainian refugees in Germany: comparison with other refugee groups

Louise Biddle

L Biddle[1], *A Marchitto*[1], *S Zinn*[1]
[1]Socioeconomic Panel, DIW Berlin, Berlin, Germany
Contact: lbiddle@diw.de

Background: 6.5 million Ukrainian refugees have been displaced globally since 2022, with 1 million seeking asylum in Germany. Little is known about the health determinants for this group, limiting the evidence base for policy intervention.

Methods: We use a nationally representative survey of adult Ukrainian refugees in Germany (IAB-BiB/FReDA-BAMF-SOEP study; n = 5943), conducted in 2023, to analyse the effect of sociodemographic, pre-migration (experienced war intensity, traumatic experiences) and post-migration factors (time since arrival, accommodation, social networks) on self-rated health using multiple logistic regression. We contrast these findings with estimates of identical models obtained from a subset of the IAB-BAMF-SOEP-sample of non-Ukrainian refugees within one year of arrival (n = 1195).

Results: In the Ukrainian sample, post-migration factors are particularly critical for health, with those experiencing discrimination (OR 1.83; 95%CI: 1.51,2.21) and social isolation (OR: 2.70; 95%CI: 2.23, 3.28) affected by ill health, while those with high German proficiency (OR 0.34; 95%CI: 0.18, 0.64) and contact with Germans (OR: 0.66; 95%CI: 0.53,0.83) are protected. Pre-migration factors do not affect self-rated health. Among refugees from other countries of origin, post-migration factors are not associated with health within the first year of arrival, with exception of social isolation (OR: 2.03; 95%CI: 1.32,3.13).

Discussion: Despite the EU Temporary Protection Directive, the health of Ukrainian refugees in Germany is shaped by adverse post-migration circumstances. While other refugee groups may have had riskier escape journeys and worse arrival conditions, this is unrelated to self-rated health in the first year. This underscores the importance of considering pre-migration contexts when evaluating subjective health. Outreach services, communication campaigns and the expansion of medical interpreting services are needed to ensure access to the health system.

Key messages:

- Despite the EU Temporary Protection Directive, the health of Ukrainian refugees in Germany is shaped by adverse post-migration circumstances.
- Outreach services, communication campaigns and the expansion of medical interpreting services are needed to ensure access to the health system.

Abstract citation ID: ckae144.2067
Variations in access to acute care services by immigrant background and sociodemographic factors

Lema Hussaini

L Hussaini[1], *K Damgaard Skyrud*[1]
[1]Health Services Research, Norwegian Institute of Public Health, Oslo, Norway
Contact: lema.hussaini@fhi.no

Background: The Emergency Medical Communication Center (EMCC) plays a vital role in the medical emergency response system by triaging contacts, notifying local physicians, and providing medical advice. The utilization of acute care services and the subsequent care pathway by individuals with immigrant background remains unclear in the Norwegian context. This study aims to investigate whether disparities exist in the acute care pathway for patients with different sociodemographic background who use ambulance services.

Methods: We examined all code red ambulance dispatches for life-threatening emergencies in 2021 in Norway. These ambulance dispatches were linked to primary health care and specialist health care contacts to trace patient pathways and outcomes. Statistical analyses were conducted using linear regression models, adjusted for patient characteristics, such as immigrant background, age, sex, municipality of residence, living condition, socioeconomic status, comorbidity and cause of emergency contact.

Results: Preliminary crude findings indicate that patients with immigrant background are overrepresented in the groups receiving acute primary care only and underrepresented in the groups transferred directly to specialist health care, within 8 hours after ambulance arrival at the patients' location.

Conclusions: The preliminary results suggest challenges for the EMCC in triaging patients with immigrant background, but further research is needed to explore potential systematic differences. This study aims to improve understanding of disparities in access to acute care and inform targeted interventions to optimize resource allocation in emergency departments.

Key messages:

- This study may improve understanding of disparities in access to acute care in Norway.
- This study can inform targeted interventions to improve resource allocation in emergency departments.

Abstract citation ID: ckae144.2068
COVID-19-related worries: A longitudinal study comparing migrants and non-migrants in Norway

Pierina Benavente Velando

P Benavente Velando[1], *LT Fadnes*[2], *GM Sandal*[3], *S Mæland*[2], *S Lehmann*[4], *E Diaz*[1]
[1]Pandemic Centre, IGS, University of Bergen, Bergen, Norway
[2]IGS, University of Bergen, Bergen, Norway
[3]Department of Psychosocial Science, University of Bergen, Bergen, Norway
[4]Department of Clinical Psychology, University of Bergen, Bergen, Norway
Contact: pierina.benavente@uib.no

Background: Health- and economic-related worries during the COVID-19 pandemic contributed to worsening of mental health, particularly affecting migrants in vulnerable situations. However, this differential impact was only clear some months into the pandemic, and there is little evidence about any differences in health and economic worries between migrants and non-migrants as the pandemic developed. To close this knowledge gap, we assessed the changes in COVID-19-related worries reported by migrants compared to non-migrants in Norway throughout the pandemic.

Methods: Our study analyzed data from three time points (April-20, January-21, March-22) for 25,305 participants of the Bergen in Change study, including 509 (2%) migrants from Asia, Africa, or Latin America (LATAM), and 1250 (5%) migrants from other regions. Worries were assessed using questions on COVID-19 infection fear, job security, and economic stability. Analysis methods included descriptive analysis, chi-squared, Sankey plots, and logistic regression, adjusting for age, gender, education, and type of work.

Results: Migrants from Asia, Africa and LATAM reported health worries more often than non-migrants [OR (95%CI) 1.9 (1.3-2.8)] without clear changes over time, 0.9 (0.7-1.3). Migrants from Asia, Africa, and LATAM, as well as from other regions, also reported economic worries significantly more often than non-migrants [3.1 (2.5-3.9) and 2.1 (1.8-2.4) respectively] at baseline. Each additional year into the pandemic increased the odds of economic worries by a factor of 1.3 (1.0-1.6) for migrants from Asia, Africa, and LATAM compared to non-migrants. The odds ratio for migrants from other regions over time was stable, 1.0 (0.9-1.1).

Conclusions: Migrants, especially those from Asia, Africa, and LATAM, reported more pandemic- related worries than non-migrants, and this persisted over time. Identifying and understanding these worries could guide preventive measures to enhance mental health in migrant population.

Key messages:

- Throughout the pandemic, migrants reported more COVID-19-related worries than non-migrants, a trend that persisted over time and was greater among migrants from Asia, Africa, and Latin America.
- Identifying the differential impact of COVID-19 on migrants' groups and understanding the factors involved is essential for guiding healthcare interventions to improve migrant health.

[5]Egas Moniz School, Egas Moniz Center for Interdisciplinary Research, Almada, Portugal
Contact: martapingarilho@ihmt.unl.pt

Background: Portugal has an important HIV burden with a total of 804 diagnosed cases in 2022. Migrants remain a significant source of HIV infections, with 45% of newly reported cases. We aimed to evaluate the characteristics of HIV-1 molecular transmission clusters (MTCs) among migrants followed in Portugal, diagnosed between 2014 and 2019.

Methods: 265 migrants, newly HIV-1 diagnosed were included in the BESTHOPE project with clinical, socio-behavioral and genomic data. Pol nucleotide-based phylogenetic analyses were used to infer HIV-1 MTC. Those were constructed using ClusterPickerGUI_1.2.3 considering SH-aLRT higher than 90 of branch support and a pairwise genetic distance of ≤ 4.5. Logistic regression analyses were used to examine the relationship between the sociodemographic and clinical data associated with HIV-1 clustering.

Results: 66.8% of the migrants included in the study were males with a median age at diagnosis of 36.0 years old (IQR:29-45). Most migrants were from African countries (50.6%) followed by Brazil (39.6%). Sixty-eight (33%) of the migrants were included in clusters. Being in cluster was significantly associated with region of origin, with individuals from South America more likely to be in cluster (OR = 14.85, 95%CI:1.52-144.79), compared to individuals from Africa; with transmission route, with men who have sex with men (MSM) more likely to be in cluster (OR = 23.52, 95%CI:2.35-235.10), compared to the heterosexuals and with subtype, with subtypes B less likely to be in cluster (OR = 0,017, 95%CI:0,001-0,254) compared with subtype non-B.

Conclusions: Migrants HIV transmission clusters in Portugal are associated with specific health determinants, such as region of origin, transmission route and subtype. Targeted prevention health strategies are needed to mitigate transmission of HIV within this population. Funded by FCT to GHTM - UID/04413/2020 and LA-REAL - LA/P/0117/2020; BESTHOPE (HIVERA:249697); and MARVEL (PTDC/SAU-PUB/4018/2021).

Key messages:

- HIV transmission clusters in migrant are associated with their region of origin, transmission route and subtype.
- Targeted prevention health strategies are needed for the migrant population.

Abstract citation ID: ckae144.2070
Roma mothers of infant children in the health system - a qualitative study

Nadezhda Mihaylova

N Mihailova[1], *K Dokova*[1], *N Feschieva*[1]
[1]Social Medicine, Medical University of Varna, Varna, Bulgaria
Contact: nadezhda.mihaylova@mu-varna.bg

Background: The Roma in Bulgaria constitute the third largest group - 4% of the population. Data on demographic processes by ethnicity are scarce. A national survey in 2003 found significant differences in infant mortality - 9.9‰ for Bulgarian, 18‰ for Turkish, and 28‰ for Roma infants. Poverty among Roma children, risk of poor education, especially for girls, barriers to accessing health services remain high. We aim to reveal the cultural specificity in prenatal behavior and infant care among Roma mothers in the context of the role of the Bulgarian health service.

Methods: In-depth interviews with Roma mothers of infants up to 1 year were utilized for data collection. To ensure heterogeneity among the interviewees, several "nests" with varying socio-cultural status in the Varna district were identified in advance for participants recruitment. A list of interview themes concerning respondents' relationships with the public health system with an emphasis on the experiences of mothers was drawn up.

Results: Ten interviews with mothers having between 1 and 7 children were conducted in 2023. The mothers recounted discriminatory experiences during their interactions with certain health facilities (maternity wards), which act as barriers to accessing and utilizing health services. Maternity and infant counselling services are highly esteemed with favorable influence on child health outcomes. There has been a positive shift away from early marriage and childbirth towards prioritizing education for Roma girls. Mothers prioritize their children, and there is no neglect in their care. Family relations and support are being upgraded, with Roma fathers becoming involved in child care. Respondents express their educational needs and hopes for community-based support to better cope with their roles as mothers.

Conclusions: Ethno-cultural factors shaping the mother's role maintain traditional family support, while also reflecting significant modernization that needs societal support.

Key messages:

- A glimpse into people's experiences of the healthcare system - a clue to its effectiveness.
- The ethno-cultural factors in Roma are subject to modernization.

Abstract citation ID: ckae144.2071
Awareness and knowledge about Female Genital Schistosomiasis among European healthcare workers

Irina Kislaya

V Marchese[1,2], A Remkes[1,2], I Kislaya[1,2], P Rausche[1,2], A Brito[1,2], J Hey[1,2], T Rasamoelina[3], R Rakotoarivelo[4], J May[1,2], D Fusco[1,2]
[1]Department of Infectious Disease Epidemiology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany

[3]Centre d'Infectiologie Charles Mérieux, University of Antananarivo, Antananarivo, Madagascar
[4]Department of Infectious Diseases, University of Fianarantsoa Andrainjato, Fianarantsoa, Madagascar
Contact: irina.kislaya@bnitm.de

Background: Female Genital Schistosomiasis (FGS) is a gynaecological manifestation of persistent infection with Schistosoma haematobium, which can lead to severe consequences, such as miscarriage and infertility. It is estimated to affect 56 million women globally, mostly in sub-Saharan Africa (SSA). Most migrants in Europe are female, often from SSA and therefore at risk of FGS, hence healthcare workers (HCWs) knowledge of FGS is essential for the provision of adequate care. This study aims to assess awareness and knowledge of FGS among European HCWs to inform strategies to improve the management of migrant health.

Methods: In June 2023 - January 2024 we conducted a cross-sectional online survey targeting medical doctors (MDs), nurses and midwives (NMs) working in fields of infectiology, gynaecology, urology, family, travel, internal or occupational medicine. The prevalence of FGS awareness and knowledge was estimated, Poisson regression was used to identify factors associated with MDs' awareness of FGS.

Results: Among 922 surveyed HCWs, 43.7% (CI95%: 39.6-47.9) of MDs and 12.0% (CI95%: 8.8-16.0) NMs have heard about FGS. FGS awareness among MDs was associated with work in clinics for migrants (prevalence ratio (PR)=1.33, CI95%: 1.10-1.59) and specialization, being lower for gynaecology (PR = 0.67; CI95%:0.51-0.88), and family medicine (PR = 0.42, CI95%:0.30-0.59). Among MDs, 7.1% (CI95%: 5.1- 9.5) had medium knowledge, while 25.3% (CI95%: 21.8-29.0) had low, and 67.6% (CI95%: 63.7-71.4) no knowledge on symptoms, complications or diagnostic tools for FGS. FGS knowledge was mostly acquired through academic curricula (34.7%), scientific literature (28.4%) and conferences (25.6%).

Conclusions: The study shows limited awareness of FGS among European MDs and NMs, and highlights that European HCWs may not be adequately prepared to deal with diseases that are gaining relevance on the European continent due to the global connectivity and the dynamic nature of our societies.

Key messages:

- In Europe, the health specialities that are the first point of patient access to the health system show a low level of awareness and knowledge of Female Genital Schistosomiasis.
- Rising knowledge of FGS among European HCWs through academic curricula and continuous medical education is important to ensure adequate diagnosis and management of disease in migrant populations.

Gastrointestinal infections and ethnicity in the UK: a systematic review and narrative synthesis

Iram Zahair

I Zahair[1,2], T Rose[1], S Clayton[1], O Oyebode[3], M Maden[1], I Ghosh[4], B Barr[1]
[1]Institute of Population Health, University of Liverpool, Liverpool, UK
[2]NIHR, Health Protection Research Unit in Gastrointestinal Infections, Liverpool, UK
[3]Wolfson Institute of Population Health, Queen Mary University of London, London, UK
[4]Warwick Medical School, University of Warwick, Coventry, UK
Contact: izahair@liverpool.ac.uk

Background: Gastrointestinal (GI) infections exert a significant public health burden on healthcare services in the United Kingdom (UK). The literature suggests an association between ethnicity and health; however, we do not know the extent of inequalities in GI infection/disease in the UK. This systematic review aimed to identify studies that ascertain differences in the incidence or prevalence of GI infections between UK ethnic groups and explore possible explanations for heterogeneity observed within the literature.

Methods: MEDLINE, CINAHL Plus, Web of Science (Science Social Science Citation Index), and grey literature were searched from 1980 to 21st June 2023 for studies reporting an association between ethnicity and GI infections in UK population samples. Two reviewers independently screened the studies and conducted quality appraisals; data extraction was undertaken by one reviewer and verified by another reviewer. A narrative synthesis was undertaken and a harvest plot supported the textual synthesis to investigate potential sources of heterogeneity in effect estimates by GI pathogen and ethnic group.

Results: The searches identified 10028 studies, of which 16 met the inclusion criteria. 15 out of 47 effect estimates from a total of 16 studies found that GI infection risk was greater in Black and Ethnic Minority Groups, mainly of Asian ethnicity, compared to the majority White population. 13 studies reported a higher risk in ethnic minorities of Asian ethnicity, while one study described a higher risk in the Non-White ethnic group. One single study on STEC reported a higher risk of GI infection in the White population compared to the Non-White population, while another single study on norovirus found no significant difference by ethnic group.

Conclusions: This systematic review demonstrates that ethnic minority groups in the UK have a higher risk of GI infections than the general or White population.

Key messages:

- There is a clear need to elucidate further the high incidence of GI infections in UK Indian, Pakistani, and Bangladeshi communities.
- Tackling ethnic inequalities requires a concerted approach and translating evidence into policy.

Abstract citation ID: ckae144.2073
Health disparities among in multicultural and non-multicultural families in South Korea

Kyung Shin Song

KS Song[1,2], EJ Lee[1], JH Lee[1,2]
[1]Department of Health Policy and Management, Korea University, Seoul, South Korea
[2]BK21 FOUR R&E Center for Learning Health Systems, Korea University, Seoul, South Korea
Contact: liclbeen@gmail.com

South Korea has experienced significant immigrant growth, with international marriages playing a key role in this demographic change. In 2019, international marriages accounted for 10.3% of all marriages, increasing the number of multicultural households. Multicultural families in Korea faced controversies over accepting new members in a society traditionally considered racially and ethnically homogenous. In rural areas, where patriarchal and conservative values prevail, there is greater discrimination and negative perception towards foreigners compared to urban areas, impacting access to healthcare. This potentially adversely affects the health of married immigrants. However, research on this issue is limited. This study aims to examine the differences in health behaviors, access to care, and health status between multicultural and non-multicultural families in rural and urban areas. Using a cross-sectional study design based on the 2023 Community Health Survey, the sample included 228,216 adults from non-multicultural families and 3,373 adults from multicultural families. Adjusted differences in outcome were estimated using regression models, including linear probability and logistic models. Overall, there were minimal or no differences in health behaviors and health status between adults from multicultural and non-multicultural families. However, significant differences were observed in access to care, such as annual health check-ups (0.72 [0.64, 0.81]) and vaccinations (0.84 [0.76, 0.94]). Non-multicultural families showed regional differences in all outcomes, whereas multicultural families exhibited minimal or no regional differences. These findings suggest that multicultural families may face barriers beyond regional environments, limiting their access to care and potentially leading to long-term negative health outcomes. Targeted policy development for multicultural families in Korea is necessary to address this issue.

Key messages:

- Access to health care may vary for individual and local factors, especially for people with different ethnicities or cultures.
- Multicultural families may encounter greater barriers than individual and regional characteristics, requiring the development of tailored policies for immigrants and multicultural families.

[5]General Management, Local Health Authority Tuscany South-East, Siena, Italy
Contact: v.falcone1@student.unisi.it

Introduction: This study examines the influence of health determinants on pregnancy and birth outcomes. The aim is to provide a clear and updated view of the overall framework characterizing the birth experience, with crucial implications for clinical practice, research, and health policy.

Methods: Data analysis pertains to the Certificate of Assistance for Birth (CAP) concerning residents in the territory of AUSL South-East Tuscany in the years 2021 and 2022. The number of women of childbearing age in Tuscany in 2022 is 150,959, while the number of births analyzed in the study is 9,053. The study conducts multivariate analysis between factors and pregnancy-related outcomes.

Results: Controlling for age, citizenship and others factors, the risk of cesarean section is significantly higher ($p < 0.05$) among mothers: over 40 years old (OR = 2.09), with education levels of lower secondary (OR = 1.21) and upper secondary (OR = 1.23) compared to a degree, not employed (OR = 1.25) and homemakers (OR = 1.45) compared to employed, overweight/obese (OR = 1.41), with gestational diabetes (OR = 1.16), smoking during pregnancy (OR = 1.27), with gestational hypertension (OR = 2.81). Controlling for age, citizenship and others factors, the risk of term low birth weight is significantly higher ($p < 0.05$) among mothers: over 40 years old (OR = 1.76), not employed (OR = 1.76) and homemakers (OR = 1.34) compared to employed, smoking more than 3 cigarettes daily during pregnancy (OR = 1.31) not significant, with gestational hypertension (OR = 5.57), nulliparous (OR = 1.42). Controlling for age, citizenship and other factors, the risk of premature birth is significantly higher ($p < 0.05$) among mothers: with gestational hypertension (OR = 5.22), nulliparous (OR = 1.89), smoking during pregnancy (OR = 1.59).

Conclusions: The results underscore the importance of carefully monitoring and managing these risk factors during pregnancy to improve outcomes for both mother and baby.

Key messages:

- Understanding the determinants that influence birth outcomes plays a fundamental role.
- The importance of Early Childhood Development and early interventions can improve children's health and well-being.

Abstract citation ID: ckae144.2075
Mortality in migrants with dementia living in the Lazio region, Italy

Anna Acampora

A Acampora[1], *L Angelici*[1], *S Cascini*[1], *L Cacciani*[1], *M Canevelli*[2,3], *I Cova*[4], *B Contoli*[2], *S Pomati*[4], *G Bellomo*[2], *AM Bargagli*[1]

[4]Center for Research and Treatment on Cognitive Dysfunctions, 'Luigi Sacco' University Hospital, Milan, Italy
Contact: a.acampora@deplazio.it

Background: Dementia is a major cause of disability and death among older people. Older migrants living in Italy are increasing and the prevalence of dementia is expected to rise in this population. Nevertheless, there is lack of real-world information concerning their health outcomes. The aim of this work was to analyse mortality in migrants with dementia living in Lazio, Italy (IMMIDEM project, GR-2021-12372081)

Methods: In a retrospective cohort study, people with dementia aged ≥50 living in Lazio on 31st December 2018 were selected using Health Information Systems (HIS) and followed-up for 5 years. The migrant status was defined according to the Country of birth as native Italians, people from High Migratory Pressure Countries (HMPC) or Highly Developed Countries (HDC). Age-standardized mortality rate (SMR) was estimated overall and by migrant status. Time to event analysis was performed using Kaplan-Meier curves, log-rank tests, and multivariate Cox regression.

Results: On 31st December 2018, 38,835 individuals with dementia were living in Lazio, 2.1% from HMPC and 0.9% from HDC. Natives and HDC were older than HPMC, while migrants showed a higher proportion of female. The SMR was lower in migrants from HPMC (42.2%; CI95% 37.0%-48.1%) and from HDC (33.2%; CI95% 25.4%-43.4%) than among natives (52.4%; CI95% 50.7%-54.1%). The age-adjusted mortality hazard ratio (HR) was lower in migrants (HDCs HR = 0.76, CI95%:0.66-0.89; HMPC HR = 0.88, CI95%:0.80-0.97) than natives.

Conclusions: The study showed a lower mortality rate among migrants with dementia compared to native Italians. Under-diagnosis, the "salmon bias", and the "'healthy migrant effect" could explain this apparent paradox, consistently with available literature. In addition, following-up migrants in the HIS may be difficult and underestimation may occur. Enhancing the comprehension of this phenomenon could allow the formulation of more effective, diversity-sensitive policies and practices for the management of dementia.

Key messages:

- The mortality rate among migrants with dementia was found lower than that among native Italians.
- Understanding the morbidity and mortality patterns in migrants with dementia is important to develop practice to adequately respond to their health needs and diversity-sensitive polices.

Background: Ethnic identity is important for positive health and wellbeing outcomes, especially for Indigenous youth and adolescents from minoritised ethnic groups. The Multigroup Ethnic Identity Measure (MEIM) is widely used to examine ethnic identity as a general phenomenon across ethnic groups. However, evidence regarding its validity for adolescents from different ethnic backgrounds is mainly limited to the US context. This study investigated psychometric properties of the MEIM, for the first time, within a large ethnically diverse population-based sample in New Zealand.

Methods: We used data from the Growing Up in New Zealand study. Participants were 4500 12-year-olds and included 22.4% Māori (the Indigenous people of New Zealand), 16.7% Pacific, 14.8% Asian and 51.9% European young people. 45.7% were cisgender boy, 37.4% were cisgender girl, and 16.4% were non-binary, trans or unsure. We conducted factor analysis for the 12-item MEIM.

Results: Confirmatory factor analysis model fit tended to be best for a solution with two factors representing two ethnic identity subcomponents of Exploration and Affirmation/Belonging. A single 'ethnic identity' factor showed a slightly weaker model fit. Exploratory factor analysis revealed a 2-factor structure with a slightly different item composition as compared to the original MEIM subscales. The findings were largely comparable across ethnic groups.

Conclusions: The MEIM appears to be a valid measure for Māori, Pacific, Asian and European young people. However, nuances may exist due to unique contexts including structural factors, societal norms and challenges, opportunities and access to cultural engagement. Ethnic identity is strongly linked to health and wellbeing including quality of life, self-esteem and life satisfaction. Therefore, we recommend acknowledging nuances of ethnic identity during an important time of development within diverse cultural contexts, by applying subscales and subgroup analyses where possible.

Key messages:

- The Multigroup Ethnic Identity Measure is valid and appropriate to use at age 12-years among diverse ethnic groups including Māori, Pacific, Asian and European.
- Nuances of ethnic identity should be acknowledged as an important factor for health and wellbeing, especially during critical times of transition for adolescents within diverse cultural contexts.

Abstract citation ID: ckae144.2077

Promoting vaccination for newly arrived migrants: a multistakeholder collaboration pilot

Maria Laura Russo

ML Russo[1], ME Tosti[2], G Marchetti[2], A Bellini[1], C Ferrari[1,3], PA Napoli[3], F Trani[3], B Coraci[4], E Rusi[4], S Declich[2]

[2]National Center for Global Health, ISS, Rome, Italy
[3]Local Health Authority, ASL ROMA 2, Rome, Italy
[4]Staderini, First Reception Center - Medihospes, Rome, Italy
Contact: marialaura.russo@uniroma1.it

Access to vaccinations for Newly Arrived Migrants (NAMs) is a critical public health issue. In the context of the project 'Increased Access for Newly Arrived Migrants-AcToVax4NAM' (Grant No. 101018349, 3rd EU Health Program), DPHID-SAP and GLOB-ISS conducted a pilot aimed at developing and testing a system pathway to promote and vaccinate NAMs. The pilot began with the creation of a team between researchers from DPHID-SAP and GLOB-ISS, professionals from two services of the Local Health Authority and from a first reception centre (CAS) in Rome area. An integrated knowledge translation approach was used, which facilitated the collaborative development of strategies and actions of the pilot. The team then reached out to other 'professionals FOR health' involved in the vaccination process of NAMs, i.e. physicians from Temporarily Present Foreigners (STP) outpatient clinics, General Practitioners and Pediatricians. Between July 2023 and April 2024, four actions were developed. 1) analysis of the current access of NAMs to vaccination services and the subsequent development of a contextualized pathway to facilitate vaccinations for NAMs, including catch-up strategies; 2) identification of informed consent and other materials needed to be included in the pathway; subsequently, translated in 10 languages; 3) implementation of vaccine literacy session for CAS staff and NAMs; 4) improvement of immunization information flows to enable assessment of vaccination coverage of NAMs. To evaluate the pilot, the vaccination rate observed during the pilot (January-April 2024) was compared to that occurring in 2023, showing a 36.5-fold increase in the vaccination rate (4 x 100 person-year in 2023 and 155 x 100 p/y in 2024; RR = 36.5 (95%CI 14.6-117.6). The pilot highlighted that a research collaborative approach among various actors facilitated the access to vaccination for NAMs and was an opportunity to turn knowledge into action.

Key messages:

- It is essential to ensure equitable vaccination coverage to reduce under-immunized groups.
- Access to vaccination is a key element of the right to health and for collective health protection and it should be a shared responsibility.

Abstract citation ID: ckae144.2078

Child COVID-19 rates and migrant status: A quantitative study in the Lisbon area (Mar 2020-Jun 2022)

Iolanda Banha Alves

I Banha Alves[1], R Becker Loesch[1], M Neto Conceição[1], S Carmezim Pereira[2], A Carlos Silva[3], MR Oliveira Martins[1]

[1]Global Health and Tropical Medicine R&D Unit, IHMT, NOVA University of Lisbon, Lisbon, Portugal
[2]Public Health Unit, Amadora Primary Healthcare Cluster, Lisbon, Portugal
[3]Public Health Department, ARS-LVT, Ministry of Health, Lisbon, Portugal
Contact: iolandaa@ihmt.unl.pt

Introduction: According to OECD data, immigrant children were over-represented among COVID-19 cases compared to non-immigrant children. However, evidence is missing on whether their migrant status is associated with testing positive for COVID-19. Therefore, we aimed to estimate COVID-19 positivity rates among children residing in five municipalities of the Lisbon metropolitan area, Portugal, and to analyze migrant status as a determinant of health.

Methods: We conducted a prospective cross-sequential cohort study with 989 children born in 2015, 2018, and 2020 (48.5% non-immigrants; 51.5% immigrants). Sociodemographic data were collected through interview-based questionnaires, and the child's birth weight and gestational age were obtained from the primary health center's information system (SClinico). COVID-19 test results (conducted between March 2020 and June 2022) were obtained from the national surveillance system (SINAVE Lab) and categorized into two primary outcomes: ever positive for COVID-19 (yes/no) and positivity frequency for COVID-19 (count). Robust and standard Poisson regressions were used to estimate the association between primary outcomes and demographic, socioeconomic, and clinical variables. We estimate relative risks (RR) and prevalence ratios (PR) with 95% confidence intervals.

Results: The positivity rate is lower for immigrant children (12% vs 17%). Compared with non-immigrant, and adjusting for other factors, immigrant children are 52% less likely to be ever positive for COVID-19 ($PR = 0.482$; IC 95%: 0.392-0.594), and the estimated number of positive tests is 54% lower ($RR = 0.456$; IC 95%: 0.362-0.574).

Conclusions: Being an immigrant is a protective factor against testing positive for COVID-19, aligning with the well-known immigrant paradox. These results underscore the need for further research into the immunological profiles of this population and are crucial for guiding strategies to manage emerging public health crises.

Key messages:

- Immigrant children living in the Lisbon metropolitan area may have a protective factor against testing positive for COVID-19, consistent with the well-known immigrant paradox.
- Understanding COVID-19 positivity rates and associated factors in children is crucial for guiding effective strategies to manage and mitigate emerging public health crises.

Breastfeeding duration, children's diet and physical activity in immigrant children living in Lisbon

Regina Becker Loesch

R Becker Loesch[1], *I Banha Alves*[1], *M Neto Conceição*[1], *MR Oliveira Martins*[1]
[1]Global Health and Tropical Medicine R&D Unit, IHMT, NOVA University of, Lisbon, Portugal
Contact: regina.loesch@ihmt.unl.pt

Background: In 2023, 25% of children born in the Lisbon metropolitan area were from foreign mothers. Children of immigrant parents often face an unbalanced diet and unhealthy lifestyle, preventing them from reaching their full potential. The aim of this study was to analyse the associations between migrant status and breastfeeding duration, fruit and vegetable consumption and physical activity in children living in the Lisbon metropolitan area, Portugal.

Methods: Cross-sequential cohort study in Lisbon Region. Between May 2022 and April 2024, 729 children (49.4% immigrants) born in 2018 and 2020 were enrolled in the study. Data were collected in a face-to-face interview with the parents using a structured questionnaire with information on children's diet (fruit and vegetable consumption) and physical activity. We used X2, Mann-Whitney U and t-tests to compare immigrant and non-immigrant children. Adjusted odds ratios (aOR) with a 5% level were estimated by logistic regression.

Results: Immigrant children (49.4%) live in socio-economically disadvantaged families. Breastfeeding practices are more common among migrant mothers with a higher median duration of exclusive breastfeeding (6 versus 4 months, $p < 0.001$) and a higher median duration of breastfeeding (14 versus 8 months, $p < 0.001$). Parental migration background is associated with the frequency of fruit ($p = 0.039$) and vegetable ($p < 0.01$) consumption and with the practice of physical activity ($p < 0.01$). The odds of consuming three or more portions of fruit are 1.37 times higher for non-immigrant children, and the odds of consuming two portions of vegetables are higher for non-immigrants than immigrants ($aOR=2.04$, $p < 0.01$). Practicing sports is most frequent in non-immigrants ($aOR =2.25$; $p < 0.01$).

Conclusions: Migrant status was associated with a less healthy lifestyle in childhood for children living in the Lisbon metropolitan area.

Key messages:

- Breastfeeding is an essential source of nutrition for children, especially in socio-economically disadvantaged families.
- The migrant status is often associated with inequalities in childhood, challenging immigrant children to achieve their full potential.

Meaning-making of mental health among reception center clients in Finland

Katariina Mankinen

K Mankinen[1,2], *C Nordberg*[2,3], *N Skogberg*[1]
[1]Equality, THL, Helsinki, Finland
[2]Social Policy, Åbo Akademi University, Vaasa, Finland
[3]Swedish School of Social Science, University of Helsinki, Helsinki, Finland
Contact: katariina.mankinen@thl.fi

Introduction: Asylum seekers and refugees face significant challenges, including high rates of mental health issues, as they navigate unfamiliar societal systems and norms. However, little is known about their subjective experiences of mental health and the mental health support in everyday social encounters. This study aims to explore the meaning-making of mental health and the experiences of receiving mental health support among clients of Finnish reception centers (FRCs).

Methods: Semi-structured individual in-person interviews were conducted with 11 reception center clients from various locations in Finland, with an interpreter present in four interviews. Interviews lasted approximately 60-90 minutes. Thematic analysis was employed to identify recurring themes and subthemes.

Results: Preliminary findings indicate a diversity in the meaning-making of mental health among participants. While some discussed mental health in terms of stress, others approached the topic analytically, while some avoided it altogether. Participants highlighted the importance of access to external resources, such as schools, language courses, and employment, for enhancing overall well-being. Trust in FRC staff emerged as a crucial factor in seeking and receiving assistance for mental health concerns. Additionally, participants exhibited resilience, suggesting benefits of empowering them during this challenging period.

Conclusions: Adopting a holistic approach to mental health care within FRCs is imperative. Understanding how clients construct meaning around mental health is particularly relevant for training FRC staff, who serve as primary points of contact for asylum seekers and refugees in Finland. Moreover, amplifying the voices of reception center clients can contribute to improving services and enhancing the health and well-being of this population in Finland.

Key messages:

- It is necessary to adopt a holistic approach to mental health care within reception centers, one that addresses broader social determinants of mental health.
- Trust in the staff of Finnish reception centers is a critical factor in facilitating the seeking and receiving of assistance for mental health concerns among asylum seekers and refugees.

Contact: aao31@leicester.ac.uk

Background: Long COVID (LC), characterised by persistent symptoms post-acute COVID-19 infection, presents a growing public health concern. Data on prevalence among healthcare workers (HCWs) are lacking. Our study aimed to establish the proportion of UK HCWs with symptoms lasting beyond five weeks and identify factors associated with LC in a diverse cohort.

Methods: We conducted a cross-sectional analysis from December 2020 to March 2021. The main outcome was LC in relation to self-reported ethnicity. Univariable and multivariable logistic regression identified associations. Odds ratios (ORs) and adjusted odds ratios (aORs) were calculated with 95% confidence intervals (95%CIs). The multivariate analysis adjusted for demographic information, job role, household factors, health status, and existing long-term conditions. Missing data were imputed via chained equations.

Results: From 11,513 HCWs, 2,331 (20.2%) reported COVID-19, with 525 (22.5%) experiencing LC. 80.0% of those reporting LC were female, compared to 74.3% without LC were female. Participants with LC (median age 46 [IQR 36-54)]) were slightly older than those without LC (median age 41 [IQR 31-52]). In multivariable analyses of those who reported having had COVID-19, HCWs in nursing/midwifery roles (aOR 1.76, 95% CI 1.26-2.46, $p = 0.001$) and allied health professions (aOR 1.42, 95% CI 1.05-1.93, $p = 0.023$) had higher odds of reporting LC compared to those in medical roles. Significant associations were also found with self-reported depression, anxiety, and asthma. There was no significant association between ethnicity and experiencing LC.

Conclusions: In this large ethnically diverse cohort study, there is a substantial burden of LC among UK HCWs. Further research and collaborative efforts are urgently needed to address these factors effectively, develop targeted public health interventions, and understand the temporal and longitudinal dynamics of the condition.

Key messages:

- One in five UK healthcare workers reported long COVID, indicating critical needs for targeted public health interventions.
- Our study highlights urgent public health responses to address long COVID among healthcare professionals.

Abstract citation ID: ckae144.2082
Ethnic disparities in clinical severity of COVID-19 as predictor of long COVID

Maria Goldschmidt

M Goldschmidt[1,2], *T Benfield*[2], *M Nørredam*[1,2]
[1]Centre for Migration, Ethnicity and Health, Institute of Public Health, Copenhagen University, Copenhagen, Denmark
[2]Department of Infectious Diseases, Copenhagen University Hospital, Hvidovre, Denmark
Contact: maria.goldschmidt@sund.ku.dk

Background: Recent studies from Europe have shown a higher incidence of long COVID among ethnic minorities compared to the majority population. Little is known of these disparities, but they might be related to factors such as COVID-19 disease severity, barriers in access to health and individual factors such as working and living conditions. This study will elucidate possible predictors of long COVID related to COVID-19 disease severity in an ethnic diverse hospitalised cohort.

Methods: A retrospective cohort study of 1648 patients admitted with COVID-19 at three hospitals in Copenhagen, Denmark, between 1st February 2020 and 31st May 2022. Clinical data was extracted from health care records, and subsequently linked to data from Statistics Denmark on long COVID diagnosis (ICD-10 "DB948A") as well as migration status.

Results: 1361 patients were discharged alive and of those, 113 (8,3%) patients got a long COVID diagnosis. Preliminary analyses show no excess risk of getting a long COVID diagnosis as a migrant compared to patients of Danish origin ($RR = 1{,}20$, $p = 0{,}35$). Some ethnic disparities are seen in disease severity among all patients discharged alive. Patients with migrant background were admitted to the hospital later (6,8 vs 5,6 days, $p < 0{,}0001$), and at a greater risk of needing high flow oxygen administration upon admission ($RR = 1{,}46$, $p = 0{,}0012$) compared to patients of Danish origin. Furthermore, a higher degree of systemic inflammation is seen among migrants with regards to lactate dehydrogenase (LDH) compared to patients of Danish origin (349,7 vs 317,2 U/L, $p = 0{,}0014$). No significant differences in c-reactive protein (CRP) levels (92,8 vs 85,9 mg/L, $p = 0{,}11$).

Conclusions: Preliminary analyses indicates possible ethnic disparities in COVID-19 disease severity among patients discharged alive possibly playing a role as predictors of long COVID. Low health literacy or language barriers might partly explain this. Further analyses are needed.

Key messages:

- In preliminary analyses of 1381 patients previously admitted with COVID-19, we find no excess risk of a long COVID diagnosis (DB 948B) among patients with migrant background.
- Preliminary analyses show some ethnic disparities in COVID-19 disease severity that might act as possible predictors of long COVID.

Abstract citation ID: ckae144.2083
Gestational diabetes and pregnancy outcome in Kurdish, Somali and general population in Finland

Sanna Tähkäpää

S Tähkäpää[1], *F Mohamed*[1], *N Pallasmaa*[1], *S Grénman*[1], *K Mäkikallio*[1], *L Lehtoranta*[1,2]
[1]Department of Obstetrics and Gynecology, University of Turku, Turku, Finland
[2]Public Health, THL, Helsinki, Finland
Contact: smetah@utu.fi

Gestational diabetes (GDM) increases the risk of type II diabetes and cardiovascular morbidity later in life but GDM incidence in women from different cultural backgrounds varies. This study aims to examine treatment of GDM and pregnancy outcomes in Somali, Kurdish and general population women. Patient data of 312 Kurdish, 254 Somali and 508 general population women was collected from Turku University Hospital records from 2008 to 2019. The general population was selected by randomization with matching year, BMI, age, and parity. Singleton deliveries after 34th gestational week with no prior diabetes mellitus were included. Descriptive and comparison analyses (SPSS, version 29.0) were used to identify associations between ethnic background and pregnancy outcomes in women with GDM. The incidence of GDM was 22 % (CI 95 % 17-27) in

Somali, 36 % (CI 95 % 31-42) in Kurdish, and 16 % (CI 95 % 13-19) in the general population women. Kurdish women had medication for GDM more often (43 % CI 95 % 34-53) than the Somali (22 % CI 95 % 11-33) and general population women (18 % CI 95 % 9-26). Metformin was more commonly used among Kurdish (30 % CI 95 % 22-39) compared to the general population (12 % CI 95 % 4-18) and Somali women (13 % CI 95 % 4-22). There was no difference in insulin or combined metformin and insulin treatment between the groups. In GDM group, vaginal deliveries were more common in general population (89 % CI % 81-95) than in Somali women (67 % CI % 64-81). Induction of labour (indication GDM or other) and instrumental vaginal delivery rates were similar between the groups. Newborns of all Somali women had a lower weight (SD -0.3 CI 95 % -0.7 - -0.2) compared to the general population (SD 0 CI 95 % -0.1 - 0.3). The prevalence of GDM was increased and dietary treatment decreased in Kurdish women compared to the general population in Finland. In the future, the treatment of GDM should be adjusted to better optimize the care for different cultural background women.

Key messages:

- Kurdish women have increased incidence of GDM and less dietary treatment compared to the general population with similar risk factors. The pregnancy outcomes remain good in all groups.
- With Somali women, the birth weight of the child is lower despite GDM status. This might direct clinicians to underestimate the effect of GDM when considering individual treatment.

Reflecting (on) power?Critical reflections by healthworkers in Germany on racial power and privilege

Hürrem Tezcan-Güntekin

H Tezcan-Güntekin[1], S Papadopoulou[1], E Stüwe[1], K Meshkova[2], S Merz[1]
[1]Alice Salomon University of Applied Science, Faculty of Health and Education, Berlin, Germany
[2]Fulda University of Applied Science, Fulda, Germany
Contact: tezcan@ash-berlin.eu

Background: Healthcare users have increasingly reported on experiences of racial discrimination in healthcare encounters in Germany (Aikins et al. 2020). While research on the experiences of racialised users predominates, examining the perspectives of white professionals, especially those holding positions of authority, regarding their internalised stereotypes and discriminatory practices is also crucial. This study therefore investigated the prevalence of conscious or unconscious biases related to critical whiteness and anti-racism among healthcare workers (doctors, nurses and therapists) and how these attitudes shaped their professional practice.

Methods: Problem-centred expert interviews (Döringer 2021) with 20 healthcare professionals from medicine, nursing, and therapeutic professions working in hospitals or rehabilitation facilities across three German federal states. Data were analysed using documentary method (Bohnsack 2002).

Results: Respondents exhibited varying degrees of reflective abilities, and there are limited opportunities for structured self-reflection focused on recognizing and addressing racism. The research interview constituted a much-needed space for such reflection. Those who are sensitised about their own positions of privilege often are so due to external influences and personal trajectories (teenaged children, trade union activism) rather than through the values or structures of their institutions. Unconscious racism nonetheless still manifests, demonstrating the need to create more inclusive environments where critical self-reflection on racism is encouraged.

Conclusions: To effectively combat racism, German healthcare institutions must systematically implement anti-racist and intersectional interventions. This also entails creating spaces for reflection where staff can openly examine and acknowledge their own biases, fostering an environment conducive to collective action for promoting anti-racist workplace practices.

Key messages:

- Opportunities for self-reflection critical of racism should also be offered across institutions in order to ensure trusting, non-hierarchical spaces.
- Reflections on one's own social positioning and privileges are not common in all circles, so the necessity of this attitude should be communicated in an error-friendly manner.

Abstract citation ID: ckae144.2085
A framework to guide the commissioning of healthcare services for people seeking asylum in England

Karen Lau

I Al-Sharabi[1], A Deal[1,2], K Mackey[1,2], N Rangel[3], A Joseph[3], L Davies[4], L Bryant[4], J Carter[1], F Knights[1], S Hargreaves[1]
[1]Migrant Health Research Group, St. George's University of London, London, UK
[2]LSHTM, London, UK
[3]British Red Cross VOICES Network, England, UK
[4]British Red Cross, England, UK
Contact: m2210868@sgul.ac.uk

The increasing number of people seeking asylum (PSA) in England, compounded by delays in processing their cases, has led to an urgent need for tailored practices to overcome barriers to healthcare access. While local examples of excellence in healthcare provision for PSA exist, a national framework to guide healthcare for these groups is lacking, leading to fragmentation and inconsistency in service provision. This collaborative research project with the British Red Cross took a co-production approach, involving three peer researchers with lived experience from the outset. From a literature review of case studies on improving access to healthcare for PSA, a preliminary framework of good practice was developed and explored with participants with lived experience of seeking asylum during three in-person workshops refined this. Finally, two focus groups with policymakers and healthcare professionals (HCPs) explored challenges in commissioning services, ensuring final framework relevance to the policy context. In total, 60 participants with lived experience attended three workshops and 19 policymakers and HCPs attended focus groups. Workshop participants emphasised the critical role of improving communication in healthcare settings and educating HCPs and PSA on entitlements and the NHS system. Policymakers highlighted the importance of robust leadership and a standardised national approach that can be adapted locally. Capacity constraints within the NHS and primary care system were highlighted as barriers to good quality care provision. Findings were collated into a practical framework, describing five pillars of good practice; 1)Working in partnership; 2) Upskilling the healthcare workforce; 3) Including lived experience voices; 4) Improving data on local needs; and 5) Strengthening pathways into healthcare. The framework provides guidance to enhance the accessibility, consistency and quality of healthcare services for PSA, addressing critical gaps in the current system.

Key messages:

- A novel framework to guide commissioning and provision of healthcare for people seeking asylum has been developed, drawing from existing pockets of excellence to aid a consistent national approach.
- The framework presents five pillars of systemic good practice, highlighting the importance of strategic partnerships, workforce training and data collection in providing good quality care.

"We must make sacrifices" - coping among left-behind adolescents in Georgia after parental migration

Khatia Antia

K Antia[1,2], *V Winkler*[2], *A Berner Rodoreda*[2]
[1]Prevention and Evaluation, Leibniz-Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany
[2]Heidelberg Institute of Global Health, University Hospital Heidelberg, Heidelberg, Germany
Contact: antia@leibniz-bips.de

Background: Adolescence is challenging, particularly for those left-behind in their countries of origin while parents out-migrate for work. The Eastern European country Georgia has one of the highest percentages of left-behind children and adolescents worldwide, yet how they cope with migratory separation remains unknown. This study is the first to explore strategies of Georgian left-behind adolescents to cope with parental absence.

Methods: From December 2021 to January 2022, we conducted 29 narrative interviews with left-behind adolescents aged 12-18 in Georgia. We purposively sampled participants from a relatively large public school in the Samegrelo region, the second-largest region of Georgia. Interviews were audio-recorded, transcribed, and coded using NVivo 12. Resilience theory underpins this study, and reflexive thematic analysis is applied to identify main themes and sub-themes.

Results: Under the overarching theme of coping and resilience, we identified the following four main themes: (1) the time dimension (2) family connectedness (3) positive attitudes and self-care (4) social interactions beyond the family. Our findings revealed that adolescents whose parent(s) migrated when they were toddlers coped well, while children aged 6-10 felt heavily affected and vulnerable. Closeness with the migrant parent, siblings, caregivers, and other family members was crucial for children's coping. Self-care, self-encouragement, and positive attitudes helped them overcome negative emotions related to parental absence. Awareness of parents' motivation to migrate and appreciation of material benefits positively contributed to adolescents' coping and resilience. In addition, those with many friends coped better and were more resilient than socially less active peers.

Conclusions: Self-motivation, positive attitude, supportive family, and social interactions help left-behind adolescents to cope with negative emotions related to parental absence.

Key messages:

- left-behind children especially at the age of 6-10 need support to cope with migratory separation.
- Interventions are needed to strengthen family ties and support children in intensifying social interactions beyond family.

Digital Literacy Among Migrants in Portugal: Access, Usage, and Trust in Health Information

Maria João Marques

S Hamwi[1], *MJ Marques*[1,2], *S Dias*[1,2]
[1]Public Health Research Centre, NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[2]CHRC, REAL, NOVA University Lisbon, Lisbon, Portugal
Contact: maria.joao.mrqs@gmail.com

Background: Digital literacy is crucial for effective utilization of health-related services and information. This study evaluates digital literacy among migrants in Portugal, focusing on three key components: access to digital services, usage of these services for health information, and trust in online health resources.

Methods: A cross-sectional survey was conducted to assess migrants' access to digital devices such as smartphones and computers, their ability to use these devices for health-related purposes, and their perceptions of the credibility of online health information. Data were analyzed across various sociodemographic and migration-related factors.

Results: 1,048 migrants were included, of which 90.3% had access to digital services, and 64.9% reported ease in using these services to obtain health information. Despite widespread access and usability, about 45.6% of migrants doubted the reliability of online health information. Access and usage varied significantly with age, education, income, employment status, and region of origin. Older, less educated, lower-income, and African migrants faced more significant challenges in access and usage. Additionally, trust issues were predominantly reported by females, those with lower education levels, recent arrivals, and non-Portuguese speakers.

Conclusions: The study highlights significant disparities in digital literacy among migrants, influenced by socio-economic and demographic factors. While access to digital tools is high, challenges in usage and trust present barriers to effective health communication.

Key messages:

- High access to digital services among migrants, yet significant disparities affect older, less educated, and lower-income groups.
- Usage difficulties combined with low trust in online health info highlight the need for targeted digital literacy interventions.

Are post-communist countries paying increased healthcare costs because of risky behaviour?

Jarmila Zimmermannova

J Zimmermannova[1], *K Helman*[2], *M Hajek*[3]
[1]Faculty of Health Sciences, Palacký University Olomouc, Olomouc, Czechia
[2]Faculty of Informatics and Statistics, Prague University of Economics and Business, Prague, Czechia
[3]Faculty of Forestry and Wood Sciences, Czech University of Life Sciences Prague, Prague, Czechia
Contact: jarmila.zimmermannova@upol.cz

Background: Based on the annual Country Health Profiles, we can see the difference in population behaviour across EU countries and the associated health risks. At first glance, the so-called post-communist countries are characterised by above-average per-capita harmful consumption of sin goods, alcohol and tobacco. Is this harmful consumption associated with increased healthcare costs?

Methods: The idea of the study is based on balanced panel-data published in Country Health Profiles. The member countries were divided into groups based on their health risk scores - high risk (above average), and low risk (below average). The group of countries with high risk is mostly composed of post-communist countries. The detailed per-capita annual data for the period 2013-2021 was collected, such as GDP, consumption of sin goods, alcohol, and tobacco. The analysis is based on fixed-effects linear regression models, following recent recommendations on suppressing the excessive role of statistical-inference tools.

Results: We built various models for different groups of countries, and in this abstract, we present results for the group of post-communist countries - a simple model of harmful consumption (sin goods, GDP) and a more complex model (alcohol, tobacco, GDP). The results show that in the case of the post-communist countries group, for a fixed level of GDP per capita, higher consumption of sin goods by EUR 1 per capita corresponds with total healthcare expenditures higher by EUR 0.244 per capita. For a fixed level of GDP per capita and tobacco consumption per capita, higher consumption of alcohol by EUR 1 per capita corresponds with total healthcare expenditures higher by EUR 1.367 per capita.

Conclusions: Harmful consumption has a multiplier effect in the health sector; besides direct impact, it influences an increase in healthcare expenditures. More emphasis should be placed on prevention and awareness of consumers to reduce harmful consumption.

Key messages:

- For fixed GDP per capita, higher harmful consumption corresponds with higher healthcare costs in post-communist countries.
- For fixed GDP per capita and tobacco consumption per capita, a €1 higher alcohol consumption corresponds with more than €1 higher healthcare expenditure in the post-communist countries.

Abstract citation ID: ckae144.2089
Solutions for reducing the severe economic burden of musculoskeletal diseases

Marjetka Jelenc

S Sedlak[1], *M Jelenc*[1,2]
[1]Center for Health Care, NIJZ, Ljubljana, Slovenia
[2]Faculty for Health Sciences, University of Maribor, Maribor, Slovenia
Contact: marjetka.jelenc@nijz.si

Issue: In Slovenia the big group of over 150 musculoskeletal and connective tissue diseases (MSCTD) constitute a serious public health problem, a major burden on health systems and society as a whole. Patients with these diseases have a poorer quality of life and often retire early. Any early retirement that could have been prevented represents a loss of human capital, which is a major social and economic cost to society. The aim of this study was to analyze the economic burden of the six most common MSCTD in Slovenia for the period from 2020 to 2022, to contribute to a better understanding of this problem and suggest solutions.

Methods: At the Slovenian National Institute of Public Health, in collaboration with the Faculty of Economics at the University of Ljubljana, we calculated the burden of six most common MSCTD for the period 2020-2022. We used the National Transfer Accounts (NTA) methodology to calculate the indirect costs; direct costs were calculated based on the national routine health data.

Results: The calculated economic burden of the six most common diagnoses of MSCTD represents 5% of total health expenditure or 0.4% of Slovenian gross domestic product on average. Direct costs amounted to 2% of total health expenditure (hospitalizations 22.5%, costs for medicines 9.3%, first curative visits at the primary level and visits to the outpatient clinic at the secondary level 2.7%). Indirect costs amounted to 3% of total health expenditure.

Conclusions: Despite the reduced access to the health system due to COVID-19 the economic burden of MSCTD is high in Slovenia and would be significantly higher considering all diagnoses from this group of diseases. The research requires interdisciplinary cooperation between medicine and economics regarding demanding NTA methodology which is innovative in our country.

Key messages:

- One of the main public health priorities in Slovenia should be to raise awareness of MSCTD.
- In the light of the aging population prevention activities with focus on MSCTD should be intensified as soon as possible.

[4]Institute of Agri-food and Life Sciences, Hellenic Mediterranean University, Heraklion, Crete, Greece
[5]School of Public Health, University of West Attica, Athens, Greece
Contact: kougioumtzogloui@vianex.gr

Background: The increasing prevalence and incidence of autoimmune and respiratory diseases is a leading public health concern. This study aims to quantify the public health and broader economic gains from treating autoimmune and respiratory diseases in Greece.

Methods: A decision-analytic model was constructed evaluating the socioeconomic and fiscal gains of established standard of care treatments against 4 autoimmune disorders namely, rheumatoid arthritis, psoriatic arthritis, psoriasis, ankylosing spondylitis and against the respiratory diseases of asthma, and COPD. Morbidity reductions from treatment were translated into averted loss of income and absenteeism and averted tax revenue loss and prevented disability pensions. Targeted literature reviews were conducted to obtain the effectiveness of treatments on productivity-related outcomes. Economic data were obtained from official sources.

Results: Treating 1,000 patients for the autoimmune and respiratory conditions is estimated to generate annual gains of 196.3 productive life years (PLYs), to avert 48,547 absenteeism days and to prevent 1.2 disabilities. The annual socioeconomic and fiscal gains of treatments against autoimmune disorders are estimated at €6.5 million and €1.3 million, respectively. Preventing asthma and COPD-related morbidity, among 1,000 patients, is estimated to yield annual socioeconomic gains of €1.2 million and fiscal gains of €0.4 million.

Conclusions: Effective treatment of autoimmune and respiratory diseases may generate substantial public health, socioeconomic and fiscal gains, simultaneously promoting population's health and the sustainability of the healthcare system.

Key messages:

- It is the first study carried out in Greece aimed to assess the positive impact on public health and the broader economic value of treating autoimmune and respiratory diseases.
- Therapeutic value of pharmacological interventions transcends the potential benefits to patients and public health.

Abstract citation ID: ckae144.2091
Health economics and services research in symbiosis: STREAMLINEing mental health services in Austria

Judit Simon

J Simon[1], *on behalf of STREAMLINE Consortium*[2,3,4]
[1]Centre for Public Health, DHE, Medical University of Vienna, Vienna, Austria
[2]AIHTA, Vienna, Austria
[3]Austrian National Public Health Institute, Vienna, Austria
[4]Universidad Loyola, Seville, Spain
Contact: judit.simon@meduniwien.ac.at

Objectives: The cost of mental diseases exceeds 4% of GDP in Europe. In Austria, every 5th person lives with mental ill-health (MIH). Ongoing epidemiological, demographic and societal changes increase the need for easily accessible, better integrated and good value services. In STREAMLINE, we combine, harmonize and implement the latest methods in human service mapping and economic costing to optimize future service provision and financing for MIH in Austria.

Methods: We comprehensively assess the availability, activity and affordability of human services targeting MIH in Vienna within the health and social care, education, labour and justice sectors based on a conceptual mind map. We identify services through extensive literature, document and web searches plus expert consultations. Services are mapped and costed according to the European PECUNIA methods: classification of the main service types using the international DESDE taxonomy of human services; development of Reference Unit Costs using the PECUNIA RUC templates with primary data; validation of the results with secondary data; compilation of a comprehensive multi-sectoral service catalogue; and synthesis for spatial and policy analyses.

Results: We identified 756 sources, 75% individual organisations, 5% multi-organisations and 20% existing provider lists. 84% relate to health and social care, 10% labour, and 3% education and justice sectors each. 58% deliver care to adults, 37% to children & adolescents, and 5% support carers. Further service mapping and RUCs will be presented.

Discussion: STREAMLINE pioneers in coordinated public mental health services and economics research at scale. Assessed levels of fragmentation call for better integration, improved transition, reduced spatial inequity and increased support for carers. Results increase the feasibility of service evaluations from a societal perspective. Planned public service atlas facilitates information and access for service users and carers. Funding: WWTF

Key messages:

- New methods for harmonized health services and economics research allow comprehensive information for optimized future mental health service planning and financing.
- Assessed levels of fragmentation highlight the need for better integration, improved transition, reduced spatial inequity and increased support for carers.

Abstract citation ID: ckae144.2092
The shift from inpatient to outpatient settings of a surgical DRG for pediatric patients in Portugal

Diana Alecsandra Grad

DA Grad[1], *J Souza*[2,3], *F Lopes*[3], *V Pinheiro*[3,4], *A Freitas*[3], *JV Santos*[3,5]
[1]Department of Public Health, FSPAC, Babes-Bolyai University, Cluj-Napoca, Romania
[2]Institute of Engineering, Polytechnic of Porto, Porto, Portugal

[4]Public Health Unit, ULS Matosinhos, Matosinhos, Portugal
[5]Public Health Unit, ULS Santo António, Porto, Portugal
Contact: diana.a.grad@gmail.com

Background: The shift of selected surgical procedures from inpatient to outpatient settings has been seen as a solution to improve health care provision. These shifts often occur under pay-for-performance schemes, pay-for-efficiency schemes, or other forms of financial incentives. For this study, we aimed to assess the effect of Decree 132/2009, implemented on February 1, 2009, which increased the relative weights of DRG 60 ("tonsillectomy and/or adenoidectomy, age <18") performed in outpatient settings, thus acting as a financial incentive.

Methods: We performed a quasi-experimental study and employed interrupted time series (ITS) and controlled interrupted time series (CITS) designs, using monthly pediatric data provided by The Central Administration of the Health System (ACSS), with discharges between January 2006 and February 2012 (having 37 months pre- and post-decree implementation) of inpatient and outpatient episodes for DRG 60 (affected group) and DRG 163 ("hernia procedures age <18", the selected control group). We used as study outcomes proportions (number of outpatient episodes divided by the sum of outpatient and inpatient episodes) to quantify increases in outpatient episodes and ratios (number of outpatient episodes divided by the number of inpatient episodes) to quantify decreases in inpatient episodes. Fourier terms were included to adjust for seasonality.

Results: We obtained statistically significant results only at the trend level for ratios when using the ITS model (0.01574) and for proportions only when using the CITS model (0.00310), although small non-statistically significant increases were obtained for the employed ITS as well as for the CITS design.

Conclusions: Decree 132/2009, which created financial incentives for the shift from inpatient to outpatient for DRG 60, showed low and non-statistically significant increases using both ITS and CITS models.

Key messages:

- We analyzed the impact of Decree 132/2009 on the pediatric surgeries under DRG 60 performed in outpatient settings in Portugal using interrupted time series and control interrupted time series.
- The decree had a small effect at the national level for DRG 60.

Abstract citation ID: ckae144.2093
Economic burden of suicide in Sweden in 2022

Anneli Ivarsson

I Feldman[1], *P Martínez de Alva*[1]
[1]Department pf Public Health, Uppsala University, Uppsala, Sweden
Contact: anneli.ivarsson@umu.se

Background: Suicide and suicidal behaviors bring massive human, social and economic impacts. Estimates of the cost of suicide can give some guidance as to where research on developing new interventions might be focused to give the greatest potential gain. The aim of the study is to quantify the economic cost of suicide in Sweden in 2022.

Methods: Incidence of suicide attempts and mortality due to suicide, intentional and undetermined (ICD10 X60-X84 and Y10-Y34) were sourced from the Swedish National Board of Health and Welfare databases for 2022. Cost were estimated from a societal perspective, including costs for inpatient and outpatient care, medication, police and justice activities as well as productivity losses due to early mortality.

Results: In 2022, a total of 1,569 suicide death were registered in Sweden (1,102 men and 467 women). The incidence rate remains stable during the last ten years, 17 death per 100 000. In total, 18,854 patients (10, 359 women and 8,459 men) were treated in inpatient and outpatient hospital care with suicide-related diagnoses, generated 32,843 days in inpatient care and 11,471 outpatient care visits. Direct costs for suicide death including forensic examination, emergency services, police investigation and property damage were estimated as €6,02 million, while indirect costs for productivity losses totaled €690 million. Direct healthcare costs for suicide related treatment were estimated at €54.3 million. Overall, suicide and suicide attempts cost around €750 million per year to society.

Conclusions: Estimates of the economic burden of suicide are needed for the Swedish setting, and these amounted to €60.3 million in direct costs and €690 million in indirect costs in 2022. The cost might be underestimated because the societal cost of suicide bereaved persons was not considered. These cost estimates can provide useful inputs to a cost-effectiveness analysis of a specific preventive intervention, and to its subsequent evaluation.

Key messages:

- Economic burden of suicide is substantial for society.
- Public health policies aimed at the prevention of suicide should be increased.

Abstract citation ID: ckae144.2094

Productivity loss due to acute COVID-19 and post COVID-19 condition in the Northern Netherlands

Guilherme Monteiro Sanchez

G Monteiro Sanchez[1], *R van Ooijen*[1], *JGM Rosmalen*[1], *T Fens*[1,2], *T van Asselt*[1], *S Brouwer*[1], *SKR van Zon*[1,3]
[1]Faculty of Medical Sciences, University Medical Center Groningen, Groningen, Netherlands
[2]Faculty of Science and Engineering, University of Groningen, Groningen, Netherlands
[3]Unit Healthy Living & Work, Netherlands Organisation for Applied Scientific Research, Leiden, Netherlands
Contact: g.m.sanchez@umcg.nl

Introduction: The COVID-19 pandemic caused significant socioeconomic and health shocks worldwide. Yet, research is still scarce on how acute COVID-19 and post COVID-19 condition (PCC) have impacted workers productivity in terms of absenteeism, presenteeism and reduced unpaid work. This study examines the effect of acute COVID-19 and PCC on Dutch workers' loss of work productivity in standardized hourly costs compared to those with neither disease.

Methods: This study included data from 31 waves (March 2020 - October 2022) of the Lifelines COVID-19 cohort, a populational cohort from the Netherlands. Productivity was measured in 7 waves in terms of absenteeism, presenteeism, and loss of unpaid work using the Medical Technology Assessment Productivity Costs Questionnaire. We selected workers aged 18 to 64 in the first wave ($n = 10{,}950$). Using administrative data, average hourly costs of productivity were calculated as 38.67€ for absenteeism and presenteeism and 15.94€ for unpaid work. The friction cost method was used. To compare group differences, a Kruskal-Wallis rank sum test with Holms-Bonferroni p-value adjustment was performed.

Results: In total, 33.4% of participants had acute COVID-19, 5.7% had PCC, and 60.9% had neither disease. The mean total combined productivity loss per person of those with PCC was 7,118€, compared to 3,410€ for those with acute COVID-19, and 3,076€ for those with neither. When comparing groups, significant differences in costs were found for all aspects of productivity, except for unpaid work loss between acute COVID-19 and those with neither disease.

Discussion: Although the number of people with acute COVID-19 represents a large societal cost in terms of accumulated loss, those with PCC incurred on average twice as much productivity losses per person across all domains. This study highlights the high costs associated with PCC, which continues to chronically burden workers. Policies should be aimed at lessening this burden.

Key messages:

- Post COVID-19 condition is associated with significantly higher average productivity costs per person than acute COVID-19, which highlights the individual burden of this chronic disease.
- Acute COVID-19, despite relatively lower average productivity costs, represents a large societal cost in terms of accumulated loss.

Abstract citation ID: ckae144.2095

Mapping the Out-of-Pocket Healthcare Costs for Terminal Cancer Patients across Europe

Aviad Tur-Sinai

A Tur-Sinai[1], *N Bentur*[2]
[1]School of Public Health, University of Haifa, Haifa, Israel
[2]School of Health Professions, Tel-Aviv University, Tel Aviv, Israel
Contact: atursinai@univ.haifa.ac.il

Background: In many countries, including those with universal health insurance, cost-sharing for healthcare is prevalent, resulting in out-of-pocket expenses for cancer patients. However, the proportion of government contribution to national healthcare expenditure varies across countries. This study aims to determine the prevalence and magnitude of out-of-pocket expenditure among cancer decedents in their final year of life and to assess whether decedents' characteristics or their country's welfare regime have a greater impact on out-of-pocket expenditure.

Methods: SHARE data was analyzed for individuals aged 50 and above from seven European countries (including Israel) who passed away from cancer. Interviews were conducted with the decedents' family members to gather information about out-of-pocket expenditure on behalf of their deceased relatives.

Results: The study identified 1,950 cancer decedents with an average age of 74.4 (S.D.=9.39), of which 58.0 percent were male. In their last year of life, 58 percent of the decedents incurred out-of-pocket expenditure on healthcare services. The welfare regime is found to be the primary factor influencing the likelihood of out-of-pocket expenditure, while patients' characteristics have minimal impact. The proportion of out-of-pocket expenditure varies significantly across welfare regimes, with the highest probability observed in the Continental and Social Democratic regimes and the lowest in the Mediterranean and East European regimes.

Conclusions: A country's welfare regime plays a crucial role in determining the generosity of its public healthcare spending and its ability to alleviate the financial burden on the households of cancer patients. Increasing public funding for cancer care may reduce patients' out-of-pocket expenditure in all countries, particularly in those where out-of-pocket expenditure is the highest.

Key messages:

- A country's welfare regime significantly impacts the likelihood and magnitude of out-of-pocket healthcare expenditure for cancer patients in their last year of life.
- Increasing public funding for cancer care may help reduce the financial burden on patients and their families, particularly in countries with high out-of-pocket expenditure.

From crisis to chronic: a comparative analysis of Long COVID impact in Italy and the United States

Aurora Heidar Alizadeh

MC Nurchis[1], *A Heidar Alizadeh*[1], *J Garlasco*[2], *H Safwat Mhmoued Abdo Elhadidy*[2], *GM Raspolini*[1], *MM Gianino*[2], *G Damiani*[1,3]
[1]Università Cattolica del Sacro Cuore, Rome, Italy
[2]Università di Torino, Turin, Italy
[3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: aurora.heidar@gmail.com

Background: The aftermath of COVID-19 is bringing about socioeconomic consequences, such as diminished quality of life (QoL), decreased productivity, and considerable healthcare expenditures. Despite the emerging acknowledgment of a clinical syndrome following COVID-19 disease, known as Long COVID (LC), notable research gaps persist. This study aims to assess the epidemiological and economic impact of LC in both Italy and the United States (US).

Methods: This ecological analysis comprises epidemiologic and economic data from 2020 to January 2023, regarding working-age individuals (18-64 years). An Italy/US incidence rate ratio (eIRR) was estimated to compute LC cases in each country. The product between the value of a year spent in good health, individual Quality-Adjusted Life Year (QALY) loss, and LC cases yielded total lost QoL. Temporary productivity loss (TPL) was calculated through the Human Capital Approach. All estimates were deemed significant at a p-value less than 0.05.

Results: Up to date, the eIRR was 0.78 [0.43 - 0.91] implying 22% fewer LC cases in Italy with respect to the US. Total LC cases were 11 [8.7 - 13.5] and 1.8 [0.9 - 2.1] million in the US and Italy, respectively. The relative QALYs loss was 1.5 [0.8 - 3.1] and 0.2 [0.1 -

0.9] million. Reduced QoL cost roughly $189 [164 - 214] billion in the US and €6 [1 - 11] billion in Italy. TPL amounted to $37 [21 - 57] billion in the US and €2.8 [1.2 - 7.4] billion in Italy. Americans aged 30-39 years showed the largest income loss (26.6%), while in Italy it occurred in the age group 50-64 years (38%).

Conclusions: LC places a substantial burden in Italy and the US, impacting both the productivity of the working-age population and influencing the younger generation, who constitute the future workforce. Our study underpins the necessity for comprehensive health policies, programs, and interventions alongside effective tertiary prevention strategies to tackle the challenges posed by LC.

Key messages:

- According to this analysis, both countries show significant productivity and quality-adjusted life years loss due to LC among working age individuals.
- Steering the formulation of evidence-based sounding health policies to address LC burden, among working age individuals, both in Italy and in the US.

Abstract citation ID: ckae144.2097
Factors Affecting Household Health Expenditures: Evidence from Iran

Parnian Jalili

F Jalili[1], A Akbari[2], B Karami Matin[3], M Soofi[3]
[1]School of Health Administration, Dalhousie University, Halifax, Canada
[2]Sobey School of Business, Saint Mary's University, Halifax, Canada
[3]School of Public Health, Kermanshah University of Medical Sciences, Kermanshah, Iran
Contact: parnian.jalili@ucdconnect.ie

Background: Productivity plays a crucial role in driving economic growth, and its primary determinant is human capital. Human capital, in turn, is influenced by health and education investments, leading both households and governments to allocate substantial resources toward these sectors. Understanding the factors influencing health expenses is vital for designing effective policies.

Methods: This study investigates the factors affecting health costs by analyzing data from various provinces in the Islamic Republic of Iran, spanning from 2006 to 2019. The data, sourced from the Statistics Center of Iran, was analyzed using the panel data approach to uncover the relationships between health expenditure and several key variables.

Results: The analysis revealed significant disparities in health expenditure among provinces. Sistan & Baluchestan had the lowest health expenditure per household, while Tehran reported the highest. Inflation emerged as a significant factor, having a negative impact on health expenses due to its influence on purchasing power. Conversely, the education and salary of household heads had a positive impact on health expenditure. Notably, economic growth did not exhibit a significant relationship with health expenses.

Conclusions: The study highlights the importance of education and income levels in shaping health expenditures, while inflation can curtail spending on health due to reduced purchasing power. Policymakers should consider these factors to ensure equitable and effective allocation of health resources.

Key messages:

- Improving health and well-being, essential for comprehensive progress and human development, relies significantly on household health expenditure.
- The efforts to enhance human capital should focus on reducing inflation.

Abstract citation ID: ckae144.2098
Using advanced computing to improve outcome monitoring in substance use disorder treatment in Alaska

Ryan Ray

R Ray[1], A Madison Pohl[2], P Licht[2], W Crews[3]
[1]61Sixty Social Innovation Lab, Palmer, AK, USA
[2]Set Free Alaska, Palmer, AK, USA
[3]Crewsing IT, Canyon Lake, CA, USA
Contact: ryanray@61sixty.org

Issue: In Alaska, crime associated with substance misuse is a massive public health and safety concern costing over $2.3 billion annually. Government officials make substantial investments to address this challenge but have little ability to monitor the long-term effectiveness of these interventions. Treatment providers are also stifled by minimal feedback regarding their lasting impact. While government databases exist that contain relevant information related to long-term treatment outcomes, low knowledge transfer continues to occur between these big data systems and treatment providers.

Description: To determine if emerging database technology can effectively monitor long-term recidivism outcomes, a prototype was implemented by Alaska's leading treatment provider, Set Free Alaska. The Recidivism Tracking Interface is an innovative database system that strategically connects treatment records with the criminal justice system database. While maintaining high confidentiality and security standards, the first-of-its-kind interface assessed long-term recidivism outcomes of Set Free Alaska's former clients from 2010 to 2023.

Results: Of those who successfully completed treatment (n = 970), only 12.06% were convicted of a new crime with an average of 1,167 days between discharge and new criminal charges. The current recidivism rate in Alaska is 66.3%. In addition to recidivism outcomes, the interface also revealed data incredibly useful for informing treatment services and relapse prevention practices. The Recidivism Tracking Interface effectively demonstrated that advanced computing systems can be utilized to monitor long-term outcomes in a manner that was previously unavailable to treatment providers.

Lessons: In the age of advanced cloud computing and generative AI, treatment providers around the world and their government partners can overcome current knowledge transfer barriers to monitor long-term outcomes in a manner that is automated, inexpensive, and easy to use.

Key messages:

- Advanced computing offers new opportunities to improve long-term outcome monitoring.
- Expanding secure access to relevant government databases can ultimately improve treatment outcomes and advance outcome-based funding models.

Abstract citation ID: ckae144.2099
Fall risk factors and prevention among older adults in primary care in Belgium, 2019-2021

Sarah Moreels

S Moreels[1], *S Bensemmane*[1], *R De Schreye*[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
Contact: sarah.moreels@sciensano.be

Background: Falls are a major public health problem and ageing populations further increase the burden of fall-induced injuries. Falling among older persons is a multifactorial health condition needing multifactorial care. General practitioners (GPs) are well placed to implement a multifactorial management. A surveillance study of accidental falls studied characteristics of falls, risk groups and fall risk factors as well as fall prevention by GPs.

Methods: A 3-year retrospective population-based study by the Belgian network of Sentinel General Practitioners (SGP) on all patients aged $\geq$ 65 years consulting their GP for new fall-related injuries.

Descriptive statistics were used to characterize falls, fallers, fall risks and preventive measures. Logistic regression analyses were performed to identify factors associated with a multifactorial fall risk profile.

Results: During 2019-21, 1138 accidental falls were registered. Medical and/or nursing intervention was required for 24% and 22% had a severe injury. During consult, 30% was referred to hospital. 61% of patients showed at least one of the four most prevalent fall risks, i.e. deficits of mobility or balance, polypharmacy, cognitive impairment or psychotropic medication. A multifactorial fall risk profile was observed in 45% of fallers and was associated with recurrent falling ($p < 0.001$), fall location ($p < 0.05$), activity when falling ($p < 0.01$) and pandemic year 2020 ($p < 0.05$). Addressing surrounding and walking problems were the most frequently delivered preventive measures. For 28% of patients, other primary care providers (mainly nurse and physiotherapist) were involved in preventive care.

Conclusions: This study highlights the importance of identifying fall risk factors among fallers in primary care. Preventive fall measures, taken in about one in four general practice patients in collaboration with other healthcare providers, are crucial for preventing accidental falls in older persons in Belgium.

Key messages:

- A multifactorial management of fall risk factors by GPs is crucial for preventing accidental falls in older primary care patients.
- Strengthening collaboration between primary healthcare professionals is needed for improving fall prevention in Belgium.

Abstract citation ID: ckae144.2100
Gendered trends in unpaid labour by educational level in Sweden 2004-2022

Anu Molarius

A Molarius[1,2], *F Granström*[3], *J Ervin*[4]
[1]Centre for Clinical Research, Region Värmland, Karlstad, Sweden
[2]Department of Public Health Sciences, Karlstad University, Karlstad, Sweden
[3]Department of Health, Medicine and Caring, Linköping University, Linköping, Sweden
[4]Centre for Health Policy, The University of Melbourne, Parkville, Australia
Contact: anu.molarius@regionvarmland.se

Background: Unpaid labour has recently been recognised as an important yet neglected social determinant of health. Our aim was to investigate the gendered trends in unpaid labour/domestic work by educational level in prime working-age Swedish adults (30-49 years) from 2004-2022.

Methods: The study is based on a postal survey sent to a random general population sample of adults from central Sweden in 2004, 2008, 2012, 2017 and 2022. The 30-49-year age group included between 5,500 and 12,200 respondents depending on the survey year. Trends in hours spent in domestic work and in experiencing domestic work as burdensome by gender and educational level were estimated by age-standardised proportions with corresponding 95% confidence intervals.

Results: Women reported spending more time in domestic work than men throughout every survey period from 2004 to 2022. For example, in 2022, 31% of women spent more than 20 hours per week in domestic work compared to 20% of men. Over time, hours spent in domestic work decreased in women whereas no trend was observed in men. Among women, educational level appeared to make no difference to prevalence of high domestic work time whereas, among men, it was consistently greater among those with higher educational levels. In general, women experienced domestic work as burdensome to a higher degree than men did.

Conclusions: As gender differences in unpaid labour/domestic work persist in Sweden, more effort is needed to implement social policies to increase men's participation in domestic work, especially among men with low and middle educational levels, which has the potential to reduce gendered health inequities.

Key messages:

- Amongst Swedish adults aged 30-49 years, the gender gap in unpaid labour has declined during the last two decades, but this is only due to women reducing their domestic work time.
- For men, prevalence of high domestic work time was consistently greater among those with higher educational levels, whereas no difference was observed among women.

Prevalence of potentially inappropriate medication use in the older population living in Germany

Giselle Sarganas

G Sarganas[1,2], *D Grams*[1], *A Ordoñez-Cruickshank*[1], *J Fuchs*[1], *H Neuhauser*[1,2], *B Gaertner*[1,2], *P Thuermann*[3]
[1]Department Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
[2]German Centre for Cardiovascular Research, Berlin, Germany
[3]Philipp Klee-Institut für Klinische Pharmakologie, Universität Witten/Herdecke, Wuppertal, Germany
Contact: sarganas-margolisg@rki.de

Background: Potentially inappropriate medications (PIM) are medicines for which the risks for adverse events (AEs) usually outweigh the clinical benefits in older adults. PIM is associated with an increased risk of AEs, hospitalizations, mortality and higher health care costs. This analysis presents the prevalence of PIM use and associated factors in people aged 66+ years living in Germany.

Methods: Data from the nationally representative Study on Health of Older People in Germany (Gesundheit 65+) conducted between 2021-2023 by the Robert Koch Institute, was analyzed. All medicines used, prescribed and over-the-counter (OTC), in the 7 days before the interview were classified into anatomical therapeutic chemical codes. PIM use was identified based on the PRISCUS 2.0 list. Weighted prevalences and associated factors for PIM use are presented.

Results: 96% of the sample ($N = 1,474$) took at least 1 medication in the 7 days before the interview. The prevalence of PIM use was 29% (95% CI: 26%-32%), 23% took 1 PIM and 6% 2+. There were no sex differences but a significant increase with age: 23% in the age group 66-74, 33% in the age group 75-84, and 39% in the age group 85 + (29% 1 PIM and 10% 2+). People with a low educational level had a PIM prevalence of 32% compared to 21% in those with a high educational level. Among those reporting having chronic diseases, the PIM prevalence was 34% compared to 19% among those not reporting them. The prevalence of PIM increased with the number of medicines used: 13% in 1-4 medicines, 31% in 5-9 medicines, and 53% in 10+ medicines. The most frequently used PIM in this sample was ginkgo biloba leaf extract (plant-based antidementia drug) followed by diclofenac (non-steroidal anti-inflammatory drug), and then by tricyclic antidepressant drugs (opipramol and amitriptyline).

Conclusions: PIM use was higher than suggested by prescription data analysis. It was associated with higher age, chronic diseases, polypharmacy and a low educational level.

Key messages:

- PIM use was common, affecting more people with chronic diseases, older age groups and people with a low educational level.
- Strategies to promote and monitor appropriate medication use are needed.

Abstract citation ID: ckae144.2102
Health Impacts of Disasters and Social Indicators: An Ecological Study

Nüket Paksoy Erbaydar

M Özden[1], *N Paksoy Erbaydar*[1]
[1]Department of Public Health, Hacettepe University Medical Faculty, Ankara, Türkiye
Contact: erbaydar@hacettepe.edu.tr

The objective of this study is to investigate the correlation between certain social indicators and the mortality and morbidity in disasters recorded in the EM-DAT database within countries in the last decade. The correlation between the mortality and morbidity in disasters recorded in the EM-DAT database between March 1, 2014-2024 and the most recent data on Human Development Index (HDI), Gender Inequality Index (GII), Gini Coefficient (GC), Government Health Expenditure as a share of GDP (GHE/GDP) and Corruption Perception Index (CPI) were analyzed. During the period of the study, disasters from a total of 207 countries/regions were recorded in the database. The median (IQR) values of countries in disasters were found to be 35.1 (67.5) for death per million and 76.3 (783.0) for injury per million. The most frequent types of disasters, the most frequent cause of mortality and the most frequent cause of injury in each country were found to be floods, extreme temperatures, and epidemics, respectively. While there was no significant difference between the social indicators analyzed and the total number of deaths, there was a negative correlation between the number of injuries and the HDI, CPI, GHE/GDP values of the countries, and a positive correlation between the GC and GII values (for all tests, Spearman correlation test, $p < 0.001$). The correlation coefficient was interpreted as 'weak' in all other pairwise analyses except for the GHE/GDP value (moderate). Countries with social indicators closer to the positive threshold have been found to have less injuries in disasters. The possible reason for the insignificant correlation with the mortality is thought to be the difficulties in detecting mortality, especially in 'extreme temperatures', and the fact that it is mostly recorded in countries where social indicators are relatively more advanced. More research is needed to investigate the relationality between social indicators and disaster harms.

Key messages:

- Disasters are critical mediators between social determinants and health. Addressing and reducing inequalities should remain on the public health agenda to prevent disasters and protect health.
- Analysis of disasters shows that 'extreme temperatures', which cause the most deaths in some countries, are barely detected in developing countries. Disaster recording systems need to be strengthened.

Abstract citation ID: ckae144.2103
Exploring the dynamics of alcohol use, poverty and the role of social context in Athens, Greece

Sotiria Kyriakidou

S Kyriakidou[1], *C Temenos*[1], *C Henry*[1], *T Paparrigopoulos*[2], *K Triantafyllou*[2]
[1]Geography Department, University of Manchester, Manchester, UK
[2]School of Medicine, National and Kapodistrian University, Athens, Greece
Contact: sotiria.kyriakidou@manchester.ac.uk

Background: A body of research conducted across diverse national context, including the United Kingdom, Russia, Denmark and Norway, shows a robust link between poverty and increased alcohol related harm, even after accounting for different drinking patterns. This paper examines the unexplored relationship between poverty and alcohol use in Athens, Greece, focusing on alcohol's impact related to the familial and social life of individuals and whether this system is affected by poverty.

Methods: This is a 2021 cross-sectional study, with 300 adult participants of mean age 45.8. We administered four questionnaires. The participants were equally distributed above and below the poverty threshold, sampled randomly. The latter were beneficiaries of social services. The data analysis established two scoring variables: the level of dysfunction from alcohol use and the level of strength of family ties. We computed their correlation and multiple linear regressions to assess their relationships.

Results: Individuals not residing in poverty exhibit a higher frequency of alcohol use (81.9%) than their counterparts (57.1%), however, those living in poverty tend to consume greater quantities of alcohol per occasion ($p < 0.001$) and reported elevated levels of dysfunction within familial and social interactions.

Conclusions: This study indicates that different consumption patterns are tied to diverse socioeconomic strata, with binge drinking behaviours specifically linked to financial hardship. Also, alcohol related dysfunction and family and social dynamics are affected by poverty. Our findings show that as dysfunction attributed to alcohol use increases, participants socialize less and report lower levels of well-being. In contrast those with balanced family ties and social encounters exhibit the opposite trend. This study warrants further exploration in cities in Southern Europe.

Key messages:

- To mitigate alcohol use, policies empowering social and familial connections are of high importance.
- Uncovering poverty as a factor for binge drinking can inform prevention strategies.

Abstract citation ID: ckae144.2104
Non-medical use of tranquilizers and sedatives by 15-16-year-old adolescents in Estonia, 2003–2019

Liina Veskimäe

L Veskimäe[1,2], *S Vorobjov*[1,2], *K Pärna*[1]
[1]Family Medicine and Public Health, University of Tartu, Tartu, Estonia
[2]Department of Risk Behaviour Studies, National Institute for Health Development, Tallinn, Estonia
Contact: liina.veskimae@gmail.com

Background: Non-medical use of prescription drugs has become a global concern in recent decades. This study aimed to explore trends in non-medical tranquilizers and sedatives use (NTSU) among adolescents in Estonia from 2003 to 2019.

Methods: Utilizing data from the cross-sectional European School Survey Project on Alcohol and Other Drugs (ESPAD) conducted in 2003-2019, study included 15-16-year-old Estonian schoolchildren ($n = 11{,}328$; 48.6% boys). Cochran-Armitage test was employed to assess changes in NTSU trends, with statistical significance set at $p < 0.05$. Prevalence rates and 95% CIs used as outcome measures.

Results: From 2003 to 2019, the lifetime prevalence of NTSU significantly increased for both genders, with girls consistently showing higher rates. Among boys, NTSU rose from 5.0% (95% CI 3.8-6.5) to 11.3% (95% CI 9.6-13.3), particularly among those reporting NTSU 1-2 times, from 3.0% (95% CI 2.1-4.2) to 8.2% (95% CI 6.7-9.9), $p < 0.001$. Similarly, for girls, NTSU rose from 12.6% (95% CI 10.7-14.7) to 17.5% (95% CI 15.4-19.7), $p < 0.001$. There was an increase among girls reporting NTSU 1-2 times from 7.5% (95% CI 6.0-9.2) to 10.6% (95% CI 9.0-12.4), $p < 0.001$, and those reporting NTSU three or more times, from 5.1% (95% CI 3.9-6.6) to 6.9% (95% CI 5.6-8.4), $p = 0.017$. Among boys reporting medical tranquilizers and sedatives use (MTSU), NTSU rose from 21.1% (95% CI 13.9 to 30.0) in 2003 to 41.4% (95% CI 32.3 to 50.9) in 2019, $p = 0.006$. However, there was no statistically significant change in NTSU among girls reporting MTSU, remaining at 44.1% (95% CI 36.0 to 52.4) in 2019, $p = 0.951$.

Conclusions: Study reveals a significant increase in lifetime NTSU from 2003 to 2019, with girls consistently showing higher prevalence. Targeted interventions are needed to address adolescent non-medical prescription drug use, particularly among girls. Moreover, substantial NTSU among those reporting MTSU highlights the need to monitor and address non-medical usage in this subgroup.

Key messages:

- Estonian adolescent non-medical tranquilizers and sedatives use surged from 2003 to 2019, particularly among girls, highlighting the need for targeted interventions.
- The high prevalence of non-medical tranquilizer and sedative use among those reporting medical tranquilizer and sedative use underscores the necessity for vigilant monitoring.

Abstract citation ID: ckae144.2105
The impact of garbage codes on the quality of death coding in Belgrade in 2010, 2015, and 2020

Jovana Todorovic

M Šantrić Milićević[1,2], N Rosić[3], Ž Stamenković[1,2], J Todorović[1,2], B Branković[3], A Stevanović[1,2], G Tamburkovski[3], S Miltenović[3], S Janković-Mladenović[3], A Wengler[4]

[1]School of Public Health and Health Management, Faculty of Medicine University of Belgrade, Institute of Social Medicine, Belgrade, Serbia

[2]Laboratory for Strengthening the Capacity and Performance of Health System and Workforce for Health Equity, Belgrade, Serbia

[3]City Institute of Public Health, Belgrade, Serbia

[4]Robert Koch Institute, Berlin, Germany

Contact: jovana.todorovic@med.bg.ac.rs

Background: Accurate data on the causes of death (CoDs) is the foundation for analyzing the health situation and developing health policy in various countries. The percentage of garbage codes (GCs) indicates the quality of the CoDs data. Within the Western Balkan Strategic Partnership Project (Work Package 4: Use of Population Health Metrics for Improved Surveillance), we evaluated the impact of the four levels of GCs on the quality of mortality data of Belgrade.

Methods: In a retrospective study, we examined the underlying CoDs of Belgrade residents by age and sex and the change in GCs' share in the CoDs in 2010, 2015, and 2020. We used anonymous individual mortality data and population age and sex annual data from the electronic databases of the City Institute of Public Health of Belgrade, as well as the list of GS levels 1-4 from the 2019 Global Burden of Disease Study.

Results: Over the observed years, the percentage of all GCs in underlying CoDs was approximately 20%. The GCs with profound policy implications level 1 accounted for 52% of all GCs in 2020, higher than those recorded in previous years - 46.3% in 2010 and 45.1% in 2015. The total number of GCs per 100,000 inhabitants in Belgrade was the highest in 2020, with a rate of 325.2/100,000 (males: 374.4, females: 301.3). This rate has increased by about one-third since 2010 (both sexes: 245.4, males: 269.2, females: 221.1) and by about two-fifths since 2015 (both sexes: 235.8, males: 262.7, females: 211.8).

Conclusions: This research has revealed a significant decline in the quality of data related to the causes of death in Belgrade. One-fifth of the recorded causes of death are inaccurate or unreliable. The study highlights the importance of maintaining strict protocols for data collection, analysis, and management to ensure the accuracy and reliability of CoDs data in developing effective public health policies.

Key messages:

- The rate of total garbage codes per 100,000 inhabitants of Belgrade has increased by about two-fifths since 2015.
- Failure in quality, accuracy, and reliability of causes of death can lead to suboptimal health policymaking.

Abstract citation ID: ckae144.2106
The burden of executive dysfunction after ischemic stroke (Bulgaria, 2019-2021)

Ivanka Veleva

I Veleva[1], M Valkova[2], P Chumpalova-Tumbeva[1]

[1]Department of Psychiatry and Medical Psychology, Medical University of Pleven, Pleven, Bulgaria

[2]Neurology Clinic, University Hospital 'Sofiamed', Sofia, Bulgaria

Contact: ivanka.sirashky@gmail.com

Background: Executive dysfunctions have great impact on behavior and quality of life in elderly. They also play important role for post-stroke functional outcome. The aim of our study was to examine the frequency, severity and types of executive dysfunctions at the third month after the ischemic stroke.

Methods: We examined 108 patients 3 months after ischemic stroke (66.67±9.03 years old, 66 males and 42 females) via 128-Wisconsin Card Sorting Test (WCST). WCST is a standardized instrument for detecting various executive dysfunctions. It is applicable for patients after stroke, because the test doesn't require preserved arm motor functions. It measures global executive functioning (GEF), inhibitory control system (ICS), executive attention (EA), cognitive flexibility (CF) and working memory (WM). Our patients' results were compared to the normal population test results. SPSS 24 was used for statistical analysis.

Results: Impaired GEF were found in 46% of our patients, most of them had mild or moderate impairment. One fourth of them showed impaired ICS, although the impairment in most of the cases was mild. EA deficits were found in 43% of our cases (17% had mild, 15% mild to moderate, 7% moderate and 4% severe impairment). WM dysfunction was found in 1/3 of them (the average result was about 27 percentiles; 29% had mild and 5% had mild to moderate deficits) and about ¼ of our patients had borderline results. CF was impaired in 68% of our patients (11% had mild, 28% mild to moderate, 16% moderate and 13% severe impairment).

Conclusions: GEF impairment is frequent after stroke. Patients had problems in ICS, EA, CF and WM. However, in most of the cases the dysfunction is mild or moderate and can be found only if it is actively searched and accessed. The most impaired functions were CF and EA. Patients with executive dysfunction require cognitive rehabilitation and specific social support.

Key messages:

- Executive dysfunctions are frequent after ischemic stroke. The impairment is mild or moderate, but however it impacts the quality of life, behavior, prognosis and outcome of post-stroke survivors.
- Patients with executive dysfunctions require specific cognitive rehabilitation and social support.

Abstract citation ID: ckae144.2107
Assessing the severity of COVID-19 waves: beware of surveillance bias

Stefano Tancredi

S Tancredi[1], *S Cullati*[1,2], *A Chiolero*[1,3,4]
[1]Population Health Laboratory, University of Fribourg, Fribourg, Switzerland
[2]Quality of Care Service, University Hospitals of Geneva, Geneva, Switzerland
[3]School of Population and Global Health, McGill University, Montreal, Canada
[4]Institute of Primary Health Care, University of Bern, Bern, Switzerland
Contact: stefanotancredi@gmail.com

Background: Indicators to assess the severity of epidemic waves during the COVID-19 pandemic were influenced by differences in detection modalities over time, leading to surveillance bias. We compared four indicators across three pandemic periods to assess surveillance bias.

Methods: We used data from one region of Switzerland. We compared seroprevalence, cases, hospitalizations, and deaths during three periods (period 1: Feb-Oct 2020, including the 1st wave; period 2: Oct 2020-Feb 2021, including the 2nd wave; period 3: Feb-Aug 2021, including the 3rd wave and after the start of the vaccination campaign). Data were retrieved from the Swiss Federal Office of Public Health or population-based studies. We compared each indicator to a reference indicator (seroprevalence during periods 1 and 2 and hospitalizations during period 3). We also assessed the timeliness of the indicators, i.e., the duration from data generation to the availability of the information to decision-makers.

Results: According to seroprevalence estimates, the severity of the 2nd wave was slightly larger (by a ratio of 1.4) than the severity of the 1st wave. Compared to seroprevalence, cases largely overestimated the 2nd wave severity (2nd vs 1st wave ratio: 6.5) while hospitalizations (ratio: 2.2) and deaths (ratio: 2.9) were more suitable to compare the severity of these waves. According to hospitalizations, the 3rd wave severity was slightly smaller (by ratio of 0.7) than the 2nd wave. Compared to hospitalizations, cases or deaths slightly underestimated the 3rd wave severity (3rd vs 2nd wave ratio for cases: 0.5; for deaths: 0.4) and seroprevalence was very biased due to high vaccination rates. Across all waves, timeliness for cases and hospitalizations was better than for deaths or seroprevalence.

Conclusions: To assess the severity of pandemic waves accounting for surveillance bias, different types of indicators must be used across time.

Key messages:

- Differences in detection modalities over time can skew the assessment of the severity of COVID-19 pandemic waves, leading to surveillance bias.
- The effectiveness of indicators in describing the severity of COVID-19 pandemic waves depends on the type of indicator used and the stage of the pandemic.

Abstract citation ID: ckae144.2108
Quality indicators of long-term care for older people in OECD countries; a rapid scoping review

Ana Magdalena Ordonez Cruickshank

A Ordonez Cruickshank[1,7], *A Zanuzdana*[2], *V Marujo*[3], *K Heldt*[4], *J Fuchs*[1], *B Gaertner*[1,5], *M Hasseler*[6], *T Eckmanns*[2], *C Scheidt-Nave*[1]
[1]Epidemiology and Health Monitoring, Robert Koch-Institut, Berlin, Germany
[2]Infectious Disease Epidemiology, Robert Koch-Institut, Berlin, Germany
[3]Infectious Diseases, Robert Koch-Institut, Berlin, Germany
[4]MFI, Robert Koch-Institut, Wernigerode, Germany
[5]German Centre for Cardiovascular Research, Berlin, Germany
[6]Faculty of Health Care, Ostfalia University of Applied Sciences, Berlin, Germany
[7]Charité – Universitätsmedizin Berlin, Berlin, Germany
Contact: Ordonez-CruickshankA@rki.de

Background: The COVID-19 pandemic has exposed the vulnerability of older people living in long-term care facilities (LTCF), highlighting the urgent need for research on the quality of care for this group of the population. There is no universal definition for quality of care in LTCF, and yet, multiple tools and indicators have been developed to measure it. In this rapid scoping review, we aim to provide a comprehensive overview of the current knowledge on quality of care concepts and indicators for older people in LTCF in OECD countries.

Methods: This review follows the World Health Organization (WHO) guide for rapid reviews and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA-ScR) extension for scoping reviews, including protocol registration (https://doi.org/10.17605/OSF.IO/34B2S). The electronic bibliographic databases MEDLINE (PubMed), EMBASE, and CINAHL were searched in September 2023 for studies published between 2013 and 2023 for quality indicators in LTCF. Experts in quality of care in LTCF were contacted and consulted to retrieve sources of grey literature. Information on the definition or framework of quality of care, quality of care dimensions, measurement instruments, context and purpose of the measurement will be extracted.

Results: Of the 8,516 identified records, 6,449 were screened by title and abstract after removing duplicates. A total of 469 publications will be screened in full-text. Experts recommended 40 websites to be screened for quality indicators. The PRISMA flowchart diagram will be provided to describe the selection process.

Conclusions: This review aims to improve the quality of care for older people living in LTCF. Our results will identify which concepts and dimensions of care are currently being measured in OECD countries, whether they are backed by any definition and scientific framework of quality of care for older residents of LTCF, and whether there is consideration of closing gaps in quality measurement.

Key messages:

- Quality of care is an understudied field in the context of long-term care facilities for older people.
- In order to further improve quality in long-term care for older people, it is necessary to systematically review the current state of knowledge on quality concepts and indicators.

Abstract citation ID: ckae144.2109
Characteristics of web-based and paper-based respondents in The Danish Capital Region Health Survey

Marie Stjerne Grønkjær

MS Grønkjær[1], *MH Eliasen*[1], *P Elsborg*[1], *AH Andreasen*[1]
[1]Center for Clinical Research and Prevention, University Hospital - Bispebjerg and Frederiksberg, Frederiksberg, Denmark
Contact: marie.stjerne.groenkjaer@regionh.dk

Background and aim: This study aims to investigate the potential impact of adopting web-only surveys on the representativeness of survey participants by examining the sociodemographic characteristics of participants in the Danish Capital Region Health Survey (DCRHS) who respond online versus those who respond using a paper-based questionnaire.

Methods: The study utilizes data from the DCRHS including participants invited by a mixed-mode approach and given the choice to respond to a web-based or paper-based questionnaire in 2021 ($N = 53{,}874$) and 2017 ($N = 51{,}902$). Information on age and sex was obtained from national registers.

Results: The proportion of paper respondents decreased significantly from 18% in 2017 to 16% in 2021. In both years, women had higher odds of responding on paper compared with men ($OR = 1.20$; 95% CI: 1.16-1.24). In 2017, the highest prevalence of paper respondents was observed among participants aged ≥80 (29%) and 16-24 years (21%). In 2021, the highest prevalence was likewise observed among participants aged ≥80 (28%) but with the second highest among the 65-79 years age group (17%). The decrease in paper responses from 2017 to 2021 varied across age groups, with a greater decrease among younger participants than among older participants.

Conclusions: This study highlights the potential risk of excluding a significant proportion of elderly citizens from large population surveys if the web-based response option is the only option provided. Elderly individuals are less likely than younger individuals to switch to digital responses, emphasizing the importance of considering alternative modes of data collection to ensure representativeness in survey samples.

Key messages:
- The use of web-only surveys has increased; however, we risk excluding a significant proportion of elderly citizens from large population surveys if only the web-based response option is provided.
- Elderly individuals are less likely to switch to digital responses, emphasizing the importance of considering alternative modes of data collection to ensure representativeness in survey samples.

Abstract citation ID: ckae144.2110
Optimizing Colorectal Screening in Portugal with Process Mining

Hugo Monteiro

H Monteiro[1], M Oliveira[2], J Reis[1], F Tavares[1]
[1]National Screening Program Coordination, Executive NHS Board, Porto, Portugal
[2]Center for Health Technology and Services Research, Faculty of Medicine, Porto, Portugal
Contact: hugo.filipe.b.monteiro@gmail.com

Background: Efficient healthcare screening programs management influences patient outcomes. Process mining has emerged as a powerful tool to enhance these programs by refining complex workflows and pinpointing operational deviations.

Objectives: This study utilizes process mining techniques to analyze the colorectal cancer screening program in Northern Portugal, focusing on detecting deviations and performance bottlenecks in process models.

Methods: This screening program started in March 2018, but process mining was only used on data posterior to 2020. Over 1 million case observations from administrative data were included in the process model analysis, involving more than six key process activities and numerous resources. We used new software and statistical tools for process mining to rapidly compute observations and filter for different operational needs and monitor interventions.

Results: The discovery analysis identified deviations, such as unexpected performance issues and irregular activity sequences. Although over 100 traces were identified, fewer than five traces accounted for more than 90% of all case paths, indicating the most common traces that have a true impact in participation rates, referral rates, and treatment rates. Notable differences in resource performance during specific periods, such as COVID-19 or seasonal events, were also observed. These findings provided insights for adjusting resource allocation and improving coordination, with impact in minimizing seasonal phenomena or peak production periods.

Lessons: Process mining offers actionable insights for effective health program coordination, enabling the monitoring and timely response to process deviations. With key areas for action identified in a more timely and precise manner, we can enhance efficiency, and expand population coverage and treatment referral. Future initiatives will focus on further process optimization and national coverage expansion using these management tools.

Key messages:
- Process mining revolutionizes healthcare by enabling the strategic management of complex oncological screening program workflows.
- Comprehensive data analysis across the patient pathway enhances program efficiency and expands treatment access.

Associations of adolescent academic performance, sports, disordered eating, and menstrual dysfunction

Sara Moro

S Moro[1], E Holopainen[2], S Kosola[1,3]
[1]Pediatric Research Center, Helsinki University Hospital and University, Helsinki, Finland
[2]Department of Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland
[3]Research, Development and Innovations, Western Uusimaa Wellbeing Services County, Espoo, Finland
Contact: sara.moro@helsinki.fi

Background: Regular menstruation is a crucial indicator of comprehensive well-being in adolescents. We aimed to assess risk factors associated with menstrual cycle dysfunction in a population-based cohort of high school students, focusing on academic performance, sports participation, and disordered eating.

Methods: In 2022, we recruited 1161 female first-year students from 21 diverse high schools in the capital region of Finland. They completed an online survey comprising questions about menstrual cycle, academic achievement, sports involvement, disordered eating and school burnout.

Results: Of 935 (81%) participants (mean age 16) not using hormonal preparations, 336 (37%) reported irregular menstruation. Adolescents with irregular menstruation showed higher middle school grade point average (GPA) (OR 1.4, 95% CI 1.1-1.8), lower body mass index (OR 2.2, 95% CI 1.3-3.5), and more disordered eating symptoms (OR 2.1, 95% CI 1.4-3.0) than adolescents with regular menstruation. While overall physical activity showed no significant correlation with irregular menstruation, casual exercisers with irregular menstruation exhibited both higher GPAs (OR 1.4, 95% CI 1.4-1.9) and more disordered eating symptoms (OR 2.6, 95% CI 1.6-4.1) than competitive athletes, whereas competitive athletes with irregular menstruation showed higher school burnout scores than casual exercisers but no disordered eating.

Conclusions: We recommend the use of screening tools to recognize disordered eating and school burnout among female high school students facing menstrual irregularities.

Key messages:
- A third of adolescent females had irregular menstruation. Casual exercisers with irregular menstrual cycle were at risk of eating disorders and competitive athletes at risk of school burnout.
- Screening of disordered eating and school burnout among adolescent females facing menstrual irregularities could be beneficial.

Abstract citation ID: ckae144.2112
Prevalence of adults with fatigue in Germany: results of the 'German Health Update 2023' study

Ana Magdalena Ordonez Cruickshank

A Ordonez Cruickshank[1], C Poethko-Müller[1], A Schaffrath Rosario[1], G Sarganas[1], C Scheidt-Nave[1], R Schlack[1]
[1]Epidemiology and Health Monitoring, Robert Koch-Institut, Berlin, Germany
Contact: Ordonez-CruickshankA@rki.de

Background: Fatigue is a non-specific symptom complex associated with exhaustion, lack of motivation and concentration. It has high public health relevance due to impairments in quality of life and work ability and increased risk of accidents. Fatigue has increasingly gained attention as one of the most common post-acute consequences of SARS-CoV-2 infection. Fatigue is also common among non-infected people and there is a lack of population-based background data. Therefore, we investigated the prevalence and factors associated with fatigue in a population-based epidemiological study in Germany.

Methods: The analyses are part of the national population-based cross-sectional telephone survey 'German Health Update' (GEDA 2023) in adults (3/2023-2/2024). Fatigue was surveyed using the Fatigue Assessment Scale (FAS) and dichotomized into yes (at least mild/moderate) versus no fatigue. The FAS is an instrument for mild-to-moderate fatigue, which must be distinguished from chronic fatigue syndrome (CFS). Weighted analyses of the data from 9,766 adults were carried out descriptively and in multivariable Poisson models, considering sociodemographic and health-related determinants.

Results: The prevalence of fatigue in Germany was estimated to be 29.7% (95% CI 28.1-31.2) and was highest in 18- to 29-year-olds at 39.6% (35.0-44.4). The prevalence decreased up to 65- to 79- year-olds (20.6% (18.2-23.3)) and was again higher in people aged 80 and over (33.2% (28.9-37.7)). Women had a higher risk of fatigue than men (aRR 1.19 (1.08-1.32)). Lower education (aRR 1.29 (1.13-1.49)) and medium education (aRR 1.13 (1.01-1.27)) were associated with increased risk of fatigue. There were significant associations between fatigue and chronic illness, depressive symptoms and long COVID.

Conclusions: Fatigue is a common symptom among adults in Germany. Female gender, young and very old adulthood as well as lower education are associated with higher risk of fatigue.

Key messages:

- The correlations between fatigue and socio-demographic variables as well as parameters of physical and mental health provide important indications of groups particularly affected by fatigue.
- The fatigue survey in GEDA 2023 is one of the few current European studies that describe the frequency of fatigue in the general population and analyzes health and sociodemographic determinants.

The burden of sepsis in Italy: an analysis of treatable mortality trends

Andrea Sanna

G Guarducci[1], *D Golinelli*[2], *A Sanna*[1], *G Fabbri*[3], *N Nante*[4]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Evaluative Research and Health Services Policy, Romagna Local Health Authority, Ravenna, Italy
[3]Healthcare Management, University Hospital Trust of Ferrara, Ferrara, Italy
[4]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: doc.andrea.sanna@gmail.com

Background: The burden of sepsis, a life-threatening condition triggered by the body's extreme response to infection, remains a critical global healthcare concern. Sepsis-related deaths often result from delayed recognition, insufficient treatment, or gaps in healthcare delivery. The study aims to analyze treatable mortality for sepsis in Italy and its regions.

Methods: A retrospective study was conducted on data of treatable mortality for sepsis in Italy and its regions. According to joint OECD/Eurostat list, we included sepsis deaths with the ICD-10 codes A40 (excl. A40.3 [sepsis due to Streptococcus pneumoniae]) and A41 (excl. A41.3 [sepsis due to Hemophilus influenzae]) from 2006 to 2019. Through data on the resident population two-year age-standardized rates by region were calculated.

Results: From 2006/7 to 2018/9 an overall increase was observed in Italy, from 1.6 to 2.2 age-standardized mortality rates with a maximum peak in 2014/5 (+46.7%). This trend was confirmed for Lombardy (+47.8%), Veneto (+48.8%), Emilia-Romagna (+49.3%), Tuscany (52.0%), Marche (+58.4%%), Abruzzo (39.4%), Molise (26.7%), Apulia (+57.0%), Sicily (+57.2%), and Sardinia (+46.8%). Aosta Valley (+72,5%) had a maximum peak in 2010/1, while Piedmont (+42.5%), Autonomous Province (A.P.) of Bolzano (+27.8%), A.P. of Trento (+45.0%), Friuli-Venezia Giulia (+23.3%) in 2012/3, Calabria (+46.4%) in 2016/7 and lastly Campania (+52.9%) and Basilicata (+73.0%) in 2018/9. Liguria (+49.8%), Latium (47.2%) and Umbria (49.3%) showed two maximum values, one in the 2012/3 and the other in the 2014/5.

Conclusions: We observed an overall increase in age-standardized mortality rates throughout Italy, with a peak in 2014/5. This trend was resumed in ten regions, while three regions showed multiple peaks, indicating fluctuations in mortality rates. These findings underline the importance of targeted health interventions and policy initiatives to address region-specific health challenges.

Key messages:

- Regional disparities in mortality rates highlight the necessity for customized health interventions and policy measures between Italian regions.
- Recognizing fluctuating mortality trends in specific regions is crucial to effectively address various health challenges.

Diabetes mellitus EU comorbidity index: using data from EHIS 2019 and GBD disability weights

Nour Mahrouseh

N Mahrouseh[1], *N Kovács*[1], *O Varga*[1]
[1]Department of Public Health and Epidemiology, University of Debrecen, Debrecen, Hungary
Contact: nour.mahrouseh@med.unideb.hu

Background: Individuals with diabetes mellitus (DM) exhibit several of comorbidity burdens, with lower perceived quality of life also being a factor. Literature on the impact of DM is available, including studies on the index devised by (A. Andreella et al., 2023) for the assessment of comorbidities of health conditions. This study aims to adapt and validate this index for use as a standardized DM comorbidity index within the EU.

Methods: A cross-sectional study was carried out using microdata from the European Health Interview Survey (EHIS) 2019. The study included adults aged 25 years or older who reported having DM ($n = 20,042$) from 27 EU member states. Comorbidity index was calculated to assess the comorbidity of having 9 non-communicable diseases using disability weights obtained from the Global Burden of Disease 2019 and self-perceived general health using multiplicative approach. Beta regression analysis was used to evaluate the association between comorbidity index and several demographic, socio-economic and lifestyle variables. Comorbidity index was calculated for each nomenclature of territorial units for statistics (NUTS 2).

Results: The comorbidity index ranged from 0.049 to 0.993. The results indicated that having a higher education and residing in urban areas were less likely to have a high comorbidity index. Being unemployed or in other employment statuses demonstrated a significant, positive association with the index. Income exhibited a gradual, positive association with each quintile, while consuming fruits and vegetables less than once a week was found to be associated with an increased index. The highest comorbidity index was observed in Calabria (Italy), followed by Lubuskie (Poland), and the lowest was observed in Antwerp (Belgium), followed by Övre Norrland (Sweden).

Conclusions: By identifying comorbidity burden, targeted interventions and regional-specific strategies can be implemented to improve the quality of life for individuals with DM.

Key messages:

- Quantifying the burden of comorbidities allows understanding of health status of DM patients.
- Comorbidity index shows geographic variation in the EU which contributes to tailored policy interventions.

Abstract citation ID: ckae144.2115
Fast lane for decision making: The PHIRI Rapid Exchange Forum

Claudia Habl

C Habl[1], *J Weiss*[1]
[1]IPED, Austrian National Public Health Institut, Vienna, Austria
Contact: claudia.habl@goeg.at

Issue & Problem: The COVID-19 pandemic demanded swift, yet structured exchange of knowledge, data and good practices between experts and institutions supporting national governments in decision making for crisis response. Thus, in March 2020 population health experts from several European countries started to meet online, complementing the more formal EU Health Security Committee meetings. The European Commission understood the high need of Member States for evidence-based, and structured cross-country exchange and supported it as part of the Population Health Research Infrastructure (www.PHIRI.eu) project. Since then, the PHIRI Rapid Exchange Forum (REF) is a knowledge-sharing platform that brings together public health researchers, practitioners, policymakers, and other stakeholders to share information, experiences, and best practices in public health implementation research even if the EU co-funded PHIRI project has ended. The forum aims to promote collaboration and networking, facilitate the dissemination of research findings, and accelerate the translation of evidence into policy and practice.

Lessons: Through the PHIRI REF, participants can engage in interactive discussions, workshops, and presentations on various public health topics, including infectious diseases, digitalisation, health emergency simulations, health systems strengthening, and community health interventions. The platform is designed to be user-friendly and accessible to all, with a particular focus on European countries. By May 2024, the REF-Secretariat at the Austrian National Public Health Institute GÖG had organised 60 REF meetings, with in average 20 attendees from 12-15 countries. The monthly 1-hour online meetings cover in a moderated, structured format pre-agreed topics that are proposed by the participating countries. All findings and topics are documented and publicly available at the EU Health Information Portal (https://www.healthinformationportal.eu/rapid-exchange-forum).

Key messages:

- The success of the Rapid Exchange Forum highlights the importance of collaboration and information exchange between population health experts in addressing global health challenges.
- Having a pre-established information exchange network on urgent public health issues is of utmost importance as it enables rapid and trustworthy communication among relevant stakeholders.

Abstract citation ID: ckae144.2116
Development of health care expenditures in Finland up to 2040

Jaakko Reinikainen

J Reinikainen[1], *M Pihlava*[1], *T Härkänen*[1], *J Honkatukia*[1]
[1]Department of Public Health and Welfare, THL, Helsinki, Finland
Contact: jaakko.reinikainen@thl.fi

Background: Increasing health care expenditures are threatening public health by complicating the supply of adequate health services. Exploration of possible future developments of the expenditures is needed to understand how to prepare for future or to change an unwanted course of development. We provided projections by health care sectors taking into account demographic and other developments.

Methods: We used national data on the realized expenditures per capita by age group, sex and health care sectors from 2017 to 2020, and official forecasts of the population in Finland up to 2040. Future per capita expenditures were projected with Bayesian linear regression models incorporating a priori dependency structure for the slope parameters of the age groups such that the time trends of adjacent groups would be more similar than other groups. These projections were then combined with the population forecasts to estimate the total expenditures.

Results: The greatest increase (164%) was estimated for the total costs of the primary outpatient healthcare: from 2153 to 5677 million euros in 2020-2040, such that 7% of the growth was attributed to demographic developments. The estimated growths were 68% for the primary inpatient healthcare, 14% for the specialised somatic healthcare, and 52% for the urgent and emergency health services, of which 91%, 98% and 21% were attributed to demographic developments, respectively.

Conclusions: Notable increases in expenditures are expected in all considered health care sectors, but there are great differences in the proportions of the growth attributed to demographic developments. Due to the limited role of demographic changes, it is worth focusing on controlling the impacts of other developments by, e.g., improving the population health and the efficiency of the health care system.

Key messages:

- Notable increases are expected in health care expenditures up to 2040.
- Impacts of demographic changes varies markedly between health care sectors.

Abstract citation ID: ckae144.2117
Inclusion of Long Covid patients in the care trajectory post-Covid-19: evidence from Belgium

Sarah Moreels

S Moreels[1], *R De Schreye*[1], *S Bensemmane*[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
Contact: sarah.moreels@sciensano.be

Background: Evidence suggests that 10-30% of COVID-19 infected people develop persistent symptoms that can be diagnosed as Long Covid. Most Long Covid cases are in patients with a mild acute COVID-19 infection and are mainly treated in primary health care. In July 2022, a care trajectory (CT) post-Covid-19 was launched in Belgium, in which Long Covid patients can benefit from reimbursement of treatment costs when consulting health professionals in primary health care for their rehabilitation. Patients are included in this CT mainly through their general practitioner (GP) and depending on patients' care needs, treatment is organized in a monodisciplinary or multidisciplinary way.

Methods: A population-based study on data collected by the Belgian network of Sentinel General Practitioners (SGP) on all Long Covid patients consulting their GP during March-December 2023. Information on inclusion in the CT post-Covid-19 was also registered. Descriptive statistics were performed.

Results: End of 2023 in Belgium, GPs initiated the CT post-Covid-19 for more than 1000 patients, this mainly for monodisciplinary treatment, less than 10% of included patients received multidisciplinary follow-up. By the SGP, among the registered Long Covid sufferers ($N = 14$), a total of six cases were included in the CT post-Covid-19. Of these cases, the majority were female, of older age, higher educated and had one or two chronic conditions. Most had a mild or moderate prior COVID-19 infection and all were vaccinated multiple times against COVID-19. Symptoms lasted one year or more for 83.3% of included patients. Treatment focused mainly on self-management, energy management and physical exercise programs, mainly in collaboration with physiotherapists.

Conclusions: This study yields recent data on patients included in the CT post-COVID-19 in primary care in Belgium. It is important to focus on guidance, follow-up and rehabilitation of Long Covid sufferers by healthcare professionals in Belgium.

Key messages:

- Long Covid patients included in the care trajectory post-Covid-19 in Belgium experience years of debilitating symptoms after their prior COVID-19 infection.
- The establishment of the care trajectory post-Covid-19 for Long Covid patients in primary care since July 2022 stimulated collaboration between care givers in Belgian primary health care.

Abstract citation ID: ckae144.2118

The Norwegian Counties Public Health Survey (NCPHS)

Leif Edvard Aarø

LE Aarø[1], TS Nilsen[2,3], M Knapstad[1], JC Skogen[1,4,5], RB Nes[2,3], Ø Vedaa[1,6], KI Klepp[4]
[1]Department of Health Promotion, Norwegian Institute of Public Health, Bergen, Norway

[3]Promenta Research Center, University of Oslo, Oslo, Norway
[4]Centre for Evaluation of Public Health Measures, Norwegian Institute of Public Health, Oslo, Norway
[5]Centre for Alcohol and Drug Research, Stavanger University Hospital, Stavanger, Norway
[6]Department of Psychosocial Science, University of Bergen, Bergen, Norway
Contact: leea@fhi.no

Effective public health initiatives should be based upon a thorough understanding of important health-related factors. The purpose of The Norwegian Counties Public Health Survey (NCPHS) is to gain insights from the adult population on topics relevant for planning of public health policy, interventions, and action at the county and municipality levels. The survey includes a core questionnaire on public health-related topics such as health behaviour, subjective quality of life, distress, subjective health, social support, social capital, community contexts, and demographics, including indicators of socio-economy, with additional optional questions and scales varying across data collections. Samples are drawn from the Norwegian National Population Register. NCPHS was piloted in three counties in 2015 and in one county in 2018. After some revision of instruments and sampling procedures, surveys have been carried out in most Norwegian counties since 2019. The total number of participants has now passed 400 000. Expedient data analysis and reporting has enabled the Norwegian Institute of Public Health to present comprehensive reports within six weeks after completed data collections. In these, outcome variables are analysed against district (within counties), gender, age, educational attainment, and assessment of household economy. Tables are also made available at the municipality level. The NCPHS represent a valuable addition to existing health registries and regional health surveys, providing critical information for planning purposes for local and regional public health authorities, for assessing trends over time, comparisons across counties and regions, and for evaluation of policies and interventions. The value of such a system during times of crises was demonstrated during the COVID-19 pandemic. At the Lisbon 2024 European Public Health conference, a few selected examples of use of data from the NCPHS system will be presented.

Key messages:

- Large-scale community surveys provide important insights for planning of public health policies and action.
- Strong involvement and collaboration with regional and local public health personnell as well as with media and local people is a prerequisite for succeeding.

Abstract citation ID: ckae144.2119

Monitoring the level of health and inequality over time using the Population Health Performance Index

Anina Grün

A Grün[1], K Bozorgmehr[1], A Nowak[1]
[1]Bielefeld School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: anina.gruen@outlook.de

Background: The Population Health Performance Index (PHPI) is a composite measure that combines average health outcomes and their distribution within a population, thereby allowing for a comprehensive assessment of population health and inequality. The aim of this study is to examine the extent to which the PHPI adds value to monitoring of health and inequality over time in comparison to absolute and relative inequality.

Methods: Data from the WHO Equity Monitor database on under-5 mortality disaggregated by wealth quintiles for Nepal, Ethiopia, Peru, Rwanda, and Zimbabwe were analysed using different years between 1994 and 2020. Descriptive comparative statistics were employed to assess trends in the PHPI and conventional pairwise measures of absolute and relative inequalities, with consideration of different weights for inequality aversion.

Results: PHPI trends correspond to the trend of absolute inequality in all five countries, although they exhibit less volatility over time. Relative inequality follows the trend of the PHPI in only two of the five countries (Ethiopia and Zimbabwe), reflecting the methodology utilised for the PHPI. PHPI scores vary based on different inequality aversion weights, highlighting the sensitivity of the index to methodological adjustments.

Conclusions: The PHPI demonstrates notable convergence of trends with conventional methods, thereby substantiating its utility as a comprehensive tool for the simultaneous measurement of health and inequality. As it is able to consider both absolute and relative inequality within its own calculations, the PHPI allows for independent analysis of its two key components. The PHPI facilitates a more nuanced understanding of population health and may be more easily understood by policymakers and other stakeholders. As it does not address the underlying causes of changes in health inequalities, further research is necessary to supplement monitoring activities.

Key messages:

- PHPI is a valuable tool for health and inequality monitoring by integrating both average health and disparity in a single index, facilitating communication of trends over time.
- The dual focus complements conventional methods with its multidimensionality and may enable stakeholders to assess health and inequalities in alignment with broader health policy objectives.

Abstract citation ID: ckae144.2120

Functioning in Older Adults: Prevalence and Implications for Policy and Digital Services

Katri Sääksjärvi

K Sääksjärvi[1], M Holm[1], S Koskinen[1], A Aalto[1], M Pennanen[1], K Ilmarinen[1], T Hammar[1], P Sainio[1]
[1]Department of Public Health and Welfare, THL, Helsinki, Finland
Contact: katri.saaksjarvi@thl.fi

Background: Actions maintaining and promoting functioning, and proactively preparing for the surge in demand for services in near future, are needed as the population is aging. Policy actions need to base on up-to-date picture of the situation. We examined the prevalence of limitations in different dimensions of functioning in the older population.

Methods: Data consisted of participants aged 75 years or older (n = 9,686) in the nationally representative Healthy Finland Survey in 2022. The questionnaire included questions on various aspects of functioning (physical, cognitive, psychosocial, need and use of help), quality of life, internet use and digital competence. Weighted prevalence of functional limitations by age (75-79, 80-84, 85-89, ≥90 years) was analyzed for men and women using logistic regression, sampling design and non-response acknowledged.

Results: Difficulties in most aspects of functioning increased rapidly with age. In ≥ 90-year-olds, one third experienced major difficulties in activities of daily living (vs. 4% in 75-79-year-olds), and 30% of men and 45% women aged 90 or over experienced major difficulties in getting out of their home (vs. 4% in 75-79-year-olds). The prevalence of loneliness doubled by age, from 9% in the youngest to 21% in oldest age group. The corresponding increase in psychological distress was from 9% to 15%. Need for help increased dramatically with age, but the unmet need among those needing help did not, being around 20% in all age groups. In ≥ 90-year-olds, 83% of men 92% of women reported little or no internet skills (vs. 40% in 75-79-year-olds), and 55% of men and 75% women did not use digital services at all, i.e. neither independently nor with help from others (vs. 25-28% in 75-79-year-olds).

Conclusions: Difficulties in functioning and need of help were common among the oldest age groups which underlines the urgency to ensure sufficient resources for elderly care.

Key messages:

- While developing health and social care services, equal access to services must be ensured even for those not able to use digital services.
- Functioning must be supported not only by measures aimed at the individual, but also by improving the environment so that people with a lower level of functioning can cope with their everyday lives.

Abstract citation ID: ckae144.2121
Prevalence and accumulation of metabolic risk factors of cardiovascular disease in Finland

Annika Santalahti

L Lehtoranta[1], A Santalahti[1], J Ikonen[1], S Parikka[1], T Jääskeläinen[1], K Sääksjärvi[1], J Lahti[1], S Männistö[1], P Jousilahti[1], A Lundqvist[1]
[1]Population Health Unit, THL, Helsinki, Finland
Contact: annika.santalahti@thl.fi

Background: Cardiovascular disease (CVD) remains the leading cause of death and disability in the world. We aimed to examine the prevalence of metabolic risk factors of CVD and their accumulation in the Finnish working-age population.

Materials and methods: The data consisted of individuals aged 20 to 69 who participated in the population-based Healthy Finland health examination survey in 2023 (n = 4375; participation rate 56%). We studied the accumulation of four risk factors: hypertension, hypercholesterolemia, diabetes and central obesity. The information was collected using health examination measurements and blood samples. Information on medical conditions and medication use was collected using questionnaires and national register data. All analyses utilized weighting coefficients. Adjusted results (age, sex) were calculated via logistic regression.

Results: The most common CVD risk factor was hypercholesterolemia (male= 69%, female= 63%), followed by central obesity (m = 41%, f = 44%), hypertension (m = 44%, f = 34%) and diabetes (m = 11%, f = 6%). At least three risk factors were present in 26% in male and 23% in female participants, while 17% of males and 22% of females had no risk factors. The prevalence and accumulation of metabolic risk factors became more common with age. Of those aged 60-69, more than 10% had all four risk factors and almost half had at least three. Central obesity increased the risk of hypertension (OR 3.11; 95% CI 2.61-3.71), diabetes (OR 3.97; 95% CI 2.86-5.52) and hypercholesterolemia (OR 1.75; 95% CI 1.48-2.07) compared to those without central obesity.

Conclusions: 81% of all participants had at least one metabolic risk factor for CVD and 50% had at least two. High prevalence and accumulation of CVD risk factors remains a major threat to future morbidity, mortality, and increased healthcare costs in the Finnish working-age population. It is particularly important to identify those individuals with several simultaneous risk factors.

Key messages:

- Metabolic risk factors for CVD are common in the Finnish working-age population, with high prevalence especially hypercholesterolemia and central obesity.
- If the increasing prevalence of risk factors is not addressed, morbidity, mortality and health care costs can be expected to increase in the future as the population ages.

Abstract citation ID: ckae144.2122
Exploring non-smokers' attitudes toward e-smoking: results from the Minerva Project Europe

Dario Gregori

D Gregori[1], NM Khan[1], H Ocagli[1], D Azzolina[2], M Martinato[1], G Lorenzoni[1]
[1]Biostatistics, Epidemiology and Public Health, University of Padova, Padua, Italy
[2]Dpartment of Environmental and Preventive Science, University of Ferrara, Ferrara, Italy
Contact: dario.gregori@ubep.unipd.it

Background: In the shifting paradigm of tobacco use, the attitudes of non-smokers toward e-cigarettes are crucial for public health planning, as in the literature it has been suggested that non-smokers who use e-cigarettes could be more prone to switch to tobacco. This multi-center study investigates the interplay between traditional smoking and the potential benefits of transitioning to e-smoking, through a comprehensive examination of smoking behaviors, dietary, and lifestyle practices.

Methods: MINERVA (My changINg lifEstyles, our Research, and eVeryone's heAlth) is an ongoing prospective international cohort study aimed at investigating the association between smoking habits and dietary and lifestyle habits among the study participants. The secondary objective pertains to the assessment of subjects' willingness to try e-cigarettes. We implemented an univariable logistic regression analysis on a dataset comprising 2367 nonsmokers to identify factors influencing their willingness to smoke e-cigarettes.

Results: Employment significantly predicted willingness, with employed non-smokers showing a higher likelihood to consider e-smoking (OR 2.5, p = 0.002). Household dynamics, specifically the presence of children, also affected the decision, indicating a protective effect against adopting e-smoking (OR 1.26, p < 0.001). Lifestyle choices, particularly fitness and dietary habits, played a discernible role. Surprisingly, age inversely correlated with the willingness to try e-smoking, as younger non-smokers were more likely to consider it (OR 0.97 per year increase, p < 0.001), suggesting that this openness could increase their risk of future tobacco use, which carries important public health consequences.

Conclusions: The study's outcomes underscore the impact of socio-economic and lifestyle factors on non-smokers' openness to e-cigarettes. These insights are pivotal for devising culturally competent educational campaigns and regulatory policies.

Key messages:

- In the shifting paradigm of tobacco use, the attitudes of non-smokers toward e-cigarettes are crucial for public health planning.
- By thoroughly analyzing smoking habits, diet, and lifestyle choices, the Minerva Project research aims to shed light on the complex dynamics between health behaviors and smoking.

Abstract citation ID: ckae144.2123
Measuring functioning and disability in Korea: comparing general and dedicated surveys using the ICF

Jiin Kim

J Kim[1,2], M Selb[3], YT Cho[4], WH Kim[5], C Sabariego[1,6]
[1]Faculty of Health Sciences and Medicine, University of Luzern, Luzern, Switzerland
[2]National Rehabilitation Center, Ministry of Health and Welfare, Seoul, South Korea
[3]ICF Research Branch, Nottwil, Switzerland
[4]Population Policy Research Center, Seoul National University Graduate School of Public Health, Seoul, South Korea
[5]Haeundae Sharing and Happiness Hospital, Busan, South Korea
[6]Swiss Paraplegic Research, Nottwil, Switzerland
Contact: jiin.kim@stud.unilu.ch

Background: Functioning is the third health indicator besides mortality and morbidity. Although Korea periodically collects functioning information, the functioning indicator has not been generated yet. This study aimed to evaluate how functioning information is currently collected in Korea's health and disability surveys, especially in terms of comparability and comprehensiveness, using the International Classification of Functioning, Disability and Health (ICF) as a reference framework.

Methods: Data sources included three health and disability surveys in Korea (Population and Housing Census, Korean National Health and Nutrition Examination Survey, Survey on the Living condition of Persons with Disabilities) and two international ICF-based surveys (International Spinal Cord Injury Survey, Model Disability Survey). Functioning information was linked by category to the ICF Generic-30 Set utilizing the ICF linking rules.

Results: Three ICF categories (walking, washing oneself, dressing) were covered by all the data sources. Excluding the Census, which inherently differs from the other data sources, all the surveys addressed six ICF categories-b152 emotional functions; b280 sensation of pain; d240 handling stress and other psychological demands; d450 walking; d510 washing oneself; d540 dressing. Despite of the common ICF categories, important differences in the operationalization of questions and response options were found.

Conclusions: The overlap of content of health and disability surveys in Korea enables interoperability with other data sources. Available functioning data can be used for estimating the functioning indicator and metric, as recommended by WHO, which can serve as a valuable epidemiological indicator for complementing mortality and morbidity indicators and for estimating and monitoring rehabilitation or long-term care needs of the Korean population.

Key messages:

- Korea's health and disability surveys periodically collect functioning information at the national level, and the level of overlap across surveys enables interoperability with other data sources.
- This study can contribute to generate a Korean common health metric based on functioning that can serve as a valuable epidemiological indicator by utilizing the international standard ICF.

Abstract citation ID: ckae144.2124
Lifestyle habits and openness to alternative tobacco products: insights from the Minerva Project

Giulia Lorenzoni

D Gregori[1], NM Khan[1], H Ocagli[1], D Azzolina[2], M Martinato[1], G Lorenzoni[1]
[1]Biostatistics, Epidemiology and Public Health, University of Padova, Padua, Italy
[2]Dpartment of Environmental and Preventive Science, University of Ferrara, Ferrara, Italy
Contact: giulia.lorenzoni89@gmail.com

Background: Recent studies have suggested that the use of alternative tobacco products (ATPs) is a significant predictor of cigarette smoking, particularly among young individuals. The present study evaluates the association between dietary patterns, specifically junk food consumption, and the willingness to try ATPs among non-smokers.

Methods: MINERVA (My changINg lifEstyles, our Research, and eVeryone's heAlth) is an ongoing prospective international cohort study primarily focused on investigating the link between smoking habits and the dietary and lifestyle habits of participants. Subjects are given a web-based survey to report socio-demographic characteristics, dietary and lifestyle habits, smoking habits, and attitudes towards ATPs. This analysis concentrates on respondents from Italy who do not smoke traditional tobacco products.

Results: The survey included 7,535 respondents from Italy; of these, 40% (2,992 subjects) were non-smokers. Among the non-smokers, 219 (7%) were identified as fast-food consumers (defined as consuming fast-food at least once a week). Fast-food consumers were significantly more likely to consume junk food as snacks (87% vs. 62%) and were less likely to report daily consumption of fruits and vegetables. Notably, fast-food consumers were 2.5 times more likely to be willing to try ATPs compared to those who do not consume junk food (Odds Ratio [OR] 2.55, 95% Confidence Interval [CI] 1.68-3.88).

Conclusions: Junk food consumption has been identified as being associated with an increased willingness to use ATPs among non-smokers. This finding is significant from a public health standpoint, highlighting the crucial influence of unhealthy eating habits in fostering an interest in ATP use.

Key messages:

- The Minerva study evaluates the association between dietary patterns, specifically junk food consumption, and the willingness to try alternative tobacco products among non-smokers.
- The study underscores the public health importance of addressing dietary patterns alongside smoking habits.

Abstract citation ID: ckae144.2125
Hand grip strength in older and very old people: Results of the study Gesundheit 65+

Judith Fuchs

J Fuchs[1], B Gaertner[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: fuchsj@rki.de

Background: Functional capacity decreases with increasing age. Hand grip strength (HGS) is considered as an objective general measure of health and a parameter of muscle strength, a component of functional capacity and is part of the evaluation of frailty. HGS is important for many everyday functions, such as holding heavy objects or supporting oneself to prevent a fall. Low HGS is associated with a higher mortality risk. In our study we describe HGS in people aged 66 to 101 years in Germany and identify groups with low HGS.

Methods: Gesundheit 65+ is a longitudinal epidemiologic study of the health status of persons 65 years and older in Germany by the Robert Koch Institute. In 2022/23, one year after baseline, isometric HGS was measured during the examination part of the study using a hand-held dynamometer (Smedley, Scandidact, Denmark, 100 kg). Two values were recorded for each hand. Maximum HGS from all attempts was used for analyses. Weighted prevalence estimates and 95% confidence interval (CI) for grip strength are reported by sex, age-group, height, self-rated health, chronic conditions, and difficulties in activities of daily living (ADL).

Results: HGS was measured in 1,457 persons aged 66 to 101 (48% women). Mean maximum HGS was 28.8 kg (CI 28.4-29.3). HGS was significantly related to sex (men: 35.4 kg, CI 34.8-36.0, women 21.8 kg, CI 21.4-22.2) and age (66-79: 31.0 kg, CI 30.1-31.9, 80+: 23.9 kg, CI 23.0-24.7). In both sexes, shorter persons and persons with bad self-rated health, chronic conditions or difficulties in ADL showed lower HGS than their reference group.

Conclusions: HGS was reduced in very old people, people with support needs, and people with poor health or chronic diseases, identifying these people as important risk groups for preventive measures. These should aim to improve not only endurance but also strength in older and very old people. In the long term, this could also maintain independence and reduce serious injuries from falls.

Key messages:

- We found sex and age-related differences in hand grip strength in older people in Germany.
- Based on the results, planning of prevention and intervention could be enhanced.

Abstract citation ID: ckae144.2126
Significant pre-post effects on a patient-reported outcome measure in inpatient rehabilitation

Manuela Marquardt

M Marquardt[1], M Utsch[1], A Zembic[1], F Basedow[1], G Garuffi[2], S Tobler[2]
[1]Institute for Medical Sociology, Charité - Universitätsmedizin Berlin, Berlin, Germany
[2]ANQ - Swiss National Association for Quality Development in Hospitals and Clinics, Bern, Switzerland
Contact: manuela.marquardt@charite.de

Background: We conducted a pilot study for the Swiss National Association for Quality Development in Hospitals and Clinics (ANQ) in the inpatient rehabilitation setting. The aim was to assess the suitability of a generic health-related quality of life patient-reported outcome measure (PROM) as an outcome quality indicator for public reporting across all rehabilitation domains on a national level.

Methods: In a multi-stage expert-based selection process, the PROMIS Global Health 10 was selected for piloting. We collected data from 29 rehabilitation clinics from April to December 2023. Mean T-scores and effect sizes were analysed across different rehabilitation domains. Patients' need for assistance in completing the questionnaire was also assessed.

Results: A dataset of 2261 cases yielded a cleaned sample of 2083, with 1217 complete cases. Mean T-scores for physical health (PHS) and mental health (MHS) significantly differed ($p < 0.001$) at admission and discharge across all rehabilitation domains. The largest effects were observed in PHS for pulmonary (38.9(7.3); 46.0(7.6); $dz = 0.95$) and cardiologic rehabilitation (41.7(7.4); 47.9(7.2); $dz = 0.85$), and in MHS for internal medicine (44.1(6.9); 49.1(5.6); $dz = 0.80$) and psychosomatic rehabilitation (36.0(7.2); 45.2(8.2); $dz = 1.19$), while the smallest effects were noted in PHS for paraplegia (36.3(7.2); 39.8(7.2); $dz = 0.50$) and in MHS for the musculoskeletal rehabilitation domain (46.2(7.9); 48.7(7.4); $dz = 0.33$). Of all complete cases, 40.5% needed assistance in filling in the PROM and support needs were distributed unequally across rehabilitation domains, ranging from 10.0% in psychosomatic to 70.3% in geriatric rehabilitation.

Conclusions: The study presents a nuanced understanding of HRQOL across various rehabilitation domains, with notable effects observed across all domains, alongside significant assistance needs.

Key messages:

- PROMIS-GH10 shows significant pre-post effects on physical and mental health in Swiss inpatient rehabilitation, with notable effects observed across all domains.
- Observable barriers in implementation are evident due to substantial assistance requirements.

Abstract citation ID: ckae144.2127
Quality of Life among the Sámi Population

Thomas Nilsen

T Nilsen[1], LE Torheim[1], H Gulseth[1], HM Tvedten[1]
[1]Norwegian Institute of Public Health, Oslo, Norway
Contact: thni@fhi.no

Introduction: The Sámi, indigenous to Northern Europe, maintain rich traditions like reindeer herding and unique languages. Continuous efforts are made to preserve their cultural identity and practices. Systemic barriers, including cultural marginalization and environmental challenges, exacerbate these inequalities, impacting their ability to preserve traditional lifestyles. It is not known, until now, how this impacts Quality of Life (QoL).

Aims: Describe QoL in the Sámi population in Norway

Methods: In 2019/20, the three northernmost Counties in Norway took part in the Norwegian Counties Public Health Surveys (NCPHS), which also has a comprehensive QoL module (comprises subjective and objective measures, Cantril scale). NCPHS is an internet-based survey. On average 25 % of the adult population was invited to participate in the NCPHS.

Results: Being Sámi was through self-identification, $n = 3312$. Satisfaction with Life was 7,34 versus 7,41 for the general population. For Loneliness, 15,9 % percent of the Sámi were characterized as lonely (score 6-10) versus 13,3 %, and for positive emotions, there was no difference, with a score of 6,69 for both groups. Sex, age and educational gradients are similar to the general population, for all measures. Minor differences were found according to if one lived in a Sámi-majority municipality or not.

Conclusions: Overall, being Sámi is associated with slightly lower QoL on several measures, but effect sizes are general small to insignificant. Due to lack of data on the Southern Sámi population, findings cannot be generalized to all Sámi.

Key messages:

- Overall, being Sámi is associated with slightly lower QoL on several measures, but effect sizes are general small to insignificant.
- Due to lack of data on the Southern Sámi population, findings cannot be generalized to all Sámi.

Background: The Infant Mortality Rate (IMR) is a fundamental health indicator that reflects the overall well-being of populations. Recognizing the need for more timely data to inform public health strategies, the authors have presented a novel method for monitoring IMR monthly instead of traditional annual reporting. Our work aims to increase further the robustness of a novel method for monitoring IMR monthly.

Methods: This new approach leverages the Portuguese E-Death Certification System (SICO) and Statistics Portugal (2016-2024) data. It provides the most recent insights into IMR trends in Portugal, highlighting the post-pandemic period. This method allows for the analysis of cumulative deaths under one year of age against live births over the previous 12 months, offering a more responsive metric to guide interventions.

Results: The updated analysis reveals a continued pattern influenced by the dynamic public health landscape of the COVID-19 pandemic, including the phasing out of restrictions and the end of mandatory mask usage. The pandemic has significantly impacted IMR trends, with Portugal experiencing a decline in IMR during the stringent phases, reaching historically low levels. This trend slightly reversed following the lifting of restrictions, underscoring the urgent need for understanding the complex interplay between public health policies and infant mortality. In the post-pandemic period, the IMR increased until October 2023, showing a later (up to February 2024) global decreasing trend within the range of 2.5 and 2.9 deaths per 1000 live births.

Conclusions: Recent updates confirm the effectiveness of real-time IMR monitoring as a vital tool for policymakers and health professionals. Portugal's experience underscores the importance of real-time health indicators in managing public health crises. It stresses the need for further research to understand factors affecting IMR and to continue reducing infant mortality.

Key messages:

- COVID-19 restrictions correlated with a historical low in Portugal's IMR, showcasing the impact of stringent public health measures.
- Post-lockdown, the rise in IMR after the phasing out COVID-19 restrictions and later stabilization underscores the challenges and the necessity for dynamic health policies.

Abstract citation ID: ckae144.2129
Main challenges and measures taken by public health institutions in response to war in Kyiv Region

Nataliia Rodyna

N Rodyna[1,3], I Kuzin[2], M Husovych[1,3], V Maiboroda[1,3], I Kozolii[1,3], T Kupriianova[1,3], W Aaronson[4], L Hasiuk[1,3], R Savchuk[3], AM Tomosky[4]
[1]SI Kyiv OCDC of the MoH of Ukraine, Kyiv, Ukraine
[2]Ministry of Health of Ukraine, Kyiv, Ukraine
[3]All-Ukrainian Association of Public Health Specialists, Ivano-Frankivsk, Ukraine
[4]College of Public Health, Temple University, Philadelphia, USA
Contact: natarodyna@gmail.com

Background: The establishment of martial law due to Russia's military aggression against Ukraine led to specific adjustments in the functioning of the Centers for Diseases Control and Prevention (Ð¡DÐ¡). The negative impact of hostilities is determined by the increased morbidity rate of communicable and non-communicable diseases, insufficient supply of safe drinking water and food to damaged sites, inadequate living conditions, etc.

Objectives: The purpose of the work was to create an effective system for responding to biological, chemical and radiation hazards and eliminating the consequences of an emergency situation in the realities of martial law.

Methods: We used the most common methods, namely descriptive, statistical, microbiological and chemical laboratory tests.

Results: The activities of the CDC under martial law include daily monitoring studies of environmental objects. The epidemic situation of acute intestinal infection (AII) and other communicable diseases (CD) is constantly analyzed. The Kyiv Oblast CDC became the basic institution for the implementation of the 'pilot project' in the direction of sanitary and epidemic assessment and monitoring of environmetal objects in 188 de-occupied areas. The main public health risks were identified: providing the population with high-quality drinking water; low immunization rate of the population; sites for the location of internally displaced persons; natural foci of especially dangerous diseases, such as tularemia, leptospirosis, infection fevers, etc. In 2022, the overall level of CD in the Kyiv region decreased by 44.0% from 2021. The most common nosologies were acute respiratory viral infections and influenza (98.9%), AII (42.4%), tuberculosis (15.3%), Lyme disease (15.3%), and viral hepatitis (14.2%).

Conclusions: Based on the research conducted, mechanisms have been developed for responding to hazards of various origins by public health institutions, including risk assessmant and laboratory studies.

Key messages:

- The main focus of the Centers for Diseases Control and Prevention is aimed at effective response to hazards of various origins in order to ensure public health under martial law.
- Risk assessment in de-occupied territories has become an important tool for identifying correct approaches to prevent negative consequences for public health.

Abstract citation ID: ckae144.2130
The importance of healthcare monitoring systems

Antonio Marco Miotti

AM Miotti[1], S Tikvina[2], A Calzavara[2], M Nesoti[3], E Zilli[3]
[1]NRC, Veneto Region, Venezia, Italy
[2]Hygiene and Public Health Unit, University of Padova, Padua, Italy
[3]Medical Board of Directors, University of Padova, Padua, Italy
Contact: antoniomarco.miotti@aulss6.veneto.it

Issue: Healthcare evaluation is an important tool of governance in the health sector that reinforces its key components: evidence-based care, effectiveness, programme standards, performance monitoring, quality improvement, risk and incident management and patient-centered care. One of the evaluation systems used by the Veneto Region (north italian region of about 4.8 million inhabitants) consists of the National Outcomes Programme (PNE) developed by the Italian National Agency for Regional Healthcare Services (AGENAS) on behalf of the Health Ministry.

Description: The PNE is an instrument used to measure, analyze, evaluate and monitor clinical and welfare assistance performances of Italian healthcare facilities. The Veneto Region, in particular, utilizes a regional epidemiologic service to periodically monitor 21 performance indicators based on "treemap" methodology. These indicators are used to assess processes, outcomes and volumes. The data used to monitor these practices derive from the hospital discharge documentation (SDO) and tax registry information system. The aim of this monitoring system is to track any critical situation that is not in alignment with national guidelines and to improve the efficacy, efficiency, appropriateness and safety within the healthcare system.

Results: In the Veneto region, over the course of nearly 10 years, this method of management has led to the development of various training courses that guide clinicians to correctly document and code different diagnosis and treatments. The treemap process of analysis has also made possible various clinical audits that have provided significant policy changes regarding risk and overall health management.

Lessons: Having a constant view of healthcare performance has proven to be helpful not only to identify some common gaps in care given from different facilities on a national level, but also guides different regions to develop specific strategies that lead to quality improvement.

Key messages:

- Data on healthcare quality can be used as comparative information and for quality improvement.
- Continuous monitoring of specific performance indicators can help identify difficulties in healthcare facilities and create strategies for long term solutions.

Abstract citation ID: ckae144.2131

Reporting social inequalities in health dashboards: data source mapping of 14 European countries

Sebastián Peña

S Peña[1]*, M Francis*[1]*, T von Wright*[1]*, E Lindell*[1]*, L Kestilä*[1]
[1]Department of Health and Welfare, THL, Helsinki, Finland
Contact: sebastian.penafajuri@thl.fi

Background: Monitoring health inequalities is an essential public health task. This includes reporting social inequalities using data dashboards to inform citizens and policy-makers. To date, there is a dearth of evidence on the extent of health inequality reporting and which equity dimensions are being reported in European countries. The aim of the study is to systematically map data sources and identify the equity dimensions reported in national and subnational data sources in 14 European countries.

Methods: Study design is a cross-sectional data source mapping in 14 European countries (Bulgaria, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Iceland, Malta, Norway, Portugal, Slovenia, Spain). We will conduct a survey among more than 400 collaborators of the EU-funded Joint Action to Prevent NCDs (JAPreventNCD) to identify existing population health dashboards at national and subnational levels. On a second stage, we will carry out a structured content audit to identify inequality dimensions and health indicators in each dashboard. The dashboard content audit will be done in duplicate by native speakers using keyword search and annotated navigation. Inequality dimensions will be categorised using PROGRESS-plus categories. We will pre-register the protocol in OSF prior to data collection and analysis. Data analysis will use a modified version of the template developed by the World Health Organization. Data analyses will be conducted in R. Work is under development but given the resources committed to JAPreventNCD, results will be ready by November 2024.

Key messages:

- Reporting social inequalities using data dashboards to inform citizens and policy-makers is an essential public health task.
- Systematic data source mapping can be a reliable, efficient method to monitor the routine reporting of health inequalities.

Abstract citation ID: ckae144.2132

The impact of the COVID-19 pandemic on physical activity among primary school children in Ireland

Nandakumar Ravichandran

O Kilduff[1]*, J Slattery*[1]*, C Lee*[1]*, E Hunt*[1]*, A Douglas*[1]*, S O'Brien*[2]*,*
C Murrin[1]*, C Kelleher*[1]
[1]School of Public Health, Physiotherapy and Sports Science, National Nutrition Surveillance Centre, Dublin, Ireland
[2]Healthy Eating and Active Living Policy Programme, Health Service Executive, Dublin, Ireland
Contact: nanda14032001@gmail.com

Background: The containment measures implemented during COVID-19 to curb the virus's spread disrupted family life globally and profoundly impacted children's daily behaviours. A decrease in children's physical activity during COVID-19 is one such health behaviour change that was observed in many European countries. This study aimed to understand the pandemic's impact on primary school children's physical activity in Ireland which is important given the epidemic of childhood obesity and chronic diseases in the long term.

Methods: All Childhood Obesity Surveillance Initiative (COSI) participating countries (n = 45) could voluntarily implement the COVID study as part of their COSI Round 6 (R6) data collection or separately. The parents of First and Second-class primary school children (n = 2,784) who consented to participate in COSI-Ireland R6 were invited to complete the family survey which included the standardised COVID study. The COVID module assessed children's lifestyles and health behaviours before and during the pandemic through 12 questions. Consenting parents supplied their email or postal address and completed the survey in hardcopy or electronically using LimeSurvey. Descriptive statistics were then calculated on the cleaned pseudonymised dataset (n = 1,060) using IBM SPSS Statistics 27.

Results: The time spent playing actively outside school hours remained the same for some children on both weekdays and weekends (24.2% and 37.1%, respectively). An increase rather than a decrease in the time spent in active play was also observed among almost twice as many children across Ireland on both weekdays (47.3% and 24.2% respectively), and weekends (40.10% and 21.80% respectively).

Conclusions: The positive findings show that the public health messaging from the Irish Government which emphasized the importance of staying active during COVID-19 may have been effective. Further research to assess children's physical activity during COVID-19 is warranted to inform future pandemics.

Key messages:

- In Ireland, unlike in many European countries, a substantial number of primary school children increased their time spent playing actively during the COVID-19 pandemic.
- A unique trend in Irish children's physical activity levels compared to their European counterparts.

Abstract citation ID: ckae144.2133

Wastewater-Based Epidemiology of Influenza Viruses: a systematic review

Luca Viviani

L Viviani[1]*, L Pellegrinelli*[2]*, R Vecchio*[1]*, L Sandri*[2]*, S Binda*[2]*,*
E Pariani[2]*, A Odone*[1]
[1]Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy
[2]Biomedical Sciences for Health, University of Milan, Milan, Italy
Contact: luca.viviani97@gmail.com

Background: Influenza viruses (IVs) are responsible for annual epidemic outbreaks during the winter months. Beyond conventional surveillance systems, the circulation of these pathogens can be monitored using Wastewater-Based Epidemiology (WBE), an epidemiological tool that describes the health status of an entire community by analyzing the presence of pathogens within wastewater. Systematically reviewing existing experiences in this emerging field is crucial to highlight the best practices to establish a WBE surveillance system providing useful information for public health actions.

Methods: The study protocol for this systematic review has been registered on the PROSPERO website (registration ID: CRD42024532435). Three academic databases (PubMed, Web of Science and Scopus) were accessed to collect studies examining the presence of IVs in wastewater. Studies included were those reporting quantitative measures of viral concentration or detailing molecular/phylogenetic characterization of IVs in wastewater.

Results: Databases were searched on July 8th, 2024. After de-duplication and screening of the 400 remaining records, 42 were included in the review. IVs detection in wastewater was reported in all papers except from one, although with high variability in terms of positivity titers and concentration levels. More than half of the collected papers (52.4%) evaluated association between environmental viral concentration and clinical data, generally showing concordance between the two aspects. Moreover, 28.6% of papers described subtyping of IVs in wastewater through different methods (specific PCR assays being the most used).
Conclusions: WBE is a promising approach for surveilling viral circulation, and IVs represent a high value target for implementing this innovative system. Systematically reviewing previous experiences can be useful to obtain information for the establishment of a novel environmental surveillance system of Influenza Viruses

Key messages:

- Nucleic acids belonging to Influenza Virus are detectable in wastewater, even though we report high levels of variability in sampling techniques, laboratory methods and data management systems.
- Association between environmental data and number of clinical cases is reported to be generally strong in collected papers; subtyping of IVs present in wastewater is also feasible.

Abstract citation ID: ckae144.2134
Vaccination Coverage among Institutionalized Elderly Population: A Case Study in Cascais, Portugal

Carlos Quelhas

C Quelhas[1], M Lopes[1], C Moniz[1], M Fernandes[1]
[1]Cascais Public Health Unit, Western Lisbon Local Health Unit, Cascais, Portugal
Contact: carlos.quelhas@ulslo.min-saude.pt

Vaccination stands as a cornerstone of public health, significantly reducing the morbidity and mortality associated with infectious diseases. However, the aging demographic, with declining homeostasis and immunosenescence, presents new challenges. Those residing in nursing homes face heightened risks of infectious diseases due to proximity and interactions with multiple staff members. In Portugal, elderly vaccination against tetanus/diphtheria (Td) is integrated into the National Vaccination Program, with additional official recommendations for pneumococcal (Pn), seasonal influenza, and COVID-19 vaccinations. Specific vaccination campaigns in nursing homes for influenza and COVID-19 are coordinated by Public Health Units. This study aimed to assess the vaccination coverage for these vaccines among the institutionalized elderly in Cascais municipality and evaluate the implementation of official recommendations. A survey of nursing homes in Cascais was conducted, and the vaccination status of residents was assessed through electronic records in February 2024. Statistical analysis was performed. Vaccination status for each vaccine was considered valid if individuals had received at least one dose of Pn13 or Pn23, a Td vaccine dose within the last 10 years, and vaccinations against influenza and COVID-19 within the last 6 months. Among 2189 institutionalized elderly in Cascais, 87% were vaccinated against both influenza and COVID-19, 39% against Td, and 17% against pneumococcal disease. While influenza and COVID-19 vaccination coverage is high, the tetanus/diphtheria vaccination rate is low, and pneumococcal vaccination is very low, despite official recommendations. This population remains at increased risk for preventable diseases. Monitoring vaccination status and implementing targeted vaccination campaigns are crucial for increasing coverage, realizing health and economic benefits and preventing severe diseases.

Key messages:

- Vaccination is essential for safeguarding the health of institutionalized elderly populations. There is a need for targeted interventions to address preventable diseases and protect these individuals.
- Monitoring vaccination status and implementing targeted campaigns are critical for increasing coverage and realizing health and economic benefits among elderly populations in nursing homes.

Abstract citation ID: ckae144.2135
Data dashboards in health inequalities monitoring - A qualitative study of subnational policy-makers

Tuuli von Wright

T von Wright[1], S Peña[1], M Francis[1], E Lindell[1], L Kestilä[1]
[1]THL, Helsinki, Finland
Contact: tuuli.vonwright@thl.fi

Background: Despite sustained improvements in life expectancy and health during past decades, substantial health inequalities persist. Subnational jurisdictions are increasingly recognised for their pivotal role in addressing health inequalities. While data dashboards offer a promising solution for monitoring health inequalities, their utilisation in supporting local policies to reduce inequalities remains largely unexplored. This study examines the utilisation of health equity data and data dashboards (i.e. Sotkanet, Sotekuva, Tietotarjotin and Hyvinvointivajemittaristo) for health policy-making in Finnish wellbeing services counties, identifies barriers in using existing dashboards and determines the data needs for improved health inequalities monitoring.
Methods: A qualitative case study design with reflexive thematic analysis will be used. The study will be pre-registered in the OSF framework. Semi-structured interviews will be conducted with policy-makers involved in health policy development. Data analysis will involve open and axial coding to identify themes in participants' responses. Themes will be organised into a coding framework, and the analysis will continue iteratively until data saturation is achieved. The study will include a pre-approved interview guide and peer debriefing sessions. Findings will be reported according to the Consolidated criteria for reporting qualitative research (COREQ) guidelines, with thematic diagrams illustrating key themes and sub-themes. The study is expected to reveal varying levels of utilisation of data and data dashboards among local policymakers, along with specific challenges and gaps in their current use. Policymakers may express needs for additional data or new features in dashboards to better monitor health inequalities. The study will conclude with recommendations for improvements in current data dashboards. Work is under development but by funders requirement the results will be ready by November 2024.

Key messages:

- Data dashboards offer a promising solution for monitoring health inequalities, but their utilisation in supporting local policies to reduce inequalities remains largely unexplored.
- This study examines the utilisation of data dashboards for health policy-making subnationally, identifies barriers for use and determines the data needs for improved health inequalities monitoring.

Abstract citation ID: ckae144.2136
Viral pathogen surveillance in wastewater using metagenomic approaches: obstacles and prospects

Sofia Seabra

SG Seabra[1], AF Santos[1], M Nunes[2], F Manjate[1], A Silva[3], T Crespo[3], V Pimentel[1], P Libin[4], AB Abecasis[1], R Parreira[1]
[1]Global Health and Tropical Medicine, IHMT, Universidade NOVA de Lisboa, Lisbon, Portugal

[3]iBET - Instituto de Biologia Experimental e Tecnológica, Oeiras, Portugal
[4]Department of Computer Science, Vrije Universiteit Brussel, Brussels, Belgium
Contact: sgseabra@ihmt.unl.pt

Background: Wastewater monitoring offers an important tool for pathogen detection and tracking within large populations at a minimized cost and labor. Untargeted metagenomic approaches for the detection and sequencing of viruses still face limitations. In this study we tested the application of the sequence-independent single-primer amplification (SISPA) protocol in conjunction with nanopore sequencing to the study of viromes in wastewater samples.
Methods: Influent wastewater was collected from four Wastewater Treatment Plants located in the Lisbon region and Alentejo, Portugal in 2019 and 2023. Samples were processed with different methods including filtration, flocculation, Nanotraps or absorvent tampons. We applied the SISPA protocol, that includes a random amplification step, followed by nanopore sequencing on flow cells R9.4.1. We used the CZ ID (https://czid.org) pipeline for metagenomic analysis and taxonomic reporting.
Results: A large heterogeneity was found between samples in sequencing output (ranging from 17 thousand to 12 million reads) and the proportion of sequence reads classified as viral (ranging from 0.06% to 4% per sample). Viral taxa with higher number of reads were Picornavirales, dsDNA and ssDNA phages, Mimiviridae and Circoviridae. Known viral pathogens included Rotavirus A, Orthopoxvirus, Human betaherpesvirus and Avian orthoavulavirus.
Conclusions: Metagenomic studies of environmental samples generally exhibit a low proportion of viral reads, even after viral enrichment. A substantial sequencing effort is thus required to achieve a comprehensive virome characterization. As alternative, a more targeted approach, e.g. to target families of viruses of interest, may be considered. Funding: Fundação para a Ciência e Tecnologia (FCT): GHTM - UID/04413/2020; LA-REAL - LA/P/0117/2020; https://doi.org/10.54499/CEECINST/00102/2018/CP1567/CT0040 to SGS. Research council of the Vrije Universiteit Brussel (OZR-VUB): OZR3863BOF to PL.

Key messages:

- Enrichment for viruses in metagenomic approaches remain challenging in very complex samples as are influent wastewaters.
- Virome characterization still necessitates high sequencing efforts but may be used as a complementary environmental survey tool integrated with more targeted approaches.

Abstract citation ID: ckae144.2137
How Avoidable Mortality is influenced by health expenditure: an Italian 14-year panel data analysis

Andrea Sanna

A Sanna[1], *G Guarducci*[1], *D Golinelli*[1,2], *N Nante*[1,2]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: doc.andrea.sanna@gmail.com

Background: Avoidable Mortality is a widely used public health indicator to assess the quality of healthcare systems. The aim of this study was to investigate how the allocation of private and public health expenditure (PHE) could influence avoidable mortality (AM), treatable mortality (TM) and preventable mortality (PM) of Italian citizens.
Methods: A pooled cross-sectional time series study was conducted. Italian healthcare data from 2009 to 2019 was extracted from 'Health for All', a WHO-related database released periodically by the Italian National Institute of Statistics. PHE was divided by providers area (directly provided services (DPS), general and specialist medicine, pharmaceutical, rehabilitation). Data about private health expenditure, gross domestic product per capita (GDPPC), level of education, medical drug consumption per capita (MDCPC), general practitioners per capita (GPPC), physical exercise, tobacco use, and obesity were collected. AM was divided into TM and PM using OECD/Eurostat lists of causes of death (2022). A fixed-effects regression was used to assess the effects of economic and social variables on AM, TM and PM.
Results: Higher spending on DPS (-0.027), higher MDCPC (-0.859) and higher GDPPC (-0.001) were associated with lower rates of AM. Higher sport activity (c -0.673) was associated with lower rates of TM. Higher levels of private health expenditure (0.022) and higher number of GPPC (0.023) were associated with higher rates of PM; these counterintuitive results could be caused by the inappropriateness of medical treatment directly requested by patients. Other variables were not significantly associated with AM, TM or PM.
Conclusions: The results highlight the importance of medical DPS by NHS (emergency departments, hospital care, specialized care, primary care, etc.). Analyzing health data divided by areas of NHS we could help policy makers to allocate human and economic resources more efficiently.

Key messages:

- The allocation of public health resources could influence the health status of the polulazion.
- Italian National Health System could reduce avoidable mortality through the use of directly provided services.

Background: Comprehensive sexuality education (CSE) is globally acknowledged as the most effective approach to promoting sexual health and preventing Sexually Transmitted Infections (STIs). However, in Italy, CSE is not consistently part of the school curriculum. The EduForIST project, funded by the Ministry of Health, introduced and tested a unique CSE model in a sample of secondary schools across six Italian regions, aiming to develop an evaluation model for potential nationwide implementation.
Methods: The EduForIST partnership, comprising experts from various institutions, devised a framework for monitoring and evaluating CSE interventions. Through monthly focus group discussions from April 2023 to February 2024, they established indicators for short-, medium-, and long-term evaluation of clinical and behavioral outcomes, as well as process indicators to assess intervention implementation.
Results: A total of 35 indicators were developed, including clinical and behavioral ones for medium and long-term outcomes, short-term behavioral outcomes, and process indicators. Data for clinical and behavioral indicators can be obtained from administrative sources like the Ministry of Health and Regional Health Authorities. The National Institute of Health provides data from relevant surveillance programs. However, many process indicators require specific data collection and calculations. Challenges such as under-reporting and underestimation persist, especially in regions with limited CSE implementation.
Conclusions: Creating an effective monitoring system for CSE interventions necessitates integrating diverse data sources, including health records, administrative data, and behavioral assessments.

The proposed model's effectiveness will be fully assessed by comparing pre- and post-intervention after widespread implementation in secondary schools. Meanwhile, the selected indicators serve as a foundation for evaluating baseline status of STIs and behaviors in Italy.

Key messages:

- The EduForIST project establishes a robust framework for evaluating Comprehensive Sexuality Education (CSE) interventions in secondary schools, addressing gaps in nationwide implementation.
- By devising indicators encompassing several measures, the project lays the groundwork for a comprehensive monitoring system, vital for assessing the effectiveness of CSE interventions in Italy.

Abstract citation ID: ckae144.2139
A methodology to map chains of general practices in the Netherlands

Lilian Van Tuyl

L Jansen[1], R Timans[1], R Batenburg[1], L van Tuyl[1]
[1]NIVEL, Utrecht, Netherlands
Contact: l.vantuyl@nivel.nl

Background: Commercial entities are increasingly interested in acquiring Dutch general practices (GPs). They see profitable opportunities in upscaling by forming chains. Chain organizations integrate business processes of GPs within one organizational unit. The governance structure of these chains can be complex, leading to opacity and difficulties to see conflicts of interest and market power. To investigate how this development may have an impact on quality and accessibility of care, it is first needed to establish the ways in which these chains are formed. By mapping the chain structure in a data-driven way, impact monitoring becomes possible. For the Netherlands we investigated how chain structures of GPs can be empirically identified.

Methods: Background data of approximately 4,800 Dutch GPs from the Nivel Healthcare Professional Registries was linked with data from the Chamber of Commerce's Trade Register. This enabled the determination of the legal form, business location, ownership, and director identification for all GPs. By this data-driven manner, the variation in organizational structures of all Dutch GPs was mapped and analyzed.

Results: Four different chain variants of Dutch GP chains were identified based on three types of relations between the chain organization and their GPs: ownership, location and the composition of the board of directors. Based on ownership, two 'top-down' chain variants were identified. Two 'bottom-up' chain variants were found based on location and board composition: (1) a chain organization acquires a seat on the board of the GP, and (2) the GP and the chain organization share the same business address. Combining these variants provides a new typology of GP chains in the Netherlands.

Conclusions: Our methodology enables to empirically map chain formation in primary care. By developing a new typology in a systematic way, a foundation is created to monitor organizational developments and their impact on quality and accessibility of care.

Key messages:

- A typology of Dutch GP chains was developed based on three relations: the ownership, composition of the board and the establishment location of the chain organization and its practices.
- Our methodology was put into practice to map different chain structures of GPs in the Netherlands, but it is not limited to primary care and can also be applied in other sectors and countries.

Abstract citation ID: ckae144.2140
Radiation exposure of patients undergoing multiple-slice CT scans in Romania

Ileana Prejbeanu

I Prejbeanu[1,2], MZ Assani[1], F Niculescu[2], LA Prunariu[2], RG Prejbeanu[3]
[1]Environmental Health Department, University of Medicine and Pharmacy, Craiova, Romania
[2]Radiation Hygiene Department, Public Health Authority, Craiova, Romania
[3]Faculty of Automation, Computers, University of Craiova, Craiova, Romania
Contact: ileana.prejbeanu@gmail.com

Ionizing radiation is largely used in medicine due to its role in the diagnosis and treatment of patients. In the past 50 years computed tomography (CT) has become indispensable for medical practice because it offers sub-millimeter cross-sectional imaging of any region of the body. New CT scanners use thinner slices, providing more accurate results, but also an increased radiation exposure with possible long-term harmful effects for the patients. The parameter used as an indicator of radiation dose in CT is the dose-length product (DLP). The study included 4507 patients who were CT scanned using a 16, 32, 64 or 128-slice CT machine. DLP was measured for head, sinuses, thorax, abdomen, pelvis, abdomen+pelvis, and trunk scans - regions for which the health authorities have established national diagnostic reference levels (DRL - the expected radiation dose received by a patient in CT). One-way ANOVA was used to analyse data considering the use of contrast agents, the gender, age, and weight of patients. Average DLP values were higher (up to 80%) than national DRL for all regions in 64 and 128-slice scans. The highest DLP values were registered in contrast CT for all scanners ($p < 0.01$); the maximum average (a threefold increase compared to DRL) was measured in the 32-slice sinuses contrast CT. Average DLP correlated with patients' gender and weight ($p < 0.01$), but the influence was lower compared to the use of contrast agents. In conclusion, CT scans acquired using thinner slices lead to more accurate results and high-quality images, but the study suggests an increased radiation exposure. CT has an uncontestable contribution to a precise and rapid diagnosis, but more attention must be given to the stochastic effects risks associated with the radiation dose received during a CT scan. Are all scans necessary? Do all patients really need to receive high doses? The role of the practitioner is decisive, and the justifiable process is "a must" in all radiodiagnosis practices.

Key messages:

- CT doses must be kept "as low as reasonably achievable" while maintaining diagnostic image quality.
- Justification, dose limitation, and optimisation are fundamental principles of radioprotection.

Abstract citation ID: ckae144.2141
Monitoring the Public Health and Safety Impact of the Groningen Gas-Extraction Crisis

Jenny Gerbecks

M Dückers[1,2,3], S Berends[2], M Boendermaker[2], C D'Amore[2], B Kanis[1], J Van der Molen[2], M Rozema[1], A Scherpenzeel[1]
[1]Disasters and Environmental Hazards, NIVEL, Utrecht, Netherlands
[2]Faculty of Behavioral and Social Sciences, University of Groningen, Groningen, Netherlands
[3]ARQ National Psychotrauma Centre, Diemen, Netherlands
Contact: j.gerbecks@nivel.nl

Background: Gas extraction in the Dutch province of Groningen began in 1963 and was initially seen as an economic boon for the nation. Yet, it turned into a significant burden for the region, leading to earthquakes, damage to houses and property, complicated compensation processes, recovery, and reinforcement programs, as well as a lack of recognition. In 2016, the research group Gronings

Perspectief (GP) was established with the objective of independently monitoring the public health and safety impact of the gas-extraction crisis from the residents' perspective.

Methods: Monitoring activities take place in dialogue with sounding boards comprising residents, professionals, scientists, and local and national governments. GP employs a longitudinal mixed-methods approach, combining qualitative and quantitative research methods. Representative panel surveys are conducted yearly among residents in the provinces of Groningen (twice) and Drenthe (once). Additionally, 20 in-depth interviews are carried out each year, alongside a survey among households in the reinforcement program. GP analyses the periodic health monitors conducted by municipal health authorities. All reports are publicly accessible.

Results: Since 2016, monitoring consistently points to a profound and enduring effect of housing damage on health and well-being, subjective safety, risk perceptions, trust in governments and agencies among residents. The impact of the procedural burden imposed by governments and institutions, is as significant as the effects of earthquakes and housing damage.

Conclusions: GP's findings were included in a parliamentary inquiry, which concluded in 2023 that the interests of residents were persistently neglected in favour of economic gain. New risk reduction and reconciliation programs are introduced. Despite the recent decision to end the gas extraction, continuation of GP is needed to monitor further developments.

Key messages:

- GP's stakeholder-driven monitoring approach made the impact of the gas-extraction crisis visible.
- Enduring public health and safety risks, beyond the gas extraction, require continuing monitoring.

Abstract citation ID: ckae144.2142
Did the pandemic change behaviours in Italy? An analysis on the main NCDs behavioural risk factors

Rosaria Gallo

F Asta[1], *V Minardi*[1], *B Contoli*[1], *V Casigliani*[2], *R Gallo*[3,4], *V Possenti*[1], *M Masocco*[1]
[1]National Centre for Disease Prevention, ISS, Rome, Italy
[2]Department of Translational Research, University of Pisa, Pisa, Italy
[3]Health District 9, Local Health Unit Roma 2, Rome, Italy
[4]Department of Public Health, Sapienza University of Rome, Rome, Italy
Contact: rosariagallo.cs@gmail.com

Background: The indirect effects of the COVID-19 pandemic on healthy living behaviours are multiple and complex to assess. The aim of the study is to assess the impact of the COVID-19 pandemic in Italy on: smoking, alcohol, fruit and vegetable consumption, and sedentary lifestyle, through the Italian Behavioral Risk Factor Surveillance System (PASSI) data.

Methods: PASSI 2008-2022 data refer to a sample of 497,223 18-69-year-olds residing in Italy. For each behaviour, from the monthly prevalence data, the 2008-2022 time series was estimated with LOWESS regression and an interrupted time series (ITS) analysis was conducted, using the generalized least squares (gls) model, taking into account autocorrelation (ARMA matrix) and considering March 2020 (start of WHO-declared pandemic) as the month of 'interruption' of the series, to show the difference between what was observed and what was expected under the assumption that the pandemic had not happened ('counterfactual' scenario).

Results: In December 2022 the share of people who consume at least 5 servings of fruits and vegetables per day is lower than the counterfactual scenario (6.7% vs 9.1%), while the share of higher-risk alcohol users is significantly higher (19.5% vs 16.9%). In contrast, the share of sedentary people (according to WHO guidelines) is significantly lower than the counterfactual (27.9% vs 31.8%). The pandemic does not seem to have had a significant impact on smoking.

Conclusions: These results show a worsening impact of the pandemic on alcohol consumption and fruit and vegetable consumption. Sedentariness shows better data at the end of 2022 and smoking remains mostly unchanged. It will be necessary to continue monitoring the impact of the pandemic over longer periods to confirm the findings.

Key messages:

- Understanding changes in lifestyle indicators is critical to design ad hoc interventions to reduce the burden of noncommunicable diseases, and especially during health emergencies such as pandemics.
- Through this work it is possible to clearly observe how the pandemic has impacted lifestyle habits.

Abstract citation ID: ckae144.2143
Adverse Drug Reactions to *β*-Lactam Antibiotics: A Portuguese Pharmacovigilance Database Analysis

Edna Ribeiro Parracha

M Silva[1], *JP Fernandes*[1], *E Ribeiro Parracha*[1], *A Gamboa*[1], *C Lima Alves*[1]
[1]INFARMED - National Authority of Medicines and Health Products, I.P., Lisbon, Portugal
Contact: edna.parracha@infarmed.pt

Background: The β-lactam antibiotics are one of the most relevant drug classes globally. They accounted for the largest share of systemic antibiotics consumption in Portugal across both community and hospital settings. Due to their significance, continuous monitoring of adverse drug reactions (ADR) associated with β-lactams is fundamental.

Aim: To analyse and characterise cases related to β-lactam antibiotics received by the Portuguese National Pharmacovigilance System.

Methods: Retrospective analysis of cases containing at least one medicinal product classified as suspect under the Anatomical Therapeutic Chemical (ATC) code J01C or J01D, reported to the Portuguese Pharmacovigilance System between 2014 and 2023. Characterisation of cases considered patient demographics, reported suspected medicines, MedDRA Preferred Term (PT), seriousness and type of reporter.

Results: A total of 3557 cases were identified (54.0% females; median age = 42.0 years; interquartile range = 52.2), with 95.9% originating from spontaneous reporting and 93.5% being reported by healthcare professionals. The most frequently reported medicines were those belonging to ATC J01CR. Around 70% of cases were classified as serious, with 38.7% being related to situations of disability or other criteria of greater seriousness. Most frequently reported PTs were related to skin disorders. Anaphylactic reaction was the most reported Designated Medical Event term. The PTs "Drug ineffective" and "Off label use" were reported in 5.2% and 2.4% of the cases, respectively.

Conclusions: Despite the majority of cases are serious, most of the ADR identified are related to already known hypersensitivity reactions. To improve the knowledge regarding these medicines and to generate evidence to address emerging public health issues it is of paramount importance to strength the Portuguese Pharmacovigilance System. This can be achieved through enhancing spontaneous reporting and implementing active pharmacovigilance programs.

Key messages:

- Monitoring the efficacy and safety profile of β-lactams in a real-world context is crucial to mitigate the impact in public health and associated economic burden.

- Enhancing the surveillance systems improves data collection and evidence generation, supporting tailoring treatment approaches and implementation of public health policies.

Abstract citation ID: ckae144.2144
Dispensing of antibiotics in community pharmacies before, during, and after the COVID-19 pandemic

Hélder Pinto

H Pinto[1]*, V Pessoa*[1]
[1]Public Health Unit, Local Health Unit of Central Alentejo, Évora, Portugal
Contact: helderalvespinto@gmail.com

Background: Antibiotic resistance threatens our capability to successfully treat bacteriological infections, becoming a major threat to public health. Therefore, measures must be taken to minimize de incidence of multi-drug resistant bacterial infections. Antimicrobial Stewardship is a systemic healthcare approach devised to foster, enhance, oversee, and assess the judicious application of antimicrobials, aiming to safeguard their efficacy in the future, whilst advocating and safeguarding public health. In the initial phase, a correct diagnosis of antimicrobial utilization is pivotal for the proper implementation of an Antimicrobial Stewardship Program.

Methods: A cross-sectional study encompassing the Alentejo region, Portugal, with a specific focus on central Alentejo, was conducted to analyze the dispensing of antimicrobials in community pharmacies, alongside the examination of the prescribing locations, before, during, and after the COVID-19 pandemic, from 2019 to 2023.

Results: The number of antibiotic packages dispensed decreased, as expected, during the COVID-19 pandemic, but returned to pre-pandemic levels after its conclusion. In several prescribing locations, the proportion of cephalosporins and quinolones exceeded the maximum expected value.

Conclusions: The implementation of an appropriate Antimicrobial Stewardship Program in this region is necessary to ensure the correct prescription of antimicrobials, decreasing the risk that antibiotic resistance pose to public health. Emphasis on the application of the Clinical Practice Guidelines issued by the Portuguese Directorate-General of Health regarding the proper approach to bacterial infections should be intensified so that all prescribing locations exhibit proportions of cephalosporins and quinolones below the maximum expected value.

Key messages:

- Antimicrobial resistance poses a threat to public health.
- Stewardship is crucial for appropriately safeguarding public health by reducing antimicrobial resistance emergence.

Abstract citation ID: ckae144.2145
Regional inequalities in waiting times: analysis of orthopedic appointments in Slovenia

Mircha Poldrugovac

M Poldrugovac[1]*, M Kuhar*[1]*, B Kasapinov*[1]
[1]Centre for Health Care, NIJZ, Ljubljana, Slovenia
Contact: mircha.poldrugovac@nijz.si

Background: Long waiting times for healthcare services are a priority issue in the Slovenian healthcare system. Over the past decade the system for monitoring waiting times has evolved and is currently linked to the eReferral system, which allows detailed monitoring of data in particular related to secondary care services, such as outpatient specialist visits. Our aim was to explore the differences in waiting times between Slovenian regions in the case of first orthopedic outpatient visits in order to identify potential causes or contributing factors.

Methods: The analysis was based on the data from the waiting list database on 1 January 2024. The database includes information on region of residence of the patient and the region where the provider is located. Data were available on the number of persons on the waiting list and on the average expected waiting time for them. Waiting times relate to each of three urgency levels, which are indicated on the referral (very fast, fast and ordinary).

Results: Average expected waiting times for first orthopedic outpatient visits differed considerably among residents of different regions, ranging from 159 day to 265 days (60% more). The regional differences were even larger if only “very fast” and “ordinary” referrals were considered. The share of appointments in each urgency referral level also varied considerably, for example the share of patients with a “very fast” referral ranged between 15,7% and 37,6%, depending on the patient region of residence. The Pearson correlation coefficient between the region of residence of patients and the region where the provider is located was 0,78.

Conclusions: Waiting times and referral patterns for first orthopedic outpatient visits for patients from different regions vary considerably. Despite a free choice of provider and public data on expected waiting times, the differences correlate closely with the geographic distribution of providers.

Key messages:

- Waiting times for outpatient visits in orthopedics differ by Slovenian region, despite free choice of provider.
- The assessment of inequalities is made more difficult by varying share of different urgency levels of referrals.

Abstract citation ID: ckae144.2146
Foregone care in the Italian elderly population: a new challenge for the National Health System

Rosaria Gallo

B Contoli[1]*, F Asta*[1]*, V Possenti*[1]*, R Gallo*[2,3]*, D Marotta*[4]*, V Pettinicchio*[4]*,*
V Minardi[1]*, M Masocco*[1]
[1]National Centre for Disease Prevention, ISS, Rome, Italy
[2]Health District 9, Local Health Unit Roma 2, Rome, Italy
[3]Department of Public Health, Sapienza University of Rome, Rome, Italy
[4]Prevention Department, Local Health Unit Roma 2, Rome, Italy
Contact: rosariagallo.cs@gmail.com

Background: The avoidance of medical care among the elderly in Italy has been exacerbated during the COVID-19 pandemic and today, according to data from the Passi d’Argento surveillance, it involves over 3 million elders. The study analyzes the medical care avoidance among the elderly in Italy, the motivations behind it and the changes over time.

Methods: Passi d’Argento surveillance system, coordinated by the Italian National Institute of Health and conducted by Local Health Units, continuously collects information on health and lifestyles, as well as care and assistance needs, of the population aged over 65 residing in Italy, through interviews with representative samples by gender and age.

Results: Between 2021 and 2022, 1 in 4 individuals over the age of 65 (24%) reported avoiding, in the 12 months before the interview, a medical visit or diagnostic test they needed. The phenomenon is higher among those reporting significant economic difficulties (37%). Among those who have waived, 31% said they did so for fear of Sarsv-Cov-2 infection; 22% due to suspension of service and/or closure of the practice because of the restrictions imposed by the COVID-19 pandemic; 36% declared that the avoidance reason was due to long waiting lists; 7% due to difficulty reaching the facility. With the end of the pandemic, this phenomenon has decreased overall (from 34% in 2020 to 23% in 2022), however, there is an increase of individuals who report renouncing due to long waiting lists or difficulties accessing services.

Conclusions: Data clearly highlights the difficulties of National Health System in meeting the health needs of elderly citizens, which persist even after the pandemic. It is important to preserve the right and the access to prevention and care for the elderly, for which timeliness is crucial. In this perspective, these data can provide important guidance for action at both national and regional levels.

Key messages:

- Having national data on foregone care allows to see the burden of the phenomenon.
- Even after the pandemic, the phenomenon of medical care avoidance among the elderly continues to be observed.

Abstract citation ID: ckae144.2147
Health behaviour and well-being in the Faroe Islands prior to and during the first COVID-19 lockdown

Marin Strøm

V Honnudóttir[3,2], AS Veyhe[1,3], M Mohr[2,3], M Mohr[1,3], M Strøm[1,3]
[1]Faculty of Health Sciences, University of the Faroe Islands, Tórshavn, Faroe Islands
[2]The Faroese Health Authority, The Faroese Ministry of Health, Tórshavn, Faroe Islands
[3]Center for Health Science, University of the Faroe Islands, Tórshavn, Faroe Islands
Contact: marins@setur.fo

Detrimental effects on health and well-being were reported during the COVID-19-induced lockdown periods in several countries, but these associations have not been studied in small-scale island societies. This study aimed to examine the lockdown period's impact on health behaviour, social media use and measures of well-being in the Faroe Islands. We used cross-sectional data from two extensive population-based surveys of public health conducted in November 2019, the pre-COVID survey ($n = 2906$), and 4-6 weeks into the first national lockdown, the lockdown survey ($n = 1204$). A larger proportion of participants in the lockdown vs. pre-COVID survey people reported high physical activity levels (42.1 vs 30.7% $p < 0.001$), while nutritional habits were rated worse and social media usage increased. Furthermore, the proportion displaying excellent/very good self-rated health was larger in the lockdown vs. pre-COVID survey (68.1 vs 62.0% $p < 0.001$), and the same pattern was observed for reporting good quality of life (85.7 vs 82.7% $p < 0.05$). These associations remained statistically significant in a logistic regression model after adjusting for characteristics for which varying impact of the pandemic has been shown. Indicators of health behaviour showed that larger proportions of participants kept active during the lockdown vs pre-COVID survey, and these differences were statistically significant for physical, mental, and spiritual activities ($p < 0.001$). On the other hand, similar stress levels in the pre-COVID/lockdown periods were observed, but stratified analysis showed that participants with a high-stress level displayed better self-rated health in the lockdown period compared to the pre-COVID period ($p = 0.001$).

Conclusions: Findings indicate that self-reported health and quality of life improved during the early phase of the COVID lockdown, and individuals reported higher activity levels associated with good mental health during the COVID-19-induced lockdown period.

Key messages:

- Physical activity improved, but dietary habits worsened during initial COVID-19 lockdown in the Faroe Islands.
- Measures of wellbeing and quality of life improved during initial COVID-19 lockdown in the Faroe Islands, while there was no overall difference regarding stress levels.

Abstract citation ID: ckae144.2148
The normalised mortality, a new measure to ensure valid conclusions from cardiovascular mortality

Susanne Stolpe

S Stolpe[1], B Kowall[1]
[1]Centre for Clinical Epidemiology, University Hospital Essen, Essen, Germany
Contact: susanne.stolpe@uk-essen.de

Background: The quality and efficacy of health systems is assessed by comparing age-standardised mortality (ASM) from cardiovascular diseases (CVD), as they are regarded avoidable by health care. Differences in CVD mortality in West-Europe are surprising and hard to explain: in 2018, ASM for CVD in Germany was much higher (women: 102, men: 155/100,000) than in the Netherlands (65 and 97). Yet, these differences do not root in health system quality, but in different shares of CVD deaths among all deaths (DE: 39%, NL: 25%), which strongly effect CVD mortality. We developed a mortality measure less sensible to differences in shares of CVD deaths to increase plausibility of comparisons and validity of conclusions.

Methods: WHO data on sex-specific all and CVD deaths, ASM for CVD and all-causes for 2000-2018 for Western-European countries was used to calculate the share of CVD deaths among all deaths. ASM for CVD was divided by the share of CVD deaths resulting in a mortality measure normalized for 1% of CVD deaths. ASM and normalized mortality for CVD were used in comparative analyses. Strength of linear association between total and (normalized) ASM for CVD was estimated (adj. R^2).

Results: Normalised CVD mortality ranked from 2.0 (CHE in women) to 4.9 (SVN in men) in 2018. While ASM for CVD was lowest in Danish women and Dutch men, Switzerland leads both rankings using the normalised CVD mortality. While ASM for CVD was much higher in Germany than in the Netherlands, the countries had the same normalized CVD mortality (2.6). ASM for CVD was moderately associated with all-cause mortality only in men (adj. R^2 0.33; in women: -0.06). Using the normalized CVD mortality yielded an adj R^2 of 0.66 in women and 0.94 in men. The normalised CVD mortality ensures reliable comparisons of CVD mortality eliminating the effect of different shares of CVD deaths. It yields plausible results and enables valid conclusions about health system quality and better decisions for public health.

Key messages:

- Age-standardised CVD mortality rates are effected by different shares of CVD deaths in countries and hinder valid conclusions on health systems efficacy and quality of health systems.
- The normalised mortality rate eliminates the effect of different shares of CVD deaths in countries and allows to validly compare CVD mortality.

Abstract citation ID: ckae144.2149
Preventing dementia is possible. The fraction of cases attributable to modifiable factors in Italy

Rosaria Gallo

M Masocco[1], V Minardi[1], B Contoli[1], F Asta[1], R Gallo[2,3], V Possenti[1], F Lombardo[1], N Vanacore[1]
[1]National Centre for Disease Prevention, ISS, Rome, Italy
[2]Health District 9, Local Health Unit Roma 2, Rome, Italy
[3]Department of Public Health, Sapienza University of Rome, Rome, Italy
Contact: rosariagallo.cs@gmail.com

Background: Worldwide, approximately 50 million people live with dementia. The Lancet Commission, in its latest report in 2020, identifies 12 'modifiable' risk factors associated with dementia, estimating that they account for about 40% of overall dementia cases. The study aimed to estimate the population attributable fraction (PAF) of dementia cases in Italy due to these factors.

Methods: Relative risks (RR) of each factor and formulas for estimating PAF are derived from the Lancet Commission's report. Prevalence data were obtained from the Italian surveillance systems PASSI and PASSI d'Argento (PdA), which provide information on 11 of the 12 identified risk factors. The total sample 2017-19 included 86,494 individuals aged 18-64 and 48,516 individuals aged over 65. The Communality, used for 'weighted' estimates of PAFs, was calculated via principal components analysis of the inter-risk-factor tetrachoric correlation matrix, using data derived from the overall PASSI and PdA sample.

Results: In Italy, it is estimated that 39.5% of dementia cases are attributable to 11 of the 12 modifiable risk factors, equivalent to 445,150 out of 1,126,961 estimated cases as of January 1, 2023. Among the risk factors with the greatest impact are hypertension before the age of 65 (weighted PAF=6.3%); sedentariness after the age of 65 (weighted PAF=5.9%); low education in youth (weighted PAF = 5%); depression and social isolation after the age of 65 (weighted PAF=4.5% and 4.4%), as well as diabetes (weighted PAF=3.9%) and smoking (weighted PAF=2.4%).

Conclusions: Although it is necessary to to gather further evidence on the role and mechanisms of action of each factor, the importance of prevention and promotion of health and social well-being in the field of dementia is now evident.

Key messages:

- Having an overall national sample of adults and elderly people is a unique tool that allows an estimation of dementia cases attributable to modifiable risk factors.
- Dementia prevention may also be possible by acting on modifiable risk factors.

Abstract citation ID: ckae144.2150
Assessing progress towards viral hepatitis B and C elimination in prisons in the European region

Lara Tavoschi

S Fondelli[1], R Pisetta[1], S Mazzilli[1], ML Montanari[2], T Seyler[2], F Azevedo e Silva[3], L Tavoschi[1]
[1]Department of Translational Research, University of Pisa, Pisa, Italy
[2]Public Health Unit, European Monitoring Centre for Drugs and Drug Addiction, Lisbon, Portugal
[3]Health In Prisons Programme, WHO/Europe, Copenhagen, Denmark
Contact: lara.tavoschi@unipi.it

Background: In 2016 the WHO launched the global health sector strategy for the elimination of viral hepatitis, alongside a dedicated monitoring&evaluation (M&E) framework to assess progress at national, regional and global levels. Despite being a priority setting for viral hepatitis elimination in Europe, prisons are rarely integrated into national monitoring efforts. Besides, prisons are particular contexts with a high viral hepatitis prevalence, where it is possible to utilize adequate micro-elimination strategies.

Objectives: We aimed to assess available metrics of viral hepatitis burden and coverage of prevention and control interventions in prison settings in Europe using routine sources of data.

Methods: We adapted the WHO M&E framework for viral hepatitis elimination to the prison context. The resulting M&E framework has 49 indicators of which 10 are defined as core. Data were sourced from available European prison surveillance systems at European level, namely: European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) and WHO Health in Prisons European Database (HIPED).

Results: In total 38 countries in the European region provided data to either data sources for 2020. For WHO-HIPED, among core indicators, 3 out of 10 could be calculated for HCV, and covered prevalence, HCV treatment availability and treatment outcome. Concerning HBV, 3 core indicators out of 10 could be calculated and covered prevalence, screening availability and treatment coverage in prison. With EMCDDA surveillance system we could calculate 4 HCV core indicators and 6 HBV core indicators.

Lessons: Availability of health data from prison settings is scarce, hampering the current capacity to monitor the progress in the viral hepatitis elimination within prisons contexts strategies and its relative contribution to global health goals achievement. A coordinated and standardised M&E framework tailored to this specific setting is needed to foster data collection and systematic monitoring.

Key messages:

- Micro-elimination strategies in prison context contribute to the global health goals achievement.
- A coordinated and standardized M&V framework, adapted to the prison context, is needed to foster data collection and monitoring of the viral hepatitis elimination strategy.

Analysis of the mpox outbreak in Europe in 2022: vaccination rollout in the most affected countries

Gonçalo Augusto

M Paiva Pessoa[1], G Figueiredo Augusto[2]
[1]Health Policies and Systems Management, NOVA University Lisbon, Lisbon, Portugal
[2]Health Strategies, NOVA University Lisbon, Lisbon, Portugal
Contact: figueiredo.augusto@cns.min-saude.pt

Background: The mpox virus spreads through contact with infected material and causes flu-like symptoms and skin lesions. Common in Central and West Africa, a global rise in mpox cases in 2022 was observed, affecting mainly men who have sex with men.

Methods: The study analysed vaccination policies in the most affected WHO-EURO countries during the mpox outbreak, including the Netherlands, France, UK, Spain, Germany, Belgium, Portugal, and Switzerland. Epidemiological data from May to October 2022 (first wave) were compared. Additionally, the role of EU health institutions in assisting member states in controlling virus spread across the region was examined.

Results: By the end of May 2022, three countries (The Netherlands, France, and UK) initiated post-exposure vaccination shortly after the first case identification. Portugal, one of the most affected countries, implemented pre-exposure prophylaxis for high-risk groups by September, followed by Switzerland in November. Vaccination access for non-exposed priority groups varied, with France not requiring a medical prescription. EU cooperation in health was pivotal during the outbreak, with vaccines distributed through the EU4Health program budget via HERA to ensure preparedness. However, detailed information remains limited.

Conclusions: Countries' responses to the mpox virus outbreak varied significantly, with discrepancies not always aligning with epidemiological data. These differences could stem from various factors, such as behavioural patterns, prior immunisation rates, and neighbouring countries' policies. However, the unequal access to vaccines across the region underscores existing health disparities, particularly affecting stigmatised populations. Data on immunisation records were notably scarce in most countries, hindering thorough analysis of policy implementation and effectiveness. Additionally, further exploration is warranted into the role of LGBT associations and evidence of stigma surrounding the outbreak.

Key messages:

- The mpox 2022 outbreak in Europe provides an important picture of cross-border health policies and public health responses for future emergences in a European cooperative environment.

- Most national authorities provided limited information during the mpox 2022 outbreak; data on immunisation records and vaccine access is pivotal to assess countries' health policies.

Abstract citation ID: ckae144.2152
HiCorr: an influenza surveillance model using over-the-counter sales from community pharmacies

Sónia Romano

Contact: sonia.romano@anf.pt

Background: In large-scale community transmission, such as seasonal influenza, monitoring geographic trends and estimating the transmission intensity are critical to support public health decision-making. Previous studies have successfully used sales data from over-the-counter (OTC) products in community pharmacies to detect and monitor different epidemiological outbreaks, developing surveillance systems that are able to anticipate the load on primary care services and hospitals by up to 3 weeks.

Methods: The subset of OTC products sold in Portuguese community pharmacies was selected by correlating sales data to primary care attendance in previous flu seasons. This data pertained to daily coded episodes of influenza-like-illness (International Classification of Primary Care, 2nd Edition, code R80) in the Portuguese health cluster Oeste Sul. By fitting a moving epidemic method to historical sales data and then applying it to daily collected sales data, the developed index was used to anticipate the relative load to the primary care system as well as the start and the peak of epidemic activity for the current flu season. Results were compared to the public health data available on respiratory infections in Portugal.

Results: The model pinpointed the onset of the 2023-2024 flu epidemic in week 47 and its peak in week 52. The index curve showed a high correlation with the data published by the Portuguese national health service, with no time lag. However, the availability of consolidated public data was delayed, on average, by approximately two weeks.

Discussion and conclusions: Data from community pharmacies significantly enhance the early detection of seasonal flu trends, while reflecting population distribution. This underscores their invaluable contribution to public health assessments and the potential for improving the timeliness and accuracy of seasonal flu surveillance.

Key messages:

- Community pharmacy data significantly enhance the early detection of seasonal flu trends.
- Real world sales data maybe useful to support epidemic surveillance in public health.

Abstract citation ID: ckae144.2153
Examining Cycle Threshold values in Repeat SARS-CoV-2 Cases: A Retrospective Analysis in Ireland

Jwenish Kumawat

J Kumawat[1], *F Butler*[3], *R Jalal*[1], *M Codd*[1], *E Gormley*[2], *J Loughrey*[1], *K Conyard*[1], *P Wall*[1]

[2]School of Veterinary Medicine, University College Dublin, Dublin, Ireland
[3]School of Biosystems and Food Engineering, University College Dublin, Dublin, Ireland
Contact: jwenish.kumawat@ucdconnect.ie

Background: Effective public health management during the COVID-19 pandemic requires accurate differentiation between re-infections and residual viral RNA detections in repeat positive cases. This study investigates cycle threshold (CT) trends in repeat SARS-CoV-2 cases to discern between persistent viral remnants and active infections. Collaboration between contact tracing and laboratories is essential for shaping robust public health strategies.

Methods: A retrospective analysis was conducted on 427 individuals with repeat positive PCR tests. Data was collected at a contact tracing centre from March to August 2021. Key variables including age, gender, and biomedical markers (test intervals, CT values) were examined. Regression and correlation techniques assessed CT trends and their implications.

Results: Younger individuals (<60 years) occasionally exhibited significantly lower CT values in subsequent tests, suggesting potential re-infections, while older adults generally displayed higher CT values indicative of residual RNA. These age-specific CT trends were statistically significant and instrumental in refining testing protocols and isolation guidelines. Further analysis is expected to strengthen these findings

Conclusions: Collaborative approaches between contact tracing and laboratories are vital in shaping robust public health strategies for distinguishing between types of repeat infections. Revision of health policies is imperative to prevent unnecessary isolation and optimise healthcare workforce allocation during ongoing transmission periods.

Key messages:

- Decisive decision-making skills are crucial in managing repeat SARS-CoV-2 infections.
- Revised health policies align testing and isolation practices with empirical CT data, enhancing public health efficacy.

Abstract citation ID: ckae144.2154
Rapid increase of multi-drug resistant Pseudomonas aeruginosa in Greece - WHONET-Greece (2020-2023)

Michalis Polemis

M Polemis[1], *E Theofili*[1], *K Tryfinopoulou*[2]
[1]WHONET - Greece AMR Surveillance Network, Central Public Health Laboratory, National Public Health Organisation, Vari, Greece
[2]University General Hospital of Heraklion PaGNI, Crete, Greece
Contact: m.polemis@eody.gov.gr

Background: Multidrug-resistant (MDR) Pseudomonas aeruginosa has been documented as a significant threat associated with adverse patient outcomes. We aimed to describe the rapid increase in the prevalence of an MDR P.aeruginosa phenotype at the national level, as detected through the Greek Electronic System for the Surveillance of Antimicrobial Resistance (WHONET-Greece).

Methods: Routine susceptibility data of 22,236 P.aeruginosa isolates of hospitalized patients in forty-five hospitals, isolated over the past four years (2020-2023) were analyzed using 'Resistance profiles' analysis of WHONET software(ver.2023), considering five antimicrobial groups/agents.

Results: We confirmed the rapid increase in the prevalence of a carbapenem-resistant P.aeruginosa (CRPA) phenotype resistant to all five antimicrobial groups/agents tested (carbapenems, piperacillin-tazobactam, cephalosporins, fluoroquinolones and aminoglycosides). The prevalence increased by 63.8% in 2023 (from 15.2% to 24.9%, 1.64-fold increase), whereas in the last 24 months of the study period a 2.13-fold increase was observed (from 11.7% to 24.9%). In parallel, the prevalence of all other CRPA profiles decreased in 2023 from 22.5% to 17%. We also examined the prevalence of this MDR phenotype in the different NUTS-1 regions of the country, which revealed that the rapid increase is mainly observed in Attika (EL3, 19/45 hospitals) and Central Greece (EL6, 8/45 hospitals) where prevalence reached 25.4% and 26.2% in the second half of 2023 respectively. Northern Greece (EL5, 15/45 hospitals) showed a steady increase over the four years (12% to 19.3%), while in the Aegean Islands/Crete region (EL4, 3/45 hospitals) the prevalence levels were stable.

Conclusions: There is an emerging multi-drug CRPA phenotype in Greece. Only with systematic, nationwide surveillance could we identify and verify such threats. The findings of this study should be used for targeted interventions and further analysis through molecular techniques.

Key messages:

- The early detection of such emerging multi-drug CRPA phenotype in Greece allows for for targeted interventions and further analysis through molecular techniques.
- Systematic surveillance of antimicrobial resistance based on routine susceptibility data is a great way to identify and verify emerging public health threats.

DV. Poster display: Public health policy and politics

Passing the hot potato: a multinational study on public trust in the health policy process

Federica Zavattaro

F Zavattaro[1,2], *F Gille*[1,2], *V von Wyl*[2]
[1]Digital Society Initiative, University of Zurich, Zurich, Switzerland
[2]Institute for Implementation Science in Health, University of Zurich, Zurich, Switzerland
Contact: federica.zavattaro@uzh.ch

Background: Health data-sharing initiatives are central to European and national e-health strategies, aiming to improve healthcare quality, inform policymaking, and drive research. Public trust is crucial for their success, influencing public participation and policymakers' legitimacy. This study investigates the role of public trust in the health policy process at both the European level and in Italy, France, and Switzerland to determine 1) if a common conceptual understanding of public trust across different countries and policy stages exists, and 2) if policymakers explicitly discuss and implement trust-building measures in their legislative work

Methods: A total of 60 interviews were conducted with 16 European, 15 Italian, 14 French, and 15 Swiss policymakers from the World Health Organization, the Council, Parliament, and Commission at the European level, along with representatives from the Ministry of Health, Parliament, regional councils, local health authorities, frontline staff, and relevant agencies at the national levels

Results: Preliminary results reveal that a common definition of public trust in health data sharing is missing. Associations to public trust are observed at the European level with citizens' reassurance about their sensitive data being shared, and in Switzerland with data security. In France, public trust is connected to public engagement, while no distinct patterns were identified in Italy. Findings also reveal a consensus among interviewees on the central role public trust plays in health data-sharing initiatives; yet public trust is perceived as a vague concept, often addressed implicitly without a clear strategy

Conclusions: The study reveals widespread ambiguity among policymakers regarding the definition of public trust and its translation into policy. Practical guidance is crucial to effectively integrate elements of public trust into policymaking, thereby actively reinforcing trust in health data sharing through legislative efforts

Key messages:

- While policymakers recognize the importance of public trust for data-driven health initiatives, they lack a common conceptual understanding on what trust is and how to build it.
- Guidance is needed to help policymakers actively contributing building trust in health data sharing through their legislative work.

Abstract citation ID: ckae144.2156
What characterizes the eldercare debut? A registry-based study of pre-entry health care use

Pernilla Alencar Siljehag

P Alencar Siljehag[1,2], *Å von Berens*[1,2], *B Meinow*[1,2], *C Lennartsson*[2,3], *J Agerholm*[2]
[1]Stockholm Gerontology Research Center, Stockholm, Sweden
[2]Aging Research Center, Karolinska Institutet and Stockholm University, Stockholm, Sweden
[3]Swedish Institute for Social Research, Stockholm University, Stockholm, Sweden
Contact: Pernilla.AlencarSiljehag@aldrecentrum.se

Introduction: Timely identification of needs due to functional loss in old age is important. Policy guidelines requires local collaborative care action. Eldercare debut circumstances are poorly investigated from a collaborative perspective. This study explored the socio-demographic characteristics, functional status and patterns of health care use leading up to the first application for eldercare, and how older people's intensity of primary care use was associated with their intensity of granted eldercare at debut.

Methods: Data on socio-demographics, functional status, and informal care in people $\geq$65 years (July '21 to June '22; $n = 3{,}649$) were combined with data on inpatient and outpatient care six months preceding debut in Stockholm, Sweden. Descriptive and regression statistics were used.

Results: Every second person debuted following a hospital stay and one in four had extensive functional limitations. The majority made one or two visits in primary care, but 13% had a high intensity of use and 20% made no visits at all. More than half received informal care weekly or daily. Non-use and high use of primary care were both significantly associated with increased probability of receiving high intensity of eldercare.

Conclusions and implications: The intensity of primary care use can provide an indication of people's intensity of eldercare at debut, which is important for resource allocation. Deeper collaboration between eldercare and primary care actors can facilitate early identification of people in need of support, thereby alleviating individual suffering, enabling secondary and tertiary prevention, and optimizing the management of welfare resources.

Key messages:

- The intensity of primary care use can provide an indication of people's intensity of eldercare at debut.
- Deeper collaboration between eldercare and primary care actors can facilitate early identification of older people with social support needs.

Abstract citation ID: ckae144.2157
Assessing contextual factors influencing scale-up: a interactive approach involving stakeholders

Carlotta Carboni

C Carboni[1]*, Y Lambert*[1]*, L Plessis*[1]*, T Bardon*[1]*, S Vreden*[2]*, M Suarez-Mutis*[3]*, A Sanna*[1]*, M Douine*[1]
[1]CIC Inserm 1424, Cayenne Hospital, Cayenne, France
[2]SWOS Foundation, Paramaribo, Suriname
[3]Laboratory of Parasitic Diseases, Oswaldo Cruz Institute, Rio de Janeiro, Brazil
Contact: dr.carbonicarlotta@gmail.com

Issue: Pilot interventions are not always put into practice at scale. When they are, effectiveness is often highly reduced in the field due to contextual factors. To effectively implement a scale-up, stakeholders' involvement is crucial. Curema is an international research evaluating an intervention aiming to reduce malaria transmission by distributing RDTs and treatments in mobile hard-to-reach populations. This intervention might be scaled-up in Brazil, Suriname, and French Guiana as a tool of national malaria programs for specific areas and populations.

Description of the problem: An interactive pre-planning assessment was conducted involving key stakeholders -implementers, decision-makers, and researchers - in working sessions, semi-structured interviews, and formal meetings. Mendelow's Power/Interest Matrix was used to map stakeholders and a SWOT analysis was conducted using ExpandNet/WHO Framework to evaluate contextual factors and identify levers and obstacles influencing the scale-up.

Results: A total of 23 participants were involved. Health authorities had high power and generally high interest, while implementers and recipients had lower power and different interest levels. National engagement for WHO E2025 or E2030 enhanced scalability and represented a main opportunity in the three countries. Nevertheless, several regulatory and administrative aspects were identified as potential obstacles to be addressed to make scale-up realistic. Funding was also a major concern for sustainability. The need for regional cooperation was emphasized to achieve malaria elimination.

Lessons: Despite financial and regulatory challenges, a window of opportunity is open to scale-up Curema. Identifying and involving stakeholders in a pre-planning assessment and advocating for foster regional cooperation are crucial steps to support the scale-up. Stakeholder analysis should be refined during the scaling-up to capture further changes in factors that might influence the process.

Key messages:

- Engagements with WHO represent windows of opportunity to enhance Curema scale-up.
- Stakeholder involvement and regional cooperation are crucial for scaling up Curema in Brazil, French Guiana and Suriname.

Abstract citation ID: ckae144.2158
Reception of health data using the Australian Burden of Disease study as an example

Aline Anton

A Anton[1]*, M Gourley*[2]*, L Kirkland*[3]*, AM Chapman*[3]
[1]Department of Epidemiology, Health Reporting Unit, Robert Koch Institute, Berlin, Germany
[2]Burden of Disease and Mortality Unit, Australian Institute of Health and Welfare, Canberra, Australia
[3]Epidemiology Directorate, Department of Health, WA, Perth, Australia
Contact: antona@rki.de

Background: Health data, especially on Burden of Disease (BoD), are vital for evidence-based health promotion and effective dissemination is crucial due to resource intensiveness. Germany's national BoD study is currently transitioning to permanence. Analysing the Australian Institute of Health and Welfare's (AIHW) well-established collaboration with stakeholders and their reception of health data at national and regional level offers insights for improved knowledge translation.

Methods: To follow the path of stakeholder engagement, this 3-month project involved scientific exchanges with the AIHW and Department of Health, Western Australia. It compiled communication strategy examples and documents stating examples of BoD data use. A quantitative online survey accompanied by a series of 18 qualitative 45-minute interviews was conducted. The survey implemented via Swift Digital has been running for 20+ days. Interview partners originated from the fields of health research, politics, planning and advocacy for patients or population groups. Results were analysed, illustrated digitally as a booklet and refined in a participatory workshop.

Results: Communication strategies such as embargoed press and stakeholder releases as well as regular online formats were identified. The survey and interviews displayed the required technical and content-detail level from key facts to raw data and visualisation needs. Noteworthy are the demand to link data to economic aspects like disease expenditure, trends and future scenarios. It elucidated how diverse target groups utilize data to place disease significance and preventive public health measures, aiding dissemination. Alongside, it shows examples of knowledge translation by emphasizing impact over indicators when targeting communities.

Conclusions: Prioritizing target group identification and employing tailored communication strategies regarding data format and detail level are essential when utilizing new data.

Key messages:

- Analyzing a well-established collaboration with stakeholders offers insights for improved knowledge translation and reveals leveraging engagement strategies for others.
- Understanding stakeholder needs is essential for promoting broader health data use in policy and practice, fostering evidence-based decision-making, and enhancing public health outcomes.

Emergency department frequent users in the paediatric population: a retrospective analysis in Rome

Giuseppe Furia

A Vinci[3,2]*, A Barbara*[2]*, P Chierchini*[2]*, M Maurici*[6]*, G Damiani*[4,5]*, C De Vito*[1]
[1]Department of Public Health, Sapienza University of Rome, Rome, Italy
[2]Borgo Santo Spirito, Local Health Authority Roma 1, Rome, Italy
[3]Department of Biomedicine and Prevention, University of Rome, Rome, Italy
[4]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[5]Department of Woman and Child Health, Università Cattolica del Sacro Cuore, Rome, Italy
[6]Department of Biomedicine and Prevention, University of Rome, Rome, Italy
Contact: giuseppe.furia@uniroma1.it

Background: Recent studies have reported the increasing utilisation of the Emergency Departments (EDs) for non-urgent attendances by people aged <18 years. The aim of this study is to describe the characteristic of the paediatric frequent user (FU) population, highlighting the differences between FUs and non-FUs, and to identify factors linked to appropriate ED attendance, comparing the level of variability attributed to the geographical and family physician components.

Methods: A retrospective cohort study was carried out of the ED attendances in 2022 in the 8 EDs of the Local Health Authority Roma 1 geographical area, in Rome. The cohort was enrolled from the regional Healthcare Emergency Information System. Records included information on number of attendance, age and gender, usage of emergency medical service (EMS), triage code, appropriateness of attendance. Multivariable nested logistic regression was performed to identify the characteristics of FU and non-FU attendances and the predictors for appropriateness of attendances.

Results: In 2022, the total number of children with at least 1 ED attendance is 24.824 and a total of 35.691 attendances were recorded. The regression analysis highlights that the appropriateness of attendances is associated to the female gender (OR male: 0.84), age <1 year (OR: 2.06), the usage of EMS (OR: 2.00), high triage code and being a FU (OR FU: 1.53). The family physician group have a greater influence of District group but lower influence of single patient characteristics group to determine the appropriateness of paediatric ED attendances (MOR District: 1.73; MOR PCP: 1.84; MOR single patient characteristics: 2.75).

Conclusions: Frequent use of the ED is partially associated with an inappropriate use of EDs, mostly due to the specific patients' characteristics. It is therefore necessary to adopt strategies to improve the appropriate use of health service resources in order to provide quality health solutions to real health needs.

Key messages:

- This is the first study that defines an ED paediatric FU profile in Italy.
- It compares the level of variability attributed to the geographical component and family physician components.

Abstract citation ID: ckae144.2160
Boosting influenza vaccination rates through policy gamification: the 'Let's Control Flu' project

Henrique Lopes

H Lopes[1], *C Hermenegildo*[1], *D Franco*[1]
[1]Center for Global Health, NOVA-IMS, NOVA University, Lisbon, Portugal
Contact: hlopes@novaims.unl.pt

Background: Influenza remains a public health challenge globally, leading to substantial morbidity and mortality, particularly among vulnerable groups. Despite the benefits of vaccination, achieving the desired vaccination coverage rates (VCR) proves challenging across Europe. The 'Let's Control Flu' (LCF) tool emerges as a new contribution, merging gamification with epidemiological data and public health policies to help increase influenza VCR.

Methods: The LCF tool, developed from an extensive literature review and validated by a National Advisory Board, initially showcased its capabilities in Sweden. Offering an interactive simulation, it allows stakeholders to explore the outcomes of implementing 13 targeted public health policies (PHP) on influenza VCR and health outcomes such as infection rates, hospitalizations, and mortality. This approach simplifies epidemiological complexities, paving the way for informed decision-making.

Results: Following its success in Sweden, the LCF tool was extended to Germany and Czechia, underlining the value of gamified tools in public health decision-making. The application across these new countries not only resulted in paths to improve VCR but also provided insights into the tool's scalability and adaptability different landscapes.

Conclusions: The LCF project underscores the efficacy of integrating gamification into health policy decision-making, offering a replicable model for enhancing influenza vaccination uptake across Europe. With the tool now successfully applied in multiple countries, its potential for broader European and global application is evident. This initiative aligns with WHO's objectives, spotlighting gamification as a relevant component in improving vaccination strategies and readiness for influenza and other preventable diseases, thereby reinforcing the importance of innovative approaches in public health policy development.

Key messages:

- The LCF tool integrates gamification with public health strategies to help effectively raise influenza vaccination coverage.
- By merging gamification and epidemiological insights, the LCF tool also serves as a scalable model for Europe, supporting WHO's goals to improve vaccine strategies and preparedness.

Abstract citation ID: ckae144.2161
What's pension got to do with it? Mortality inequality at older ages

Johan Fritzell

J Fritzell[1], *M Forslund*[2], *O Östergren*[1,3]
[1]Aging Research Center, Karolinska Institutet and Stockholm University, Stockholm, Sweden
[2]Public Health Agency of Sweden, Stockholm, Sweden
[3]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
Contact: Johan.Fritzell@ki.se

Background: The potential role of social protection systems and welfare states for population health and mortality has attracted increased interest in recent decades but mostly focused on overall characteristics or clusters of countries. Moreover, often neglecting older people even though the great majority of all deaths in high-income countries occur at later ages. We focus on the key social protection scheme for old adults: the generosity of the level of pensions. We compare pensions based on previous work history to basic minimum pensions. Our study is novel both by linking pension system to remaining life expectancy at age 65(LE65+), but also by studying the association to variation in LE65+, since that gives a measure of inequality. We do so across countries and over time.

Methods and Materials: Our sources of data are from the Human Mortality Database and the Social Policy Indicator Database. Data for OECD countries are matched over a long period of time and analysed by pooled time-series regression analyses with fixed effects.

Results: Although the results indicate that the generosity of pensions based on both pervious work history and basic minimum income our results primarily show the importance of basic minimum income. Here the effect sizes are larger and especially for women than for men (0.149*** vs. 0,.0715***). Concerning the variation in LE (65+) we find that more generous basic pensions are associated with reduced variation for women -4.64e-05**.

Conclusions: We provide new insights in how pension policies potentially influence mortality among older persons especially by extending our analyses also to inequality in mortality. Our results points to the importance of basic pensions. The gendered division of labour is a plausible explanation for the findings and to have an adequate pension for all should be of primary concern for public health.

Key messages:

- Adequate basic pension for all of importance for remaining life expectancy among older people.
- Adequate basic pension for all of importance for reducing mortality inequality among women.

Abstract citation ID: ckae144.2162
Setting targets for antibiotic use in general practice in Europe: a scoping review

Nathaly Garzon-Orjuela

N Garzon-Orjuela[1], *K Roche*[2], *V Vornhagen*[3], *A Moran*[1], *S Walkin*[4], *W Cullen*[5], *C Blake*[1], *A Vellinga*[1]
[1]School of Public Health, Physiotherapy and Sports Science, University College Dublin, Dublin, Ireland
[2]School of Psychology, University of Galway, Galway, Ireland
[3]Insight Centre for Data Analytics, University of Galway, Galway, Ireland
[4]Irish College of General Practitioners, Dublin, Ireland
[5]School of Medicine, University College Dublin, Dublin, Ireland
Contact: nathaly.garzonorjuela@ucdconnect.ie

Background: National Action Plans (NAPs) aim to address antimicrobial resistance (AMR) understanding and awareness but struggle to translate targets into clinically relevant guidance for general practice. This scoping review aims to identify and map antibiotic use targets in European general practice and explore if and how these targets are linked to NAPs.

Methods: A systematic search strategy was carried out in MEDLINE (OVID), EMBASE and SCOPUS, with additional manual searches. Two research questions were addressed: 'What are existing targets for antibiotic use in general practice in the 31 European countries?' and 'How are these targets linked to the NAPs on AMR?'. The results are presented narratively.

Results: 77 reports were included, of which 33 focused on national targets and general practice or linking national targets to local areas. Reports describe local strategies or initiatives to achieve targets, such as feedback to prescribers, systems with benchmarks (at local, regional, and national levels) and financial incentives. However, these reports provide aggregated targets for general practice, such as a percentage reduction of antibiotics prescribed. These targets are set in general, for a specific type of antibiotic, for an amount per number of patients, in defined daily doses (DDD) or in items. None of the reports translate national targets into clinically relevant or practical targets for general practitioners (GPs).

Conclusions: Most European countries have a NAP with national targets. The type of targets and their implementation at the national and local level vary between countries. Translating national targets into daily clinical practice is challenging and often lacks the involvement and input of prescribers (GPs).

Key messages:

- Translating targets into daily clinical practice is challenging and often lacks the involvement and input of prescribers (GPs).
- Local strategies, feedback to prescribers, benchmark systems (local, regional, national), and financial incentives drive successful target achievement.

Abstract citation ID: ckae144.2163
Mapping the Public Health and Health Promotion Capacity in Oman

Stephan Van den Broucke

H Al Riyami[1,2]
[1]Département de Psychologie, Université Catholique de Louvain, Louvain-la-Neuve, Belgium
[2]Health Promotion Unit, Ministry of Health, Muscat, Oman
Contact: stephan.vandenbroucke@uclouvain.be

Background: An essential condition to enabling people to increase control over their health is to have sufficient capacity for public health (PH) and health promotion (HP). Despite the recognition of its importance, a comprehensive view of the PH and HP capacity in the sultanate of Oman is not yet available. This study provides a mapping of the country's PH and HP capacity at national, governorate and district levels.

Methods: An online quantitative survey was performed amongst 70 health policy maker and experts in PH and HP using a questionnaire based on the PH capacity framework of Aluttis et al., yielding data on the country specific context with relevance for PH and 6 PH capacity domains, each divided in subdomains: leadership and governance; organizational structures, workforce, financial resources, partnerships, and knowledge development. Internal consistencies of the scales measuring the capacity subdomains ranged from .75 to .99.

Results: The survey revealed relatively low scores, representing partial development of capacities, for most of the public health capacity domains. The highest levels of capacity were observed for knowledge development (health information and monitoring systems, reporting systems and knowledge infrastructure), organizational structures (institutional capacity, program delivery structures, PH within health services, and response emergencies) and partnerships (formal consortia, informal partnerships and multisectoral coordination). In contrast, leadership and governance, workforce development, and financial resources score lower.

Conclusions: Mapping the strengths and weaknesses of PH and HP capacity in Oman allows to make recommendations for improving population health. Whereas all domains of PH and HP capacity are partially developed, there is a need to further improve capacity in all domains.

Key messages:

- PH and HP capacities are partially developed in Oman.
- Mapping the PH and HP capacity allows to identify strengths and weaknesses and make recommendations for improving public health.

Study on access to social protection policies by homeless people during the COVID-19 pandemic

Wanessa Debôrtoli Miranda

A Andrade de Souza[1,2]*, AL Jorge Martins*[2]*, G Drummond Marques da Silva*[2]*, AC de Moraes Teixeira Vilela Dantas*[2]*, R Alves Marinho*[2]*, L da Matta Machado Fernandes*[2]*, H Miranda Magalhães Júnior*[2]*, W Debortoli*[2]*, R Paes-Sousa*[2]
[1]ENUT/DENCS, Universidade Federal de Ouro Preto, Ouro Preto, Brazil
[2]GPPSPS, Institute René Rachou, Fiocruz Minas, Belo Horizonte, Brazil
Contact: wanessamiranda@ufmg.br

The study analyzed the access of homeless people (HP) to health and social protection policies, including emergency measures, during the COVID-19 pandemic in Belo Horizonte (BH), capital of the state of Minas Gerais, Brazil. Its main objective was to provide data on the profile of HP in the municipality, in addition to evaluating existing public policies focused on HP, based on the time frame of the health emergency. Study with mixed methods design with triangulation of quantitative and qualitative data. It used official databases in parallel with document analysis, interviews and focus groups. As a result, the cartography showed that in the first months of the pandemic the municipality had difficulty reorganizing the health system, which underwent constant protocol updates, consolidating, however, over the months. Important emergency interventions in the municipality of BH involved activities that facilitated HP's access to the provision of services, including intersectorality between health services, social assistance and the third sector. The temporary offer of various intersectoral services, simultaneously with the offer of daytime shelters by organized civil society, was considered a key factor for the expansion and intensification of care networks for HP during the emergency phase. Itinerant services were among those with the greatest positive evidence of service to HP, with emphasis on the 'Consultório na Rua'. The study concluded that understanding the profile of homeless people in BH and the intersectoral variables that impact HP contributes to better directing investments in interventions for these individuals and increasing the effectiveness of health and social protection systems, in line with with the work carried out by the third sector.

Key messages:

- Understanding the inter-sector variables that impact Homeless People contributes to better targeting of investments in interventions in protection social.
- Knowing the profile of the homeless population makes it possible to organize more effective health care and social assistance.

Background: Achieving the SDG Sustainable Development goals represents a major global challenge. The Community of Portuguese Speaking Countries (CPLP) is made up of countries: Angola, Cape Verde, Guinea-Bissau, Equatorial Guinea, Mozambique, São Tomé and Príncipe, Brazil, Portugal, and East Timor. Studies on SDG indicators are little studied among these countries. The study analyzes SDG health indicators in the Community of Portuguese Speaking Countries (CPLP) and their projections for 2030, and investigates the correlation between the countries' level of development and the performance of these indicators.

Methods: Ecological epidemiological study. Estimates from the Global Burden of Disease (GBD) study between 1990 and 2021 were analyzed, referring to fifteen indicators: universal health coverage, sanitation, smoking, maternal and child health, vaccination coverage and communicable diseases. The GBD study generated projections by calculating the annual change since 1990 for each country and year and then calculating the weighted annualized rate of change. The correlation between the Sociodemographic Index (SDI) and the SDG indicators was investigated using the Spearman test, at a significance level of 5%.

Results: The best performances of the analyzed indicators were seen for Portugal, followed by Brazil, Cape Verde and São Tomé and Príncipe. In other countries, high rates of infectious diseases, maternal and childhood mortality, malnutrition, low vaccination coverage and sanitation were observed. There was a negative correlation between the SDI and the indicators of childhood mortality rate ($R=-0.82$; $p<0.05$), malnutrition ($R=-0.7$; $p<0.05$), incidence of tuberculosis ($R=-0.73$; $p<0.05$) and positive between SDI and sewage coverage ($R=-0.83$; $p<0.05$).

Conclusions: The CPLP presents internal differences regarding the health indicators analyzed, making it essential to advance cooperation between countries to achieve the SDG targets in 2030.

Key messages:

- There are great inequalities between SDG indicators in Portuguese-speaking countries.
- It is important to advance technical cooperation between countries to formulate solutions and leave no one behind.

Maximising the potential of National Cancer Mission Hub-like structures: A SWOT analysis approach

Jinane Ghattas

J Ghattas[1,2], M Delnord[1], L Abboud[1], ECHoS WP 2.3 KEP participants[1]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Institut de Recherches en Sciences Sociales, UCLouvain, Brussels, Belgium
Contact: jinane.ghattas@sciensano.be

Cancer is a significant and urgent concern in public health, particularly in the context of an aging population like in Europe. It is estimated that new cancer cases will increase by 21% by 2040 in Europe. With the ambition of improving the lives of 3 million people by 2030, the European Commission launched 2 major initiatives: Europe's Beating Cancer Plan (EBCP) and the Mission on Cancer (MoC). The EBCP is a policy-driven initiative aimed at supporting Member States in addressing the whole cancer continuum. It is supported by the MoC, a research driven initiative. Member States are implementing the EBCP and MoC in a way that fits their national contexts. This can take different forms, such as 'cancer hub,' 'mirror group,' or other similar structures. The role of these entities can vary, ranging from purely coordinating activities to involving more technical work. We performed a SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis with different national mission-hub-like (NCMH-like) structures to explore their strategic positioning. We collected results from 6 countries (Belgium, Italy, the Netherlands, Portugal, Poland, and Sweden) as part of the EU project ECHoS on setting NCMHs. Participants perceived that formal government endorsement, existing stakeholder mapping, and good stakeholder engagement as strengths for the structure. Whilst, they identified overlap with other ongoing initiatives and low stakeholder engagement as weaknesses that need to be addressed, the future of existing structures could be threatened by financial and human resources as well changing political landscape. National, regional alignment and the leverage of EU funding were recurrent opportunities to build on. Ultimately, NCMH-like structures can be leveraged to achieve national and European alignment on cancer initiatives, if they succeed in building a sustainable financial and governance structure.

Key messages:

- National Cancer Mission Hub-like structures can build on existing initiatives to support the implementation of EU cancer initiatives if they achieve sustainable financial and governance structures.
- SWOT framework is a good tool for a comprehensive overview of the strategic positioning of National Cancer Mission Hub-like structures in different European countries.

Background: The burden of disease (BoD) methodology is a valuable tool for evidence-based policymaking. However, there is currently no systematic analysis available regarding its use in the European Union (EU) legislation framework. This study aims to describe the implementation of BoD methodology in EU legislation.

Methods: A search was conducted on EUR-Lex, the official and most comprehensive platform to access EU legal documents. The main inclusion criteria in the analyses were date of publication (between 2004 and 2023, accounting for EU-25) and inclusion of BoD metrics (years of life lost - YLL, years lived with disability - YLD or disability-adjusted life years - DALY). Descriptive and network analysis were conducted to analyse the legislation content.

Results: Out of 2592 documents, 191 met the set criteria. Ten were legally binding, and 69% were published after 2018. The European Commission (n = 152) was the most regular issuing institution. BoD was mainly used as an argument (n = 93) and for impact assessment (n = 50). The metrics were commonly presented in the main text (n = 122) and in the annex (n = 48). EuroVoc domains like environment and social questions prevailed. The most frequent EuroVoc terms were climate change policy (n = 45), EU environmental policy (n = 32) and pollution control measures (n = 32).

Discussion: Despite the growing recognition of BoD metrics in supporting policymaking, only 191 documents published over the past 20 years within the EU legislation make reference to this methodology. Greater efforts in knowledge dissemination and directing research towards specific policy uptake may increase the application of BoD studies in EU policies. By advocating for increased awareness, promoting collaboration between researchers and policymakers, and targeting research efforts towards specific policy needs, a more comprehensive integration of BoD methodologies into EU legislation can be achieved, contributing for evidence-informed policies.

Key messages:

- There were only 191 documents of the EU legislative documents published in the past 20 years mention burden of disease metrics, mainly addressing environmental and social issues.
- There is a need to increase EU policy uptake from BoD studies, by conducting policy-oriented research, and building capacity among researchers and policymakers on BoD methodology.

A comparative analysis of national dementia plans: preventive strategies in five European countries

Anna Odone

L Blandi[1,2], *T Clemens*[2], *H Brand*[2], *A Odone*[1]
[1]Department of Public Health, Università di Pavia, Pavia, Italy
[2]Department of International Health, Maastricht University, Maastricht, Netherlands
Contact: anna.odone@mail.harvard.edu

Background: About 8.5% of people aged +65 live with dementia in Europe. Preventive measures can avert up to 40% of cases. The aim of the study is to analyse National Dementia Plans (NDP) in Europe, to elicit how much dementia prevention is considered a priority and whether policies are evidence-based.

Methods: A qualitative comparative analysis was performed between NDPs of countries with the best healthy life expectancy in the elderly in Europe. The NDPs of France, Ireland, Italy, Spain, and Sweden were included. The consensus on actions and elements of prevention policies was evaluated, according to the WHO recommendations and to Cheung's framework designed for evaluating chronic diseases policies.

Results: All the NDPs prioritised early diagnosis, public awareness, and community engagement for dementia risk reduction. They fostered the development of information system for data collection and established committees for progress monitoring. However, not all NDPs defined timelines for policy implementation and most of them expired years ago. NDPs included prevention research agenda, but their preventive actions did not address alcohol consumption, traumatic brain injury, and air pollution, representing 3 well-known risk factors attributable for the 15% of preventable cases. Neither integration of dementia with other chronic disease preventive strategies was present and a clear allocation of funds for NDPs always missed.

Conclusions: NDPs partially address risk factors of preventable cases. All countries need to update their NDPs, integrating new scientific evidence and allocating clear financial funds. This can potentially prevent millions of new cases, decreasing the burden of disease and improving the sustainability of health systems.

Key messages:

- NDPs do not target adequately dementia in Europe.
- New evidence-based preventive policies, including most recent identified risk factors, would have a clear impact on burden of disease and health systems' sustainability.

Abstract citation ID: ckae144.2169
Exploring UK adult and policy stakeholder perspectives on obesity prevention policy and inequalities

Olivia Brown

O Brown[1,2], *T Langley*[1,2], *R Murray*[1,2], *I Bogdanovica*[1,2], *M Bains*[1]
[1]Population and Lifespan Sciences, University of Nottingham, Nottingham, UK
[2]Spectrum Consortium, Spectrum Consortium, Edinburgh, UK
Contact: Olivia.brown1@nottingham.ac.uk

In England, 14 obesity strategies have been published, including 689 proposed policies, while rates of obesity persist, and inequalities worsen. This study explores adults' attitudes in relation to food-related obesity policy and how socioeconomic inequalities in obesity are considered throughout the policy process through the perspective of policy stakeholders (PSH). 31 semi-structured interviews with UK-based adults (GPP) (18+) and 14 interviews with PSH categorised as government officials, academics, and advocacy group representatives were conducted and analysed using Braun and Clarke's thematic analysis. Both PSH and GPP attributed obesity causation primarily to the food environment rather than to individual behaviour. The PSH identified the food industry's role in shaping the environment. Level of deprivation was believed to exacerbate the barriers to healthy weight in both samples. All participants agreed that, in the UK, there was an unequal opportunity to attain a healthy diet. A disconnect was found between the GPP perspectives towards the barriers to healthy weight and their attitudes towards policy action. The GPP described mistrust in the government's motives and willingness, fuelling the perspective that policy lacked impact and was disconnected from their lived experiences, particularly among participants of lower socioeconomic status and higher weight classifications. The PSH raised concerns regarding barriers to policy implementation, including inconsistent government commitment, competing priorities, and resistance to state intervention. PSH suggested that it was unfeasible to prioritise inequalities while population rates remain high, and the failure of implement proposed policies continue. This study shows the necessity of incorporating a health equity lens, breaking down policy silos, and amplifying community voices in the policy process to challenge assumptions regarding lived experiences and ensure healthier equitable policy outcomes.

Key messages:

- The study shows the importance of integrating a health equity lens, breaking policy silos, and amplifying community voices to challenge assumptions and achieve more equitable policy outcomes.
- Obesity policy requires greater consideration to inequalities to strengthen policy impact as demonstrated by all participants recalling the unequal opportunity to sustain a healthy weight in the UK.

Proficiency in Personalized Medicine and Health Data Sharing in the EU

Francesco Andrea Causio

FA Causio[1], F Beccia[1], Ll Kreeftenberg[2], GE Calabrò[1], R Pastorino[1], C van El[2], S Boccia[1]
[1]Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Section Community Genetics, Amsterdam UMC, Location Vrije Universiteit, Amsterdam, Netherlands
Contact: francescoandrea.causio@unicatt.it

Personalized medicine, leveraging genetic, environmental, and lifestyle data, has already transformed healthcare by tailoring prevention, diagnosis, and treatment to individual patients. The successful development and implementation of personalized approaches rely on the public's proficiency and awareness of personalized medicine, enabling access to innovative techniques and fostering a willingness to share health-related data. We distributed a survey to 6,581 respondents from 8 EU countries: France, Germany, the Netherlands, Italy, Spain, Poland, Hungary, and Romania. 52.5% of respondents were female ($n = 3{,}458$), with a mean age of 48.5 years (range 18-89 years, median $= 49$ years, $SD = 15.96$), and 37.91% of the participants reported achieving tertiary education. Our survey investigates the general public's knowledge of personalized medicine, support for genetic testing, and willingness to share health data among EU citizens while assessing their perception and acceptance of these medical paradigms. Knowledge levels vary among different EU countries. Only 12.11% of respondents had a high knowledge of the topics presented in this survey. Support for implementing genetic testing in healthcare was high, with 81.52% supporting the implementation of genetic testing in their healthcare systems, and nuanced differences in acceptance were observed based on testing purposes. 52.35% reported willingness to share health data. Both support for implementing genetic testing and the willingness to share health data correlated positively with knowledge and education levels. Geographical differences within the EU highlighted variations in attitudes toward personalized medicine and data sharing, with respondents from Southern Europe displaying higher odds than their peers in Central and Eastern Europe. The results emphasize the need for targeted communication and education strategies to enhance public understanding and trust in personalized medicine and health data sharing.

Key messages:

- High support for genetic testing across the EU highlights the need for enhanced public education on personalized medicine to boost understanding and data sharing willingness.
- Geographical differences in attitudes toward personalized medicine in the EU suggest targeted strategies to build trust and knowledge, particularly in Central Europe.

Abstract citation ID: ckae144.2171
Outcomes of integrated knowledge translation: A comparative, multi-country case study

Kerstin Sell

K Sell[1,2], EA Rehfuess[1,2], J Osuret[3], LM Pfadenhauer[1,2]
[1]Chair of Public Health, IBE, LMU Munich, Munich, Germany
[2]Pettenkofer School of Public Health, Munich, Germany
[3]School of Public Health, Makerere University, Kampala, Uganda
Contact: sell.kerstin@t-online.de

Background: Integrated knowledge translation (IKT) seeks to establish continuous relationships between researchers and knowledge users, in particular decision-makers, to enhance evidence-informed decision-making in public health and healthcare. IKT is, however, difficult to evaluate and outcome evaluations remain scarce. The German-African Collaboration for Evidence-based Healthcare and Public Health in Africa (CEBHA+) undertook research on IKT and non-communicable diseases in Ethiopia, Malawi, Rwanda, South Africa, and Uganda. Over six years, we implemented an IKT approach and evaluated it according to a pre-defined programme theory.

Methods: We conducted qualitative interviews and surveys with CEBHA+ researchers and their decision-making partners at two stages (3/2020-2/2021; 9/2022-5/2023) and collected IKT-related documents (see protocol: https://rdcu.be/dyfBP). Transcripts and documents were analysed using qualitative content analysis and surveys were analysed descriptively, with subsequent integration, cross-case analysis, and revision of the programme theory.

Results: We collected 92 IKT-related documents; and 55 researchers and decision-makers participated in surveys, focus groups or interviews. Proximal outcomes were collaborative research; capacity-building related to research skills and evidence use; and relationship-building, establishing trust and partnerships. Intermediate outcomes were changes in attitudes and knowledge; decision-makers became attuned to research and researchers increased their understanding of the decision-making context, and developed a vision for research impact. Distal outcomes were the production of applicable research and the consideration of evidence by decision-makers. High opportunity costs associated with IKT implementation constituted unintended effects.

Conclusions: Our study presents rich, theory-informed insights into IKT outcomes, based in particular on the experience of researchers implementing the CEBHA+ IKT approach.

Key messages:

- A multi-country research collaboration offered an opportunity to examine IKT implementation and investigate proximal, intermediate, and distal IKT outcomes based on a pre-defined programme theory.
- Beyond our initial conceptualisation, the IKT approach was linked to researchers developing a vision for 'research impact' and gaining a better understanding of the decision-making context.

Abstract citation ID: ckae144.2172
Mapping the Policy Alternatives for Rare Cancer

Kostadin Kostadinov

K Kostadinov[1], E Hristova-Atanasova[1], N Musurlieva[1], G Iskrov[1], R Stefanov[1]
[1]Social Medicine and Public Health, Medical University of Plovdiv, Plovdiv, Bulgaria
Contact: drkostadinkostadinov@gmail.com

Issue: This policy research addresses the issue of rare cancers in the European Union (EU). Rare cancers have an annual incidence rate of less than 6/100 000 and face challenges in diagnosis, clinical care, and research investment. Survival rates for rare cancers are lower compared to common cancer types, with significant variations among EU Member States.

Description of the problem: Policy frameworks for rare cancers are often fragmented and greatly vary across the EU. This study aims to develop a tool for assessing policy alternatives by reviewing existing national rare cancer policies, conducting interviews with experts, and analysing core stakeholders at the EU level.

Results: The main policy alternatives covered five domains: definition, registration, organisation of care, access to innovative therapies, and funding. Interviews revealed four policy options for each domain. Six core stakeholders were determined: patient organisations, healthcare professionals, researchers, industry, health legislators, and health authorities. A pilot policy assessment tool was developed on this basis.

Lessons: The pilot study coherently explored policy alternatives for rare cancers in the EU. Using these findings, policymakers and researchers can assess the impact of different policy options at a national level and contribute to the development of a unified EU policy framework for rare cancers. The pilot survey was also useful to collect input from the core stakeholders.

Key messages:

- This study identifies key policy domains and feasible alternatives. A pilot preference assessment study based on these options can aid in EU policy development.
- Navigating rare cancer policy complexities demands collaboration and innovation. Engaging stakeholders and exploring alternatives can forge a more effective EU framework for addressing rare cancers.

Abstract citation ID: ckae144.2173

Alcohol-related premature mortality in Northern Dimension partnership countries 2003-2021

Pekka Jousilahti

P Jousilahti[1], *K Harald*[1], *M Vienonen*[1], *T Laatikainen*[1,2]
[1]Public Health and Welfare, THL, Helsinki, Finland
[2]Faculty of Medicine, University of Eastern Finland, Kuopio, Finland
Contact: pekka.jousilahti@thl.fi

Background: Potential Years Life Lost (PYLL) is an established method to measure, follow trends and compare disease burden within and between countries. Northern Dimension Partnership in Health and Social wellbeing (NDPHS) network was established in 2003 and includes the following countries: Estonia, Finland, Germany, Iceland, Latvia, Lithuania, Norway, Poland, Russia, and Sweden. Due to the Russian invasion to Ukraine, Russia is now excluded from the collaboration. Iceland is not included in the analyses due to too small number of events.

Methods: Premature mortality was defined as a death before the age of 70 years. Alcohol-related deaths included the following ICD-codes: E24.4, F10, G31.2, G62.1, G72.1, I42.6, K29.2, K70, K85.2, K86.0, Q86.0, R78.0, X45, X65, Y15, K73, K74.0-K74.2, K74.6, O354, P043 and G4051. PYLL-rates per 100,000 population are presented separately for men and women in four time points: 2003, 2013, 2017 and 2021. Data were obtained from Eurostat and analyses are standardized to EU standard population.

Results: In the whole NDPHS area, alcohol related PYLL-rates declined between 2003 and 2017: from 527 to 458 in men, and from 159 to 134 in women. However, between 2017 and 2021 the rates increased: to 509 in men and to 154 in women. In 2021, the highest alcohol-related PYLL-rates were in Latvia (1696 in men and 530 in women) and the lowest in Norway (94 in men and 43 in women). Thus, the differences between countries in alcohol-related PYLL-rates were 20-fold in meles and 10-fold in females. In all countries the rates were 2-3 times higher in men compared to women.

Conclusions: Alcohol use is an important cause of premature mortality and disease burden in NDPHS area. There are marked differences in alcohol-related PYLL-rates between sexes and countries. The increase in alcohol-related PYLL-rates between 2017 and 2021 may be related to the Covid-pandemic.

Key messages:

- Alcohol use is an important cause of premature mortality and disease burden in NDPHS countries, and there are marked differences in alcohol-related mortality between sexes and countries.
- Reduction of total alcohol consumption is an evidence-based most effective public health measure to reduce alcohol-related health harms.

Abstract citation ID: ckae144.2174

Revisiting the Science-Policy Interface: Lessons from the Swiss Response to the COVID-19 Pandemic

Sophie Meyer

S Meyer[1,2], *A Frahsa*[1]
[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland
[2]Graduate School for Health Sciences, University of Bern, Bern, Switzerland
Contact: sophie.meyer@ispm.unibe.ch

Background: In the wake of the COVID-19 pandemic, Switzerland found itself grappling with unforeseen challenges, particularly in the realm of the science-policy interface. Despite various post-crisis reflections on 'lessons learned', a cohesive and comprehensive assessment of these pivotal interactions has been notably absent. We aim to contribute to closing this gap by mapping interactions at the science-policy interface and critically analyze the interaction between researchers and policymakers during the COVID-19 pandemic in Switzerland.

Methods: Using Critical Discourse Analysis, we examine the socio-political influences on the discourse surrounding science-policy interaction. Our dataset includes tweets from Swiss National COVID-19 Science Task Force members, Federal Office of Public Health members, and government representatives, as well as print media articles and official press releases from public health departments. Drawing on Foucault's notion of power-knowledge dynamics, we explore how researchers and decision-makers interact in the public sphere.

Results: Key aspects identified: (1) power struggles surrounding accountability and role clarity among stakeholders, (2) the dual role of print and social media as both vehicle for dissemination and communicator shaping public perception, and (3) the pervasive ambiguity in science-policy collaboration throughout the Swiss COVID-19 response.

Conclusions: Our study emphasizes the importance of reflective learning, drawing on insights from the COVID-19 pandemic. It reveals the complexities in navigating public health crises, emphasizing the challenges of transparency, accuracy, and delineation of responsibilities. These dynamics stress the need for continuous evaluation and refinement of strategies to foster collaboration between researchers and policymakers for effective pandemic preparedness and response.

Key messages:

- Understanding and Addressing Power Dynamics in Science-Policy Interactions.
- Necessity for continuous evaluation to enhance collaboration between researchers and policymakers for future preparedness and response efforts.

Abstract citation ID: ckae144.2175

Everyday household costs of raising a child with cerebral palsy

Gun Roos

G Roos[1], *AI Alecu*[1], *MH Austgulen*[1]
[1]Consumption Research Norway, Oslo Metropolitan University, Oslo, Norway
Contact: groos@oslomet.no

Background: Caring for a child with a disability can be costly in terms of time and energy, and it is also associated with lower incomes and higher direct costs, such as costs for assistive technologies, transport, food, clothing and leisure activities. However, few studies that have focused on households' everyday costs associated with raising a child with disability. This study is based on the capability approach. The economic costs of a child with cerebral palsy are defined as the economic costs associated with achieving the same capabilities, or functionings, as a child without cerebral palsy. The purpose of this study is to explore the needs and economic costs in households raising a child with cerebral palsy. The results are important to inform, plan and justify targeted policies and interventions.

Methods: Digital in-depth interviews with caregivers from 15 Norwegian households raising children with cerebral palsy (aged 4-17 years, GMFCS levels 1-5). 12 women, 2 men and a couple were interviewed two times (1-2 hours each).

Results: The caregivers who took part in the interviews described their demanding role and that they spend a lot of time organizing daily routines, activities, health services, assistive technologies and assistants. Many of them initially reported that they do not have many daily extra costs, but when discussing the different areas of consumption, it emerged that households have extra housing costs because they need to make adaptations, remodeling and maintenance to their homes. An adapted car, which requires service, insurance and fuel, is often used for transport. The washing machine runs regularly and towels, sheets and clothes need to be frequently changed. Sometimes they also end up buying food, clothes or toys that are not used.

Conclusions: Households caring for children with cerebral palsy have additional costs for several types of expenses, including especially high costs for housing and transportation.

Key messages:
- Households raising a child with cerebral palsy have needs that generate additional costs.
- The costs vary and it is important to cover a broad range of cost areas.

Abstract citation ID: ckae144.2176
Enhancing Labor Market Participation of Older Adults: Health and Workplace Adaptations

Ieva Reine

I Reine[1,2], *O Rajevska*[1]
[1]Statistics Unit, Riga Stradins University, Riga, Latvia
[2]Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden
Contact: ieva.reine@rsu.lv

Background: The labor market dynamics for older adults have significantly shifted due to extended life expectancy and evolving socioeconomic conditions. This study examines the prerequisites for older adults to remain longer in the labor market across various European countries, emphasizing the interplay between health status, workplace adaptations, and economic factors.

Methods: This cross-sectional study analyzed data from several European surveys focusing on older workers. The methodology included logistic regression to evaluate the impact of health status and workplace adaptations on continued employment among older adults. Data were further stratified by country to assess regional differences in employment patterns for this demographic.

Results: Preliminary results indicate that older adults with access to workplace adaptations-such as flexible working hours and ergonomic interventions-show a significantly higher likelihood of remaining in the labor market (OR = 2.3, 95% CI 1.8-2.9). Additionally, those reporting good to excellent health were 1.5 times more likely to continue working compared to their peers with poor health outcomes. The results also highlight substantial regional variability, with Scandinavian countries showing higher employment rates among older adults compared to Southern European regions.

Conclusions: The data strongly support the need for policy interventions that promote health maintenance among older workers and encourage employers to implement adaptive measures. Such strategies are likely to enhance the labor market participation of older adults, contributing to economic stability and reducing the potential strain on social security systems. Innovative public health policies aimed at supporting aging workers are crucial for sustaining workforce productivity in the face of demographic shifts. NordForsk supports the study Sustainable working-life for aging populations in the Nordic-Baltic region, Project No.: 139986.

Key messages:
- Workplace adaptations and good health significantly extend working life among older adults.
- Regional differences in employment for older workers highlight the need for tailored public health policies.

Abstract citation ID: ckae144.2177
The Health-Employment-Longevity Nexus: Implications for Retirement Age Policies in European Countries

Aviad Tur-Sinai

A Tur-Sinai[1], *D Gottlieb*[2]
[1]School of Public Health, University of Haifa, Haifa, Israel
[2]School of Social Work and Social Welfare, The Hebrew University of Jerusalem, Jerusalem, Israel
Contact: atursinai@univ.haifa.ac.il

Background: Advances in medical knowledge and technology have led to increased general and healthy life expectancy in Europe. Combined with declining fertility rates, these trends have resulted in an aging population. Many European countries have been reluctant to adjust the retirement age, putting pension funds and Pay-As-You-Go social insurance systems at risk. Linking entitlement age to life expectancy could mitigate this risk and extend working life, but such policies are politically unpopular. This study investigates the empirical relationship among self-perceived health, employment, job quality, and life expectancy in the European context.

Methods: The study analyzes the determinants of self-rated health using the SHARE database, combined with general and healthy life-expectancy data from EUROSTAT and, where missing, the WHO, focusing on European countries.

Results: In Europe, both past and present employment improve self-rated health. Job quality has a detrimental effect on self-rated health for women and a positive effect on men. Life expectancy and healthy life expectancy raise self-rated health, while poverty rates negatively affect it. Job quality is widespread among European women, and its negative effect on health rises with age. For European men, job quality has a positive effect, peaking around age 56. The effects of employment and job quality on self-rated health are simultaneous. In European countries with an elasticity >1, healthy life expectancy rises faster than general life expectancy at higher ages, suggesting an improved ability to work at older ages. This finding indicates that adjusting the retirement age could be a powerful tool for improving the sustainability of social insurance systems in Europe.

Conclusions: For younger European women, it may be rational to set higher retirement-age increments and put them on a declining course as they age, considering the gender-specific age dynamics and job quality effects on health.

Key messages:
- In Europe, employment and job quality significantly influence self-rated health, with gender-specific effects that vary with age and impact retirement age policies.
- Adjusting retirement age in line with healthy life expectancy could improve the sustainability of European social insurance systems, considering health-employment dynamics.

Abstract citation ID: ckae144.2178
The practice of defensive medicine among Italian physicians: a cross sectional study in Rome

Giuseppe Furia

G Furia[1], HA Alizadeh[2], M Sapienza[3], MG Tarsitano[3], C Patrizi[3], G Capelli[4], G Damiani[2], C De Vito[1]
[1]Department of Public Health, Sapienza University of Rome, Rome, Italy
[2]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[3]Directive Council of Order of Physicians and Dentists of the Province, Rome, Italy
[4]National Center for Disease Prevention, ISS, Rome, Italy
Contact: giuseppe.furia@uniroma1.it

Background: To identify the perception and the reason of defensive medicine among Italian physicians, and identify the socio-demographic and work-related determinants of the increased practice of defensive medicine.

Methods: This study is a cross sectional web survey. A questionnaire was sent by e-mail to all the physicians registered to the Order of Physicians and Dentists of the Province of Rome. The collection period was from mar 2024 to may 2024. Descriptive analysis and multivariable linear regression models were conducted to describe differences between groups and to estimate the relationships between variables.

Results: A total of 291 physicians completed the survey and were included in this analysis. Almost 60% of respondents feel under pressure due to the possibility of legal disputes. 73,8% adopted defensive medicine behaviours during the last year. More than 80% are aware that defensive medicine represents a limitation for their profession and a unfavourable factor for patients. Who answered that they practice defensive medicine think that it is a factor limiting their professional activity (OR: 2.3) and an unfavourable factor for the patient's health (OR: 1.1).

Conclusions: Defensive medicine is an important factor in health care costs without increasing the benefits to the patient. The study contributes to a deeper understanding of the perception of defensive medicine among physicians. Defensive medicine practice is common among physicians with concerns about increasing pattern in the future.

Key messages:

- Our study highlights physicians' awareness of adopting defensive medicine behaviors in their clinical practice.
- The study contributes to a deeper understanding of the perception of defensive medicine among physicians.

Abstract citation ID: ckae144.2179
An overview and comparison of approaches used for health policy analysis: What to use and when?

Elizabeth Berghuis-Mutubuki

E Berghuis-Mutubuki[1], H Hilderink[1]
[1]Center for Health and Society, RIVM, Bilthoven, Netherlands
Contact: elizabeth.mutubuki@rivm.nl

Background: Public health challenges are complex and analyzing them requires advanced approaches such as, societal cost-benefit analysis (SCBA), health impact assessment (HIA), and strategic foresight. Analyzing health policy is a multifaceted process, and depends on, among others, the scope, approach, and policy goals. Given this complex and multifaceted nature, it is not always clear which approach to use, and how the approaches can complement each other. Therefore, health policy analysis could benefit from practical and explicit guidance regarding clear identification of cases and types of analysis. Hence in this paper we aim to develop a framework that can provide this guidance.

Methods: In this paper we describe the differences and similarities of three distinct health policy assessment approaches, SCBA (an economic evaluation approach that takes into account the impact on society as a whole), HIA (is a combination of tools that focus on evaluating the potential health effects of a given policy) and strategic foresight (a systematic and participatory approach used to anticipate and plan for future trends and uncertainties that may impact policy), their application, and how they can complement each other within the field of public health. A framework that can be used when deciding which health policy approach to use for a given case will be developed, based on existing literature, frameworks, and a case study.

Discussion: This paper contributes to knowledge on health policy analysis and towards efficiency and clarity in analyses conducted in this field.

Key messages:

- There is little guidance regarding how to conduct health policy analysis.
- Clear guidance on which approaches to use and how they complement each other will contribute towards efficiency and clarity in health policy analysis.

Abstract citation ID: ckae144.2180
ERIMS assessment Tool Enhances Emergency Response in WHO Europe Region

Hugo Monteiro

H Monteiro[1,2], M Shapiro[3], M Tran Ngoc[3], M Elamein[3], C Matos[4], C Smallwood[3]
[1]National Screening Program Coordination, Executive NHS Board, Porto, Portugal
[2]Local Public Health Unit, Local Health Unit Gaia Espinho, Porto, Portugal
[3]EURO/WHE/EMO, WHO/Europe, Copenhagen, Denmark
[4]Regional Public Health Department, Northern Regional Healthcare Services Administration, Porto, Portugal
Contact: hugo.filipe.b.monteiro@gmail.com

Issue/problem: The implementation of an Emergency Response Information Management System (ERIMS) assessment tool improves health emergency responses within the World Health Organization - European Region. The tool's deployment aims to refine data management processes and bolster preparedness strategies. Managing health information systems (HIS) effectively during emergencies is a persistent challenge, as technologies keep innovating and potential challenges are constant. The ERIMS assessment tool addresses this by offering a structured approach, ensuring improved emergency responses and system resilience.

Description of the problem: Adopting a systems approach, the ERIMS tool was designed to be flexible, allowing adaptation to various HIS architectures and emergency coordination mechanisms. Its design and development process included consultations with digital health and emergency management experts and field testing across three WHO member states.

Results: Field applications of the ERIMS assessment tool demonstrated its capacity to evaluate, including, digital capability and knowledge management with focus on emergency scenarios. The tool identified systemic gaps, offered strategic guidance on enhancing data processes, and fortified decision-making protocols. These outcomes not only highlighted the tool's utility in assessing HIS readiness but also its impact in improving emergency response mechanisms.

Lessons: The deployment of the ERIMS assessment tool enhanced HIS by providing an evaluation of emergency preparedness and response capabilities with a focus at the national perspective level. The tool's application showcased its role in advancing public health emergency preparedness, illustrating how assessments can lead to substantial improvements in health information management and emergency response readiness.

Key messages:

- ERIMS assessment implementation improves emergency data management.

- Better preparedness relies on boosting digital capabilities and knowledge management.

Abstract citation ID: ckae144.2181
Hybrid accountability in global health public-private partnerships: a literature and case study

Julian Hein

J Hein[1], *M Bekker*[1]
[1]Health and Society group, Wageningen University, Wageningen, Netherlands
Contact: julianhein@gmx.de

Background: Recent global health public-private partnerships (PPPs) offer novel approaches to public health issues, yet they lack clear public accountability. Hence, it remains unclear how accountability is organised and practiced. This research examines accountability in global health PPPs, how it is manifested, and derives lessons for developing an accountability framework.
Methods: The study utilized both a scoping literature review, examining the databases SCOPUS, Web of Science and MEDLINE, which yielded 35 eligible articles from 334 records, and an exploratory case study focused on an accountability event within the Global Stop Tuberculosis Partnership (STBP), incorporating a document analysis and an expert interview to enhance insights from the literature review.
Results: Authors studying PPPs often conceptualized accountability broadly and favoured a view tied to hierarchical state-led governance and democracy. However, at the global level, this political accountability is largely absent. In PPPs, it is replaced by a mix of bureaucratic, legal, social, audit, fiscal, and rather soft accountability mechanisms. Also, PPPs' accountability landscape is dynamic, shaped by different normative considerations and by the interdependence among partners. In 2020, the allegations for misconduct at the STBP exemplified public reputational accountability, followed by audit accountability leading to an enforced soft accountability to STBPs' mission & purpose.
Conclusions: This study highlights the necessity for rethinking accountability in global health PPPs due to the limitations of existing structuralist frameworks. A new hybrid accountability framework is proposed. It considers a strong accountability focus on PPPs' purpose, their processual dynamics, and normative aspects. Lastly, it is recommended to further investigate the trade-off between transparent accountability mechanisms and the practical necessity for confidential backstage processes in PPPs.
Key messages:

- Exploring a hybrid accountability framework in global health PPPs beyond only static accountability snapshots, helps to understand PPPs' true dynamic, purpose-driven and individualized accountability.
- Without regulatory mechanisms and state governance, individual action and new collaboration become essential, requiring soft accountability mechanisms as increased trust and cooperation among partners.

Abstract citation ID: ckae144.2182
The HEROES (HEalth woRkfOrcE to meet health challengeS) Joint Action

Giacomo Diedenhofen

G Diedenhofen[1,2], *L Baldini*[1], *G Menin*[1], *M Di Marco*[1]
[1]UOS PNE e Rapporti Internazionali, Agenzia Nazionale per i Servizi Sanitari Regionali, Rome, Italy
[2]Specialization School for Medical Statistics, Department of Public Health - Sapienza University of Rome, Rome, Italy
Contact: diedenhofen@agenas.it

Background: The HEROES (HEalth woRkfOrcE to meet health challengeS) Joint Action aims to advance health workforce planning across the EU, addressing the pressing need for a resilient, sustainable, and accessible health service systems. Given the evident strain on health systems demonstrated during the COVID-19 pandemic, this initiative seeks to address the critical need for strategic HWF planning. Building on previous projects, HEROES will foster the capacity of EU states in workforce planning, preparing the health systems to meet future challenges.
Methods: The study adopts a collaborative framework involving 19 EU countries, segmented into clusters based on health system characteristics. A stepwise approach ('AS IS,' 'TO BE,' 'TO DO') characterizes the methodology, incorporating extensive data collection, stakeholder engagement, and scenario forecasting. Country-level information on HWF Data and Planning will be compared both across countries in clusters and across clusters.
Results: Initial findings indicate significant disparities in health workforce data quality, availability, and planning methodologies among the states. Identified methodologies also involve real-world data applications and predictive analytics to refine health workforce planning. Efforts are underway to define an Advanced Minimum Dataset (AMDS) to synchronize health workforce data and define planning tools across the clusters, as country-level AS IS reports have been finalized and cross-country comparisons are ongoing.
Conclusions: Collaborative, data-driven health workforce planning can significantly enhance health system resilience and responsiveness. Recommended public health actions include enhancing HWF data integration, forecasting capabilities, and stakeholder participation, with the aim of shaping national health policies and practices. The public health impact is profound, as it allows to improve health service delivery and workforce adaptability in response to dynamic health demands.
Key messages:

- The HEROES Joint Action advances EU health workforce planning, with the aim of enhancing the resilience and responsiveness of health systems.
- Strategic data-driven approaches in health workforce planning are pivotal for resilient, accessible and sustainable healthcare systems.

Abstract citation ID: ckae144.2183
Positive effects from the introduction of fully subsidised nicotine replacement therapy in Ireland

Peter Naughton

P Naughton[1], *A Sheridan*[2], *E Murphy*[2], *M Blake*[2], *P Kavanagh*[1,2]
[1]National Health Intelligence Unit, Health Service Executive, Dublin, Ireland
[2]Tobacco Free Ireland Programme, Health Service Executive, Dublin, Ireland
Contact: peter.naughton3@hse.ie

Smoking remains a leading cause of preventable death in the Europe. Despite recent declines in prevalence, the adverse health and economic effects of smoking are felt disproportionately by disadvantaged groups. Nicotine replacement therapy (NRT) is well established as an effective smoking cessation aid; however, its financial cost may act as a barrier to uptake. In February 2023, eligibly for fully subsidised NRT was expanded to all users of smoking cessation services in Ireland. This study evaluated the impact of universal access to NRT on smoking cessation. This study utilised secondary analysis of routinely collected data from service users attending Irish smoking cessation services. Individuals were followed for twelve weeks. Changes in self-reported quit status and NRT use were analysed before (January 2021 - February 2023) and after (March 2023 - December 2023) the introduction of fully subsidised NRT. Logistic regression modelling identified factors associated with smoking cessation. The total number of participants was 19,717. There was higher uptake of NRT among service users who were eligible for free NRT (59% vs 40%, $p < 0.001$) and higher quit rates at four (41% vs 29%, $p < 0.001$) and twelve (29% vs 20%, $p < 0.001$)

weeks. Logistic regression models demonstrated that NRT use was significantly associated with smoking cessation at four (aOR 1.88, 95%CI 1.47 - 2.41) and twelve (aOR 1.76, 95%CI 1.37 - 2.28) weeks. This study confirms the effectiveness of NRT in an Irish context and illustrates the benefits of universal access to this life saving medicine. Targeted interventions are required to intensify services offered to disadvantages groups if the ambitious objectives of Tobacco Endgame are to be achieved. These findings represent an urgent call to action for European policy makers to deliver equitable access to NRT across the continent. Such action can transform the public health landscape and help bring us closer to achieving a tobacco free Europe.

Key messages:

- This study confirms the real-world effectiveness of NRT use as a smoking cessation aid.
- The removal of financial barriers is associated with increased NRT use and successful smoking cessation.

Abstract citation ID: ckae144.2184
Impact of COVID-19 measures on psychosocial outcomes in Austria – a qualitative vignette study

Michael Vorstandlechner

M Vorstandlechner[1], *J Harlfinger*[2], *C Kien*[2], *V Ritschl*[1,3], *A Chapman*[2], *G Schneckenreither*[4], *G Zauner*[5], *G Gartlehner*[2], *N Popper*[5], *T Stamm*[1,3]

[2]Department for Evidence-based Medicine, University for Continuing Education Krems, Krems, Austria
[3]Ludwig Boltzmann Institute, Arthritis and Rehabilitation, Vienna, Austria
[4]Technical University of Vienna, Vienna, Austria
[5]dwh GmbH, Vienna, Austria
Contact: michael.vorstandlechner@meduniwien.ac.at

During the COVID-19 pandemic, Austria implemented frequent and restrictive containment measures. We aimed to explore the perspectives of individuals affected by political and epidemiological decisions in Austria, particularly in Vienna and Lower Austria. A qualitative vignette-based study conducted from July to Oct 2023 utilized two hypothetical future pandemic scenarios to prompt in-depth discussions in semi-structured interviews with Austrian residents about their perspectives, either private or from the fields of healthcare, education, citizen representation, business, research, public health and politics. Interview data was analysed using a thematic analysis approach. To ensure results' rigor and accuracy, we followed the COREQ guideline and included two citizen research partners. This project is funded by WWTF (Grant ID: LS22071). Preliminary thematic analysis from 28 interviewees (53.6% female) aged 19-77 (mean 53.0 years) shows that the negative effects of school closures was a major concern among participants. Despite diverging points of view on other topics, there was a broad consensus that school closures would have negative consequences, such as unstable educational modalities impairing young people's individual development, decreasing psychosocial support in their peer groups, leading to long-term educational losses, not only for individuals but also for society as a whole, and having a negative impact on economic growth, social justice and innovation. The participants also described a lack of evidence for the necessity of the frequent school closures during the pandemic as had happened in Austria and suggested a different approach in a future pandemic. Further topics were the deterioration of mental health, incentives instead of mandatory measures, more transparent communication by authorities, agreement between experts and researchers, reducing uncertainties regarding pandemic management, compliance by the general public and democratic social cohesion.

Key messages:

- Addressing the multi-faceted impact of a pandemic requires a comprehensive approach that considers mental health, social justice, communication and social cohesion alongside containment measures.
- This work represents a learning from the COVID-19 pandemic. From the conclusions of this study, recommendations can be derived to be better equipped in future pandemics.

Abstract citation ID: ckae144.2185
Accounting for health equity in policy evaluation: a content analysis of primary research

Kerstin Sell

K Sell[1,2], *S Rabbani*[1,2,3], *J Burns*[3]
[1]Chair of Public Health, IBE, LMU Munich, Munich, Germany
[2]Pettenkofer School of Public Health, Munich, Germany
[3]Professorship of Public Health & Prevention, Technical University of Munich, Munich, Germany
Contact: sell.kerstin@t-online.de

Background: Public Health researchers increasingly make use of sophisticated study designs and methods to evaluate the effects of policies on health and social outcomes. Natural experiment evaluation (NEE) conceptualises policies as 'natural' experiments that occur outside of the control of researchers. Often, NEE employs quasi-experimental methods (QEM) which enable researchers to rigorously evaluate the effect of population-level interventions. As for other health-related research, it is unclear to what extent such public health evaluations can and do consider the (health) equity implications of policies. We sought to investigate how health equity is addressed in NEEs and other policy evaluations that employ QEM.

Methods: We identified a random sample of primary research as part of a pre-registered scoping review (https://osf.io/3h6cb/). Studies that employed methods labelled as interrupted time series, difference-in-differences, controlled before and after, regression discontinuity, and synthetic control were included. Through content analysis, we examined how health equity was considered in data analysis and discussion sections.

Results: We analysed 59 studies, of which 25 were stratified for one or more socially-stratifying factors. Results were mainly stratified by sex ($n = 15$, 25.4%), age ($n = 13$, 22%), and diverse measures of socioeconomic status ($n = 14$, 23.7%), i.e. income, employment, education, or other factors. Of these, 21 studies included a discussion of health equity-related results, ranging from a few sentences to a holistic discussion including recommendations for decision-makers. Most commonly, researchers recommended monitoring of policy effects in different sub-populations, and careful policy design that conceptualises complex policy effects, including unintended and unequitable effects.

Conclusions: Policy evaluations have great potential for informing public health decision-making but health equity aspects were under-examined in these studies.

Key messages:

- Health equity is assessed by evaluating policy effects in relevant sub-populations. Only 25 of 59 studies included results that were stratified for one or more socially stratifying factors.
- Studies that were focused on disadvantaged populations commonly included recommendations for policymakers, calling for better policy design and improved monitoring of policy effects.

Abstract citation ID: ckae144.2186
The meta-governance of quality registries for public health

Melanie Maria Kuhrn

MM Kuhrn[1], *A Laschkolnig*[1], *A Degelsegger-Márquez*[1]
[1]International, Policy, Evaluation, Digital, Austrian Public Health Institute, Vienna, Austria
Contact: melanie@kuhrn.com

Issue/problem: Healthcare-related planning and policy requires evidence, which in turn requires data. Generating sensitive, high-quality data is expensive. Given the constraints of routine or study-related data for quality monitoring, quality registries are commonly used. But when is it adequate, from a public health meta-governance point of view, to establish dedicated quality registries?

Description of the problem: Many countries have established public patient registries over time. The lack of a meta-governance framework complicates decision-making for establishing and funding dedicated quality registries. Simultaneously, legal advancements like the European Health Data Space may enhance the use of routine data in healthcare policy, potentially transforming both registry and meta-governance practices.

Results: We identified key meta-governance challenges, such as setting criteria for the creation, modification, or closure of registries, deciding on public funding and choosing between routine and specially collected data. We argue against using absolute thresholds like disease prevalence, advocating for a scorecard approach that evaluates epidemiologic reasoning, policy relevance, healthcare impact and factors like data availability and registry synergies.

Lessons: The EHDS will enable enhanced secondary data use, necessitating decisions on when to use routine versus specifically collected data. Decision-makers must consider sustainability, ethics, practicability and data linkability, while recognizing risks such as data quality limitations and potential bias from original data collection purposes.

Key messages:

- The necessity for quality registries varies by case, serving specific policy questions. Optimizing funds and avoiding arbitrary decisions require a strategy based on a meta-governance framework.
- With the introduction of EHDS, the focus may shift more toward data curation and quality control, making it critical to align registry efforts with the broader health information system.

Abstract citation ID: ckae144.2187
Confronting the Global Crisis of Youth and Firearms in the Wake of Serbia’s First School Shooting

Vladimir Sebek

V Sebek[1,2], *V Opancina*[3], *YT Yang*[4]
[1]Department of Criminalistics, University of Kragujevac, Faculty of Law, Kragujevac, Serbia
[2]Regional Police Directorate of Kragujevac, Ministry of Interior Republic of Serbia, Police Directorate, Kragujevac, Serbia
[3]Department of Radiology, University of Kragujevac, Faculty of Medical Sciences, Kragujevac, Serbia
[4]Center for Health Policy and Media Engagement, George Washington University, Washington DC, USA
Contact: dr.vladimir.sebek@gmail.com

Issue: School shootings reflect crucial systemic flaws, notably the ease of firearm access and training for children, despite rigorous firearm regulations.

Description: In May 2023, Serbia was rocked by its first school shooting in Belgrade, where a 13-year-old boy, armed with guns and Molotov cocktails, killed 9 and injured 6.His actions were amplified by his proficiency with firearms, a skill honed under his father’s guidance at shooting ranges. This tragic event ignited a nationwide debate on gun control. Our study seeks to attain an in-depth analysis on regulations on minimum age for firearm training in context of school shootings in Serbia and USA as countries with highest rates of civilian gun ownership globally.

Results: Serbian regulations lack a definitive minimum age for firearm training at shooting ranges, mirroring a situation in the USA, where 17 states do not have child access prevention laws, and 43 states lack mandated safe storage requirements. A worrying trend is the escalation in mass shootings by individuals aged 21 or younger, deviating from the earlier trend of middle-aged perpetrators. This younger demographic often seeks fame, inspired by previous mass shooters, contributing to the rise in both deliberate and accidental shootings by young people.

Lessons: We need to consider the implementation of regulations on minimum age for children firearm training at shooting ranges, as well as stricter control of the ranges. This problem extends beyond national boundaries, reflecting a global issue. The accessibility of firearms to youth, coupled with their developmental susceptibility to impulsive and aggressive behavior, raises significant concerns.

Key messages:

- To increase global awareness and stricter regulations on youth firearm access, emphasizing the stricter regulations on shooting ranges and the integration of firearm safety education into curricula.
- Firearm control and children safety is a collective international duty, crucial for addressing a concern that impacts public safety and youth welfare.

Abstract citation ID: ckae144.2188
An Irish public health policy research team: impact and lessons learned, one year on

Michelle Norris

M Norris[1], *C McDowell*[1], *V Power*[1], *S Spillane*[1], *M Ryan*[1,2], *M O’Neill*[1]
[1]Health Information and Quality Authority, Dublin, Ireland
[2]Department of Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland
Contact: mnorris@hiqa.ie

Issue: In 2023, in Ireland, a public health policy research team was established in the Health Information and Quality Authority to conduct evidence syntheses and provide evidence-based advice to inform national decision-making, at the request of the Department of Health. One year on, we reflect on the impact of this team and outline lessons learned. These findings may support other countries in creating and developing public health policy research teams.

Description of the problem: We aim to answer the following questions: What impact can a public health policy research team have and what are the lessons learned, one year on? Projects completed by the team in 2023 were reviewed for stakeholder engagement (such as expert and public and patient involvement) and impact (feedback from policymakers, resulting public health actions or policies and online report downloads).

Results: Seven public health projects were completed in 2023, in areas including: Long COVID, public health reform, rapid multiplex testing, and medical countermeasure stockpiling. National and international stakeholders were engaged with via expert advisory group membership, document review and project presentations. Patient representatives were included from Long COVID Advocacy Ireland and Rare Diseases Ireland. Project reports were downloaded a total of 281 times. Positive feedback was received from all stakeholders. Project findings were presented to policymakers to inform national public health and rare disease strategy development, and the Long COVID model of care in Ireland.

Lessons: Early and ongoing stakeholder engagement is key when translating research to practice, via policy. Innovative methods of engagement, including public and patient involvement, can ensure meaningful collaboration. Adapting methodologies to meet stakeholder needs, such as rapid evidence synthesis, enhances impact. Lastly, research impact on policy takes time, and an understanding of national policy development is required.

Key messages:

- A public health policy research team provides impactful evidence synthesis to advise national policymakers.
- Stakeholder engagement is key to developing impactful policy advice.

Abstract citation ID: ckae144.2189

How do industry and other actors undermine tobacco control policies post-adoption? A scoping review

Britta K Matthes

BK Matthes[1]*, R Hiscock*[1]*, I Fitzpatrick*[1]*, H Alaouie*[1]*, T Gatehouse*[1]*, ABC Gilmore*[1]
[1]Department for Health, University of Bath, Bath, UK
Contact: bkm28@bath.ac.uk

Background: Over recent decades, many countries have strengthened their tobacco control policies. To be effective, full implementation is needed. Tobacco industry interference is widely recognised as a key barrier to tobacco control progress and evidence-based models like the policy dystopia model (PDM) list industry strategies, focusing on those avoiding and undermining policy adoption. While prior research highlighted industry activities post-adoption, these have not been captured systematically. This review aimed to map the efforts of industry, front groups and other actors to undermine the implementation of policies, including marketing, packaging, smokefree and flavour measures.

Methods: We searched six literature databases, relevant bibliographies and grey literature, and consulted experts. We included articles describing one or more attempts to undermine adopted policies, including marketing, packaging, smokefree and flavour. The PDM served as starting point for coding; additional strategies were identified inductively. Strategies were charted against aims and policies.

Results: Several aims and strategies were identified which were similar across policies. Following policy adoption efforts to 1) overturn and 2) weaken measures, and 3) delay implementation continued. Legal strategies were utilised and there were attempts to influence stakeholders. In addition, tobacco industry and other actors sought to 4) undermine policy effectiveness by creating confusion, circumventing policies, and noncompliance, and 5) use implementation as an opportunity to enhance industry reputation.

Conclusions: Interference from tobacco industry and other actors threatens effective tobacco control policy implementation. The public health community must continue to monitor, expose and counter industry conduct after policy adoption. More research is needed to enhance our understanding of how industry interferes in policy implementation, and how this can be pre-empted and countered.

Key messages:

- The interference from tobacco industry and other actors following policy adoption threatens effective tobacco control, and needs to be monitored, exposed and countered by the public health community.
- Policymakers and civil servants need to be wary of efforts to undermine tobacco control policies and act to ensure effective policy implementation.

Abstract citation ID: ckae144.2190

Proton-pump inhibitor use in older adults: Public vs. Private Prescribing in Portugal

Sónia Romano

S Romano[1,2,3]*, A Teixeira Rodrigues*[1,4,5]*, C Torre*[6,7]*, J Perelman*[2,3]
[1]Centre for Health Evaluation & Research/Infosaúde, Lisbon, Portugal
[2]NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[3]Comprehensive Health Research Center, NOVA University Lisbon, Lisbon, Portugal
[4]Life and Health Sciences Research Institute, School of Medicine, Braga, Portugal
[5]ICVS/3B's-PT Government Associate Laboratory, Braga/Guimarães, Portugal
[6]Faculdade de Farmácia, Universidade de Lisboa, Lisbon, Portugal
[7]Laboratory of Systems Integration Pharmacology, Clinical and Regulator, Lisbon, Portugal
Contact: sonia.romano@anf.pt

Background: Proton pump inhibitors (PPI) are frequently overprescribed, posing challenges to patients and healthcare systems. In Portugal, the publicly funded National Health Service (NHS) provides universal coverage and reimburses the cost of medications regardless of the prescription origin. If private practices may benefit from longer consultation times allowing better prescription, they do not face any incentive to avoid over-prescription. We aimed to compare outpatient prescription trends, patterns, and costs of PPI among older adults in private and public sectors.

Methods: Nationwide retrospective ecological study on PPI prescribed for older adults in Portugal 2020-2022. Data on defined daily doses (DDD) and costs were obtained from a national public database by healthcare sector, sex (female/male), and age group (65-74, $\geq$75). We analysed trends, market share of DDD per 1000 older adults per day (DID), and mean cost per DDD (€/DDD) for all PPI substances.

Results: We observed a decrease in prescribed PPI from 349.0 DID in 2020 to 341.9 DID in 2022. Omeprazole (reference and cheaper substance) was the most prescribed drug for females and pantoprazole for males in the public sector. Similar pattern was observed among those aged $\geq$75 in the private sector while for those aged 65-74, esomeprazole was the most prescribed drug. Overall, the private sector prescribed PPI with a 20% higher price (0.126 €/DDD) than the public (0.106 €/DDD), with greater differences among the most expensive substances (rabeprazole +0.032 €/DDD; lansoprazole +0.029 €/DDD; esomeprazole +0.021 €/DDD).

Conclusions: PPI prescription followed similar trends in both sectors, but private practitioners tend to prescribe more expensive drugs, because their patients can afford them and because there is no incentive for more rational prescription. Since the NHS financially supports drugs prescribed in private practices, financial incentives towards rationale prescription should also fall in this sector.

Key messages:

- Overall, the private sector prescribed PPI with a 20% higher price (0.126 €/DDD) than the public (0.106 €/DDD), with greater differences among the most expensive substances.
- Since the National Health Service financially supports drugs prescribed in private practices, financial incentives towards rationale prescription should also fall in this sector.

Abstract citation ID: ckae144.2191

Can more CVD prevention increase life expectancy in Germany? Analysis with European data 2000-2019

Susanne Stolpe

S Stolpe[1]*, B Kowall*[1]
[1]Centre for Clinical Epidemiology, University Hospital Essen, Essen, Germany
Contact: susanne.stolpe@uk-essen.de

Background: Life expectancy (LE) in Europe is increasing since long - while mortality from cardiovascular diseases (CVD) declines, attributed to advances in therapy and prevention. Whether this is still applies the last 20 years is unclear. Recently, Germany's low LE compared to other Western European countries (2019: 81.3 yrs; Spain: 84, Italy 83.6) was seen as result of high CVD mortality due to insufficient prevention. This led to the establishment of the German Federal Institute for Prevention and Education in Medicine, aimed at reducing CVD and -in the long term - narrowing the gap in LE. We explore whether data on CVD mortality and morbidity support this idea.

Methods: With data from OECD, WHO and IHME (GBD 2021), we calculated the mean annual change in LE and in age-standardised mortality (ASM) for CVD for 2000-2019 for European countries by sex. We estimated the linear association (adj R^2) between the mean annual change in LE and ASM for CVD for West- and East-Europe, and -country-specific- between incidence and ASM from CVD.

Results: For 2000-2019, mean annual change in LE was lower in West- than in East-Europe: 0.25 yrs vs. 0.30 in men and 0.17 vs 0.22 in women; for ASM in CVD, it was about half as large: -6.6/100.000 vs. -11.1 for men and -4.1 vs. -8.0 for women. Similarly, the adj R^2 for the association between mean annual change in LE and in ASM for CVD was lower in West- compared to East-Europe: 0.43 vs. 0.24 in men and 0.21 vs. no association (adj R^2 -0.01) in women. Courses of CVD incidence were heterogeneous (linearly or wave-shaped in- or decreasing, stable or u-shaped). In Germany, it decreased wave-shaped, with an adj R^2 for linear association with ASM for CVD of 0.79 in women and 0.63 in men. The association between LE and ASM for CVD is low in West-European countries. Even if amplified prevention lowers CVD mortality, a positive effect on LE is questionable. Differences in LE are stable since long. Non-morbidity related factors might decisively effect LE.

Key messages:

- Life expectancy in Europe-and it's mean annual change since 2000 is not associated with age-standardised CVD mortality in women, and only moderate in men in West-Europe, in contrast to East-Europe.
- Course of CVD incidence is country-specific and very heterogeneous and reveals no overall association with CVD mortality rates.

Empowering health literacy: Turkiye's Health Literacy Action Plan 2022-2026

Seyma Yusra Soganda

SY Soganda[1,2], MB Oztop[1,3], S Uner[4], M Ornek[1], G Kerman[1]
[1]General Directorate of Health Promotion, Ministry of Health, Ankara, Türkiye
[2]Institute of Health Sciences, Istanbul University, Istanbul, Türkiye

[4]Public Health Department, Faculty of Medicine, Lokman Hekim University, Ankara, Türkiye
Contact: yusrasoganda@gmail.com

Issue/Problem: The 'Health Literacy Action Plan 2022-2026' of the Turkish Ministry of Health addresses the critical public health issue of limited health literacy, leading to increased hospital admissions, inappropriate emergency department use, and poor health outcomes. This underscores a significant challenge in individual health self-management and higher healthcare expenditure within the country.

Description of the Problem: The Health Literacy Action Plan aims to tackle disparities in health literacy levels among people. It employs customized teaching schemes, digital communication, and inclusive healthcare practices to reach every demographic group. The plan seeks to enhance health knowledge and empowerment among Turkish people by increasing access to medical information, simplifying clinician instructions, and promoting closer communication between patients and healthcare professionals.

Results: Comparative evaluation of nationwide surveys conducted in 2017 and 2023 with 15,000 participants shows remarkable improvements. Despite delays due to the pandemic, the action plan led to a notable increase in adequate health literacy levels from 31.9% in 2017 to 46.1% in 2023. Additionally, significant improvements were observed in ailment prevention and health promotion, with health literacy levels in disease prevention increasing from 28.4% to 45.7%.

Lessons: The Health Literacy Action Plan plays a crucial role in developing and implementing multifaceted public health strategies based on data and stakeholder participation. These interventions, requiring continuous monitoring and adjustment, are essential steps toward achieving high-level health literacy.

Key messages:

- Strategic health literacy interventions are essential for improving health outcomes and optimizing the use of public resources.
- Evidence-based interventions and ongoing evaluation are key to promoting health literacy.

Innovation in border regions: from inequality to equity! Starting with acknowledgment in policy

Brigitte Van Der Zanden

B Van Der Zanden[1,2,3], L Nemer[4]
[1]euPrevent, Heerlen, Netherlands
[2]AWPG Mosa, South Limburg Public Health Service, Heerlen, Netherlands
[3]CAPHRI, Maastricht University, Maastricht, Netherlands
[4]Center for Investment for Health and Development, WHO/Europe, Venice, Italy
Contact: vanderzanden@euprevent.eu

Living in a border area can create health inequalities due to limited access to healthcare compared to people in central regions. In centrally located areas, citizens can choose healthcare providers 360 degrees around them, benefiting from full prevention and health promotion coverage. In contrast, border residents have only 180 degrees of access, leading to partial inclusion in health services. National systems typically prioritize health equality but not necessarily equity, especially for those living in border regions. To address this gap, innovative policies that account for cross-border interactions are needed, benefiting over 35% of the EU population living in border areas. A key question is how to ensure health equity in border regions. To explore this, cross-border case studies, like air pollution, food purchases, antibiotic availability and q fever were looked at to identify the situation, the public health challenges it entails and existing solutions. The Essential Public Health Functions (EPHF) framework, developed by the World Health Organization and the International Association of National Public Health Institutes, was used to evaluate public health functions with a focus on achieving greater equity and inclusiveness. Currently in cross-border health key EPHF functions such as health promotion and disease prevention are emphasized, while others like public health governance and community participation need improvement. To better implement health equity in border regions, for use of the EPHF framework an additional and short guideline was developed on how border regions should be considered in national, regional, and local public health policies. This approach offers a pathway to addressing health inequalities in these unique environments: a crucial step towards creating health equity.

Key messages:

- The EPHF framework as an innovative tool to strengthen public health in border regions.
- Take the geographical living space of citizens in a border region into account to achieve health equity.

Abstract citation ID: ckae144.2194
Impact of time and COVID-19 pandemic on GP mental health consultations in deprived neighborhoods

Shakib Sana

S Sana[1], T Magnée[1], S van Pelt[1], PL Kocken[1], PJ Bindels[2], S Denktas[1], EIT de Schepper[2]
[1]ESSB, Erasmus University Rotterdam, Rotterdam, Netherlands
[2]EMCR, Erasmus Medical Center, Rotterdam, Netherlands
Contact: sana@essb.eur.nl

Background: The stringent lockdown measures and limited physical access to GP care at the start of COVID-19 pandemic resulted into a decrease of mental health consultations. It raised concerns about the access of patients with mental health problems. The aim of this study is to investigate the mental health GP consultations amongst patients from deprived neighborhoods before and during COVID-19 pandemic, especially after the stringent lockdown in the Netherlands.

Methods: In an observational study (2018-2022), medical data of 360,645 patients were analyzed for the proportions of mental health consultations (segmented per month) by comparing the lockdown phase (March 2020-May 2020) and post-lockdown phase (June 2020-June 2022) with the pre-pandemic period the patients living in deprived and non-deprived neighborhoods.

Results: Analyzing a total of 759,863 mental health consultations showed that during the lockdown phase of COVID-19, less mental health problem consultations were observed than pre-pandemic. This decrease was not significant for patients from deprived neighborhoods, but the decrease was significant for patients from non-deprived neighborhoods, RR = 0.990; 95%CI=0.934-1.051 and RR = 0.918; 95%CI=0.885-0.953 respectively. Conversely, the number of post-lockdown phase consultations for patients in deprived neighborhoods was significantly increased compared to pre-pandemic levels (RR = 1.074;95%CI=1.002-1.152), but not for patients in non-deprived neighborhoods (RR = 1.000; 95%CI=0.959-1.043). This increase in post-lockdown phase consultations in deprived neighborhoods can be explained by the higher frequency of consultations per patient.

Conclusions: Consistently over time, demand for GP mental health care was and remains higher among patients from deprived neighborhoods, with an increase in post-lockdown consultations. Sufficient access to primary health care should be guaranteed to ensure treatment of mental health problems for social-economic disadvantaged groups.

Key messages:

- Socioeconomic status has a negative sustainable impact on demand for mental health consultations in deprived neighbourhoods.
- To ensure the treatment of mental health problems for social-economic disadvantaged groups, sufficient access to the primary health care should be guaranteed at all times.

Abstract citation ID: ckae144.2195
Strengthening Equity, Diversity, and Inclusion in medical education via an intersectional approach

Gemma Hunting

G Hunting[1], *O Hankivsky*[2]
[1]Interdisciplinary Studies, Simon Fraser University, Vancouver, Canada
[2]School of Public Policy, Simon Fraser University, Vancouver, Canada
Contact: gemgemhunting@gmail.com

Background: In the wake of COVID-19, equity, diversity, and inclusion (EDI) policies have been taken up in the health field, yet the actual impact of these initiatives, particularly for multiply marginalized individuals, is debated. Despite progress in areas such as diversity promotion, EDI has been critiqued as superficial and as failing to challenge the drivers of health inequity. This presentation discusses how an intersectionality-informed approach can help harness the transformative potential of EDI.

Methods: This research is informed by a literature review of EDI initiatives in the health field, and is an offshoot of a 4.5 year international project funded by the Canadian Institutes for Health Research focused on evaluating and strengthening intersectionality-informed policy guidance.

Results: There is a disconnect between EDI commitments and substantive action on health inequities and an intersectional approach can help bridge this divide. We demonstrate this with a case example which brings an intersectional approach to EDI initiatives in medical education - including bias trainings, courses on the social determinants of health, and the engagement of community groups. Drawing on promising equity promoting work across these areas, we show how intersectionality can harness the potential of EDI by bringing to the fore what has often been missing, including the promotion of health stakeholder reflexivity, attention to interacting systems and structures shaping health, and meaningful engagement with underrepresented communities.

Conclusions: An intersectionality-informed approach to EDI has the potential to enhance the health equity impacts of initiatives within medical education and the broader health field.

Key messages:

- EDI initiatives in health often have limited impact on health inequities.
- An intersectionality-informed approach to EDI can help health stakeholders drive transformative action on health inequities.

Abstract citation ID: ckae144.2196
The adoption of a place-based framework to inform municipal health strategies

Angela Freitas

A Freitas[1], *R Almendra*[1], *P Santana*[1]
[1]CEGOT, University of Coimbra, Coimbra, Portugal
Contact: angelafreitas30@gmail.com

Background: Health is a place-based issue. Research shows that inequalities in health are significantly influenced by social, economic, and environmental factors, making local policies related to these domains critical determinants. Yet, place-based health planning remains underutilized by local practitioners, not receiving adequate attention from policy-makers. Departing from the Municipal Health Strategy of Coimbra, this presentation aims to showcase the framework used for guiding municipal health planning, addressing multidimensional factors, geographic analysis, intersectoral collaboration and participatory approaches.

Methods: The conceptual and methodological framework followed a population health approach with a geographic lens, looking at how the health outcomes and health determinants were geographically distributed across the municipality (data disaggregated at sub-municipal level), as well as the extent to which policies from multiple sectors can address them. The planning cycle followed an iterative seven-stage process based in five key actions: 1 - Assess (Health Profile), 2 - Prioritize (Priorities), 3 - Plan (Objectives and Strategies), 4 - Implement (Action Plan) and 5 - Monitor (Targets and Measures, Monitoring Plan). Participatory processes were conducted involving local stakeholders and citizens to identify needs, establish priorities and actions.

Results: The framework for action integrates 14 goals and 94 actions across six policy domains: Sustainable Mobility and Public Places, Safe and Adequate Housing, Accessible Healthcare, Social Cohesion and Participation, Education and Health Literacy and Intersectoral and Collaborative Leadership.

Conclusions: Adopting a place-based framework to health planning, involving a geographical and multidimensional health assessment as well as the participation of local stakeholders and citizens, was considered effective in turning evidence into practice.

Key messages:

- Municipal health strategies should be developed with a place-based perspective, prioritizing health as the focal point across various intersectoral municipal policies.
- The integrated framework shed light on the experience of co-creation to inform health-oriented planning, ensuring that actions address specific needs of localities.

Abstract citation ID: ckae144.2197
Analyzing Public Discourse on the Affordable Care Act through YouTube Comments

Teresa McKelvy

T McKelvy[1], J Garman[1], K Green[1], J Mongeaux[1], L Ivanitskaya[1], R Bizri-Baryak[1]
[1]Herbert H. & Grace A. Dow College of Health Professions, Central Michigan University, Mount Pleasant, USA
Contact: mckel1td@cmich.edu

Introduction: Social media's pervasive role in daily life provides a unique avenue for understanding public sentiments. This study utilizes YouTube comments on an MSNBC video about the Affordable Care Act (ACA) to explore public opinions on the policy and its political implications.

Methods: A qualitative analysis of YouTube comments on an MSNBC video was conducted. Netlytic, a scraping tool, gathered 1,949 comments. Thematic analysis, based on a coding framework derived from Semetko and Valkenburg's frames, identified three predominant frames: Responsibility, Human Interest, and Economic Consequences.

Results: Of the 1949 comments posted in response to the ACA video on YouTube, 488 were analyzed. Three media frames were used to categorize the comments. Among the analyzed comments, 42% fell within the Responsibility Frame, indicating that 205 comments attributed responsibility for ACA-related issues, healthcare access, and costs to political parties, individual politicians, and government entities. The Human-Interest Frame accounted for 11% of the comments, with 53 remarks reflecting individual experiences related to healthcare access and costs. Additionally, 26% of the comments fell within the Economic Consequences Frame, signifying those 125 comments included remarks concerning the economic impacts of the ACA, such as increased healthcare access, taxes, and penalties. The remaining 21% of comments did not align with the three frames.

Conclusions: This study embarked on a comprehensive exploration of public discourse surrounding the Affordable Care Act (ACA) within the context of the 2024 presidential election, utilizing YouTube comments as a rich source of qualitative data. Through a meticulous methodological approach, which included thematic framing analysis and intercoder reliability assessments, valuable insights into the diverse perspectives and sentiments expressed by social media users regarding this critical healthcare legislation were gained.

Key messages:
- Social media allows for real-time understanding of people's thoughts, beliefs, opinions, and ideas, as well as serves as a useful tool that fosters broad, unfiltered data/content.
- Researchers conducted a qualitative analysis of public discourse on YouTube to explore the range of sentiments regarding the ACA.

[2]Institute of Oncology Ljubljana, Public Relations, Ljubljana, Slovenia
[3]Institute of Oncology Ljubljana, Oncological Surgery, Ljubljana, Slovenia
[4]Institute of Oncology Ljubljana, Medical Oncology, Ljubljana, Slovenia
Contact: stomsic@onko-i.si

Issue: Strategic documents addressing major public health concerns should extend beyond health sector. Cancer control is commonly perceived only as a health issue, thus involving diverse stakeholders is challenging.

Description of the problem: The inclusion of stakeholders within and beyond the health sector is crucial in the preparation, and through implementation of National Cancer Control Programmes (NCCP). Lessons learned on how to involve and maintain fruitful collaboration with diverse stakeholders in Slovenian NCCP are presented.

Results: Over the past 14 years Slovenia's NCCP has built a reliable and reputable partnership with diverse stakeholders, a collaboration that continues to evolve. Efforts extend across multiple sectors, encompassing health, education, employment, research, environment, technology, and non-governmental organizations. NCCP has set up multistakeholder governance structures: an advisory board, board of experts, specialised expert groups, and a group of representatives of cancer hospitals. These groups engage a diverse range of experts and institutions nationwide. Whenever feasible, representatives of patient organizations are included. All these structures hold regular meetings, complemented by an annual event that convenes all stakeholders and also provides an invaluable platform for informal networking. To ensure seamless coordination of all activities, a dedicated team is essential. Our approach has evolved to embrace a dual leadership, comprising both a public health specialist and a clinical expert. Additionally, we benefit from the expertise of communication experts, who offer valuable insights into effectively reaching diverse audiences.

Lessons: Governing Slovenia's NCCP by involving diverse stakeholders in planning and implementation activities has demonstrated its effectiveness. Furthermore, we are witnessing an increasing number of new stakeholders actively seeking out to participate in the NCCP.

Key messages:
- Slovenia's NCCP is recognized for its credibility and strategic approach.
- Involving diverse stakeholders in cancer control endeavours has proven effective, fostering trust and partnerships.

[3]Institute of Public Health, College of Medicine, United Arab Emirates University, Abu Dhabi, UAE
[4]Department of Psychiatry and Behavior, United Arab Emirates University, Abu Dhabi, UAE
[5]MRC Epidemiology Unit, University of Cambridge, London, UK
Contact: ma4643@nyu.edu

Background: This cross-sectional study is apart from one of the first and largest population-based prospective cohort studies in the UAE called the United Arab Emirates Healthy Future Study (UAEHFS). The aim of this study is to investigate the association between self-perceived sleep duration and self-perceived depression after adjustment for sociodemographic factors. Baseline line data from UAEHFS cohort participants were included in this cross-sectional study. Univariable and multivariable logistic regression models were fitted, with the binarized self-reported sleep hours as an outcome. The predictors were the self-reported PHQ-8, sociodemographic factors, and body mass index (BMI). Odds ratios with 95% confidence intervals (CI) were reported.

Results: Of 11,455 participants, 4,295 (37.5%) were included in the complete case analysis after omitting missing values. We applied a complete case analysis following omitting missing values. Participants' median age was 32.0 years (Interquartile-Range: 24.0, 39.0). In total, 63.6% of the participants reported sleep duration of more than 7 hours. Statistically significant negative association was observed between the total PHQ-8 score and binarized self-reported sleep, OR = 0.961 (95% CI: 0.948, 0.974). For one unit increase in age and BMI, the odds ratio of reporting shorter sleep with OR of 0.979 (95% CI: 0.969, 0.990) and 0.987 (95% CI: 0.977, 0.998) respectively.

Conclusions: The study findings indicate a correlation between higher total PHQ-8 scores and an increased probability of individuals reporting shorter self-perceived sleep durations when considering some sociodemographic factors such as age, marital status and employment status. However, there was no difference between females and males in reporting self-perceived sleep duration among depressed individuals.

Key messages:

- There is a correlation between higher total PHQ-8 scores and an increased probability of individuals reporting shorter self-perceived sleep durations.
- Our results can help contribute to the knowledge based on current and potential population mental health in the UAE and Gulf Region.

Abstract citation ID: ckae144.2200
Poor psychosocial status and cardiovascular risk factors are associated with depression or anxiety

Nasheeta Peer

N Peer[1], *T Mashiane*[2], *J Hill*[2], *AP Kengne*[2]
[1]Non-communicable Diseases Research Unit, South African Medical Research Council, Durban, South Africa
[2]Non-communicable Diseases Research Unit, South African Medical Research Council, Cape Town, South Africa
Contact: nasheeta.peer@mrc.ac.za

Background: Depression and anxiety are rising in South Africa but their associations with psychosocial and cardiovascular risk factors (CVRFs) remain under explored. This study determined the associations of depression and anxiety traits with poor psychosocial well-being, risky lifestyle behaviours and cardiometabolic diseases.

Methods: In a population-based cross-sectional study, data were collected via administered questionnaires, clinical examinations and biochemical assessments. Depression and anxiety traits were ascertained via the Patient Health Questionnaire-9 and Generalised Anxiety Disorder screening questions. Multivariable logistic regressions determined the associations with depression and anxiety traits; the basic model comprised sociodemographic factors, physical inactivity, tobacco smoking and alcohol misuse (CAGE ≥ 2). Psychosocial and cardiometabolic variables were entered individually in separate models.

Results: Among 678 participants, median age 52 years and mainly women (81%), prevalence of depression scores ≥ 10 were 14.2% (men:12.7%, women:14.6%, $p = 0.498$) and anxiety scores ≥ 10 were 10.2% (men:10.3%, women:10.2%). In the basic regression models, depression, but not anxiety, was associated with being separated, living as married/widowed vs. single (OR:2.01, 95%CI:1.02-3.94), and alcohol misuse (2.07, 1.13-3.78). Depression and anxiety were associated with decreasing social support (depression: 1.09, 1.04-1.12; anxiety: 1.09, 1.04-1.14), and increasing number of adverse life events. Hypertension (1.76, 1.07-2.90, $p = 0.025$), diabetes (1.98, 1.03-3.82, $p = 0.041$) and dyslipidaemia (1.97, 1.01-3.85, $p = 0.048$) were associated with depression but not anxiety.

Conclusions: The high burden and associations of depression and anxiety traits with poor psychosocial wellbeing suggest a need for holistic care approaches. The associations of depression traits with CVRFs warrant screening and care of depression in the presence of cardiometabolic diseases and alcohol misuse.

Key messages:

- The high burden of depression and anxiety traits in South Africa is associated with poor social support and quality of life, and increasing adverse life events experienced.
- The associations of depression traits with hypertension, diabetes, dyslipidaemia, and alcohol misuse highlight the need for integrated management strategies.

Abstract citation ID: ckae144.2201
Adolescent well-being in time of crisis: The role of social and residential contexts

Sarah Bitar

S Bitar[1], *L Minary*[1], *B Lalloué*[2], *Y Kestens*[3,4], *F Manneville*[1,2], *J O'Loughlin*[4], *F Ligier*[1], *N Agrinier*[1,2]
[1]UMR 1319 INSPIIRE, Université de Lorraine, Vandoeuvre-lès-Nancy, France
[2]CHRU-Nancy, INSERM, Université de Lorraine, CIC, Epidémiologie Clinique, Nancy, France
[3]École de Santé Publique, Université de Montréal, Montreal, Canada
[4]Centre de Recherche, Centre Hospitalier de l'Université de Montréal, Montréal, Canada
Contact: sarah.hamade@univ-lorraine.fr

Background: It is unknown whether social or residential context during the COVID-19 lockdowns may impact mental well-being. We identified classes of each of social and residential context during the lockdown and examined their associations with mental well-being among French adolescents one-year after the first lockdown.

Methods: We used data collected in a cross-sectional study design in 2021 from 387 adolescents ages 12 to 15 years enrolled in the school-based pilot study for EXIST. Participants reported social and residential characteristics during the lockdown retrospectively, and current mental well-being in self-report questionnaires. We used latent class analysis to identify classes of social and residential contexts, and linear regression models to study their association with mental well-being.

Results: Four social context classes were identified: class 1 'Low opportunities for social contacts at home', class 2 'Moderate opportunities for social contact at home", class 3 'High opportunities for social contact at home', and class 4 'Very high opportunities for social contact at home'. Compared to class 4, lower levels of mental well-being were observed among adolescents in class 1 (b= -4.08, 95% CI [-8.06; -0.10]) one year after the lockdown. We identified four residential context classes, with differences across classes in proximity to nature, type of residence (e.g., apartment, house), and level of neighborhood deprivation. No association was found between residential context during the lockdown and adolescent mental well-being one year later.

Conclusions: An unsupportive social environment during the lockdown may have long-term effects on mental well-being among adolescents. Given the observed disparities in social support, future intervention should aim to strengthen social support for adolescents living in unsupportive environments (e.g., remote homework assistance, support for isolated parents, provision of virtual chat rooms for adolescents).

Key messages:

- Mental well-being was challenged among youth with lower levels of social connectedness and support during lockdown, residential context was not associated with adolescent well-being after one year.
- During crisis, a critical need among adolescents does not pertain to the physical attributes of their living environment, but rather to social support from friends or family within and outside home.

Abstract citation ID: ckae144.2202
How to improve the inclusion of the elderly in the local community for better mental health?

Olivera Stanojevic-Jerkovic

O Stanojevic-Jerkovic[1], *S Oreski*[2]
[1]Regional Unit Maribor, NIJZ, Maribor, Slovenia
[2]NIJZ, Ljubljana, Slovenia
Contact: olivera.stanojevic@nijz.si

Issue/problem: Social exclusion, ageism and low health/digital literacy intertwine with growing trends in mental disorders, including abuse in Slovenian elderly. To cope with these issues, besides rising competencies, there is a need for stable and continuous partnerships of all relevant stakeholders in the local communities.

Description of the problem: Despite previous efforts of the Interdisciplinary Working Group (IWG) for mental health promotion in the elderly (established according to the Resolution of the National Mental Health Program, 2018-2028), there was a need for reconsidering approaches in the next Action plan (2024-2028). A national conference on decreasing social exclusion in the elderly contributed as a road map.

Results: Previous activities (events in the local communities, supported materials) were upgraded with a broad destigmatization campaign, (recruitment of the >>ambassadors<<) and collection of culturally adapted good practices. Better availability of information through >>info-spots<< and easier participation of the elderly in cultural events was enabled. Activities of the reinforced IWG were promoted.

Lessons: Empowerment of key actors and their continuous cooperation could improve information flow, competencies, the inclusion of the elderly in the local community, and decrease ageism and discrimination. Developing local strategies with the crucial involvement of elderly representatives is the opportunity for more intensive and better cooperation between local policy/stakeholders, public health experts, and the target population. Regular financial support will prevent additional inequities.

Key messages:

- The empowered, connected, and proactive community is key to preventing the elderly's exclusion.
- Approaches should be fresh, accessible, and tailored to the heterogeneous population.

Abstract citation ID: ckae144.2203
Involuntary singlehood, gender equality and mental health in contemporary Sweden

Maria Wemrell

M Wemrell[1,2]
[1]Social Work, Linnaeus University, Växjö, Sweden
[2]Social Epidemiology, Lund University, Malmö, Sweden
Contact: maria.wemrell@lnu.se

In recent years, acts of violence against women have been tied to online communities of men who self-identify as involuntary celibates or 'incels'. These men experience an inability to enter intimate relationships with women, attributing the issue to a gynocentric order in which women hold power and men are victims. This is while evidence suggests that in contemporary societies at large, growing numbers of men live without, or face difficulties in forming, intimate relationships with women, and while many men in Sweden, particularly young ones, report loneliness. At the same time, in Sweden we see a growing polarization between men and women regarding views on gender equality, especially among youth, as young men express gender conservative values and the notion that feminism is to blame for some men's feelings of societal marginalization. Increased knowledge about these issues, and how they may be connected, is of strong importance for public mental health. In an ongoing research project, we take the incels phenomenon as our starting-point and as one area of attention, while also directing focus toward involuntary singlehood and celibacy among men and women in Sweden more broadly. The latter is investigated through a survey, which is the focus of this presentation. The survey explores the prevalence of short- and long-term experiences of involuntary singlehood and celibacy among men and women in the general population ($n = 5000$), and how such experiences are made sense of. Any correlations between such experiences and self-rated mental health and satisfaction with life, and attitudes towards gender equality and violence against women, are investigated, including any noteworthy differences along lines of gender, age and socioeconomic background. Experienced loneliness, irrespective of relationship status, is also assessed. The presentation will discuss preliminary results of the survey study and discuss their implications for public mental health.

Key messages:

- Involuntary singlehood among men is a public health issue warranting further investigation.
- Correlations between involuntary singlehood and mental health as well as attitudes towards gender equality will be discussed.

Abstract citation ID: ckae144.2204
Determining the trauma levels of individuals living in temporary housing after an earthquake

Ayşe Baran

A Baran[1], *M Sülü*[1], *C Kekilli*[3], *G Boz*[2], *A Özer*[1]
[1]Public Health, Inonu University Faculty of Medicine, Malatya, Türkiye
[2]Public Health, Ordu Provincial Health Directorate, Ordu, Türkiye
[3]Psychiatry, Kahramanmaraş Sütçü İmam University Faculty of Medicine, Kahramanmaraş, Türkiye
Contact: abaran88@hotmail.com

Background: Earthquakes cause many deaths and injuries in the region in which they occur. In addition, earthquakes can lead to significant mental health among survivors living in affected areas. The aim of this study is to determine the trauma levels of people living in temporary housing after an earthquake.

Methods: This descriptive cross-sectional study was conducted between September and December 2023. The target population consisted of people living in temporary housing, with a sample size of 260 people. Data were collected from a questionnairerelated to sociodemographic and earthquake experience status as well as the Post-Earthquake Trauma Level Determining Scale (PETS). The dependent variable in this study was the total PETS score, and the independent variables included age, being trapped under debris, and experiencing the loss of a loved one. The Student's t-test and a one-way ANOVA were used in the statistical analyses.

Results: In the research group, 35.4% of the participants reported a job loss and 34.2% reported the loss of relatives. The mean total

PETS score was 56.13±16.87. The total scores of individuals who were trapped under debris, lost first-degree relatives, and lost their jobs were significantly higher than others ($p < 0.05$). In addition, individuals whose houses were destroyed due to the earthquake had significantly higher total PETS scores ($p < 0.05$). Of the individuals who participated in the study, 88.8% stated that they did not receive psychosocial support after the earthquake.

Conclusions: In the study group, trauma levels were higher among individuals who experienced the loss of a home, job, family members, and relatives due to the earthquake. Alarmingly, more than three-quarters of the participants did not receive psychosocial support after the earthquake.

Key messages:

- All individuals housed in temporary settlements after an earthquake should be evaluated in terms of trauma, and psychosocial support should be provided according to risk groups.
- The trauma experienced by individuals who lost their homes and jobs after the earthquake should be reduced by making plans such as providing shelter and job opportunities as soon as possible.

Abstract citation ID: ckae144.2205
Modification in Quality of Life and Health in Medical Students across Graduation

Szymon Szemik

S Szemik[1], M Kowalska[1]
[1]Department of Epidemiology, Medical University of Silesia in Katowice, Katowice, Poland
Contact: sszemik@sum.edu.pl

Background: Medical students experience numerous demands during the education process, determining their quality of life (QoL) and health status. POLLEK study aims to identify and evaluate the quality of life by simultaneously assessing their determinants in Polish medical students during long-term observation. We have also examined the prevalence of chronic diseases, specifically focusing on overweight and obesity, and identified their risk factors.

Methods: The POLLEK is the follow-up cohort study conducted among medical students at the Medical University of Silesia in Katowice. Students were followed during two observation periods: in their first year of studies, the academic year 2021/2022 (T1), and in their second year, the academic year 2022/2023 (T2).

Results: The total number of participants in the first year of observation (T1) was 427 while in the second year (T2) was 335. We identified that the QoL score significantly decreased in their second year of studies mainly in the somatic and psychological domain. The determinants of QoL domains common to T1 and T2 remained self-declared health status, frequency of physical activity, and current financial situation. In the initial year of evaluation, 56 students (13.10%) were overweight or obese, and 52 (15.8%) in the second. Regardless of the academic year, the increased risk of being overweight or obese was significantly associated with dissatisfaction with personal health, financial deficiencies, and a diet abundant in animal products.

Conclusions: The QoL of medical students and selected indicators of their health status deteriorated during the observation period. Our findings suggest that medical schools should actively promote the activity needed to achieve a balance between schoolwork and the personal life of medical students from the beginning of university study.

Key messages:

- Medical students experience numerous demands during the education process, determining their quality of life (QoL) and health status.
- Medical schools should actively promote the activity needed to achieve a balance between schoolwork and the personal life of medical students from the beginning of university study.

Abstract citation ID: ckae144.2206
Sociodemographic disparities in depression and anxiety symptom severity among young adults in Sweden

Maria Granvik Saminathen

M Granvik Saminathen[1], S Brolin Låftman[1], V Östberg[1]
[1]Public Health Sciences, Stockholm University, Stockholm, Sweden
Contact: mia.granvik@su.se

Background: Young adults are disproportionately affected by mental health problems such as depression and anxiety. While previous studies have identified sociodemographic predictors using the four-item Patient Health Questionnaire (PHQ-4), differences in symptom severity remain less explored. This study aimed to evaluate the sociodemographic predictors of different levels of depression and anxiety symptoms among young adults in Sweden.

Methods: Survey data from a population-based sample of Swedish adults aged 20-21 ($n = 3,226$) was used. Symptom severity was categorized into three levels: normal/mild, moderate, and severe, based on established cutoff scores on the PHQ-4. Gender, parental education and birth country, and upper secondary education were assessed through linked registry information. Multinomial logistic regression was used.

Results: Females had a higher risk of moderate (RR = 1.8, 95% CI 1.5, 2.2) and severe (RR = 2.3, 95% CI 1.8, 3.1) symptoms (compared to no or mild symptoms) relative to males. Among males, the risk of moderate symptoms was higher without a secondary degree (RR = 1.9, 95% CI 1.0, 3.4) compared to an academic degree. Males with parents born abroad faced elevated risks of moderate (RR = 1.9, 95% CI 1.3, 2.9) and severe (RR = 2.2, 95% CI 1.3, 3.7) symptoms relative to males with Swedish-born parents. Among females, parental tertiary education was associated with a lower risk of moderate symptoms (RR = 0.7, 95% CI 0.5, 0.9) compared to lower education. Further, females having a vocational (RR = 1.5, 95% CI 1.1, 2.1) or no secondary degree (RR = 3.6, 95% CI 2.1, 6.1) had an increased risk of severe symptoms compared to females with an academic degree.

Conclusions: This study identified sociodemographic predictors for moderate and severe symptoms of depression and anxiety among young men and women in Sweden. Mental health promotion and prevention should specifically target young adults at elevated risk of experiencing moderate to severe symptoms.

Key messages:

- Understanding sociodemographic predictors of depression and anxiety symptoms in young adulthood is essential for public health work.
- Mental health promotion and prevention needs to include appropriate interventions for young men and women from diverse socioeconomic and cultural backgrounds.

Abstract citation ID: ckae144.2207
The UFair-Questionnaire: Perceived university fairness and its association with mental health

Corinna Anneliese Soedel

CA Soedel[1], RM Herr[1], VM Deyerl[1], K Diehl[1]
[1]Professorship Epidemiology and Public Health, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany
Contact: corinna.soedel@web.de

Introduction: University students face different stressors that might jeopardise their mental health. Hitherto, mainly general stress perceptions were assessed, which appeared inappropriate to indicate stress directly linked to the university or for deriving specific preventative measures. The aim of this study was to adapt the concept of organisational justice to universities, develop and validate a corresponding questionnaire (UFair: University Fairness Questionnaire), and estimate its association with mental health.

Methods: In total, 1,105 students (average age: 25.5 years [SD: 5.43]; female: 50.1%; university: 67.2%, university of applied sciences: 32.8%) were surveyed online. Perceived unfairness at the university was measured using the newly developed 20 item UFair Questionnaire. Mental health was measured using the Patient Health Questionnaire (PHQ-8, depression) and Maslach Burnout Inventory for Students (MBI-SS, burnout). Linear regression models estimated the adjusted (age, gender, type of university, lifestyle factors) relationship between perceived university injustice and mental health indicators.

Results: The UFair questionnaire showed good psychometric properties (Cronbach's alpha = .960) and a unidimensional factor structure. There was a considerable association with depression (beta = .485; $p < .001$; R2 = .261) and burnout (beta = .481; $p < .001$; R2 = .250).

Conclusions: Perceived injustice represents not only a stressor at the workplace but also in the university setting, showing a considerable relationship with students' mental health. University justice includes the perception of organisational aspects, the treatment of students, and consideration of the individual situation of students. The relevance of these aspects to the health of students should be recognised and taken into account by universities. The valid measurement by the UFair Questionnaire represents the basis for possible preventive approaches and interventions.

Key messages:

- Organisational injustice exists not only in the workplace but also among students in the university setting.
- Perceived unfairness among students is associated with depression and burnout.

Abstract citation ID: ckae144.2208
Rising Mental Health Issues from Remote Work Challenges in South Korea Amid COVID-19

Juho Sim

JH Sim[1], *BY Yun*[1], *HJ Park*[2], *JY Oh*[2], *JH Yoon*[1,3]
[1]Preventive Medicine, Yonsei University, Seoul, South Korea
[2]Department of Public Health, Yonsei University Graduate School, Seoul, South Korea
[3]The Institute for Occupational Health, Yonsei University, Seoul, South Korea
Contact: yodasim@yuhs.ac

The COVID-19 pandemic significantly increased remote work, raising concerns about its impact on mental health. This study assessed the relationship between the challenges of remote work during the pandemic and mental health outcomes such as anxiety, depression, and sleep disorders. An online survey was conducted among South Korean adults, with data from 507 participants analyzed using the Generalized Anxiety Disorder 7-Item Scale (GAD-7), the Patient Health Questionnaire-9 (PHQ-9), and the Insomnia Severity Index (ISI). Results indicated that participants in the 'difficult' remote work category experienced higher rates of anxiety (26.6%), sleep disorders (37.3%), and depressive symptoms (38.4%) compared to the 'non-difficult' category (14.1% anxiety, 24.8% sleep disorder, and 24.8% depressive symptoms), with all differences statistically significant ($p \leq 0.005$). Logistic regression models adjusted for demographics and socio-economic factors revealed increased odds of mental health issues in the 'difficult' group (ORs ranging from 2.241 to 3.210). Sub-group analysis highlighted significant disparities, particularly among blue-collar workers and men. The findings underscore the need for organizational strategies to mitigate the mental health challenges of remote work. Interventions should include improving technological infrastructure, enhancing workspace ergonomics, and fostering robust communication channels to replace in-person interactions. Additionally, policies should address the differential impacts observed between genders and industries, tailoring support to diverse needs. On a personal level, promoting regular indoor exercise could help workers manage stress and enhance their well-being in remote work settings. This study calls for a comprehensive approach to managing the complex impacts of remote work on mental health.

Key messages:

- This study calls for a comprehensive approach to managing the complex impacts of remote work on mental health.
- The findings underscore the need for organizational strategies to mitigate the mental health challenges of remote work.

Abstract citation ID: ckae144.2209
Dose-response associations between physical activity and mental health among USA adolescents

Mar Fornaguera

M Fornaguera[1], *M Dowda*[2], *R Pate*[2]
[1]Medicina Preventiva, Hospital Universitari Vall Hebron, Barcelona, Spain
[2]Department of Exercise Science, Arnold School of Public Health, University of South Carolina, Columbia, USA
Contact: mfornaguerapadros@gmail.com

Background: Adolescent mental health is a critical public health concern. Physical activity has been shown to reduce risk of negative mental health outcomes. However, in adolescents little is known about the dose-response nature of this relationship. This study aims to fill this gap by examining the association between varying levels of self-reported physical activity and the odds of reporting depressive symptoms and poor mental health, among US high school students.

Methods: This is a cross-sectional study using data from the 2021 Youth Risk Behavior Survey. Physical activity exposure was assessed as students' self-reported weekly frequency of $\geq$ 60min moderate-to-vigorous physical activity (MVPA), as well as frequency of participation in muscle-strengthening activities, sports teams, and physical education (PE) classes. For the dose-response analysis three categories were created for each item. Depressive symptoms and poor mental health were measured using established survey items. Multivariate logistic regression risk models were used.

Results: A total of 8,015 high-school students were included. Depressive symptoms were reported by 43% of students, and 28% reported poor mental health. Moderate doses (1-4 days) of muscle-strengthening activities reduced the odds of depressive symptoms by 23% and the odds of poor mental health by 38% compared to low doses (0 days). Higher reductions were observed for higher doses (5-7 days). Similar results were observed for sports teams (1 vs 0 teams). Moderate doses (1-4 days) of MVPA $\geq$60min showed a significant reduction in the odds for poor mental health (38%) but not depressive symptoms compared to low doses (0 days). No effect was observed for any dose of PE attendance.

Conclusions: The findings suggest a dose-response pattern in the association between physical activity and mental health in adolescents. Any increase in physical activity levels among young adults would be valuable in preventing poor mental health.

Key messages:

- A dose-response pattern was observed between self-reported mental health and physical activity exposure in adolescents.
- Moderate levels of physical activity significantly reduced the risk of self-reported poor mental health among adolescents.

Abstract citation ID: ckae144.2210
Barriers and facilitators for implementing ABCs for Mental Wellbeing intervention model in Finland

Nina Tamminen

N Tamminen[1], *T Vauhkonen*[1]
[1]Mental Health, THL, Helsinki, Finland
Contact: nina.tamminen@thl.fi

Background: The ABCs for Mental Wellbeing study aims to improve mental health and wellbeing by adopting, implementing and evaluating a universal, community-based mental health promotion intervention model in Finland. The study gathers information and experiences of the implementation processes, identifies barriers and facilitators, and best practices for the implementation, and the feasibility and contextual adaptability of the intervention in different settings and specific target groups.

Methods: The implementation took place in four municipality community settings. In total, 40 participants attended the ABC activities. The study employs a mixed methods approach to look at the implementation processes: a quantitative survey before and after the implementation, and qualitative interviews with the employees implementing the model and the participants involved with the ABC activities.

Results: Based on qualitative analysis, the most identified facilitator is management support alongside the competencies of professionals. The observed effects of group activities aligned with the ABC model on mental wellbeing show that participants not only experienced the benefits of model-compliant activities on their mental wellbeing but also increased their awareness of factors influencing their mental wellbeing. The results of the quantitative analysis will be ready during the spring.

Conclusions: The study offers fresh insights into the obstacles and enablers affecting the implementation of a mental health promotion intervention model. The best practice strategies and guidelines identified are being shared both nationally and internationally and utilised to enhance future programme implementation and adaptation of these practices in various settings.

Key messages:

- Best practice strategies and guidelines for successful implementation of mental health promotion identified.
- The ABCs for Mental Wellbeing increased participants' awareness of the factors influencing their mental wellbeing.

Abstract citation ID: ckae144.2211
Multidimensional assessment and analysis of the mental health of teachers and police officers

Csaba Oláh

C Oláh[1,2], *Z Oláh*[3,2], *S Orosz*[1], *E Baksa-Varga*[4], *B Oláh*[5], *Á Horváth*[1], *B Bánné Gál*[4], *M Papp*[4], *M Godzsák*[1], *Z Szekér*[1,4]

[3]Public Health, University of Debrecen, Debrecen, Hungary
[4]Informatic, University of Miskolc, Miskolc, Hungary
[5]General Medical, Semmelweis University, Budapest, Hungary
Contact: olahcs@gmail.com

Background: The years-long COVID-19 pandemic, the proximity of the Russian-Ukrainian war, high inflation, and the economic recession are significant stressors for the Hungarian people. Numerous domestic and international surveys are prepared every year, in which the most stressful professions are ranked. In recent years, based on Hungarian, American and European surveys, teachers and police officers have always been included in the 10 most stressful jobs. They also rank the most valued jobs and highest paid jobs every year. In this relation, police and teaching jobs never made it into the top 10, despite the fact that both professions are very important on a social level.

Methods: 20 male and 20 female teachers and police officers completed a complex quality of life and psychological assessment using international tests with ethics approval. We measured pain syndromes, such as headache, neck and back pain, joint pain, assessed depression, anxiety, sleep quality, and gastrointestinal symptoms.

Results: For police officers and teachers, gender differences were not verified with regard to any parameter. None of the parameters differed significantly for male police officers and teachers. Many significant differences were confirmed between female police officers and female teachers, in all of them the results of the teachers were worse: depression (9,4±10,3 vs 2,9±4,3; $p = 0.02$) anxiety(43,3±12,2 vs 33±4,6; $p = 0.01$), sleep disorders(32,7±8,2 vs 24,3±7,8; $p = 0.01$), gastrointestinal complaints(24,7±9,4 vs 17,6±2,3; $p = 0.01$).

Conclusions: The sleep quality, depression and anxiety levels of female teachers are worse than those of female police officers who live at least as stressful a life. There is no difference between the mental and psychological state of male teachers and police officers. It is important to pay attention to the mental support of female teachers.

Key messages:

- We consider the assessment of the mental state of police officers and teachers and the creation of primary prevention programs and a mental support network to be an important public health task.
- In particular, the mental state of female teachers should be monitored and supported.

[2]Department of Public Health, University of Patras, Medical School, Patras, Greece
[3]Department of Psychiatry, University of Patras, Medical School, Patras, Greece
Contact: ejela@yahoo.de

Background: The COVID-19 pandemic has severely tested the organizational structure and operational effectiveness of healthcare systems. We aimed to explore the experiences of patients who have been hospitalized due to COVID-19.

Methods: Employing purposive sampling, semi-structured interviews were conducted covering eight topics: 1) the experience of COVID-19 diagnosis, 2) the most difficult moments during hospitalization, 3) difficulties related to hospital conditions and safety protocols, 4) interactions with healthcare professionals, 5) received support, 6) social stigma, 7) concerns about the future, and 8) post-COVID and long COVID syndrome. Twelve individuals (six women and six men; mean age 57.5 (SD = 13) years; mean length of stay 18.1 (SD = 3.1) days) participated. The data analysis was carried out using the phenomenological method according to Colaizzi.

Results: Patients reported a spectrum of emotions including loneliness, isolation, abandonment, disappointment, insecurity and fear of death. Interactions with healthcare professionals revealed a dichotomy: experiences of respectful, reassuring care contrasted with encounters lacking psycho-emotional support within an impersonal healthcare setting.

Conclusions: This study sheds light on the experiences of patients on the nursing wards and their psychosocial burden. Most of them reported negative emotions such as loneliness, isolation, sadness, fear and anxiety rather than positive experiences such as hope, interpersonal connectedness, self-identity, empathy, caring and safety.

Key messages:

- The study highlights psychosocial challenges for COVID-19 patients, emphasizing the urgent need for robust support systems.

- The study provides insights for future similar situations and highlights the need for adaptable care models based on principles such as empathy, safety and personalized approaches.

[6]Estuar Foundation, Bucharest, Romania
[7]Mental Health Europe, Brussels, Belgium
Contact: v.bempi@prolepsis.gr

Issue: Mental ill-health has been a leading cause of disability in Europe for many years, with the COVID-19 pandemic increasing incidences of both poor mental health and mental disorders. Vulnerable groups such as children, migrants, individuals with existing mental health issues, and healthcare workers are particularly affected but often lack tailored mental health support.

Description of the problem: The MENTALITY project aims to alleviate mental health distress worsened by the COVID-19 pandemic focusing on vulnerable groups. It also involves developing capacity-building tools and disseminating research results to increase awareness and knowledge sharing. Five EU countries are currently piloting four distinct good practices to address mental health issues among vulnerable populations. Specifically, Poland is aiming to support migrants (including Ukrainian and Spanish-speaking populations), Latvia is focusing on the healthcare workforce, and Romania and Slovakia are concentrating on users and community services. Meanwhile, Greece and Slovakia are implementing initiatives for children. The implementation phase began in January 2024 with a duration of 6 months.

Results: By consulting with relevant stakeholders, a Situation Analysis and Needs Assessment framework has been conducted, allowing for informed decisions regarding the elements to be pilot. Partners have developed country specific piloting plans and external evaluators are leading a common framework for monitoring and evaluation, ensuring regular assessment of the project's progress.

Lessons: The innovative MENTALITY project aspires to enhance community-based mental health systems and promote improved mental health services across EU Member States during crises by adopting a preventative approach. Preliminary results show that the initiatives within the project were much needed and have already begun to demonstrate promising outcomes in addressing mental health challenges at both individual and community levels.

Key messages:

- The MENTALITY project aims to address mental health distress of vulnerable populations in times of crisis.
- The project seeks to advance equality in health and social rights for all individuals living in the EU.

Examining the Relationship Between Socio-Demographic Variables and Eco-Anxiety A Systematic Review

Mattia Di Russo

M Di Russo[1], *E Campo*[1], *G Congedo*[1], *GS Lombardi*[1], *L Nachira*[1], *D Zjalic*[1], *M Innocenti*[1], *C Cadeddu*[3], *S Bruno*[1], *G Fioravanti*[2]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Health Sciences, Università degli Studi di Firenze - UniFI, Florence, Italy
[3]Research Unit of Planetary Health, Erasmus School of Health Policy & Management, Rotterdam, Netherlands
Contact: mattia.dirusso88@gmail.com

Background: Eco-anxiety is a rising concern among young people, characterized by persistent feelings of fear, helplessness, and despair stemming from the looming and uncertain threats of climate change. Understanding how socioeconomic status and demographic factors influence the development of eco-anxiety is crucial in addressing this issue. This study aimed to analyze the literature to elucidate this relationship and its public health implications.

Methods: We conducted a systematic literature review using PubMed, Scopus, Web of Science, and APA PsycInfo databases. A total of 1,170 articles were initially retrieved, with 10 meeting the inclusion criteria. Quality assessment was performed using the AXIS Tool modification for cross-sectional studies. Data extraction was systematically carried out to analyze the relationship between socioeconomic and demographic determinants and young people's emotional responses to climate change.

Results: Preliminary findings indicated that various socioeconomic and demographic factors influence young people's emotional responses to climate change. Family stressors, economic instability, cultural beliefs, and social influences were identified as significant determinants, contributing to eco-anxiety, ecological distress, and climate change grief among youth.

Conclusions: The study underscores the importance of considering socioeconomic and demographic factors in addressing eco-anxiety among young people. By recognizing these influences, policymakers, educators, and mental health professionals can develop tailored interventions to mitigate the adverse effects of eco-anxiety. Public health actions may include enhancing mental health services, implementing educational programs, and addressing social determinants of health to alleviate eco-anxiety and promote resilience among youth facing climate-related challenges. This review is produced as part of the PRIN P2022JJ3LB project, funded by the Italian Ministry of University and Research.

Key messages:

- Socioeconomic and demographic factors significantly influence young people's emotional responses to climate change, including the development of eco-anxiety and ecological distress.
- Understanding family stressors, economic instability, and social influences is crucial for tailored interventions for youth.

Abstract citation ID: ckae144.2215
Past trends and future projections of psychological distress among general population in Finland

Suvi Parikka

S Parikka[1], *M Holm*[1], *J Suvisaari*[1], *J Lahti*[1], *J Reinikainen*[1], *H Tolonen*[1], *A Lundqvist*[1]
[1]Department of Public Health and Welfare, THL, Helsinki, Finland
Contact: suvi.parikka@thl.fi

Introduction: The aim was to examine past and future trends of psychological distress in Finland from 2013 to 2040.

Methods: Six representative cross-sectional surveys from the years 2013, 2014, 2015, 2018, 2020, and 2022 ($N = 172{,}547$, aged 20+ y) were used. Multiple imputation was used in projecting psychological distress (MHI-5, with cut-off value ≤ 60). As the COVID-19 pandemic had a strong effect on psychological distress which persisted after the pandemic, projections were made with and without data from the years 2020 and 2022.

Results: The prevalence of psychological distress was slightly declining during the period 2013-2018 for both men and women, ending up around 18% for men and 19% for women. When including the years 2020 and 2022, however, trends showed a steep increase in the prevalence of psychological distress during 2018-2022. Among 20-39-year-olds, the prevalence of psychological distress increased 9.8%-points over the four-year period. Similarly, among 40-54-year-olds, an 8.2%-points increase was observed. In older age groups (55-64, 65-74 and 75 years and older) psychological distress first increased from 2018 to 2020 but then plateaued especially among the oldest. Projections based on the observed past trends during the period 2013-2018 showed a steady decline in psychological distress, the prevalence of psychological distress ending up around 11% for men and around 15% for women in 2040. When including the years 2020 and 2022, however, the projections suggested an increase in psychological distress in the general population and the prevalence of psychological distress is projected to end up around 37 % for both men and women in 2030.

Conclusions: The prevalence of psychological distress has increased substantially in the 2020s particularly in young adults. Mental health needs to be given a priority in all policies in order to change the future projections.

Key messages:

- The upward trend of psychological distress did not reverse or plateau after COVID-19 pandemic in Finland.
- Increased efforts to protect and promote mental health in all policies seem indicated especially among young adults.

Abstract citation ID: ckae144.2216
Self-harming behaviours and social support among a sample of young men in Belfast, Northern Ireland

Amanda Dylina Morse

A Morse[1], *K Higgins*[1]
[1]Queen's Communities and Place, Queen's University of Belfast, Belfast, UK
Contact: amanda.dylina@gmail.com

Background: Psychiatric morbidity is substantially higher in Northern Ireland (NI) than in peer nations and men are disproportionately represented in suicide mortality data, particularly at early adulthood and middle age. To better scale interventions to reduce morbidity and mortality among young men, a mixed-methods study was conducted combining interviews and validated quantitative tools.

Methods: A non-random community sample of 30 working-class young men in Belfast aged 16-19 was recruited via organisations focused on job training, restorative justice, and youth work. Participants completed the Self-Harm Inventory and a semi-structured interview. Analyses were completed in NVivo and RStudio.

Results: The prevalence of self-harm was more than 8 times higher than for the general population of adolescents in NI, with 83.3% reporting ever engaging in self-harm. Only 2 of the 28 participants reported making a suicide attempt and most injuries were minor, suggesting nonsuicidal self-injury (NSSI) represented almost all injuries. Although the sample had a higher risk profile than the general population-with high levels of trauma, substance use, and socioeconomic deprivation-participants also endorsed strong social connections to friends, family, and community. While many expressed concerns about sharing their own emotional distress, almost all reported that disclosures are important to avert poor mental health and shared times when they or friends sought support.

Conclusions: Although there was a high prevalence of NSSI in the sample, the low prevalence of suicide attempts may be associated with the high levels of protective social connections reported by participants. Gender-based concerns regarding emotional support were common, but there was also strong endorsement for the importance of seeking support from trusted relationships. This suggests that there may be an appetite for male role models to provide education around the "bravery" of help-seeking.

Key messages:

- Prevalence of nonsuicidal self-injury may be substantially more elevated in some populations of adolescent males.
- Gender-based concerns continue to act as a barrier to young men sharing their emotional distress with trusted individuals.

Abstract citation ID: ckae144.2217
Evaluation of specific offers for mothers with mental stress

Fiona Scolik

F Scolik[1], *T Ofner*[1], *S Sagerschnig*[2]
[1]Health, Society and Equity, Austrian National Public Health Institute, Vienna, Austria
[2]Psychosocial Health, Austrian National Public Health Institute, Vienna, Austria
Contact: fiona.scolik@goeg.at

Background: As part of the Austrian early intervention programme 'Frühe Hilfen', specific interventions (a psychotherapeutic short-term intervention and a therapeutic group) were implemented in some regions. An evaluation was carried out to gain general insights into the need for and benefits of psychosocial services as well as in-depth information on the benefits of the two selected services. The results of the project should also enable further conclusions/recommendations for appropriate services.

Methods: Mixed-methods approach: qualitative (focus groups, individual interviews, online surveys, participant observation) and quantitative (screening questionnaires) instruments involving a large number of relevant stakeholders and actors. Data analysis: content-structuring qualitative content analysis according to Kuckartz; descriptive analysis of the screening questionnaires.

Results: The analysis revealed a great need for specific psychosocial services for this target group as well as a high level of satisfaction with the psychosocial services utilised. However, all respondents pointed out barriers to the utilisation of psychosocial services. The evaluation results show that the two specific services make an important contribution to improving the well-being of mothers with mental health problems. Both services largely reach their target group well and, thanks to their focus, contribute to the well-being of mothers with mental health problems. The effectiveness of the service is underpinned by the fact that all participants perceive a reduction in mental stress and notice a reduction in stress during the screenings.

Conclusions: Based on the evaluation results, it is generally recommended that low-threshold, free and needs-based services be established or expanded. In addition, there is a need for more educational and public relations work on psychosocial stress/diseases and more information on support services.

Key messages:

- There is a great need for psychosocial support among mothers.
- The high level of satisfaction with the services evaluated indicates that more such services are needed to support families.

Background: The impact of Covid-19 pandemic on mental health (MH) is still being assessed. The aim of this study was to evaluate the impact of Covid-19 on ordinary hospital admissions for psychiatric disorders in Italy.

Methods: The multicenter project "Covid-19 and mental health" (CoMeH), coordinated by the National Institute for Health, Migration and Poverty, enrolled an open cohort of subjects resident in three large areas of Italy (2018-2021) aged 10 + (N = 5,159,363), and followed-up until 2021. The study outcome was the first ordinary admission with a psychiatric disorder as main diagnosis (FMHA). Citizenship and deprivation level (DL) are the socioeconomic factor considered. Different groups of diagnosis were used to characterize the hospitalizations. The impact of Covid-19 on FMHAs was evaluated by interrupted time series (ITS) analysis, pre (until February 2020) and post (from March 2020) the outbreak of pandemic, using a step-change model.

Results: 11,171 FMHAs were observed. Patients hospitalized with a MH diagnosis were younger compared to the study population; the distributions by sex, deprivation level and citizenship were similar. A decrease of incidence of FMHAs was found after the outbreak of the pandemic, overall and for all group of diagnoses, except for post-traumatic stress disorders (PTSD). A reduction in adjusted FMHA rates after the onset of Covid-19 (RR 0.80[0.72-0.90]) were observed through multivariate ITS. The oldest patients had the lowest probabilities of FMHAs in pre Covid-19 and experienced the highest reduction in post-Covid19. PTSD presented trend in countertendency compared with the other diagnosis, with an immediate effect of Covid-19 increasing FMHAs (+97%), followed by a post-outbreak return to the pre-pandemic levels, below the counterfactual line.

Conclusions: Covid-19 pandemic determined a general reduction of admissions for psychiatric disorders. A significant impact was observed among the eldest (decrease) and for PTSD (increase).

Key messages:
- Covid-19 pandemic determined a reduction of admissions for psychiatric disorders.
- Older people were mostly affected. No significant socioeconomic impact was observed.

Abstract citation ID: ckae144.2219
Trends and gender differentials in age-specific suicide mortality, 2004-2020, Cyprus

Nicos Middleton

N Middleton[1], M Karanikola[1], A Chatzittofis[2,3]
[1]School of Health Sciences, Department Nursing, Cyprus University of Technology, Limassol, Cyprus
[2]Medical School, University of Cyprus, Nicosia, Cyprus
[3]Department of Clinical Sciences/Psychiatry, Umeå University, Umeå, Sweden
Contact: nicos.middleton@cut.ac.cy

Background: Cyprus is rarely included in international studies of suicide trends and the only published national data is two decades old. In the context of the first National Strategy for Mental Health, this study assessed suicide trends in 2004-2020, spanning the 2008 global and 2012-2013 Cyprus financial recessions, but falling short of the COVID-19 pandemic due to delays in recording.

Methods: Suicide deaths were obtained from the Mortality Registry (ICD-10, including "undetermined"). Directly standardized rates were calculated for four gender/age groups. Annual change was estimated in Poisson regression models with interaction terms to assess differential trends over time periods.

Results: There were 560 deaths (4-times more in men, >80% classified as 'violent' in both genders). In men, the suicide rate doubled from 4-5 to 9-10 per 100000, with most of the increase prior to 2012, representing 9% annual change (Rate Ratio 1.09, 95% CI 1.03, 1.15; p = 0.002). From 2013, the trend reversed (effect modification p-value < 0.001) with 4% annual decrease (95% CI -9%, 1%). Declines were not uniform across age-groups; rates in males aged 45-64 continued to rise, surpassing the previously high rate in males 25-44. In women, rates presented a declining trajectory from 4-5 per 100000 to 2-3 over this period, widening the gender differential. M-to-F ratio was 5.33 (95% CI 3.46, 8.19) in 2017-2020 compared to 2.73 (1.88, 3.95) in 2004-2008. A shift to violent methods was observed, with hanging now ranking as most common in both females (1 in 3) and males (1 in 2).

Conclusions: While relatively lower compared to other European countries, the gender differential in suicide mortality has widened in Cyprus, with steep rises in all male age-groups up to 2012 and continuing rises in males 45-64, but declines in female rates over the same period. Further analysis of trends in relation to unemployment and other socio-economic indicators is warranted as well as continuous monitoring of trends.

Key messages:
- After steep rises in suicide across all male age-groups up to 2012, against a declining trajectory in female rates, rates in males 45-64 continued to rise, further widening the gender differential.
- The age profiling and shift towards more violent methods in both genders should inform the first National Strategy for Mental Health, while continuous monitoring of trends is warranted.

Abstract citation ID: ckae144.2220
Prevalence and social determinants of anxiety and depression among adults in Ghana systematic review

Victoria Awortwe

V Awortwe[1], F Maharani[1], M Daivadanam[1], S Adjorlolo[2], EMG Olsson[1], V Rajabzadeh[1], J Woodford[1]
[1]Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden
[2]Department of Mental Health, University of Ghana, Accra, Ghana
Contact: victoria.awortwe@uu.se

Background: Anxiety and depression are major public health concerns, yet their prevalence and social determinants contributing to mental health disparities remain underexplored. This review, to our knowledge, is the first of its kind, aiming to examine the prevalence of anxiety and depression symptoms and disorders among adults in Ghana, along with social determinants associated with their occurrence.

Methods: A search of nine electronic databases and seven grey literature sources was conducted up to September 25, 2023. Two reviewers independently screened and appraised the studies. Forty-six studies were included. Prevalence estimates were pooled using a random-effects model. Subgroup analysis and meta-regression explored potential moderators. A narrative synthesis explored social determinants associated with anxiety and depression.

Results: Preliminary results showed a high prevalence of anxiety (43.7%, 95% CI: 35.6-54.4%) and depression (37.8%, 95% CI; 32.5% to 46%), with regional variations. There were significant differences in the prevalence of anxiety and depression across chronic physical conditions and method of condition assessment. Meta-regression showed significant association between average age and anxiety prevalence. Social determinants associated with anxiety included being female, non-Christian, low income, self-employed, limited social support, and basic education, while that for depression included being young (< 25yr), low income, government employed, childhood physical and sexual abuse, gender-based violence and urban residence. Protective factors for both were male gender, strong social support and higher education.

Conclusions: Preliminary results indicate a high prevalence of anxiety and depression linked to social determinants. While methodological limitations exist (eg, study heterogeneity), findings highlight a need for evidence-based interventions targeting social determinants to reduce the burden of anxiety and depression among adults in Ghana.

Key messages:

- Our review suggests addressing the social determinants of mental health, aligned with sustainable developmental goals, may reduce the burden of anxiety and depression.
- While Ghana is working towards improving mental health via its revised 12year Mental Health Policy launched in 2021, this review can facilitate planning and resource allocation for mental healthcare.

[3]University Clinical Centre Maribor, Maribor, Slovenia
[4]Paediatric Department, General Hospital Celje, Celje, Slovenia
[5]University of Ljubljana, Ljubljana, Slovenia
Contact: ajda.mlakar@mf.uni-lj.si

Background: Sleep constitutes a fundamental biological necessity, occupying approximately one-third of our lifespan. Consequently, the field of sleep research has experienced an increase in interest, prompted by the recognition of insufficient sleep as a significant public health challenge. As the majority of existing questionnaires in Slovenia have yet to undergo official translation and validation processes, the aim of our study was to conduct content validation of a questionnaire designed to assess the sleep quality among adolescents.

Methods: We developed a test battery for assessing the sleep quality of adolescents by combining a diverse array of questionnaires. We employed the Adolescent Sleep-Wake Scale, Pediatric Daytime Sleepiness Scale, Epworth Sleepiness Scale for Children and Adolescents, and Children's Morningness-Eveningness Scale. Following the development of the entire test battery, a process of back-translation from English to Slovene occurred, followed by cultural adaptation.

Results: The designed questionnaire underwent content validation by a panel of 10 experts drawn from diverse disciplines. Evaluation of questionnaire items followed a planned methodology tailored for the content validation of measurement instruments, focusing on content relevance, clarity, and classification into subscales or factors. Our analysis revealed that the individual questionnaires demonstrate content validity, supported by notably high indices of content validity.

Conclusions: Translated questionnaires demonstrate decent content validity, thus rendering them valid clinical and research tools for assessing sleep quality in adolescents in Slovenia.

Key messages:

- Our research indicates the availability of content-valid tools for sleep research.
- Further investigation is needed to determine the reliability, specificity, sensitivity, and appropriateness of the factorial structure of measures for the quality of sleep.

Abstract citation ID: ckae144.2222

Navigating Crisis: Resilience and Mental Well-being in Post-COVID Cyprus Students

Alexandros Heraclides

N Magorokosho[1]*, A Heraclides*[1]*, M Prodromou*[1]*, E Papaleontiou-Louca*[2]
[1]School of Sciences, European University Cyprus, Nicosia, Cyprus
[2]School of Humanities, Social & Education Science, European University Cyprus, Nicosia, Cyprus
Contact: a.heraclides@euc.ac.cy

Background: The mental health of university students is identified as a major challenge in public health, exacerbated by the COVID-19 pandemic. The pandemic and its aftermath have brought forth several stresses, which have had a substantial influence on university students' mental health. Understanding how resilience, which is crucial in coping with adversity, influences students' responses to these difficult circumstances is critical.

Objectives: This study aims to examine the relationship between resilience and mental health outcomes among university students in the Republic of Cyprus after the COVID-19 pandemic.

Methods: Using a parallel embedded mixed methods approach, resilience was measured using the Conner-Davidson Resilience Scale (CD-RISC) while mental health outcomes were assessed using the Symptom Checklist 90-Revised (SCL 90-R) among a preliminary sample of 470 students. The association between the two was assessed by linear regression analysis, adjusting for potential confounders, and also stratifying by gender.

Results: Preliminary findings from this ongoing study revealed a significant inverse relationship between resilience and mental health (beta= -0.58, 95% CI -0.88, -0.29), regardless of gender, age, or socioeconomic status. Stratifying by gender revealed for males, the association between resilience and mental health is (beta= -0.50, 95% CI -0.98, -0.32), whereas for females, it is (beta= -0.63, 95% CI -1.04, -0.22). In short, the influence of resilience on protecting mental health appears to be slightly more prominent in women than in males.

Discussion: This study enriches our understanding of the intricate interplay between the COVID-19 pandemic, resilience, and mental health outcomes among university students. By prioritizing the psychological well-being of this population group, our findings resonate with the World Health Organization's advocacy for heightened mental health awareness during crises.

Key messages:

- Prevalence of mental health issues post pandemic era among university students.
- Resilience as a buffer for mental health crisis in young adults.

Abstract citation ID: ckae144.2223

Needs assessment to design a multidisciplinary training programme within the EU-PROMENS project

Janine De Zeeuw

J De Zeeuw[1,2]*, F Rupppa*[2]*, V Klymchuk*[2]*, HF Königstein*[2]*, L Shields-Zeeman*[3]*,*
F Bolinski[3]*, C Marinetti*[4]*, L Sanna*[4]*, T Zuljevic-Salamon*[2]
[1]Global Health Unit, University Medical Center Groningen, Groningen, Netherlands
[2]GFA Consulting Group, Hamburg, Germany
[3]Mental Health & Prevention, Trimbos Institute, Utrecht, Netherlands
[4]Mental Health Europe, Brussels, Belgium
Contact: j.de.zeeuw@umcg.nl

Background: Mental health as a public health issue warrants a comprehensive prevention-oriented approach whereby capacity building as well as a multisectoral and life-course approach are crucial. The 'Capacity-building on mental health: multidisciplinary training programme and exchange programme for health professionals,' project enhances and improves the capacity of professionals across Europe in the field of mental health. Various professionals are targeted 1) health professionals working in the mental health sector, 2) teachers and educators working in the educational setting, 3) social workers working in various community settings and 4) prison staff.

Objectives: To understand the needs, gaps, obstacles in capacities, competencies, and to build upon existing programmes a mixed methods study, adopting a convergent parallel design is conducted to design and develop the programme. First, a literature review is conducted complemented with interviews, focus group discussions and a survey among various stakeholders to enrich the data. The training will be piloted in The Netherlands, Spain, Czech Republic, Croatia, Finland and Austria. Thereafter it will be rolled out in the 21 remaining EU countries as well as in Norway, Iceland and Ukraine.

Results: Various gaps and competencies identified from different perspectives build a solid fundament for a comprehensive multidisciplinary training programme tailored to the needs of various professionals within the mental health arena. Preliminary results show that 98 multidisciplinary training programmes exist, with about half containing training materials and limited reports on evaluation.

Conclusions: The comprehensive needs assessment will assure a multidisciplinary training programme is suitable and relevant for various professionals to ensure a well-designed capacity-building programme.

Key messages:

- Various gaps and needs among various professionals exist.
- A comprehensive study strengthens alignment of training to needs and gaps among various professionals.

Abstract citation ID: ckae144.2224
Suicide in young and middle-aged individuals: lessons from a psychosocial autopsy study

Elias Balt

E Balt[1], S Mérelle[1], M Eikelenboom[1,2], A Zeric[1], D Wiggers[1], R Gilissen[1], D Creemers[3,4], A Popma[2]
[1]Research, 113 Zelfmoordpreventie, Amsterdam, Netherlands
[2]Psychiatry, Amsterdam University Medical Center, Amsterdam, Netherlands
[3]Psychiatry, Koraal Mental Healthcare, Sittard, Netherlands
[4]Research, GGz Oost-Brabant, Boekel, Netherlands
Contact: e.balt@113.nl

Background: Sociodemographic characteristics of suicides are available from Statistics Netherlands. To improve suicide prevention, it is not only necessary to know who dies but also why people die. A psychosocial autopsy was conducted in the Netherlands to investigate differences in psychosocial characteristics and precipitating factors of suicides of young (<30) and middle-aged (40-70) suicide decedents.

Methods: Data were collected from bereaved individuals. A questionnaire detailed sociodemographic and psychosocial characteristics of the decedents. We reconstructed the suicidal process in the months preceding the suicide in an interview. Findings from the questionnaire and interview were integrated. An independent expert committee formulated recommendations for suicide prevention.

Results: 162 suicides were investigated. Young decedents showed high levels of substance use and academic pressure. Young adults with developmental disorders were vulnerable in the transition to adulthood. Young males reached out less to support and care. By contrast, suicides of young females were distinguished by comorbidity of psychiatric disorders, frequent suicidal behaviours, high levels of care use, wait lists and a loss of (treatment) perspective, harmful social media use and bullying. Work and financial problems were common in middle-aged decedents. Physical disability and pain were frequently mentioned for middle-aged females. Suicide in middle-aged males was characterized by financial distress, interpersonal conflicts such as divorce, high levels of binge drinking and addiction.

Conclusions: Our data provide a topology of the needs of individuals at risk for suicide. Suicide prevention strategies can be improved by better transition support and explicit suicide monitoring in young adults with a developmental disorder, active waitlist policies in mental healthcare, and improved collaboration between debt counsellors and mental care professionals based on shared accountability.

Key messages:

- Bereaved individuals elucidated a wide range of psychosocial problems in suicide decedents.
- Suicide prevention should adhere to a needs-based approach.

Abstract citation ID: ckae144.2225
Exploring the association between cyberchondria and attention to negative information

Richard Xu

R Xu[1], Y Lin[1], R Sun[1]
[1]Department of Rehabilitation Sciences, Hong Kong Polytechnic University, Kowloon, Hong Kong
Contact: richard.xu@polyu.edu.hk

Objectives: This study aimed to preliminarily evaluate the relationship between cyberchondria and attention to negative information.

Methods: The data utilized for this analysis was obtained from a cross-sectional and web-based survey conducted in China between March and April, 2024. All participants were recruited from an online panel belonging to a survey company. Cyberchondria was assessed using the Chinese version of the Cyberchondria Severity Scale - 12 item (CSS-12). Attention to negative information was measured using the negative subscale of the Attention to Positive and Negative Information Scale (APNIS). A multivariable linear regression model was employed to evaluate the relationship between cyberchondria and attention to negative information.

Results: Out of 344 participants, 315 (91.6% response rate) completed the questionnaire and provided valid responses. Approximately 51.7% ($n = 163$) were female, 83.8% ($n = 264$) had completed tertiary or higher education, and 52.7% ($n = 166$) were urban residents. The average age was 32.6 years ($SD = 6.0$). The mean score for CSS-12 was 40.6 ($SD = 7.8$, range: 18-59). The mean scores for the different dimensions of the CSS-12 were: excessiveness, 10.6 ($SD = 2.4$); distress, 10.3 ($SD = 2.7$); reassurance, 10.6 ($SD = 2.5$); and compulsion, 9.1 ($SD = 2.7$). The mean score for the negative subscale of APNIS was 31.9 ($SD = 8.6$, range = 12-52). Multivariable linear regression models revealed a statistically significant relationship between cyberchondria and attention to negative information ($beta = 0.42$, $p < 0.001$), after adjusting for background characteristics.

Conclusions: Our findings showed individuals with a higher level of cyberchondria tend to pay more attention to negative information. Therefore, it's beneficial to develop strategies and interventions that provide accurate, balanced online health information and educate individuals about the risks of excessive online health searches.

Key messages:

- Our findings showed individuals with a higher level of cyberchondria tend to pay more attention to negative information.
- It is beneficial to develop strategies and interventions that provide accurate, balanced online health information.

Abstract citation ID: ckae144.2226
Protocolizing social prescribing in mental health and addiction services: barriers and opportunities

Marc Olivella-Cirici

M Olivella-Cirici[1,2,3], C Casajuana Kögel[3], L Segura[3], J Alonso[1,2], J Colom[3]
[1]Health Services Research Group, Hospital del Mar Research Institute - IMIM, Barcelona, Spain
[2]CIBER of Epidemiology and Public Health, Madrid, Spain
[3]General Subdirectorate of Addictions SGAVIH, Public Health Agency of Catalonia ASPCAT, Barcelona, Spain
Contact: molivella@researchmar.net

Issue: Social Prescribing (SP) is a structured approach where health professionals recommend community activities to enhance well-being. Starting in Catalonia in 2012, it expanded to the entire primary care network by 2016. By 2023, 23,338 patients received SP, showing a 2.3-fold increase from 2022. Two-thirds experienced improvement in mental well-being. Now, efforts focus on applying SP to mental health and addiction services (MHAS), where SP can be used for restoring health and well-being.

Description: A literature review was conducted and a working group was initiated with MHAS professionals was initiated to exchange experiences and identify needs and best practices. This was done in preparation for designing a pilot experience, which will include a qualitative study through focus groups to validate the action plan and determine barriers and facilitators in MHAS. The groups will be segmented into MHAS users and frontline professionals.

Results: The results of the review process and the working group sessions demonstrated that SP can be useful and beneficial for the health MHAS users. However, barriers and opportunities were identified. The main barriers detected include: the need for strong support during referrals to community activities; increased awareness of addiction among activity providers to reduce stigmatization; define inclusion and exclusion criteria; determining monitoring and evaluation tools; and mapping and updating community assets. Regarding opportunities, the following were highligthed: the interest of MHAS professionals in promoting and implementing a SP program in this area; the existence of organizations already conducting community activities focused MHAS users; and political prioritization of this issue.

Lessons: The implementation of a SP program protocol in MHAS is considered beneficial. It is necessary to analyse barriers to effectively address them and to identify opportunities to leverage them.

Key messages:

- Social Prescribing has significantly enhanced mental health outcomes in Primary Care, which can imply a potential improvement in well-being of mental health and addiction services users.
- Implementing Social Prescribing in mental health and addiction services offers promising integrated care opportunities, requiring barriers resolution and maximizing existing prospects.

Abstract citation ID: ckae144.2227
Social inequalities in the mental well-being of adolescents in Barcelona (2016-2021)

Marc Olivella-Cirici

M Olivella-Cirici[1,2,3], G Vilagut[2,4], E Sánchez-Ledesma[1,5], G Serral[1,4,5], M Cortés-Albaladejo[1,5], MI Pasarín[1,3,5], J Alonso[2,3,4], G Pérez[1,3,4]
[1]Barcelona Public Health Agency, Barcelona, Spain
[2]Health Services Research Group, Hospital del Mar Research Institute - IMIM, Barcelona, Spain
[3]Universitat Pompeu Fabra, Barcelona, Spain
[4]CIBER of Epidemiology and Public Health, Madrid, Spain
[5]Sant Pau Research Institute, Barcelona, Spain
Contact: molivella@researchmar.net

Crises have the potential to affect mental well-being (MWB), especially at vital stages of personal development such as adolescence. The objective of this study was to investigate the 2016-21 trends of social inequalities in the MWB of adolescents in Barcelona, stratifying by sex. Sequential, cross-sectional study based on the FRESC survey, held by the ASPB, representative of 8th and 10th grade adolescents (13-16 years old) schooled in Barcelona, in 2016 (N = 2,154) and 2021 (N = 2,299). MWB was examined using the validated WEMWBS, scoring from 14 (lowest) to 70 (highest) MWB. A temporal trend analysis of inequalities in MWB was carried out using the student socioeconomic status (SES) (low/average/high), measured with the validated FAS. For each group, the effect size of the WEMWBS means was measured with Cohen's D. Linear regressions were performed, adjusting for academic grade, student country of origin, type of school and school index of vulnerable students. Adjusted β coefficients (aβ) and their statistical significance ($p<.05$) were estimated. In 2016, boys had higher MWB mean scores than girls (54.0 vs 50.8) ($p<.01$). In 2021, sex differences persisted, but with lower scores (51.7 vs 47.0) ($p<.01$) and still with a moderate effect size (0.52 in 2021 vs 0.40 in 2016). In multivariate regression models, boys in low SES showed the greatest MWB decrease in 2016 (low vs high SES: aβ= -3.44; $p<.01$). A significant temporal trend 2016-2021 of MWB worsening was observed in all groups, except for boys in low SES. The greatest deterioration in MWB was observed in girls, similarly in different SES (low SES: aβ= -3.52; $p<.01$). Boys in low SES showed the worst MWB in 2016 whereas all SES categories of girls had a significant trend of deterioration in MWB (2016-21). The latter could be attributed, among other factors, to a differential effect of the COVID-19 pandemic. These results underline the importance of addressing inequalities in the MWB, particularly among adolescent girls.

Key messages:

- This study reveals a deterioration in mental well-being temporal trends (2016-2021) among adolescents in Barcelona, especially in girls.
- Findings emphasize the need to address social inequalities for improving mental well-being outcomes in adolescent populations.

Abstract citation ID: ckae144.2228
Associations between school engagement and mental well-being among Finnish parent-child dyads

Sanna Tuomela

SK Tuomela[1], J Nordmyr[1], P Söderberg[2], AK Forsman[1]
[1]Department of Health Sciences, Faculty of Education and Welfare Studies, Åbo Akademi University, Vaasa, Finland
[2]Department of Developmental Psychology, Faculty of Education and Welfare Studies, Åbo Akademi University, Vaasa, Finland
Contact: sanna.tuomela@abo.fi

Background: To understand how individual differences in mental well-being emerge for children and adolescents, it is important to understand the amenable factors in the context in which the development takes place - that is, for children, primarily in the family and in school. There is a notable gap in the research exploring the positive impacts of school factors on parent-child dyads and their mental well-being, and if there are any associations between school engagement and the mental well-being of parents and their children.

Methods: Data from 307 parent-child dyads were included in the study, the data stemming from a Finnish l research project (CONSENSUS) encompassing longitudinal survey data collection among both children in grades 4-6 and their parents. By exploring bivariate correlations and using the Actor-Partner Interdependence Model (APIM), the present study aims to investigate actor and partner effects of school engagement and mental well-being among parents and their child in grade 4-6.

Results: Preliminary results show that there are statistically significant correlations between parents' and their children's mental well-being, but that there are no significant correlations between children's school engagement and parental school engagement. Further, statistically significant actor effects emerge between children's school engagement and mental well-being, and between parental school engagement and mental well-being.

Conclusions: By clarifying the interaction between school engagement and mental well-being in parent-child dyads, this study not only contributes to the theoretical understanding of these constructs but also offers insights that can inform future development of mental well-being promotion interventions aimed at families and educational settings in Finland and elsewhere.

Key messages:

- This study offers an innovative exploration of the links between mental well-being and school engagement among 274 Finnish parent-child dyads.
- Results show various interactions between school engagement and mental well-being among the parent-child dyads, with implications for interventions intended to support well-being in families.

Abstract citation ID: ckae144.2229
The impact of the covid 19 pandemic on eating disorders in Slovenia

Alenka Hafner

A Hafner[1]*, D Zupan*[1]
[1]NIJZ Regional Unit Kranj, Kranj, Slovenia
Contact: alenka.hafner@nijz.si

Introduction: Eating disorders are an important public health problem of adolescents. The purpose of the research was to examine the impact of the covid 19 pandemic on eating disorders, as adolescents were one of the most affected groups.

Methods: Data from the databases of the National Institute of Public Health (Outpatient Health Statistics and Database of Hospital Treatments for Diseases for the period from 2010 to 2021 and the Database of Deaths for the period from 2000 to 2021 were used for typical (F50.0) and atypical (F50.1) anorexia nervosa, typical (F50.2) and atypical (F50.3) bulimia nervosa and unspecified eating disorders (F50.9)) and the web portal To sem jaz.net for the period from 2012 to 2022. Data on of first visits and hospital treatments were processed for a twelve-year period and crude rates were calculated according to time, gender and diagnoses.

Results: Data showed that rates of first visits at the primary level and rates of hospital treatment did not change statistically significantly between 2010 and 2019 for women and for men. In 2020 and 2021, both rates increased for women and men. Based on the 10-year average for the period from 2010 to 2019, in 2021 the rate of first visits at primary level increased by 119 % for women and 91 % for men, and the rate of inpatient treatment increased by 50% for women and 80% for men. Girls predominated among treated at primary and secondary levels. The increase in first visits and hospital treatments was mainly due to anorexia nervosa. In the period from 2000 to 2021, eating disorders were the main cause of death for 24 people in Slovenia. In 2022, there were 3.7 times more questions in the field of eating disorders at web portal To sem jaz.net than in 2019.

Conclusions: Eating disorders are chronic diseases that develop over many years. The increase in mental health problems associated with the covid 19 pandemic may be reflected in the increase in eating disorders in the following years as well.

Key messages:

- Eating disorders are an important public health problem of adolescents.
- The increase in mental health problems associated with the covid 19 pandemic may be reflected in the increase in eating disorders in the following years as well.

Contact: hanna.muees@meduniwien.ac.at

Background: People with mental ill-health (PMIH) have higher cancer mortality rates than the general population. Barriers to healthcare service access may be a contributing factor. The EU-funded CO-CAPTAIN project aims to reduce health inequalities by improving overall health and reducing cancer burden by adapting and implementing the Patient Navigation (PN) Model targeted at PMIH. This qualitative study explored healthcare system experiences of PMIH in Austria, Greece, Poland, and Spain.

Methods: Eighty-one participants (22-76 years old), including 34 PMIH, 10 caregivers, 14 care team members, 12 mental health organization representatives, and 11 service manager representatives, were recruited. Semi-structured interviews focused on awareness of cancer risk factors, healthcare system experiences, and perspectives on PN as an intervention. Interviews were transcribed verbatim and analyzed using thematic analysis.

Results: Three major themes emerged: (1) somatic health relevance and preventive services utilization and (2) barriers / (3) facilitators to preventive services access. Knowledge of cancer prevention services varied greatly. Participants were aware of associations between risky health behaviors and health. Burden of mental health problems and discrimination, insufficient access to information, and lack of service flexibility were noted as barriers. Considerations of individual circumstances, social support, and empowerment were named as facilitators.

Conclusions: Tailored interventions involving healthcare professionals and PMIH in development of supportive environments and health literacy have the potential of overcoming identified barriers to the use of healthcare services.

Key messages:

- People experiencing mental ill-health are faced with significant structural barriers when accessing somatic health services.
- Understanding people's needs in terms of access and utilization of health care allows us to define guidelines for future personalized healthcare solutions.

Background: COVID-19 and subsequent lockdowns had an impact on the mental health of students, who had already been identified as a vulnerable population prior to this pandemic. At the end of the first COVID-19 lockdown, 15% of students reported suffering from moderate to severe anxiety. Psychological resilience is defined as the ability to bounce back from a stressful event and has been shown to have a positive impact on mental health parameters. This study aimed to identify factors associated with low resilience in the student population of the Grand Est region of France, at the end of the first national containment related to COVID-19.

Methods: The PIMS-CoV19 study: A cross-sectional online survey was conducted among students at the University of Lorraine to collect sociodemographic data, living and learning conditions, as well as levels of resilience and perceived health. Bivariable and multivariable logistic regression analyses were performed. Model robustness was assessed using bootstrap resampling.

Results: Among 3708 students, 50.6% had normal resilience, while 37.3% reported low resilience. Female gender (OR = 2.1, 95% CI: 1.8-2.6) and low social support (OR = 1.7, 95% CI: 1.1-2.6) were the main risk factors for low resilience. Negative thoughts (OR = 1.4, 95% CI: 1.4-1.5), lower quality of relationships with people in general (OR = 1.5, 95% CI: 1.3-1.8), and studying arts, humanities, or languages (OR = 1.4, 95% CI: 1.0-1.8) were identified as risk factors. Increased age (OR = 0.9, 95% CI: 0.9-1.0) and flat sharing (OR = 0.6, 95% CI: 0.4-0.9) were protective factors against low resilience.

Conclusions: Resilience seems to be impacted primarily by internal and micro-environmental factors. Consolidating levels of individual resilience of at-risk populations by acting on these factors could be the key to improving their mental health.

Key messages:

- Resilience seems to be impacted primarily by internal and micro-environmental factors.
- Consolidating levels of individual resilience of at-risk populations by acting on these factors could be the key to improving their mental health.

Abstract citation ID: ckae144.2232

Self-esteem and illness perception in multiple sclerosis: Unveiling key factors for self-management

Pavol Mikula

P Mikula[1], V Timkova[1], J Szilasiova[2], I Nagyova[1]
[1]Department of Social and Behavioral Medicine, PJ Safarik University, Kosice, Slovakia
[2]Department of Neurology, PJ Safarik University, Kosice, Slovakia
Contact: pavol.mikula@upjs.sk

Background: Multiple sclerosis (MS) is characterized by demyelination and variable symptomatology, and typically appears during young adulthood, making it a condition of considerable public health concern. Given its chronic nature, understanding of the illness perception plays a crucial role in long-term disease management. Our research aims to examine the factors affecting illness perception among people with MS.

Methods: The study sample consisted of 166 patients with MS (75.3% women; mean age: 40.9±11.3 years; mean disease duration: 11.6±7.1 years). People with MS underwent medical examination to assess their functional disability measured by Expanded Disability Status Scale (EDSS), and structured interview, during which data on age, sex, education, employment status, income and disease duration were obtained. Finally, they were asked to fill in the Brief Illness Perception Questionnaire (BIPQ), and the Rosenberg Self-esteem Scale (RSE). Data were analysed with multiple linear regression analysis.

Results: Our results showed an association between functional disability and illness perception ($\beta = 0.22$; $p < 0.05$). However, this association lost its significance upon adding self-esteem into the model (β=-0.53; $p < 0.001$), with overall explained variance in illness perception rising from 2.7% to 27.5%. No statistically significant contribution of other socio-demographic or clinical variables was observed.

Conclusions: Higher self-esteem in people with MS appears to be intricately connected to their illness perception. Given that the management of chronic conditions heavily relies on patients' personal resources, healthcare providers could play a crucial role in fostering self-esteem. By encouraging the development of self-esteem, patients may come to view their illness as more manageable and less daunting, potentially leading to mitigation of negative consequences of functional disability. [Grant support: VEGA 1/0608/23]

Key messages:

- Self-esteem may be stronger predictor of illness perception than functional disability in people with MS.
- MS patients may benefit from psychological support aimed at promoting self-esteem.

Abstract citation ID: ckae144.2233

Youth mental health outreach interventions: lessons from an experience capitalisation process

Alexis Krache

M Villeval[1], B Georgelin[1], E Jean-Gilles[2], J Brun[3], T Delescluse[1], A Van Hoye[4], A Krache[1], F Berdougo[1]
[1]Société Française de Santé Publique, Laxou, France
[2]EPS Consulting, Paris, France
[3]Fondation de France, Paris, France
[4]UMR1319 INSPIIRE, Université de Lorraine, Nancy, France
Contact: alexis.krache@sfsp.fr

Issue: Young people face socioeconomic, geographical and cultural barriers to access care and support in mental health. Practitioners implement outreach initiatives to improve mental health and address health inequalities, mostly developed in a 'no-request for care' context.

Methods: To better understand the implementation mechanisms of these initiatives, Fondation de France commissioned the French Society for Public Health to carry out an experience capitalisation to inspire other professionals. Experience capitalisation method was used, based on in depth interviews with project stakeholders. Covered themes were: the description of history, strategies and activities; identification of key moment and key levers; skills and knowledge used.

Results: Nine mental health outreach projects implemented across regions of France were selected with the help of a multidisciplinary steering committee. Each project was synthetised in a capitalisation document and a cross-sectional analysis was undertaken.

Lessons:

- A variety of outreach approaches were carried on: meeting adolescents in the street or at coffee shops; home-based interventions; consultations in converted van etc. • Outreach is not just a matter of physically moving outside health structures but requires non-judging and flexible stance to adjust to the youth's pace and will. To extend their approach to mobility, professionals deepen their team's multidisciplinarity, broaden cross-sector partnerships and mobilise new skills and creativity. • Adolescents' participation to care or support plans was one of projects strengths, whether they suffer from anxiety or mental disorders. However, their participation in governance and decisions regarding global projects remained limited.

Key messages:

- To reduce mental health inequalities and enhance youth participation in outreach interventions, empowerment and wellbeing of interventions practitioners should also be supported.
- Capitalisation of experience in health promotion is a promising method contributing to professional acknowledgment and development of shared knowledge on interventions implementation.

Abstract citation ID: ckae144.2234
Gambling disorder and its associated factors in university students

Si̇bel Sert

S Sert[1], *OH Aydilek*[1], *O Arslangiray*[1], *MF Onsuz*[1], *S Metintas*[1]
[1]Public Health Department, Eskisehir Osmangazi University, Eskisehir, Türkiye
Contact: sibel4397@gmail.com

Background: Gambling disorder (GD) is defined as persistent and uncontrollable gambling behaviour that has negative effects on an individual's life. This can lead to financial problems, poor academic performance, and health problems. GD has been associated with psychological disorders like depression, anxiety, and attention-deficit hyperactivity disorder (ADHD). We aimed to examine the gambling disorder and its associated factors in university students.

Methods: We conducted a cross-sectional study among students at a university in Eskisehir (Türkiye) in 2024. A stratified random sample design was used. Five faculties were randomly selected. A total of 1,201 students were included according to the stratum weight of the faculties. A questionnaire including sociodemographic characteristics, South Oaks Gambling Screen (SOGS), and Adult ADHD Self-Report Scale (ASRS) was applied. Data were analysed through descriptive statistical analyses and multivariate logistic regression models.

Results: The mean age was 21.5±2.8 years, and 46.8% were male. While 48.7% of the students stated that they had gambled at least once, 2.2% had a gambling disorder. The three most common types of gambling played by students were stock market (28.2%), bet on sports (22.0%), and scratch cards (18.2%). In multivariate analysis, being male (Odds ratio-OR:6.5, 95%CI:1.4-29.8), having lost years during education (OR:2.7, 1.1-6.8), having relatives with gambling problems (OR:8.0, 1.8-36.2), investing greater amounts of money in gambling (OR:3.7, 1.0-13.0), and having a high probability of ADHD (OR:4.3, 1.4-12.8) were found to be predictors for GD.

Conclusions: Although about half of the students had engaged in gambling activities, only a small proportion showed signs of GD. We can conclude that being male, having lost years in education, having relatives with gambling problems, investing larger amounts of money in gambling, and having a higher probability of ADHD are predictors of GD among students.

Key messages:

- Implementing educational campaigns at universities to raise awareness of the potential risks and consequences associated with GD could be beneficial.
- It may be helpful if mental health services at the university were equipped to consider mental health conditions such as ADHD, that contribute to GD.

Abstract citation ID: ckae144.2235
Luxury depiction in posts of the most popular Lithuanian influencers on Instagram and Facebook

Robertas Basijokas

R Basijokas[1], *D Austys*[1]
[1]Department of Public Health, Institute of Health Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania
Contact: robertas.basijokas@mf.stud.vu.lt

Background: Studies show that depiction of high living standards in social media is related to mental health problems. Influencers in social networks are those who might publish such content and reach high numbers of people. We aimed to assess the prevalence of luxury depiction in posts published by Lithuanian influencers on Facebook and Instagram.

Materials and methods: All publicly available posts created by 21 most popular Lithuanian influencers on Facebook and Instagram in 2022 were included. The content analysis of the posts was performed and information about luxury and other lifestyle factors was registered. Distribution of the posts depicting luxury was compared according to social networks where they were published and characteristics of the influencers: gender, age, number of followers, and the target audience.

Results: A total number of 6425 posts were analysed. Every fifth (18.2%) post depicted luxury. Posts depicting luxury were published on Facebook and Instagram with a similar frequency ($p = 0.066$). Among these posts, luxury brands were presented in 7.5%, luxury hotels and restaurants - in 7.1%, luxurious trips - in 63.0%, luxurious cars - in 27.6%, luxurious activities - in 0.8%, and jewellery - in 0.5%. Overall, men, older influencers, influencers with higher number of followers more frequently posted content depicting luxury (respectively, 29.0% vs. 10.6%, 20.2% vs. 14.5%, 20.3% vs. 15.4%, p-value less than 0.001). Luxury was more frequently depicted in posts targeted to male audience than targeted to female or unisex audiences (respectively, 46.6% vs. 10.5% vs. 20.7%, p-value less than 0.001).

Conclusions: Every fifth post of Lithuanian influencers depicts luxury. Luxurious trips are depicted most frequently. Male and older influencers, and those with more followers more frequently depict luxury-related content. Luxury is most frequently depicted in posts targeted to male audience.

Key messages:

- Every fifth post of Lithuanian influencers depicts luxury – this might be considered as an important risk factor for public mental health.
- Higher prevalence of luxury depiction targeted to male audience should be taken into account when implementing public health interventions.

Investigating the role of psychosocial stress factors in back pain patients

Julia Schmetsdorf

J Schmetsdorf[1,2], *K Krüger*[1,2], *J Posselt*[3], *W Runde*[4], *HG Zechel*[4], *C Krauth*[1,2]
[1]Institute for Epidemiology, Hannover Medical School, Hannover, Germany
[2]Center for Health Economics Research, Hannover, Germany
[3]AOK Niedersachsen, Hannover, Germany
[4]Rehabilitation Center, Bad Zwischenahn, Germany
Contact: schmetsdorf.julia@mh-hannover.de

Background: In 2022, 27.35 million people in Germany were diagnosed with back pain. This results in a 1-year prevalence of 32.64 percent of the population and 96,8 million days of incapacity to work. Moreover, patients with back pain often suffer from additional mental disorders (e.g. anxiety, depression). This study investigated the influence of other health-related factors such as psychosocial stress in these patients.

Methods: A randomized controlled study was conducted with 297 gainfully employed participants in a rural rehabilitation center in Germany Bad Zwischenahn who received a 4-week multimodal pain therapy. 150 participants were allocated to the intervention (IG) who received an additional 12-month relapse prevention treatment while

147 were allocated to the control group (CG) who received no such additional treatment. Data was obtained via questionnaire (three measurement points) and claims data. Among other health-related outcomes, the number of sick days was examined. A 10-item subscale of the Patient Health Questionnaire (PHQ) was included to measure common psychosocial stress factors.

Results: The evaluation of the PHQ (summary) scores revealed a mild stress level at all three dates. Of the ten psychosocial stress factors surveyed, the highest level was reported in the IG and CG on the scale "Worrying about health". The IG improved significantly ($p = .017$) compared to the CG after one year reporting decreased health worries. Further analyses carried out by analysis of variance (ANOVA) showed that health worries are significantly associated to a higher number of sick days in the IG ($p = .002$) and CG ($p = .010$).

Conclusions: With regard to psychosocial stressors, the participants were primarily affected by health worries. The results indicate that health concerns are the primary psychosocial stress factor associated with back pain and should be taken into account in the treatment of back pain.

Key messages:

- A 12-month relapse prevention treatment significantly reduced the psychosocial stress experienced by people with back pain after their rehabilitation treatment.
- Concerning psychosocial stress factors, the participants of both groups were primarily affected by health worries.

Abstract citation ID: ckae144.2237
The impact of telework on mental health: a secondary analysis of the 2023 BelHealth

Eduardo Bracho Montes de Oca

E Bracho Montes de Oca[1,2,3]*, L Gisle*[1]*, L Hermans*[1]*, C Duveau*[1]*, B Cagnie*[3]*, R De Pauw*[2,3]*, B de Geus*[2]
[1]Department of Epidemiology and Public Health, Sciensano, Leuven, Belgium
[2]IACCHOS, Université Catholique de Louvain, Louvain-La-Neuve, Belgium
[3]Department of Rehabilitation Sciences, Universiteit Gent, Ghent, Belgium
Contact: eduardoantonio.brachomontesdeoca@sciensano.be

Background: Teleworking gained ground in most workplaces, but questions remain about its impact on mental health. This research used data from the BELHEALTH cohort, a Belgian longitudinal wellbeing study, to investigate the relationship between the extent of telework and three mental health outcomes: anxiety, depression, and burnout.

Methods: In June 2023, the quarterly online survey assessed telework frequency (never, monthly, weekly, daily) as well as state of anxiety (GAD-7), depression (PHQ-9) and burnout (BAT-12). A complete case analysis ($n = 2{,}303$) of these cross-sectional data was performed with employed participants aged 18-65 years. Logit generalized linear mixed models were constructed, with the mental health outcomes as binary outcomes, telework as ordinal covariates, and occupation, type of job, as random effects. The anxiety, and depression models were controlled for geographical location, sex, age, and education confounders, whereas the burnout model was controlled only for sex, and education due to lack of observations.

Results: In this secondary analysis, we found that daily telework increased the odds of anxiety by 2.33 (95% CI [1.71; 3.17], $p < 0.01$), the odds of depression by 2.98 (95% CI [2.16; 4.12], $p < 0.001$), and the odds of burnout by 1.17 (95% CI [0.87; 1.58], $p > 0.05$) as compared with not teleworking while controlling for confounders. The category of monthly telework was associated with lower odds of anxiety (0.85; 95% CI [0.67; 1.07], $p > 0.05$), depression (0.91; 95% CI [0.74; 1.28], $p > 0.05$), and burnout (0.95; 95% CI [0.79; 1.15], $p > 0.05$) as compared to not teleworking.

Conclusions: Full-time teleworkers seem to have a higher odds for negative mental health outcomes. Future studies should focus on the long-term causal mechanisms that explain how telework intensity influences mental health to tailor and optimize current wellbeing initiatives at the workplace.

Key messages:

- Our survey points out that full-time teleworkers seem to be at risk of mental health problems.
- The frequency of telework has a mixed influence on mental health, indicating that different employees need tailored wellbeing initiatives.

Abstract citation ID: ckae144.2238
Social factors that promote resilience in adolescents with depression: a systematic review

Marsida Hysaj

M Hysaj[1,2]*, MR Crone*[1,3]*, JC Kiefte*[1]*, RRJM Vermeiren*[2]
[1]Department of Public Health and Primary Care, Leiden University Medical Center, The Hague, Netherlands
[2]Department of Child and Adolescent Psychiatry, Leiden University Medical Center, Leiden, Netherlands
[3]Department of Health Promotion, Maastricht University, Maastricht, Netherlands
Contact: m.hysaj@lumc.nl

Background: A socially protective environment matters. Social factors can protect against the development of depression among adolescents in community samples. There is however scant knowledge about their buffering role on the impact of depressive symptoms in adolescents in a clinical setting. Understanding these factors can help explaining why some children function well despite of their depression symptoms. In this review, we aimed to identify which social protective factors mitigate impairment from depression in adolescents.

Methods: We included peer-reviewed, cross-sectional and longitudinal studies using the following search strategy: Social protective factors AND depression or depression symptoms AND adolescents AND daily impairment, yielding 1737 hits. Included studies focused on social protective factors in relation to a depression diagnosis or depression symptoms severity, in adolescents age 11-24.

Preliminary results: We found 6 studies that examined the relationship between social protective factors and impairment or severity of depression symptoms in adolescents with a clinical depression or elevated symptoms. In these studies, higher rates of parental attachment, parental monitoring and school belonging moderated the relation between depression symptoms and daily impairment. Higher rates of family support and peer belonging were associated with the low depressed mood group. The rest of the studies tested the association of social protective factors on the development of depression symptoms in non-clinical populations.

Conclusions: There are limited studies on the buffering role of social protective factors in adolescents with clinical depression. Next, we will focus on non-clinical, longitudinal studies to explore which social protective factors moderate the development of depression over time. We aim to identify social factors that can mitigate the development of depression in community samples and are potentially important for clinical settings.

Key messages:

- There is a scarcity of studies that explored the relation between social protective factors in adolescents with elevated depression symptoms or depression diagnosis.
- The role of social protective factors that moderate the development of adolescent depression symptoms over time should be prioritized in the development of intervention programs.

Abstract citation ID: ckae144.2239
Factors Influencing Suicidal Ideation in Young and Middle-aged Adults in Korea: A Nationwide Study

Ji Eun Kim

JE Kim[2]*, SY Park*[2]*, IH Song*[1,3]
[1]School of Social Welfare, Yonsei University, Seoul, South Korea
[2]Department of Family Environment & Welfare, Chonnam National University, Gwangju, South Korea
[3]ICONS Convergence Academy, Yonsei University, Seoul, South Korea
Contact: junekim@jnu.ac.kr

Objectives: This study aims to analyze various factors influencing suicidal ideation among young (19-39 years) and middle-aged (40-64 years) adults using nationwide longitudinal data in South Korea, which has the highest suicide rate among OECD countries for more than 20 years.

Methods: An analysis was conducted using the WAVE II data (2016-2017) from a nationwide longitudinal study on the mental health of suicide survivors (LoSS). The sample included 2,002 participants (1,290 young adults, 712 middle-aged adults) recruited through stratified proportional quota sampling. Multiple regression analysis was performed to identify factors influencing suicidal ideation in each age group.

Results: In young adults, being female, having a high school education or lower, being unmarried/divorced/widowed, and having higher levels of depression were positively associated with suicidal ideation. Higher levels of social support and better subjective physical health were negatively associated with suicidal ideation. In middle-aged adults, being unemployed, living alone, drinking alcohol more than once a week, and having higher levels of depression were positively associated with suicidal ideation, while higher levels of social support were negatively associated with suicidal ideation.

Conclusions: Factors influencing suicidal ideation differ between young and middle-aged adults. Age-specific suicide prevention strategies considering these factors are needed to promote social health and stability in South Korea.

Key messages:

- Different factors influence suicidal ideation in young and middle-aged adults in South Korea.
- Age-specific suicide prevention strategies are necessary to effectively address suicidal ideation and promote social health and stability in South Korea.

Abstract citation ID: ckae144.2240
Fear of falling as a psychological consequence of fall in older adults

Marija Jakubauskiene

I Tamulaityte-Morozoviene[1]*, J Dadoniene*[1]*, R Stukas*[1]*, M Tamulaitiene*[2]*, V Alekna*[1]*, M Jakubauskiene*[1]
[1]Faculty of Medicine of Vilnius University, Vilnius, Lithuania
[2]National Osteoporosis Center, Vilnius, Lithuania
Contact: marija.jakubauskiene@mf.vu.lt

Background: Falls is one of geriatric syndromes that impact active ageing. It is a major public health problem as falls can lead to irreversible health, social, and psychological consequences, and a large economic burden.

Methods: Elderly women, aged 65 years and above, who attended the National Osteoporosis Center for diagnostic or treatment purposes, participated in telephone interviews. These interviews aimed to document the outcomes and healthcare measures associated with any falls they experienced in the preceding 12 months. There was used a specially prepared questionnaire for demographic and falls data, fear of falling questionnaire "Falls Efficacy Scale International" (FES-I) and physical activity questionnaire "Physical Activity Scale for the Elderly" (PASE).

Results: The study population consisted of 339 community-dwelling women (mean age 72.9±5.3 years) all of whom reported experiencing one or more falls. One in three of these women had fallen two or more times. Most of all their fall resulted in an injury, and 79 (23.3%) reported falls led to bone fractures. Fear of falling was reported as a consequence of experienced fall by 251 (74.1%) women. Almost half of fallers restricted their everyday activities. The primary cause for limiting everyday activities was identified as pain.

Conclusions: Fear of falling was reported by 74.1% of women who fell during the previous 12 months. Every woman who experienced hip or vertebral fractures subsequently restricted their daily activities.

Key messages:

- Fear of falling is common among elderly women who has fallen once or more.
- The restriction of everyday activities is usually reported by women who feel pain and are afraid to fall again.

Abstract citation ID: ckae144.2241
WeCare – Mental healthcare for health professionals

Nadine Sturm

N Sturm[1]*, J Goldberg*[2]*, G Djokic*[3]*, F Dagnino*[4]*, L Klapa*[5]*, S Kretschy*[1]
[1]Forschung und Innovation, Johanniter Österreich Ausbildung und Forschung gemeinnützige GmbH, Vienna, Austria
[2]Johanniter-Akademie Mitteldeutschland, Johanniter Unfall-HIlfe e.V., Leipzig, Germany
[3]Serbian Trade Union of Doctors and Pharmacists, Belgrade, Serbia
[4]Consiglio Nazionale delle Ricerche, Genoa, Italy
[5]Danmar Computers Sp zoo, Rzeszow, Poland
Contact: nadine.sturm@johanniter.at

Issue/Problem: Health professionals face physical and mental stressors (risk factors) due to challenging working conditions.

Description of the Problem: Despite high levels of health literacy among healthcare workers, maintaining healthy habits is challenging due to variable shifts, including nights, high workloads, and intense emotional and mental demands. Adopting a healthier lifestyle requires personal changes that can be difficult to implement, particularly in nursing and caregiving. This is critical, as retaining and attracting new staff in these fields is essential for the healthcare sector.

Results/Effects/Changes: To address these challenges, it's crucial to boost intrinsic motivation and provide healthcare workers with practical tools to support their well-being and encourage them to remain in the sector. The WeCare project offers a mobile app designed as a 'pocket coach,' accessible at any time. Healthcare professionals can use the app to assess their current mental well-being through self-evaluation. With built-in assessments and predefined thresholds, the app tracks stress levels and quality of life. Depending on the outcomes, users are automatically guided to appropriate information, gamified activities, and exercises tailored to their specific needs. The project, running from 2022 to 2024, is co-funded by the European Union's Erasmus+ programme.

Lessons: The app is beta-tested during 2024 in five countries: Germany, Austria, Serbia, Poland, and Italy, with local language support. The test group will consist of healthcare professionals and related professions. The results, including user engagement and motivational factors are analyzed. As the project concludes in autumn, comprehensive recommendations and lessons learned will be compiled and presented at the European Public Health (EPH) Conference. This will also include sharing the app and its solution with the broader healthcare community.

Key messages:

- The WeCare app supports healthcare workers' mental health with a mobile "pocket coach" that provides personalized exercises. Through gamification, it promotes healthy habits and boosts job motivation.

- It is critical to support healthcare workers, as retaining and attracting new persons is essential for the healthcare sector.

Abstract citation ID: ckae144.2242
"Ajudar" – a practice with people with mental disorders treated with long-acting injectables

Carlos Miguel Rocha Magalhães

M Cabral Ferreira[1], CM Magalhaes[1], F Silva[1], F Basto[1]
[1]Public Health Unit, Local Health Unit of Medio Ave, Vila Nova de Famalicao, Portugal
Contact: pasbrow@gmail.com

Issue: Mental Health problems are one of the main causes of disability and morbidity. We think it is pertinent to intervene, providing special care for people with mental disorders and their families. We developed the project "Ajudar" ("To Help"), in a municipality in Northern Portugal.

Description of the problem: "Ajudar" started in 2013. Its main goal is to contribute to reducing the impact of mental disorders. Its objectives are to identify people with mental disorders treated with long-acting injectables (LAI) and to promote treatment adherence. We identified the Health Units (HU) where these patients take the medication and verified their compliance. An informatic alert was issued when there was non-compliance and we participated in home visits when patients did not show up. We also checked the situation if there was involuntary treatment. We wanted to know if this practice contributed to treatment compliance and to reduce involuntary treatment.

Results: We gradually identified more people, from 47 in 2013 to 108 in 2024. In 2013, 7 people with mental disorders treated with LAI had an involuntary treatment, whereas in 2019 it was 4. We didn't analyze data from 2020 to 2022, due to the COVID-19 pandemic. We don't have the complete data from 2023 yet.

Lessons: Within the years of "Ajudar", there was a more than twofold increase in the identified patients and a reduction of almost fourfold of the patients that had an involuntary treatment. Analyzing these data one must be careful due to small numbers bias. We think that a similar project is feasible in other settings. In our response to this Public Mental Health issue, we collaborated with everyone involved with these patients, from health profissionals to resources in the community (social services, community leaders, etc).

Key messages:

- There was a decrease to almost 3/4 in the number of patients that had an involuntary treatment.
- Involvement with the community is key.

Abstract citation ID: ckae144.2243
Stigma towards people with mental conditions in healthcare workers: an Italian cross-sectional study

Elena Cerino

E Cerino[1], G Lo Moro[1], R Mimmo[1], A Giacobbe[1], G Scaioli[1], F Bert[1,2], R Siliquini[1,3]
[1]Department of Public Health Sciences and Pediatrics, University of Turin, Turin, Italy
[2]Local Health Unit ASL TO3, Collegno, Italy
[3]University Hospital City of Health and Science of Turin, Turin, Italy
Contact: e.cerino@unito.it

Background: Stigma towards people with mental disorders (MD) in healthcare workers (HCWs) can negatively influence the quality of care provided and hinder patients from accessing healthcare.

The aim of this study was to analyze stigma and its determinants among physicians and nurses in Italy, as a basis for future strategies to reduce its extent.

Methods: A cross-sectional study was conducted from April to September 2023. A sample of 1053 physicians and nurses working in Italy answered an online 52-item questionnaire. Variables explored demographic data, work context, burnout symptoms, and personal or family history of MD. The Opening Minds Scale for Health Care Providers (OMS-HC) was used to assess the level of stigma (score from 20 to 100, higher scores represent higher levels). Descriptive analysis and multivariable linear regression were performed.

Results: Females were 69.5% and median age was 48 years (IQR=37-58). Physicians were 60.5%. A total of 20% of the sample worked in psychiatric settings. Burnout symptoms were reported by 23.5%. Results showed a median OMS-HC score of 49 (IQR=43-54). Positive associations with stigmatizing attitudes were found for being a nurse ($p = 0.020$) and being in burnout ($p = 0.017$), while working in a psychiatric setting ($p < 0.001$) and having personal or family history of MD ($p < 0.001$) had negative associations.

Conclusions: This research unveiled a notable amount of stigma among Italian HCWs towards individuals with MD. Since people with MD experience higher rates of disability and mortality, it has to be a public health priority to develop targeted strategies to reduce stigma in HCWs, as it discourages patients from accessing healthcare. Future interventions should be tailored for different professionals and dealing with HCWs burnout.

Key messages:

- Future interventions should consider that healthcare workers in burnout and nurses tend to have more stigma toward patients with mental conditions.
- Healthcare professionals working in psychiatric settings and having personal or family history of mental disorders showed lower stigma.

Abstract citation ID: ckae144.2244
Latent class analysis of attitudes towards drug use and well-being among South Korean young adults

Jimin Lee

S Lee[1], JS Chun[1], J Lee[1]
[1]Department of Social Welfare, Ewha Womans Univeristy, Seoul, South Korea
Contact: elfreda0208@gmail.com

Background: The surge in drug use and lack of awareness about drug-related dangers among young adults have become major public health concerns in South Korea. According to the Theory of Planned Behavior, understanding attitudes towards drugs is crucial, as permissive attitudes may lead to drug use. Thus, the study aims to identify latent classes of drug use attitudes among Korean young adults and evaluate how their well-being influences each class.

Methods: A total of 301 college students in Seoul, South Korea, participated in the study. Latent class analysis (LCA) was employed to identify unique patterns of attitudes towards drug use. Subsequently, we examined the relationships between auxiliary variables (i.e., well-being, including life satisfaction, self-control, quality of life, depression, generalized anxiety disorder, childhood trauma, self-esteem, stress, family strengths, perceived social support, and stigmatization) and latent classes (i.e., attitudes towards drug use subgroups) by conducting multivariate logistic regression analyses.

Results: LCA categorized attitudes towards drug use into three groups: Class 1 (Permissive Drug Attitude Group), Class 2 (Moderate Drug Attitude Group), and Class 3 (Critical Drug Attitude Group). Class 2 showed a particularly permissive view on marijuana legalization. In multivariate logistic regression, higher stigmatization ($\beta = .900$, $p < .05$) was associated with membership in Class 1 compared to Class 3. Furthermore, being male ($\beta = 2.272$, $p < .001$) and having higher self-esteem ($\beta = .989$, $p < .05$) were linked to membership in Class 2 compared to Class 3.

Conclusions: The study enhances understanding of the complex relationship between Korean young adults' well-being and their drug use attitudes. Effective interventions by frontline social workers aimed at preventing drug use should continuously monitor and address social stigmatization and self-esteem while providing accurate information and education regarding drug use.

Key messages:

- Latent Class Analysis sorted drug attitudes into three groups: 'Permissive,' 'Moderate,' and 'Critical' Attitude Groups.
- Individuals experiencing social stigmatization had a higher risk of permissive attitudes, while higher self-esteem increased the likelihood of being in the moderate group over the critical group.

"Do not forget about us." A systematic review of needs and unmet needs in dementia care in Europe

Michelangelo Mercogliano

M Mercogliano[1], M Sorrentino[1,2], C Fiorilla[1], F Esposito[1], I Stilo[1], M Triassi[1], R Palladino[1,3]
[1]Department of Public Health, University 'Federico II' of Naples, Naples, Italy
[2]Department of Public Health, University of Pavia, Pavia, Italy
[3]Department of Primary Care and Public Health, School of Public Health, Imperial College, London, UK
Contact: michelangelo.mercogliano@unina.it

Background: In Europe, the prevalence and costs of dementia, including Alzheimer's disease, are rising due to demographic changes. The care provided does not adequately address the needs of stakeholders involved. This systematic review aims to identify the needs, and unmet needs in European dementia care, thus providing a comprehensive framework to improve dementia care services.

Methods: Our inclusion criteria, adhering to PRISMA guidelines, include studies published from 2013 to 2023, and addressing needs and unmet needs of persons living with dementia, caregivers, and dementia care professionals. Risk of bias was evaluated using the Mixed Methods Appraisal Tool.

Results: From an initial pool of 3738 articles, 48 studies meet inclusion criteria. Caregivers express need for support, notably in psychological and logistical assistance, in managing daily errands and healthcare tasks, and to navigate healthcare system, exacerbated by the stress and isolation during the COVID-19 pandemic. Persons living with dementia face challenges in social inclusion due to the lack of public understanding and community-based care. Dementia care professionals emphasise need for more training and resources to manage dementia effectively, with a recent shift towards the necessity for telehealth competencies. Furthermore, caregivers from ethnic minorities highlight the importance of culturally sensitive healthcare access to overcome cultural and language barriers.

Conclusions: Educational resources, broaden community support, clear information about available care services, and public understanding of dementia were the most commonly expressed unmet needs. Addressing these needs within the dementia care network is crucial for better service integration and improving the quality of life for all stakeholders involved. Future research should focus on developing strategies to address the unmet needs, ensuring robust support for the increasing number of individuals affected by dementia.

Key messages:

- Care dementia effectively needs more resources, training, and a culturally sensitive healthcare access to ethnic minorities.
- People living with dementia and caregivers need psychological and community-based support, social inclusion, clear information about available care services, and public understanding of dementia.

Abstract citation ID: ckae144.2246
Engaging co-creators network in a public mental health intervention: MENTBEST

Gentiana Qirjako

G Qirjako[1,2], A Cerga Pashoja[2,3], A Dushaj[2], S Qirjako[2]
[1]Department of Public Health, University of Medicine, Tirana, Albania
[2]Community Centre for Health and Wellbeing, Tirana, Albania
[3]School of Allied Health and Life Sciences, St Mary's University, London, UK
Contact: gentaqirjako@gmail.com

Background: MENTBEST, a 5-year EU-funded project, addresses mental health challenges among vulnerable groups using community-based interventions and innovative technologies. It aims to mitigate adverse impacts, focusing on migrants, older individuals, younger individuals, long-term unemployed individuals, and those with mental disorders in Albania, Germany, Spain, Denmark, Greece, Ireland and Estonia. MENTBEST seeks to provide tailored support to vulnerable populations, promoting mental well-being and resilience through two interventions (a) Mentina a mobile app and (b) a complex community intervention based upon the European Against Depression 4-level intervention.

Methods: A Participatory Action Approach has been employed through each research stage of MENTBEST where stakeholders across Europe have become part of the research team and provide input towards designing and evaluating the two interventions mentioned above. The PRODUCES framework was used to establish the Co-creators Network, ensuring inclusivity and relevance through: stakeholder mapping, prioritization, and engagement strategies. An online platform has been established for the network to collaborate as a community of practice, but also as means of upskilling co-creators through MOOCs and brief courses.

Results: The Co-creators Network comprises 24 diverse members strategically distributed among vulnerable groups through all participating Mentbest countries. Engagement activities include workshop participation on taking decisions on a range of research topics such as designing content, evaluation of the interventions, implementation of the interventions etc.

Conclusions: The Co-creators Network represents a milestone for MENTBEST, ensuring a collaborative approach to public mental health intervention. Innovative strategies highlight the project's commitment to addressing the mental health needs of vulnerable populations.

Key messages:

- Collaborative approach in MENTBEST fosters inclusive public mental health interventions.
- Co-creators Network drives innovative strategies to address mental health needs of vulnerable groups.

Abstract citation ID: ckae144.2247
Abstract Strengths and difficulties Lithuania

Aida Balukonytė

AE Balukonytė[1], E Stankevičiūtė[1], M Jakubauskienė[1]
[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania
Contact: aida.balukonyte@gmail.com

Background: Most mental health disorders begin before the age of 18, peaking at 14.5 years (Solmi, 2022) and manifest as emotional and behavioural difficulties that are more frequent in institutional social care (ISC): former foster care recipients have higher rates of depression and PTSD than the general population (Pecora, 2009). The rate of children living in residential care facilities in Europe and Central Asia is double the global average (UNICEF, 2024). This study aims to assess and compare the mental health of children in ISC centers and regular high schools.

Methods: A cross-sectional study was conducted in ISC centres and high schools in 2022-2023. The sample size consisted of children aged 11-17 living in ISC (n = 49) or in families (n = 193). Online anonymous survey was applied to assess the prevalence of endured violence, substance use and measure mental health outcomes using the Strengths and Difficulties Questionnaire (SDQ-25).

Results: A total of 242 respondents (age mean 14.6, SD = 2.12) in ISC and families showed similar poor mental health rates (42% and 44%, respectively). Prosocial behaviour problems were exhibited more by boys ($p < 0.05$), whereas emotional symptoms were more common in families ($p < 0.001$): 90% normal SDQ-25 scores in ISC vs 60% in families. Enduring psychological (38% vs 60.2%) violence was more prevalent among children in families ($p < 0.05$); smoking - in ISC, alcohol use - in families ($p < 0.05$). In both groups enduring physical violence was associated with smoking and alcohol use ($p < 0.05$), and overall poor SDQ-25 results strongly correlated ($p < 0.001$, $r = 0.815$, $r = 0.610$, respectively) with hyperactivity.

Conclusions: A significant part of study participants reported poor mental health outcomes with most problems in relationships with peers. Mental health risk factors such as violence or substance abuse are associated with poor emotional wellbeing while being more common among children living with families.

Key messages:

- Children living in ISC and in families demonstrate similar level of mental health problems.
- Varying prevalence of substance abuse among children living in different settings highlights the importance of environmental factors when addressing the issue.

Abstract citation ID: ckae144.2248
Involuntary commitment and medical education on mental health diseases across Europe

Francesca Serazzi

F Serazzi[1]*, F Barbic*[1]*, S Stranges*[2]
[1]Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy
[2]Epidemiology and Biostatistics, Western University, London, Canada
Contact: francescaserazzi@gmail.com

Background: Psychiatric diseases are projected to become one of the greatest contributors to the global burden of disease by 2030, already presenting as one of the principal causes of DALYs lost in Europe. Given the particular nature of psychiatric disorders, national legislatures have been enacted by each European country regarding the possibility of involuntary psychiatric treatment. As practical implementations vary greatly from country to country, we wish to analyse how different attitudes to involuntary treatment affect health outcomes, so as to propose a uniform guideline for European medical practitioners. We also wish to analyse whether medical education targeted at communication with psychiatric patients has an effect on involuntary treatment rates and general mental well-being.

Methods: We conducted a systematic review on PubMed to identify studies pertaining to how legislature on involuntary commitment varies between European countries, as well as to what extent it is utilised. We also looked at the extent of medical education on psychiatric diseases.

Results: Preliminary results show that involuntary hospitalisation rates vary greatly within Europe, with certain countries being almost 20 times more likely to utilise such measures than others, notwithstanding similar mental illness prevalence. Results do not seem correlated to legislation types.

Conclusions: Given the vastly different use of involuntary commitment, a more standardised European approach should be implemented, especially in sight of the growing prevalence and burden of disease of psychiatric illnesses. Furthermore, an often-overlooked aspect of medical education is how to understand and communicate effectively with patients dealing with mental diseases: we advocate for continuous education, regardless of medical specialty.

Key messages:

- Involuntary hospitalisation rates vary greatly across Europe, but the effects of this phenomenon have been poorly studied. We propose a more unified approach to maximise the efficacy of such a law.
- We advocate for a more thorough education of health professionals on mental illnesses, regardless of medical specialty, in sight of the growing prevalence of such diseases.

Abstract citation ID: ckae144.2249
Active aging, autonomy, and mental health among older adults with chronic illness - focus on optimism

Virág Júlia Karai

V Karai[1]*, S Rózsa*[1]*, ECS Kiss*[1]
[1]Department of Personality and Health Psychology, Károli Gáspár University of the Reformed Church in Hungary, Budapest, Hungary
Contact: karaivirag@gmail.com

Background: In the active aging framework, the focus has shifted to the quality of life of the elderly, where autonomy plays an important role. Chronic illnesses often lead to autonomy limitations, impacting activities of daily living (ADL) and increasing the risk of depression. Fostering an optimistic outlook can mitigate depression's severity and promote healthy aging.

Methods: The data is from a cross-sectional survey in Hungary (n = 832). 60,1% of the sample had at least one chronic illness. Measurements included the EQ-5D-5L, Mental Health Continuum-SF, Life Orientation Test, and the Geriatric Depression Scale.

Results: We found worse mental health ($p = 0{,}024$), lower levels of optimistic outlook ($p = 0{,}002$), and higher levels of depression ($p < 0{,}001$) among those who reported ADL limitations. ADL limitations (ß = -0,27, $p < 0{,}001$) showed the strongest association with perceived health status, followed by mobility (ß = -0,22, p <; 0,001) and self-care (ß =-0,14, $p < 0{,}001$). Considering mental health, only ADL limitations (ß = -0,15, $p < 0{,}001$) were a significant predictor from the above-mentioned dimensions. Additional analysis showed that depression affected mental health both directly (effect = -1,90, $p < 0{,}001$) and indirectly, mediated by an optimistic outlook (effect = -0,88).

Conclusions: 1. Limitations in autonomy were negatively linked to perceived health status and mental health. 2. The optimistic orientation toward life can mediate the association between depression and mental health among the elderly with chronic conditions. 3. The Implications of the results could enlighten the necessity of preventive initiatives on autonomy preservation and enhance an optimistic outlook to maintain healthy aging and a favorable quality of life.

Key messages:

- Preventive interventions focusing on health-preserving behaviors could be designed for specific groups with a higher risk of ADL limitations in the future.
- Optimism could mediate depression's impact on the mental health of the elderly with chronic illnesses, suggesting that interventions should target enhancing optimism for improving active aging.

Abstract citation ID: ckae144.2250
Recovery of Executive Functions in Alcohol Use Disorder: role of Neuropsychological Rehabilitation

Leonor Bacelar-Nicolau

S Ferreira[2,4]*, C Ribeiro*[1,2]*, S Pombo*[3]*, L Bacelar-Nicolau*[1,3]
[1]Institute Preventive Medicine & Public Health, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

[2]Clinica Universitaria MGF, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal
[3]ISAMB - Institute Environmental Health, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal
[4]UTRA, Centro Hospitalar Psiquiátrico de Lisboa, Lisbon, Portugal
Contact: lnicolau@medicina.ulisboa.pt

Background: Alcohol Use Disorder (AUD) is a growing public health concern with high incidence of executive functions (EFs) changes, affecting disease progression and treatment effectiveness. Inconsistencies persist in studies on the role of neuropsychological rehabilitation (NR) in EF recovery within AUD interventions. Our aim is to analyse the effect of NR on EFs in AUD interventions.

Methods: A prospective cohort study included 65 participants of both sexes, diagnosed with AUD, free of psychiatric comorbidities or severe neurological conditions. They underwent alcohol detoxification in hospital/home from 2021 to 2023, completing three evaluation moments (M1-Baseline, M2-3 months, M3-6 months). Patients receiving usual treatment (WTG-weekly therapeutic groups) - were compared to those with additional Neuropsychological Rehabilitation (NRG) regarding Sociodemographic and Severity of Alcohol Dependence Questionnaires, Hospital Anxiety and Depression Scale, Frontal Assessment Battery (FAB), Number and Letters Subscale of Weschler Adult Intelligence Scale (WAIS). Our main outcome was FAB-general executive functioning, and secondary outcome was WAIS-working memory. Friedman test compared assessments across the three points (alpha 5%).

Results: Statistically significant differences were found for FAB in both groups, ($p < 0.001$) between M1 and both M2 and M3, indicating improved executive functioning, particularly in NRG. Working memory also improved in both groups (WTG: $p = 0.036$; NRG: $p < 0.001$), with NRG showing better M2 performance.

Conclusions: There is evidence that neuropsychological rehabilitation facilitates the recovery of executive functions and may play a pivotal role in relapse prevention. It is crucial that the treatment of these situations incorporates public health, preventive and damage minimization measures.

KeyWords: Executive Function; Neuropsychological Rehabilitation; Alcohol Use Disorder.

Key messages:

- Recovery of executive functions is crucial from a Public Heath perspective in AUD populations, minimizing morbidity, permanent disabilities and contributing to more effective healthcare services.
- Integrating Neuropsychological Rehabilitation into standard Alcohol Use Disorder treatments can enhance treatment effectiveness, reducing disease burden.

Approaches to Dementia Control in a Community in Japan

Midori Kamei

M Kamei[1], M Nishina[1], C Motohashi[1], A Ohta[1], S Koizumi[1], T Miyazaki[1], M Uemura[1], M Takeda[1]
[1]Department of Social Medicine, Saitama Medical University, Saitama Prefecture, Japan
Contact: kamei@saitama-med.ac.jp

Background: In order to consider future dementia countermeasures in the community, we conducted a survey to understand the characteristics of the elderly living in the community.

Methods: A self-administered questionnaire survey was conducted in collaboration with Hanno-city, Saitama Prefecture, targeting all persons aged 65 years or older (excluding institutionalized residents) living in Hanno-city (aging rate: 32.0%). The questionnaire items included basic attributes, lifestyle, daily living conditions, and willingness to participate in activities. The survey was sent to 7,133 people, and 3,623 valid responses were received (valid response rate: 50.8%).

Results: Respondents were 1,135 males (51.2%) and 1,080 females (48.8%); 1,979 (54.6%) were aged 65-74 and 1,644 (45.4%) were aged 75 and over. The proportion of single-person households was 12.1%. 56.1% of the respondents had been living in the community for 30 years or more, and the overall membership rate of the residents' association was high at 91.0%. A total of 691 (19.1%) of the respondents had seen someone suspected of having dementia. 1,178 (32.5%) answered 'yes,' 1,452 (40.1%) answered 'no,' and 881 (24.3%) answered 'don't know. There were 472 (8.1%) dementia supporters.

Conclusions: The membership rate of local residents' associations was high at 91.0%, indicating that the community maintains relatively close relationships with its residents. Based on the National Dementia plan, further consideration will be given to long-term goals such as human resource development for each region and policies to support these goals. Main messages: In a mountainous district with an aging population similar to that of Japan as a whole, only about one-third of the respondents knew of a contact point for dementia-related issues. Based on the National Dementia Plan, the government will consider dementia policies, including long-term goals and policies to support these goals in the community.

Key messages:

- In a mountainous district with an aging population similar to that of Japan as a whole, only about one-third of the respondents knew of a contact point for dementia-related issues.
- Based on the National Dementia Plan, the government will consider dementia policies, including long-term goals and policies to support these goals in the community.

Anxiety, depression, and poor sleep quality in COVID-19 survivors of the first year of the pandemic

Catarina Lopes

N Araujo[1,2,3], I Silva[1,2], P Campos[1,2], R Correia[1,2], A Costa[1,2,3], C Lopes[1,2,3], P Freitas[1,2], J Sampaio[1,2], V Tedim-Cruz[1,2,4]
[1]EPIUnit, Institute of Public Health, University of Porto, Porto, Portugal
[2]Laboratory for Integrative and Translational, Institute of Public Health, University of Porto, Porto, Portugal
[3]Faculty of Medicine, University of Porto, Porto, Portugal
[4]Neurology Department, Local Health Unit of Matosinhos, Matosinhos, Portugal
Contact: catarina.lopes@ispup.up.pt

Background: Psychological outcomes after SARS-CoV-2 infection have been reported primarily among patients with post-COVID-19 condition followed at COVID-specific clinics who may not represent the population of COVID-19 survivors. This study compares the frequency, 2 years after infection, of symptoms of anxiety and depression and poor sleep quality between COVID-19 survivors from the first year of the pandemic and comparison groups matched for sex, age, and level of care.

Methods: Participants are users of the Local Health Unit of Matosinhos (comprising almost all citizens of this municipality) classified according to hospitalization and SARS-CoV-2 infection between March, 2020 and February, 2021 in 4 groups: group#1, hospitalized due to COVID-19 ($n = 101$); group#2, hospitalized, uninfected ($n = 87$); group#3, infected, non-hospitalized ($n = 252$); group#4, uninfected, non-hospitalized ($n = 258$). They were evaluated between July, 2022 and October, 2023, with the Hospital Anxiety and Depression Scale (HADS-A, anxiety, and HADS-D, depression) and the Pittsburgh Sleep Quality Index (PSQI). Logistic regression was used to compute OR and 95%CI adjusted for sex, age, education, marital status, employment, smoking, and level of care of the associations between the study group and clinically significant symptoms of anxiety (HADS-A scores>10), depression (HADS-D scores>10) and poor sleep (PSQI scores>5).

Results: No significant differences ($p < 0.05$) were observed for the prevalence of clinically significant symptoms of depression (overall 9.2%) and poor sleep quality (overall 59.8%) between SARS-COV-2 infected participants and comparison groups, but HADS-A scores>10 were more frequent in infected individuals (19.3% vs. 13.6%; OR = 1.92; 95%CI:1.21,3.05).

Conclusions: Healthcare services should pay special attention to COVID-19 survivors from the first year of the pandemic to identify and treat anxiety symptoms. Funding: FCT UIDB/ 04750/2020 LA/ P/0064/2020 PTDC/SAU-EPI/6275/2020

Key messages:

- COVID-19 survivors from the 1st year of the pandemic present more frequently high levels of anxiety than the general population 2 years after COVID-19.
- Specific care for anxiety symptoms are needed for COVID-19 survivors from the 1st year of the pandemic

---

Abstract citation ID: ckae144.2253
Factors affecting ageism and depression levels in individuals aged 65 and over living in society

Fatma Nevin Sisman

S Erol[1], F Nevin Sisman[1], A Aydoğmuş[1], S Cengiz[1]
[1]Nursing Department, Marmara University, Istanbul, Türkiye
Contact: nevin4083@yahoo.com

Background: The aging process is perceived negatively by some people. This perception prevents/reduces the happiness that can be gained from the aging process. As a result, depressive symptoms may occur. Therefore, this study aimed to examine the factors affecting ageism and depression levels in individuals aged 65 and over living in society.

Methods: The sample of the research, which was conducted with a cross-sectional, descriptive design, consisted of 287 individuals aged 65 and over living in a neighborhood on the Anatolian side of Istanbul. Data were collected with socio-demographic form, Ageism Questionnaire and Yesavage Geriatric Depression Scale-15. T test, variance analysis and chi-square test were used to analyze the data. Ethical permissions were obtained.

Results: Moderate depression was found in 27.5% of individuals with a mean age of 70.80±5.42. Individuals scored below the average (18.48±8.14) on the ageism survey. Ageism scores were higher for men, those aged 85 and over, those with poor economic conditions, those with chronic diseases, those hospitalized in the last year, those with severe and moderate depression, and those who needed help with daily tasks ($p < 0.05$). A statistically significant difference was found between age groups, chronic disease, continuous medication use, hospitalization in the last year, working status, need for help with daily tasks, economic status and depression levels ($p < 0.05$). Ageism scores of those with severe and moderate depression were found to be high ($F = 3.43$;$p = 0.017$).

Conclusions: Variables that are effective in ageism and depression are being aged 85 and over, having a poor economic situation, having a chronic disease, needing help with daily tasks, and receiving inpatient treatment in the last year. The results of this study show that more efforts and resources are needed within the scope of political and social services to reduce ageism in society and the level of depression in older individuals.

Key messages:

- As the level of depression in elderly individuals increases, ageism increases.
- Advanced age, economic status, chronic disease, hospitalization and dependence on daily tasks affect depression and ageism.

Abstract citation ID: ckae144.2254
Integrated models for concurrent disorders from a Public Mental Health lens: a Systematic Review

Flavia Beccia

F Beccia[1], F Grassi[2], E Marziali[1], MF Rossi[1], C Amantea[1], F Patania[2], S Navari[3], MR Gualano[4], W Ricciardi[1], P Parente[3]
[1]Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[3]Local Health Authority Rome 1, Rome, Italy
[4]UniCamillus, Rome, Italy
Contact: flavia.beccia01@icatt.it

Concurrent disorders (COD), historically defined by the World Health Organization as the simultaneous presence of a psychoactive substance use disorder and another psychiatric disorder within the same individual, pose a significant challenge to public mental health. In today's global landscape of mental health services, the prevalence of COD is on the rise, underscoring the need for an integrated approach to management. This review aims to provide an overview of existing global models and the evaluation approaches. This systematic review examined research evidence in PubMed, Scopus and Web of Science up to 2023 regarding integrated management systems for COD. Following PRISMA guidelines, we included articles describing specific models and evaluating the effectiveness of integrated versus non-integrated approaches. Quality assessment was conducted using the appropriate scales. Out of 7700 screened articles, 18 were included, all of fair or good quality. A diverse array of patient care models, programs, and interventions addressing comorbidities between mental health and substance use disorders emerged. The majority of studies focused on clinical outcomes, particularly alcohol and drug dependence, with global mental health consequences also under examination. Psychodiagnostics and social outcomes were also considered in a significant portion of the research, shedding light on health services utilization patterns. The integrated model for concurrent disorders in psychiatry stands as an effective approach, yet its implementation encounters challenges. This study showcases successful integration examples, providing valuable insights for policymakers and healthcare professionals to enhance existing models or develop new ones, particularly within European healthcare reforms like Italy's restructuring of primary care, where they could serve as a criterion for the setting and organization of community houses.

Key messages:

- COD, involving both substance use and psychiatric disorders, present a significant challenge to public mental health. Rising prevalence underscores the need for integrated management approaches.
- Insights from successful integration examples offer valuable guidance for healthcare professionals and policymakers, particularly within healthcare reforms like Italy's restructuring of primary care.

Abstract citation ID: ckae144.2255
Examining the link between age of alcohol initiation, adolescent alcohol use and adult substance use

Margaret M Brennan

MM Brennan[1], A Doyle[2], D Mongan[2], SR Millar[2,3], B Galvin[2], E Nixon[4], B Smyth[5], L Zgaga[1], JH Ivers[1], N McCarthy[1]
[1]Department of Public Health and Primary Care, Trinity College Dublin, Dublin, Ireland

[3]School of Public Health, University College Cork, Cork, Ireland
[4]School of Psychology, Trinity College Dublin, Dublin, Ireland
[5]Adolescent Addiction Service, Cherry Orchard Hospital, Dublin, Ireland
Contact: brennm32@tcd.ie

Background: Understanding the relationship between adolescent alcohol use and adult substance use is important for prevention programmes. Existing evidence presents divergent findings and potential mechanisms are debated.
Methods: We estimated associations between the age of alcohol initiation and alcohol use at age 17 and substance use at age 20 in a nationally representative cohort ($n = 4554$). Weighted logistic regression models were fitted using Generalised Estimating Equations in multiply imputed and complete case data.
Results: Our analysis identified that 27% of participants reported first alcohol use at ≤ 14 years old, with 37% engaging in risky alcohol use by age 17. At age 20, 14% reported hazardous alcohol use, while 38% used tobacco, 24% cannabis, and 28% other drugs. The age at which alcohol was initiated and risky alcohol use at 17 years old were both strongly associated with alcohol, tobacco, cannabis and other illicit drug use at 20 years old. Sequential change in effect estimates coupled with non-overlapping confidence intervals suggest a dose-response relationship between age of alcohol initiation and tobacco and other drug use at age 20.
Conclusions: First use of alcohol at 14 or younger was common. Earlier alcohol initiation and risky alcohol use are each associated with substantially elevated risk for substance use at 20 years old even after accounting for common liability factors. Acknowledgement: Growing Up in Ireland (GUI) is funded by the Department of Children, Equality, Disability, Integration and Youth (DCEDIY). It is managed by DCEDIY in association with the Central Statistics Office (CSO). Results in this report are based on analyses of data from Research Microdata Files provided by the CSO. Neither the CSO nor DCEDIY take any responsibility for the views expressed or the outputs generated from these analyses.

Key messages:

- Delaying alcohol initiation and preventing risky alcohol use during adolescence may reduce levels of substance use in young adults.
- Self-reported early use of alcohol remains common.

Abstract citation ID: ckae144.2256
The Relationship Between Mental Health Status and Daily Step Count in Adults: A Cross-Sectional Study

Gözde Özdemir

G Özdemir[1], *S Erol*[2]
[1]Department of Medical Services and Techniques, Beykent University, Büyükçekmece, Türkiye
[2]Faculty of Health Sciences, Marmara University, Maltepe, Türkiye
Contact: gozdeozdemir@beykent.edu.tr

Aim: This study was conducted to determine the relationship between the mental health status and daily step count of adult individuals.
Methods: The research was conducted between November 2023 and April 2024 with a descriptive cross-sectional design. The research population consisted of 386 individuals over the age of 18 who voluntarily filled out public electronic forums on online platforms. Data were collected with the socio-demographic characteristics diagnostic form consisting of 21 questions, the average number of steps in the last week, and the General Health Survey-28 (GHQ-28). Data were evaluated using descriptive statistics, normality statistics, analysis of variance (ANOVA), t test, Kruskal Wallis variance analysis, Mann-Whitney U test. Statistical significance level was accepted as $p < 0.05$
Results: GHQ-28 total score average was found to be 5.59 ± 6.52. 42.0% of the participants received a score of 5 or above on the GHQ-28 and were considered at risk for mental health. The individuals' average weekly step count was mean=5269±3065 steps and 43% were basal-limited active. According to GHQ-28, the average weekly step count of individuals in the mental health risk group (4528.62 ± 2892.31) was lower than those who were not at risk (5804.63 ± 3081.67) ($p < 0.05$). According to step count categories, individuals who were basal-limited active (51.2%) and low active (39.4%) were found to be at higher risk for mental health than those who were slightly active (36.0%) and active-highly active (18.4%) ($p < 0.05$). A weak negative correlation was found between the average number of steps and the scores obtained from the GHQ-28 ($r = -.187$; $p = 0.000$).
Conclusions: It was determined that more than half (51.2%) of the individuals (42.0%) in the risk group in terms of mental health were sedentary, that is, basal-limited active (less than 2500-4999 steps).

Key messages:

- Increasing awareness about the positive effects of individuals' daily step counts on mental health can contribute positively to the promotion of health.
- As part of policies aimed at enhancing mental health within society, implementations directed towards increasing daily step counts can contribute positively to the improvement of public health.

Abstract citation ID: ckae144.2257
Public health prevention programmes for mental illness in school-age children and adolescents

Francesca Serazzi

F Serazzi[1], *F Barbic*[1], *S Stranges*[2]
[1]Biomedical Sciences, Humanitas University, Pieve Emanuele, Italy
[2]Epidemiology and Biostatistics, Western University, London, Canada
Contact: francescaserazzi@gmail.com

Background: Psychiatrists, psychotherapists and other mental health professionals have long stated the importance of adequate social groups and early intervention for the prevention of severe mental diseases. With psychiatric illness incidence increasing most in the adolescent and young adult populations, we propose the use of school-age directed public mental health initiatives to combat remaining social stigma and promote mental wellbeing, as well as educate children and adolescents in how to recognise symptoms and ask for help.
Methods: We conducted a systematic review on PubMed as well as government and NGO websites to identify public health initiatives in the prevention and early identification of mental illness among young individuals.
Results: Preliminary results show that, while certain countries have delineated guidelines on how to support students' mental health, very few have implemented nation-wide, or even region-wide programmes that directly target prevention and education. A particular note should be made regarding substance abuse and addiction, one of the few illnesses for which many countries have already enacted in-school programmes, that however often overlook the medical aspect of such diseases. Of further note are certain local programmes aimed at offering quality and accessible care to adolescents struggling with mental diseases.
Conclusions: With psychiatric diseases projected to become one of the greatest contributors to the global burden of disease by 2030, and the importance of early intervention in preventing severe psychiatric illness, we advocated for European public health initiatives implemented in schools, which could be crucial in curbing the spread of mental illness.

Key messages:

- Adolescent and young adults are those most affected by the rising prevalence of mental illness. Consequently, we advocate for in-school programmes to aid in early identification and intervention.
- Early identification of mental diseases is crucial in the prevention of severe psychiatric illness, but little has been done so far in terms of public health interventions to tackle such problems.

Background: Schizophrenia is a chronic, disabling disorder that affects 23.6 million people worldwide, with patients often needing extensive assistance and care. Main caregivers are frequently family members who may present a reduced quality of life (QoL) due to the high-level burden of care. Literature mostly focuses on the burden caused by other mental disorders or by schizophrenia in both the adult and child population. We aim to assess the burden and QoL in caregivers of children and adolescents with schizophrenia.

Methods: We conducted a Systematic Review of articles published between 2013 and 2023 on MEDLINE, Scopus, Web of Science, APA PsycARTICLES, CINAHL. We included studies in which a validated instrument was used to measure the burden of caregiving and QoL for adult caregivers of children and adolescent schizophrenic patients. The results were reported following the PRISMA guidelines.

Results: We identified 1388 studies. We removed 610 duplicates. After screening 788 studies on title and abstract and 52 for full-text, we included one cross-sectional study in China based on the STROBE Checklist. Significant correlations between burden of care and schizophrenia severity, children's age, period of care, education, sex, residence, and income were reported. Additionally, we screened 7 qualitative studies. Social stigma and struggle were the most frequently reported feelings, and financial burden was the most common external factor associated with a worse quality of life.

Conclusions: This review revealed a significant research gap in this field. This lack of focused research underscores the urgent need for targeted investigations into the experiences of caregivers of children and adolescents with schizophrenia. Addressing these knowledge gaps will improve support systems and interventions tailored to the unique needs of this population, such as disease-specific advisory, mental health services, social and financial support, and self-help groups.

Key messages:

- We identified a research gap for burden and quality of life in informal caregivers of children with schizophrenia. Education, sex and income of caregivers relate to the burden of care.
- Further research is needed to develop strategies to improve support systems and interventions tailored to the unique needs of this population.

Abstract citation ID: ckae144.2259
Beyond Numbers: Investigating the Impact of COVID-19 on Suicide Rates in Austria

David Roesler

D Roesler[1]
[1]Institute for Advanced Studies, Vienna, Austria
Contact: david-roesler@outlook.com

During the COVID-19 pandemic, individuals' mental health faced substantial challenges. This study aims to provide a comprehensive examination of the pandemic's impact on suicide rates in Austria, with a particular focus on variations by gender, region, and age. The study employs a regression discontinuity in time design and an interrupted time series analysis, utilising monthly death records from January 2015 to December 2021. To account for seasonal variations and potential underreporting of suicides, harmonic Fourier terms are incorporated into the analysis, and both suicides with intended self-harm and self-harm with undetermined intent are included. While existing research offers valuable insights into the impact of the pandemic on suicidal behaviour, it does not yet allow for specific conclusions to be drawn for Austria. In contrast to the methods typically employed in previous research on other countries, this approach enables a comprehensive examination of the temporal effects surrounding the implementation and lifting of pandemic-related measures. The study reveals a significant negative trend in Austria's suicide rates before the start of the pandemic and more suicides than expected after its onset. In particular, the number of suicides among men aged 64-85 and women in the age groups 0-19, 20-34, and 65-84 was significantly higher than expected. Conversely, the data indicated a positive impact among women aged 35-64. This study contributes to understanding the impact of the pandemic on suicide rates in Austria. It demonstrates that, even within the same country, the impact can differ by gender, age, and region, thereby supporting the need for subgroup analysis. It also highlights that potential underreporting of suicides may result in an underestimation of the impact of the pandemic on suicides in previously conducted studies. Understanding these nuances is crucial for suicide prevention and informing policy decisions to improve health system resilience.

Key messages:

- The study found higher than expected suicide rates in Austria during the COVID-19 pandemic, especially among men aged 64-85 and women aged 0-19, 20-34, and 65-84.
- The underreporting of suicides may result in an underestimation of the impact of COVID-19 on suicides in previously conducted studies.

Abstract citation ID: ckae144.2260
Sense of community, life satisfaction and psychological distress among seniors – HUNT4 study, Norway

Tommy Haugan

T Haugan[1], *I Bojanic*[1]
[1]Faculty of Nursing and Health Sciences, Nord University, Levanger, Norway
Contact: tommy.haugan@nord.no

Background: Strong sense of community with one's neighbors may benefit psychosocial well-being. Moreover, local communities with high level of belonging and social cohesion can have a positive impact on public mental health. This study aims to investigate associations between sense of community and life satisfaction - at both an individual and local community level in a Norwegian county.

Methods: Data from Trøndelag Health Study 4 (HUNT4: 2017-2019) on 22 939 participants were linked to geographic data of residence from Statistics Norway. The basic statistical unit in Norwegian, known as "grunnkrets," serves to identify participants' local communities. These units are subdivisions of municipalities, covering geographically contiguous areas that typically include a few hundred inhabitants. This population-based study enables investigation of variation in sense of community, trust, life satisfaction and psychological distress on individual and community level.

Results: Seniors (median age 70.3 years) with strong sense of community with their neighbors had more than three times higher odds (95%CI 3.08-3.93) of high level of life satisfaction and less than 0.3 times lower odds (95%CI 0.26-0.33) of psychological distress symptoms vs those with low sense of community, adjusted to sociodemographic variables. The average sense of community varied between local communities (N = 284). At this local geographical unit, strong sense of community was associated with high level of trust, enjoying the neighborhood and high life satisfaction.

Conclusions: The study can inform public health policy to consider development of social infrastructures that bolster sense of community among seniors within neighborhoods. Policy and action plans targeting to increase the overall sense of community in neighborhoods may contribute to create mental health-promoting and age-friendly local communities in Norway.

Key messages:

- At individual level, sense of community with neighbors are associated with life satisfaction and psychological distress among Norwegian seniors.
- The average sense of community varies between geographic local areas and are associated with level of trust, enjoying the neighborhood, average life satisfaction, and psychological distress.

Abstract citation ID: ckae144.2261
Focus on residents' mental health: the Public Health Residents' Anonymous Survey in Italy (PHRASI)

Marta Caminiti

M Caminiti[1], F Cedrone[2], L Stacchini[3], V Gianfredi[4], G Minutolo[5], N Berselli[6], M Sabato[7], V De Nicolò[7], A Ancona[8], A Catalini[9]

The 'Public Health Residents' Anonymous Survey in Italy" (PHRASI) represented the first study to specifically investigate mental health and its determinants among Italian public health residents (PHRs). Using a voluntary, anonymous, electronic, 88-item questionnaire, the PHRASI study generated evidence on well-being, eating disorders, sleep disorders, alcohol abuse, depressive symptoms, and anxious symptoms among PHRs. This highlights the correlation with sociodemographic, lifestyle, and work-related characteristics during COVID-19 pandemic. The data was collected in a nationally representative sample of PHRs enrolled in any of the four course years of Italian Public Health schools. The recruitment took place through the communication channels of the Medical Residents' Council of the Italian Society of Hygiene and Preventive Medicine in the summer 2022. The key findings reveal prevalence rates of mental health conditions comparable to those seen in other healthcare workers during the COVID-19 pandemic: 61% of residents report depressive symptoms and 36% report anxious symptoms. The study also highlights a negative correlation of these symptoms with characteristics of the training and working environment, such as the level of supervision and peer-to-peer support. A stronger social network and higher levels of physical activity emerged to be positively associated with well-being and depression. These and other findings will be available in the final report of the survey that will be presented during the congress. PHRASI led the way to the Residents' Mental health Investigation, a Dynamic longitudinal study in Italy (ReMInDIt), that aims to explore potential cause-effect relationships between risk/protective factors and mental health outcomes. This evidence could guide the scientific community, school directors, universities, and policymakers in the continuous process of improving the educational quality and working conditions of PHRs.

Key messages:

- Residency training and work environment impact the mental health of the PHR workforce.
- It is important to deploy concrete efforts into building healthy work environments and guarantee adequate training for PHRs.

[4]Department of Social Geography and Regional Development, Charles University, Prague, Czechia
Contact: mariekuklova2@gmail.com

Background: Depressive symptoms are associated with achieved socioeconomic status (SES) in men and women. The aim of the analysis is to verify this association between severity of depressive symptoms and socioeconomic status in the Czech context. Another aim is to examine the use of psychiatric and psychological treatment among men and women.

Methods: The data come from the 2019 European Health Interview Survey (EHIS). The Patient Health Questionnaire (PHQ-8) was used to measure the symptoms and severity of depressive symptoms among respondents. Participants were aged 20 and above and resided in households. Binary logistic regression was used to test the relationship for using of treatment and depressive symptoms.

Results: The weighted prevalence of mild depressive symptoms is determined to be 10.5% (8.0 % in men; 12.8% in women), with severe depressive symptoms recorded at 3.1% (2.6% in men; 3.7% in women) within the Czech population. The psychiatric or psychological treatment is utilized by 3.8% (2.8% in men; 4.7% in women) of the Czech population. Respondents with severe depressive symptoms (37.4%) use care the most, followed by those with mild symptoms (11.9%), and the least by those with none (1.6%). Individuals with tertiary education utilize treatment the most among respondents with moderate and severe depressive symptoms. Respondents differ in the utilization of treatment; however, after stratifying the model only for respondents with mild or severe depressive symptoms, these respondents do not differ in the utilization of treatment.

Conclusions: SES level is reflected differently in the prevalence and severity of depressive symptoms for men and women. But no difference was found in the use of psychiatric or psychological care in men and women. A treatment gap was found for depressive symptoms in the Czech population.

Key messages:

- The results confirmed the relationship between the utilization of care and depressive symptoms.
- It was revealed that respondents did not differ in the utilization of care after the stratification.

Abstract citation ID: ckae144.2263
Digital strategies of public youth mental health services to raise awareness of their existence

Eulàlia Hernández Encuentra

E Hernández Encuentra[1]*, R Casañas Sánechez*[2]*, M Boixadós Anglès*[1]*, L Merino Rubio*[1]
[1]Department of Psychology and Education, Open University of Catalonia, Barcelona, Spain
[2]Research, Les Corts Mental Hygiene Center Association, Barcelona, Spain
Contact: ehernandez@uoc.edu

Background: Data from a survey of the first part of the eHealthLit4teen Project show that adolescents in the city of Barcelona (12-16 years old) are not aware of the public youth mental health services (YMHS) available in the city. Considering the intensive use that young people make of digital platforms, YMHS might leverage these channels to raise young people's awareness of available resources, which would impact on the help-seeking behaviours. The aim of this work is to analyse the social media strategies for the dissemination of public YMHS and emotional well-being services (promoted by the city council and the regional government) in Barcelona.

Methods: Identification of public YMHS and emotional wellbeing services, and interview on the use of social networks for dissemination with those responsible for the services and communication (March-April 2024). Analysis of the use of persuasive design and behavioural design techniques by the social media profiles of these services and, by way of contrast, the influencers who publish mental health content identified by the adolescents in the previous survey of the Project (March 2023).

Results: Public YMHS mainly rely on outreach through face-to-face visits to high schools. This format makes it easier for reluctant young people to access formal support, but more difficult for them to seek support because of stigma. In general, public YMHS do not show a clear strategy to disseminate their service on social media, and the information provided confusion between the characteristics of the services offered. Likewise, there is no widespread use of behavioural design or persuasive design techniques in the publications of health services on social media, nor in those of influencers.

Conclusions: Public YMHS do not make efficient use of the digital platforms that young people use intensively to raise awareness of their existence and increase usage.

Key messages:

- There is no clear digital strategy for communicating public youth mental health services (YMHS), although they recognise that digital platforms can be a good means of dissemination.
- YMHS need to be accessible on digital platforms to young people's adults of reference (especially for younger teens), as they are the ones who seek out online the existence of this type of services.

Abstract citation ID: ckae144.2264
Factors predicting a decrease in suicidality among young people (0-28 years old)

Mandy Gijzen

M Gijzen[1]*, D Van Bergen*[1]*, B Jeronimus*[1]*, T Oldehinkel*[2]
[1]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
[2]Faculty of Medical Sciences, University of Groningen, Groningen, Netherlands
Contact: mandygijzen@gmail.com

Background: Suicide, self-harm and suicidal thoughts (i.e., suicidality) are important public health concerns. Most youth that experience suicidality find a way to overcome these affronts. Preventative public health measures require an understanding of factors that can help youth overcome their suicidality.

Methods: Data come from a Dutch prospective birth-cohort study that surveyed youth from age 11 to 28 (measurements 2-3 years apart). We determined the proportion of youth that experienced suicidality across seven waves and focused on changes in suicidality, and factors associated with changes in suicidality using linear discriminant analysis. We examined a mix of individual, family, peer and socio-cultural factors in line with an ecological framework, e.g. the Interpersonal Theory of Suicide.

Results: Between 4-8% of youth experienced suicidal thoughts and between 2-5% experienced self-harm across time points. Most youth (89%-94% across time points) did not experience changes in suicidality, while between 3-6% experienced a decline of suicidal thoughts and between 2-4% a decline in self-harm across time points. Discriminant analyses could correctly identify ≈90% of subgroup per case (decline, increase, stable suicidality). But, the model was not very accurate in predicting which youth belonged to the declining suicidality subgroup. Functions with best predictive ability indicated the importance of interpersonal factors; belonging to peers, parents, classmates, teachers and religion. Also, overall happiness and positive changes in romantic relationships and family had predictive value.

Conclusions: It remains difficult to distinguish youth who experience a decrease in suicidality. Interpersonal factors may play a role in changes in suicidality, but we need to identify new factors related to declines in suicidality. Future prospective birth-cohort study should consider including factors that may be better predictors of decreases in suicidality and mental health in general.

Key messages:

- Factors that contribute to decreases in suicidality will enrich suicide prevention strategies, which have until thusfar mostly been informed by a risk perspective.
- Interpersonal factors might play an important role in changes in suicidality among youth, which indicates we need an ecological perspective on suicidality rather than an individual perspective.

Abstract citation ID: ckae144.2265
Examining Lifestyle Risk Factor Clusters and Mental Health in Adults

Perihan Torun

E Gunay[1]*, P Torun*[1]*, S Duzcan*[1]*, E Kizilyel*[1]*, H Okan*[1]
[1]Halk Sağliği, Sağlık Bilimleri Üniversitesi Hamidiye Tıp Fakültesi, Istanbul, Türkiye
Contact: ptorun@hotmail.com

Background: Lifestyle risk factors often cluster, impacting both physical and mental health. Studies reveal bidirectional relationships between lifestyle factors and health. The aim of this study is to examine the relationship between mental health problems, self-reported depression, and lifestyle risk factors in a sample of the adult population in Turkey.

Methods: 2022 Turkey Health Survey (THS) data were used. The sample group was made using cross-sectional data of approximately 22742 individuals in the adult population over 15 years of age. Two-stage clustering method was used to determine vital risk factor clusters. Regression analysis was used to determine the relationship between vital risk factor clusters and self-reported depression and mental health problems.

Results: Lifestyle risk factors were grouped into 4 clusters. It was observed that unhealthy diet, inadequate physical activity, and smoking, which are modifiable lifestyle risk factors, were together in the clusters. It was also observed that self-reported depression and mental problems were more associated with clusters with more than one lifestyle risk factor. In addition, women, married individuals, and individuals over 65 years of age were more associated with mental problems.

Conclusions: As a result of the findings, there was an association between people with mental problems and lifestyle risk factors such as smoking, unhealthy diet, and insufficient physical activity. These findings may help to plan and implement more effective health policies and individual interventions targeting groups with multiple lifestyle risk factors in the future.

Key messages:

- The target group was determined to improve community mental health and to make necessary interventions.
- Since inadequate physical activity, which is one of the vital risk factors, and unhealthy nutrition and smoking tend to cluster together, it was determined that these problems should be prioritised

---

[2]Family Medicine, Faculty of Medicine of Monastir, Monastir, Tunisia
[3]Regional Health Department, Monastir, Tunisia
Contact: imen11zemni@gmail.com

Background: Smartphone addiction is a global mental health issue with diverse psychological and socioeconomic concerns. The aim of this study was to determine the prevalence of smartphone addiction and its associated factors among medical students in the university of Monastir, Tunisia.

Methods: We conducted a cross-sectional survey among medical students of the faculty of medicine of Monastir in October 2020. The data were collected through a self-administered anonymous questionnaire that included the SAS-SV scale to assess smartphone addiction levels. A multivariate logistic regression model was employed to identify associated factors. The threshold of statistical significance was set at $p < 0.05$.

Results: A total of 626 medical students participated in this study, with an average age of 21.76 ± 3.12 years and a sex ratio of 0.41. The prevalence of smartphone addiction was 30.2% (95% CI: 26.0% - 33.79%). Associated factors with smartphone addiction included academic repetition(OR = 4.30; 95% CI [1.38 - 13.42]), fast food consumption scores (OR = 1.55; 95% CI [1.21 - 2.00]),addiction to the Facebook social network (OR = 6.36; 95% CI [1.92 - 21.07]), cohabitation with colleagues (OR = 2.13; 95% CI [1.03- 4.43]), cohabitation with family members(OR = 2.10; 95% CI [1.01 - 4.36]) and stress level (OR = 1.13; 95% CI [1.07 - 1.18]).

Conclusions: This study identified associations between smartphone overuse and other behavioral and mental health indicators. Based on these findings, several interventions should be undertaken to address this growing concern.

Key messages:

- The prevalence of smartphone addiction among medical students in the University of Monastir was 30.2% (95% CI: 26.0% – 33.79%).
- The main associated factors with smartphone addiction were academic repetition, fast food consumption, addiction to Facebook, cohabitation with colleagues and with family members and stress level.

Abstract citation ID: ckae144.2267
Psychological Capital Promotion in Universities

Andrea Fontes

A Fontes[1]
[1]BRU, ISCTE, Lisbon, Portugal
Contact: fontes.andrea@gmail.com

Background: The rise in student depression and anxiety highlights a crucial intersection between education and public health. Academic pressures intensify mental health issues, necessitating comprehensive strategies to address them.

Objectives: This study assessed the effectiveness of a Psychological Capital (PsyCap) intervention in enhancing university students' PsyCap and reducing anxiety, aligning with broader public health education goals.

Methods: A randomized controlled trial was conducted, where students either received a PsyCap intervention or were placed on a wait-list. The intervention, based on Luthans et al.'s guidelines, was delivered online and included self-reflection, goal-setting, and resource assessment.

Results: Post-intervention, the PsyCap of students in the intervention group significantly increased (M = 1.098, SD = 0.24, CI [0.98, 1.21], t(17) = 19.72, p < .001). There was also a significant reduction in GAD scores (M = -0.24, SD = 0.46, CI [-0.47, -0.01], t(17) = -2.19, p = .043). No significant changes were observed in the control group.

Conclusions: Short-term PsyCap interventions can significantly improve students' mental resilience and decrease anxiety, suggesting their integration into educational curricula. This study underlines the need for educational and public health sectors to collaborate in mitigating mental health issues among students, particularly in response to crises like COVID-19. Addressing the rising anxiety among students through brief, online PsyCap interventions shows promise. This approach not only enhances PsyCap but also lowers anxiety, advocating for their regular inclusion in educational settings to support student mental health.

Key messages:

- Results from a controlled trial revealed increases in PsyCap and decreases in anxiety.Findings advocate integrating such interventions into educational curricula promoting student mental health.
- Recent trends indicate a rise in anxiety among students, challenging both educational and public health. Addressing this, the study evaluated the impact of a brief online (PsyCap) intervention.

[3]Quantitative Sciences Unit, Stanford University, Palo Alto, California, USA
[4]Department of Sociology, Stockholm University, Stockholm, Sweden
Contact: guoqiang.zhang@ki.se

Background: Sexual identity, linked to experiences of disadvantage and discrimination, is crucial in equality monitoring. Sweden's gender-neutral marriage laws, introduced in 2009, provide a unique context. This study examines the population trends and demographic disparities in sexual identity over time.

Methods: We analyzed three population surveys (2010, 2014, 2021) from the Stockholm Public Health Cohort, including around 50,000 individuals per survey. Sexual identity was assessed via self-administered questionnaires. Demographic data were sourced from Swedish national registers. Weighted multivariate Poisson regression with robust variance estimators was used to identify demographic disparities in sexual identity. Results were presented as proportion ratio (PR) with 95% confidence interval (CI).

Results: Overall, 29,607 (2010), 20,249 (2014), and 22,558 (2021) individuals reported sexual identity. Heterosexual identity decreased from 95.7% (95% CI 95.4-96.0%) in 2010 to 89.0% (88.5-89.4%) in 2021, while bisexual identity increased from 1.4% (1.2-1.6%) in 2010 to 2.0% (1.8-2.3%) in 2014, and further up to 2.7% (2.4-2.9%) in 2021. Homosexual identity increased slightly from 1.5% (1.4-1.7%) in 2010 to 1.8% (1.6-2.0%) in 2021. Multivariate analyses showed that female, older age, and lower education were inversely associated, while never-married status and living alone were positively associated, with homosexual identity. In contrast, female, younger age, lower income (100 SEK/year) ($< =$2,500 vs $>$4,500: 2010: PR 3.32 [95% CI 1.92-5.75]; 2014: 1.83 [1.28-2.60]; 2021: 1.51 [1.14-2.01]), and never-married status (never vs currently married: 2010: 2.03 [1.47-2.80]; 2014: 1.92 [1.39-2.65]; 2021: 1.50 [1.15-1.95]) were positively associated with bisexual identity.

Conclusions: Heterosexual identity decreased while homosexual/bisexual identities increased in Stockholm County during 2010-2021. Socioeconomic disparities persist in sexual minorities and vary by sexual identity.

Key messages:

- Marked socioeconomic disparities persist in sexual minorities and vary by sexual identity in Stockholm County, although income and marital status disparities in bisexual group seem narrowing.
- Future studies are warranted to investigate the social dynamics that continue to produce sexual minority disadvantages.

Abstract citation ID: ckae144.2269
Alcohol consumption and risky sexual behaviours: consistent patterns in France and South Korea

Jiwon Jeong

J Jeong[1,2], *L Simmat-Durand*[1,2]
[1]Department of Social Science, Paris Cité University, Paris, France
[2]CERMES3, Centre for Medicine, Science, Health, Mental Health and Society, Paris, France
Contact: jiwon.jeong@etu.u-paris.fr

Background: Despite the concurrent increase in harmful alcohol use and risky sexual behaviours associated with STIs and HIV/AIDS among young adults, their relationship remains inconsistent due to the inherent influence of sociodemographic and cultural factors on drinking and sexual practices. This study aims to examine the relationship between alcohol consumption and risky sexual behaviours and cross-validate this relationship in France and South Korea.

Methods: We conducted a cross-sectional survey among young adults aged 18 to 30 in France and in South Korea in 2023-2024 ($n = 998$; 489 in France, 509 in Korea). A spearman partial correlation and a z-test on Fisher-transformed correlation coefficients were used to determine the relationship between alcohol use and risky sexual behaviours, as well as the consistency of this relationship across both samples.

Results: After controlling for age, gender, occupation, education, and perceived socioeconomic status, a positive correlation was found between the age of alcohol initiation and the age at first sexual intercourse in both samples (r=.17 in France, r=.28 in Korea; $p < 0.001$). Alcohol Use Disorder Identification Test (AUDIT) score and the frequency of drunkenness showed positive correlations with the number of sexual partners (r=.19, r=.26 in France; r=.19, r=.23 in Korea; $p < 0.001$). These two alcohol use indicators were also correlated with the frequency of inconsistent condom use (r=.15, r=.12 in France; r=.06, r=.14 in Korea; $p < 0.001$). The Z test confirmed that there is no significant difference in all correlation coefficients between the French and Korean samples. ($p > 0.05$, 95% CI).

Conclusions: An integrated health intervention aimed at simultaneously addressing harmful alcohol use and risky sexual behaviours is warranted to prevent high prevalence of sexually transmitted infections among young adults.

Key messages:

- Recent data support that alcohol use is associated with risky sexual behaviours among young adults.
- This relationship is consistent regardless of different sociodemographic and cultural settings.

Abstract citation ID: ckae144.2270
Bridging gaps: A closer look at the health of sexual and gender minorities in Austria

Gabriele Gruber

J Pfabigan[1], *R Pentz*[2], *L Teufl*[2], *R Winkler*[2], *G Gruber*[3], *S Gaiswinkler*[3]
[1]Health Professions and Long Term Care, Austrian Public Health Institute, Vienna, Austria
[2]Evidence and Quality Standards, Austrian Public Health Institute, Vienna, Austria
[3]Health, Society and Equity, Austrian Public Health Institute, Vienna, Austria
Contact: gabriele.gruber@goeg.at

Austria has long lacked comprehensive data on the health and well-being of sexual and gender minorities (SGMs). The 2022 LGBTIQ+ Health Report addresses this gap by presenting a comprehensive overview of the health status of SGMs in Austria. To contextualize SGM health issues, a review of the literature, health surveys, and action plans across Europe was conducted in the initial project phase. Then a questionnaire was developed in collaboration with an expert group for quantitative data collection. A total of 1,047 individuals participated in the survey; analyses of the quantitative data were enriched by insights from ten qualitative interviews. Detailed findings cover SGMs' health status and experiences of discrimination as well as access to healthcare and health-promoting factors. Participants rated their health status lower than the average in Austria. A high number reported encountering discrimination in healthcare, especially among intersex and trans participants. While approximately half of the respondents were satisfied with healthcare provision, around 16% expressed dissatisfaction. Finally, a significant proportion of participants reported having foregone healthcare services at least once despite having health issues. Our work underscores the importance of recognizing the diverse needs of distinct groups within the SGM spectrum. It is crucial to avoid oversimplification by grouping them into a single SGM category as this obscures the unique challenges and inequalities faced by each subgroup. The rapid evolution of terms adds complexity to this work. Moreover, attention should be directed towards intersectionality within these groups as some are hard to reach with an online survey. Navigating the seas of public health innovation, our exploration of SGM health in Austria reveals not only the challenges but also the imperative for inclusive and tailored healthcare strategies.

Key messages:

- The 2022 LGBTIQ+ Health Report Austria reveils SGM health realities: lower health status, discrimination, and unmet healthcare needs, urging targeted interventions.

- Acknowledging diverse SGM groups and evolving terminologies, our study underscores the need for nuanced, intersectional healthcare approaches.

[4]Semmelweis University, Budapest, Hungary
[5]University of Miskolc, Miskolc, Hungary
Contact: varga.laura@unithe.hu

Background: Drinking large amounts of alcohol has a negative effect on men's sexual activity and reproductive potential. High alcohol intake can interfere with hormone production in the hypothalamus. The connection between low alcohol consumption and sexual activity is not yet clear from previous research.

Methods: In the course of a prospective study with ethical approval, we examined how the consumption of 1 deciliter of white wine per day for 5 weeks affects the parameters of men's sexual life. In the course of strict inclusion and exclusion criteria, 45 healthy male volunteers were included in the study. 25 men in the active arm drank wine, while 20 men in the control arm drank apple juice instead of wine for 5 weeks. On day 0 and week 6, we examined the serum testosterone level, liver enzymes, inflammatory parameters, anxiety level, sleep quality and sexual activity of the participating men using objective tests.

Results: As a result of consuming moderate white wine for 5 weeks, the men's testosterone level increased significantly, inflammatory parameters and liver enzyme values decreased, the sleep quality of the participants in the active arm improved, their pain decreased, and their quality of life improved. The sexual performance of 85% of participants in the active arm improved, none of them deteriorated. No similar improvement occurred in the control arm.

Conclusions: Moderate wine consumption improves the sexual performance, quality of life and several laboratory parameters of healthy men.

Key messages:

- Based on our pilot prospective clinical study, men do not need to fear that a small amount of wine will negatively affect their sexual performance.
- Moderate wine consumption had a positive effect on men's testosterone levels, quality of life and also improved sleep quality.

Abstract citation ID: ckae144.2272
Operationalizing Macro-Level Structural Sexual Minority Stigma: A Scoping Review of the Literature

Arjan van der Star

A van der Star[1]*, O Garetti*[1]
[1]Department of Psychology, San Diego State University, San Diego, CA, USA
Contact: avanderstar@sdsu.edu

Background: Structural stigma, including discriminatory laws, inequitable policies, and negative attitudes, has been conceptualized as the general societal climate and institutional conditions that shape sexual minorities' lives, mental, and physical health. While multidimensional indices have been used globally, U.S.-based studies have largely relied on single indicators (e.g., a law or policy; presence of resources). This scoping review aimed to identify structural sexual minority stigma indicators relevant to the U.S. context, to inform comprehensive, multidimensional future operationalizations.

Methods: Systematic database searches in PubMed, PsycINFO, and JSTOR, and snowball techniques resulted in 70 articles. After duplicate deletion and abstract review, 25 unique indices were long-listed relevant to structural sexual minority stigma at country or state level (i.e., macro level). School (district) and county (i.e., exo level) indicators were excluded.

Results: From the long-listed indices, a total of 112 legal and policy indicators were narrowed down to relevant 33 macro-level indicators and grouped across seven domains: criminal justice, hate crime protections, non-discrimination, religious refusal, relationship recognition, parenting, and youth laws and policies. Two different quantifications of population attitudes were identified that aggregated social and policy opinions across states regarding sexual minority adoption, hate crimes, health benefits, labor and housing, public speaking or teaching, marriage, sodomy, and civil unions.

Discussion: While a large variety of legal and attitudinal indicators was identified, few U.S.-based studies used multidimensional operationalizations (e.g., law, policy, opinion) needed to reduce risk of confounding bias through population-attitudes-to-law/policy backdoor pathways. To further advance the science on structural sexual minority stigma and health globally, future studies may benefit from multidimensional approaches.

Key messages:

- With many legal and attitudinal indicators identified, few studies used multidimensional operationalizations (e.g., law, policy, opinion) needed to reduce risk of confounding bias.
- To further advance the science on structural sexual minority stigma and health globally, future studies may benefit from multidimensional approaches.

[2]Department of Public Health, IDIS University of Santiago de Compostela, Santiago de Compostela, Spain
[3]Department of Clinical Psychology, IDIS University of Santiago de Compostela, Santiago de Compostela, Spain
[4]Faculty of Education Sciences, University of Santiago de Compostela, Santiago de Compostela, Spain
Contact: elena_gles@hotmail.com

Background: Physical inactivity (PA) and sedentary behavior (SB) are modifiable risk factors for non-communicable diseases (NCDs). Data indicates that non-binary gender identified people find it difficult to perform PA, this is a disadvantage for them to reach their full health potential.

Methods: Students were selected by convenience sampling to complete a survey between October-November 2023. A validated PA questionnaire was included. PA and SB were classified into 4 levels: Active but sedentary, extremely sedentary, physically active and discreetly active. Data were analyzed using Statistical Package for the Social Sciences (SPSS).

Results: Out of 32 students did not identified themselves as binary gender. In our sample, 28,1% (vs 12.9% binary students) don't do PA. Of those doing PA, 52,2% don't meet World Health Organization recommendations. Among those who perform PA, there no difference in the amount of minutes/week of moderate or intense physical activity performed. Regarding SB, 93,8% spend

>6 hours/day in SB (vs 84.7% binary students, mean 7,82 vs 8,75, Sg. 0,032). When grouped into PA/SB categories 65,6% (vs 40,5%) were extremely sedentary in contrast to 1,4% physically active (vs 8.8%).
Conclusions: In Spain, 1 in 4 young people does not identify with the male/female categories. In our sample, physical inactivity and sedentarism are higher among those who do not identify as male/female. Once they commit to physical activity, there is no difference in the time spent between those who meet the WHO recommendations. More research is needed to understand the reasons for these differences and ensure barrier-free access to healthy lifestyle habits on campus.

Key messages:

- Non-binary gender identified students are less physically active and more sedentary than their peers.
- Once they commit to physical activity recommendations, there are no differences among their performance.

Abstract citation ID: ckae144.2274
Gender-specific impact of COVID-19 in the UAE: Analyzing gender disparities in health and well-being

Basema Saddik

B Saddik[1,2,3]*, A Shukla*[2]*, R Zeidan*[2]
[1]College of Medicine, University of Sharjah, Sharjah, UAE
[2]RIMHS, University of Sharjah, Sharjah, UAE
[3]School of Population Health, University of New South Wales, Sydney, Australia
Contact: bsaddik@sharjah.ac.ae

Background: Understanding gender disparities in health impacts during pandemics is crucial. While early observations of the COVID-19 pandemic suggested higher severity and mortality rates among males, subsequent studies hinted at a disproportionate impact on females' health and well-being. This study aimed to explore gender-specific differences related to COVID-19 in the United Arab Emirates (UAE).
Methods: Data from four independent surveys were analyzed to assess gender differences in knowledge about available vaccines, vaccine hesitancy, COVID-19 severity, admission to the Intensive Care Unit (ICU), anxiety among healthcare workers (HCWs), and psychological health of healthcare workers and the general population. Gender gaps were calculated as the absolute difference between males and females. Chi-square tests and logistic regression were performed to test the association between gender, age, and selected outcome variables.
Results: Males had a significantly higher risk of moderate to severe COVID-19 symptoms (71%) compared to females (63%). The gender gap in symptom severity was smallest among those aged 55+ and highest among adults aged 35-54. Post-discharge, 22% more females reported multiple conditions than males. Among HCWs, females showed lower knowledge (19% gap) and higher vaccine hesitancy (20% gap), with larger gaps among older age groups. Females also experienced more anxiety and psychological stress, especially in the 35-54 age group. Logistic regression confirmed higher odds for females in reporting vaccine hesitancy, long COVID-19 symptoms, and anxiety, even after adjusting for demographic factors.
Conclusions: This study highlights unequal health outcomes and burdens experienced by women and men during the COVID-19 pandemic in the UAE. The distinct challenges faced by women, including higher mental health burdens and persistent post-recovery symptoms, suggest systemic gender disparities that require targeted attention in healthcare policies and practices.

Key messages:

- Gender disparities in COVID-19 were evident in the UAE with males experiencing severe COVID-19 symptoms, while females experienced post-recovery symptons, vaccine hesitancy, and stress.
- Urgent action is required to address gender disparities in COVID-19 impacts, emphasizing mental health support and post-recovery care in policy formulation.

[5]Department of Infectious Disease, Ente Ospedaliero Ospedali Galliera, Genoa, Italy
Contact: allegraferrari@virgilio.it

Access to STI prevention and sexual health services in Italy, especially among vulnerable and marginalized groups, is inadequately documented. With the support of community organizations, a cross-sectional survey was conducted between September 2023 and March 2024 to assess health services accessibility among individuals at increased risk of STIs. A total of 1456 responses were analyzed. The respondents comprised 1327 (91.14%) cisgender men, 58 (3.98%) cisgender women, 11 (0.76%) transgender men, 10 (0.69%) transgender women, and 47 (3.23%) non-binary individuals. Overall, 93.8% were men who have sex with men, and 2.8% were women who have sex with women. Mean age was 38 (SD 12). Among respondents, 1284 (88.2%) had undergone HIV testing at least once [102 (7%) living with HIV; 45.1% diagnosed during prior year]. Overall, 563 (38.7%) had been diagnosed with at least one STI in the prior year. Chemsex was reported by 106 (7.3%), with 4.7%, 75.5%, and 35.5% using injective, inhaled or oral substances. Despite a high risk for STIs, 728 (50%) and 410 (28.2%) individuals, respectively, did not visit a specialist in infectious diseases or their primary care provider in the prior year. PrEP awareness was high: 1286 (88.2%) respondents were knowledgeable about it, but only 342 (23.5%) attended PrEP centers and 297 (20.4%) used it. Among PrEP users, 27 (7.9%) encountered difficulties obtaining the drug and 174 (50.9%) considered the cost prohibitive (before it became free). Additionally, 27 (7.9%) of those attending PrEP centers felt judged or disrespected. Overall, 1179 (80.9%) had heard of Mpox, and 1012 (69.5%) were aware of the vaccine, with 301 (20.6%) being vaccinated. Among those vaccinated, 18 (5.2%) felt judged or disrespected. Out of 55 (3.8%) individuals tested for Mpox, 13 (23.6%) tested positive, among which one reported feeling disrespected. The survey highlights critical gaps in healthcare access and awareness among individuals at increased risk of STIs in Italy.

Key messages:

- In a final open-ended question, responders commented on various issues including high costs of services, insufficient provider training and the necessity for improved inclusion of LGBTQ+ individuals.
- The robust response from typically hard-to-reach groups underscores the pivotal role of community involvement in enhancing awareness and accessibility of sexual health services, fostering inclusivity.

Abstract citation ID: ckae144.2276
Incentivization of Sexually Transmitted Infection Testing at a Large Public University

Rita Farah

R Farah[1,2]*, R Ferrara*[1]*, M Hayden*[1]*, C Holstege*[1,2]
[1]Student Health and Wellness, University of Virginia, Charlottesville, USA
[2]Medical Toxicology Division, University of Virginia, Charlottesville, USA
Contact: wwv3zr@uvahealth.org

Background: According to the United States (U.S.) Centers for Disease Control and Prevention, more than 2.5 million cases of syphilis, gonorrhea, and chlamydia were reported in 2022, with notable increases in gonorrhea and chlamydia. The highest rates of chlamydia, gonorrhea, and syphilis were found in men and women of college age. This study compared free STI testing events to usual care with regard to patient socio-economic factors and testing positivity rates.

Methods: The Department of Student Health & Wellness at a large, public university offers routine testing at a low cost, flat rate, including chlamydia, gonorrhea, hepatitis C Ab, syphilis and HIV testing. Two weeks of free testing were held during calendar year 2023. Utilization and positivity rates between free testing and regular testing weeks were compared using Pearson's chi squared and Fisher Exact tests.

Results: A total of 8705 tests were performed during routine testing weeks with associated cost averaging 174 tests per week as compared to 1177 tests for the free testing weeks averaging 589 tests per week. Testing uptake during free testing weeks was higher among females (65.6% ($n=772$) vs. 55.1% ($n=4797$); $p<0.001$) and minorities such as, Black or African American [11.3% ($n=133$) vs. 9.4% ($n=813$); $p=0.02$], Hispanic [11.4% ($n=134$) vs. 9.2% ($n=798$); $p=0.02$] and Asian [13.1% ($n=154$) vs. 8.8% ($n=763$); $p<0.001$] when compared to testing during regular weeks. Chlamydial infection positivity rate was lower during the free testing weeks [1.8% ($n=7$)] vs. [3.9% ($n=123$); $p=0.04$]. Gonorrhea, hepatitis C, HIV, and Syphilis positivity rates did not differ between the two testing periods.

Conclusions: Free STI testing in the context of a large, public university Student Health Department shows increased utilization. The establishment of free testing weeks was associated with an increase in female students and minorities use of testing services at a large public university.

Key messages:

- Incentivization can improve STI testing utilization among university students.
- The establishment of STI free testing periods can increase the use of testing services among minority students and females.

Abstract citation ID: ckae144.2277

Intention to use HIV pre-exposure prophylaxis (PrEP) in health sciences students

Miranda Hernández Rico

F Vicente Molina[1], MP Ramos Tenorio[1], YR Sosa Gonzalez[1], M Hernandez Rico[1], JE Villegas-Dominguez[1], M Hernandez Rico[1], YR Sosa Gonzalez[1]
[1]Faculta de Medicina, Universidad Veracruzana, Veracruz, Mexico
Contact: zs19023068@estudiantes.uv.mx

Introduction: HIV is a public health issue, and as such, there are currently programs for the use of pre-exposure prophylaxis for HIV (PrEP) in various public institutions, with family physicians being one of the pillars to provide information and raise awareness among individuals at risk for HIV who wish to use these strategies.

Objectives: To determine the factors associated with the intention to use PrEP among university students in the healthcare field in the Veracruz-Boca del Río region.

Methods: A cross-sectional, prospective, and analytical study was conducted from August 2023 to March 2024, including students from healthcare-related majors at universities in the Veracruz region. An instrument was used to assess the level of knowledge about PrEP (Cronbach's alpha of 0.8), with scores ranging from 0 to 10. Students were invited to participate in this research at different faculties of health sciences.

Results: 508 subjects participated, with 299 (58.9%) females and 386 (76.0%) heterosexual; 65.9% had never heard the term 'PrEP,' and 12% learned it from social media. The intention to use PrEP was positive in 81.5% of subjects in case of becoming a high-risk person for acquiring HIV. The level of knowledge about PrEP showed a score of 2.2 (SD ± 2.6), with 3.7% having high knowledge, 10.2% having a passing grade, and 55.9% scoring above the median (1.4) of the group's scores. No association was identified between gender identity, sexual orientation, academic characteristics, and sources of information with the intention to use PrEP ($p>0.05$). Knowledge level above the median of 6 points showed an odds ratio of 2.95 (95% CI 1.03-8.3) for the intention to use PrEP ($p<0.05$).

Conclusions: The level of knowledge increases the probability of the intention to use PrEP in young people, making it essential for the primary care physician to carry out this training and awareness activity within their daily interactions with young patients.

Key messages:

- It is essential to generate education programs on Prep for the population, as this will favor informed decision making on the use of these medicines in case they are required.
- It is necessary to provide people with general information about Prep, since despite the existence of active programs for its distribution, most people have never heard anything about this drug scheme.

Abstract citation ID: ckae144.2278

HPV vaccination in Croatia (2016-2023): Increased vaccine uptake and declining sex disparities

Lucija Raic

L Raic[1], I Pavic Simetin[2], E Bradasevic[1], A Jezidzic[1], T Nemeth Blazic[3], T Poljicanin[4]
[1]Health Informatics and Biostatistics, Croatian Institute of Public Health, Zagreb, Croatia
[2]School Medicine and Mental Health, Croatian Institute of Public Health, Zagreb, Croatia
[3]Epidemiology of Communicable Diseases, Croatian Institute of Public Health, Zagreb, Croatia
[4]Health Center of Zagreb County, Zagreb, Croatia
Contact: lucija.raic@hzjz.hr

Background: The Human papillomavirus (HPV) is a known cause of cervical cancer, and is associated with the development of vaginal, vulvar, anal, penile, and head and neck cancer. The availability of the HPV vaccine has enabled generations of young people to be protected from HPV-related cancers. In 2016, a national immunization program targeting 14-year-old girls and boys has been initiated in Croatia. To date, systematic data on HPV vaccination coverage (VC) in Croatia is lacking. This study aims to determine HPV VC, examine trends in HPV vaccination in Croatia from 2016 to 2023 in the context of the national vaccination program, and assess differences between sexes.

Methods: The study is designed as a retrospective analysis covering the data from 2016 to 2023, collected from primary healthcare providers. HPV VC within 2000-2008 birth cohorts (BC) are analyzed for all vaccinated with at least one dose and assessed by sex. The trend in HPV vaccination is shown using joinpoint regression. The chi-square for trend is used to compare the vaccination coverage of females (FVC) and males (MVC). The rate ratio between FVC and MVC is calculated.

Results: HPV VR increased significantly among observed BCs from 6,44 % in 2000 BC to 44,22 % in 2008 BC (FVC rose from 10,67 % to 52,78 %, and males MVC from 2,47 % to 36,05 %). Joinpoint analysis revealed a statistically significant increase in all birth cohorts, while the steeper increase is seen in 2000-2006 BCs (APC = 35,47, $P<0,05$) than in 2006-2008 BCs (APC = 13,93, $P<0,05$). FVC is significantly higher than MVC in all birth cohorts (Extended Mantel-Haenszel chi-square for linear trend = 809.23, P < 0,001). The highest FVC/MVC rate ratio was observed in the initial 2000 BC (4,31), and the lowest in the last 2008 BC (1,46).

Conclusions: In Croatia, HPV VC continuously increases among observed BCs. The positive trend is present in both sexes, and the rate ratio between female and male cohorts is decreasing.

Key messages:

- The study presents a systematical overview of HPV vaccination coverage in Croatia from the beginning of the national immunization program, which is crucial for monitoring progress.
- In the following years, if the revealed trends persist or advance, Croatia could be closer to reaching Europe's Beating Cancer Plan concerning eliminating HPV-related diseases.

Developing a nationwide dataset of UK veterans seeking help from sector charities

Giuseppe Serra

G Serra[1,2], M Tomietto[2], A McGill[2], M Kiernan[2]

[1]Department of Medicine, University of Udine, Udine, Italy

[2]Department of Nursery, Midwifery and Health, Northumbria University, Newcastle Upon Tyne, UK

Contact: giuseppe-serra@live.it

Background: The assistance to military veterans and their families in the UK is provided by both the NHS and over 1800 military charities. These charities count services using different definitions and reporting systems, so to date a national registry of service usage does not exist. The aim of the MONARCH study is to build a standardised registry of service usage data for the military charity sector, in order to identify patterns of use, gain insight on possible risk factors, and guide the allocation of resources.

Methods: Data is anonymised and a unique identifier is generated by adopting a Secure Hashing Algorithm, allowing both privacy protection and avoiding double counts. Data is standardised, and linked with an automated process to create an aggregated dataset. The dataset describes the population, using both a-priori and machine learning approaches (K-means clustering) to unveil different usage patterns. In addition, it will be linked to an online interactive dashboard.

Results: To date 5 national charities have shared data, for a total of 42,509 veterans with 128,423 needs. The mean age of beneficiaries was 60.1 years (SD 20.5), and 90% were male. 65% were receiving some other form of statutory benefit, 5% was homeless and 1% was imprisoned. 65% of the needs recorded concerned social wellbeing. 40% of veterans were helped at least in two different years. The k-means clustering approach based on the number of accesses, number of needs and repetition of need returned 4 subgroups of use that were identical to those created using a priori knowledge.

Conclusions: The dataset is the most comprehensive source of charity usage data in the UK to date. Service usage is generally homogenous among subgroups, but some differences were highlighted indicating that younger, non-officer veterans may be more at risk of presenting with more complex needs. These first useful insights can help allocate resources to build an effective preventive strategy for more complex cases.

Key messages:

- The MONARCH dataset is the first comprehensive nationwide registry in the UK of military charity data.
- The understanding of usage patterns can lead to the design of targeted preventive strategies.

Abstract citation ID: ckae144.2280

Characteristics of sick-listed employees diagnosed with a mental disorder in Germany

Fiona Starke

F Starke[1,2], I Houkes[2], A Sikora[1], U Wegewitz[1], A de Rijk[2]

[1]Division 3 Work and Health, Federal Institute for Occupational Health and Safety, Berlin, Germany

[2]Department of Social Medicine, Maastricht University, Maastricht, Netherlands

Contact: f.starke@maastrichtuniversity.nl

Purpose: Employees with mental disorders (MDs) are more likely to exit the labour market prematurely. In Western European countries, characteristics of employees diagnosed with a MD have not been reported comprehensively, hampering targeting the risk group and developing preventive interventions. The aim was to describe the socio-demographic, health, treatment, organisation, job and labour market characteristics of employees diagnosed with a MD in Germany and their gender differences.

Methods: This cross-sectional study uses baseline data from sick-listed ($\geq$6 weeks) employees diagnosed with a MD, aged 20-60 years, who were patients in the German mental health care, and recruited in the context of a return to work (RTW) intervention evaluation trial (RTW-PIA study). Descriptive T-tests/Chi-2 tests were applied.

Results: 484 individuals (58.5% female; 31% highly educated, average age 42.6) were included, of which 88.4% had affective disorders. Most were salaried employees working full-time, employed in large companies and having permanent contracts. 65.5% reported moderate depressions and the average work ability was 3.9 on a 0-10 scale. 74.2% had a positive RTW prognosis; 15.3% scored high levels of RTW self-efficacy. Gradual RTW (GRTW) was perceived the most important requirement for RTW (76.9%). More than 60% had discussed various work-related topics during therapy; further RTW-measures were prepared among 47.7%. Almost 60% received a recommendation for GRTW. Significant gender differences were found among the socio-demographic, health, job and labour market characteristics.

Conclusions: This study gives insights into a hardly investigated group. Almost two thirds had moderate depressions, 84.7% had low RTW self-efficacy and a very low average work ability. This highlights the vulnerability of persons with MDs in the labour market and suggest an urgent need for more work-related (health-)care. Gender differences need to be better addressed in mental health research.

Key messages:

- Comprehensive knowledge of the characteristics of sick-listed employees diagnosed with MDs is crucial for targeting interventions to promote RTW.
- Moderate depression scores, low RTW self-efficacy and very low work ability highlight the vulnerability of persons with MDs in the labour market, suggesting an urgent need for more work-related care.

How do working conditions change for in-person versus digital work? The case of schoolteachers

Ellen MacEachen

E MacEachen[1], P Hopwood[1], J Whitson[1], J Aurini[1], S Premji[2], M Miller[1], Y AlMomani[1], I Sultana[3]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada
[2]School of Labour Studies, McMaster University, Hamilton, Canada
[3]Department of Political Science and Sociology, North South University, Dhaka, Bangladesh
Contact: ellen.maceachen@uwaterloo.ca

Background: Telework has significantly increased in Europe and internationally in the aftermath of COVID-19 lockdowns, with estimates of 22% of Europeans now doing some form of telework. However, it is unclear how working conditions for the same job differ when work is conducted in-person versus digitally, and if occupational health risks can be considered as equal across formats. Our study addressed the profession of school teaching to examine online working conditions versus those for in-person teaching.

Methods: To allow for close consideration of employment contexts, a qualitative study was conducted. Focus groups and interviews took place in 2023-24 with 45 teachers and tutors who teach from kindergarten to secondary grades across Canada.

Results: We found that online teaching added to emotional labour of teaching work and involved new occupational exposures. These included challenges with engaging students via cameras and microphones, digital surveillance of teachers by parents and students, unwanted exposure to students' intimate home lives, and technostress.

Conclusions: The work of being an online teacher was very different than teaching in-person, yet there has been slow recognition of working condition differences for understanding of OHS exposures and for collective agreements.

Key messages:
- In the context of a significant expansion of telework, assumptions cannot be made that the job conditions and exposures are the same job when performed in-person or at-home.
- These differences will need to be recognized in job agreements and occupational risk assessments.

Abstract citation ID: ckae144.2282
Injury risk in foreign workers: a proposal for a prevention plan in South Tuscany

Elena Maria Guerreschi

EM Guerreschi[1], C Francini[2], A Giomarelli[2], N Nante[1,3]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Prevention Hygiene Safety in Workplace Department, LHA Tuscany Southeast, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: e.guerreschi@student.unisi.it

Background: There are nearly 2.3 million foreign workers in Italy, many of whom hold low-skilled and heavy jobs that expose them to greater safety risks. The aim of the study is to analyze data on the accident phenomenon by using information flows from the national work accident insurance institute, in order to ensure a safe and inclusive work environment.

Methods: The total number of foreign workers' accidents in the South Tuscany during the five-year period 2017-2021 was quantified. General injury trend was assessed, breaking down the events by province (Siena, Arezzo, Grosseto), year of occurrence and severity. We analyzed the events by nationality of the injured ones and by severity of compartment.

Results: A total of 38,254 occupational accidents were recorded, of which 6,172 (16.13%) occurred to foreign workers. Compared to the incidence of foreigners residing in the reference territory, the accident figure is 16.13% out of the 10.5% resident population. The majority involve people from Eastern Europe (60.8%). The most representative nationalities are: Romania (1,477 events), Albania (1,022), Morocco (404), Macedonia (341), Kosovo (264), Tunisia (190) and India (170). Romanian workers are the population most affected by occupational injuries in Southeast Tuscany with 1,477 events. Agriculture is the predominant sector with 17.7% of total injuries.

Conclusions: Information flows on foreign workers' accidents is the starting point for specific design of prevention plans (supervision, assistance, research, information and training, awareness raising) aimed at reducing specific accident risk factors. Language and cultural differences represent an element of possible conditioning of risk perception, which must be considered in an effective design of safety training courses for foreigners.

Key messages:
- The study of accident information flows of foreign workers provides the basis for specific design of prevention plans in order to reduce accident risk factors.
- Language and cultural differences must be considered in an effective design of safety training courses for foreigners.

Abstract citation ID: ckae144.2283
Occupational class difference in COVID-19 symptoms in France: contribution of work-related exposures

Narges Ghoroubi

N Ghoroubi[1,2], M Khlat[1], E Counil[1,3]
[1]The French Institute for Demographic Studies, Ined, Aubervilliers, France
[2]Doctoral School of Public Health EDSP, Paris Saclay University, Villejuif, France
[3]Institut de Recherche Interdisciplinaire sur les Enjeux Sociaux, Aubervilliers, France
Contact: narges.ghoroubi@ined.fr

Background: The association between socio-occupational class and SARS-CoV-2 infection remains inconclusive and may depend on the setting and the pandemic stage. Our study aims to quantify self-reported COVID-19 symptoms by occupational class (OC) in spring 2020 in France and explain observed differences using work-related risk factors.

Methods: We analyzed data from the EpiCoV population-based cohort, comprising 46,849 active workers aged 18-64 in metropolitan France. COVID-19 symptoms were sudden loss of taste/smell, fever with cough, fever with shortness of breath, or fever with chest oppression. Separating regions highly affected by COVID-19 from other regions, we related OC with reporting of COVID-19 symptoms and assessed the mediation effect of work-related SARS-CoV-2 exposures (contact with the public, using public transportation, self-perceived exposure) using the Karlson-Holm-Breen mediation analysis method.

Results: During the study period, 7.1% of the workers reported COVID-19 symptoms. In both regions, work-related SARS-CoV-2 exposures were related to higher reporting of symptoms, and those exposures were more prevalent in the lowest than in the highest OCs. However, the association of OC with reporting symptoms was not the same in the two regions. In less affected regions, the lowest OC reported COVID-19 symptoms less often than the highest OC, whereas in highly affected regions, symptoms were more frequent in middle OCs, and this was partly explained by work-related SARS-CoV-2 exposures.

Conclusions: Different socio-occupational patterns of symptoms were observed in the two groups of regions. The situation in the less affected regions, with more reporting in the highest relative to the lowest classes, may be attributable to exposure factors playing a role opposite to that of work-related exposures. Further studies on OC disparities in COVID-19 severity are needed based on hospitalization and mortality.

Key messages:

- During the early pandemic, in regions less affected by COVID-19, the upper occupational class reported more COVID-19 symptoms, whereas the middle class did so in highly affected regions.
- Work-related exposure to SARS-CoV-2 mediates the association between occupational class and reporting COVID-19 symptoms to some extent, even when the occupational gradient is reversed.

Abstract citation ID: ckae144.2284
Heavy Work Investment (HWI) and Its Effect on Employees' Physical and Mental Health

Liron Inchi

L Inchi[1]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
Contact: lironi@yvc.ac.il

Background: Economic reality and centrality of work have led to employees investing much time and effort in work. However, The number of hours spent at work may not be the only explanation, and other characteristics, such as type of work, employees' personality, economic status, motivations, etc., need to be considered. The Heavy Work Investment model (Snir & Harpaz, 2012) considers these variables and classifies employees into four types of investors. This study examines the physical and mental health consequences of each HWI group.

Methods: Participants (N = 962) were workers who came to a medical center for annual medical screenings. About 70% were males, and the average age was 50.13 years (SD = 9.53). They divided into 5 groups: Typical full-time workers (N = 208, 29.2%), 'Needy' (N = 111, 15.6%), 'Employer directed' (N = 111, 15.6%), 'Workaholic' (N = 192, 26.9%) and 'Work devoted' (N = 91, 12.7%). The personal data was cross-referenced with the respondents' health data. Differences for categorical variables were examined with Chi-square analyses.

Results: 'Employer-directed' employees, more than 'work-devoted' employees, perceived their health status as preventing them from performing mild activities. 'Employer-directed' and 'needy' employees, more than 'work-devoted' employees, perceived their health status as interfering with their social activities and their pain as interfering with their regular activities. 'Workaholic' employees suffered from more diseases than 'work-devoted' employees, and they were found to be 3.70 times more likely to be at a high risk of cardiovascular disease than typical full-time workers.

Conclusions: It is possible to anticipate types of health damage according to occupation type and develop occupation-adjusted health promotion programs. It is necessary to base labor laws on protecting employees' health, particularly regarding time and workload' outside of work' in both hours (additional or flexible) and location (hybrid work).

Key messages:

- Inspire organizations to be aware of potential injuries caused by HWI and promote the creation of intervention programs, potentially significantly improving employees' health and well-being.
- Evidence for the necessary laws that protect employees' health, particularly regarding time and workload 'outside of work' in both hours (additional or flexible) and location (hybrid work).

Association of Workplace Toilet Access with Urinary Tract Symptoms and Productivity Loss among Female

Yu Min Lee

YM Lee[1,2], *M-Y Kang*[3]
[1]Occupational and Environmental Medicine, Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea
[2]The Institute for Occupational Health, Yonsei University College of Medicine, Seoul, South Korea
[3]Department of Occupational and Environmental Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University, Seoul, South Korea
Contact: yumin.lee.oem@gmail.com

Purpose: Lower urinary tract symptoms (LUTS) are prevalent among women, affecting not only their physical well-being but also their quality of working life. We investigate workplace toilet access related to LUTS among women in the Korean workforce.

Materials and methods: An online survey was conducted to determine the demographic characteristics, occupational risk factors, and urinary tract symptoms among employed Korean women. Occupational risk factors included three survey questions on access to toilets at work: A) enduring urinary symptoms at work; B) capability to use the toilet at will during work, and C) needing to use the toilet during work but were unable to. The LUTS were assessed using the overactive bladder symptom score (OABSS) and international consultation on incontinence questionnaire-urinary incontinence short form (ICIQ-SF). Health-related productivity losses (HRPL) were estimated using the work productivity and activity impairment (WPAI) questionnaire for urinary symptoms. Multiple logistic regression was used to determined the association between workplace toilet access and LUTS. In addition, generalised linear regression analysis was performed to assess HRPL according to workplace toilet access.

Results: Of the 1057 participants, 260 (24.6%) and 294 (27.81%) had overactive bladder and urinary incontinence, respectively. More than 50% reported poor access to toilet. Multiple logistic regression analysis showed that the lower the access to toilets in the workplace, the higher the incidence of LUTS and the higher HRPL.

Conclusions: Restricted access to toilets at work are associated with poor urinary health and loss of productivity. The results highlight the need for interventions to improve the workplace environment.

Key messages:

- Restricted access to toilets at work are associated with poor urinary health and loss of productivity.
- The results highlight the need for interventions to improve the workplace environment.

Abstract citation ID: ckae144.2286
Organizational well-being in a healthcare facility in Tuscany

Federico Viti

F Viti[1], *A Rencinai*[2], *G Lazzeri*[1,3], *N Nante*[1,3]
[1]Postgraduate School of Public Health, University of Siena, Siena, Italy
[2]Hygiene and Public Nutrition Unit, LHA Tuscany South-East, Torrita di Siena, Italy
[3]Department of Molecular Medicine and Development, University of Siena, Siena, Italy
Contact: federico.viti@hotmail.it

Introduction: Organizational climate assessment provides crucial insights into work life across sectors. While corporate culture evolves gradually, the organizational climate promptly reflects employees' mood, motivation, enthusiasm, and perception of the work environment. This study aims to analyze the organizational well-being in a healthcare facility in southeast Tuscany to reveal both successful areas and critical issues within the organization.

Methods: Data on gender, age, tenure, qualification, and contract type were collected anonymously. Organizational climate was assessed using a Likert scale (1-10), covering workplace safety, stress, fairness, discrimination, career development, relationships, belonging, and other perceptions. STATA was used to conduct this analysis.

Results: Twenty-nine participants included 55.3% male, averaging 45.3 years. Thirty-one percent had less than 5 years of tenure, with only 14% in managerial roles. Workplace safety perception varied:

58% moderately safe, 20% unsafe, and 20% highly insecure. Bullying was reported by 14.3%, while 17.6% found compensation fully appropriate. Merit and career opportunities were unrelated for 65.5%, and 48.2% found their role aligned with their profile. Fifty-five percent felt part of a team, and 27.5% perceived good integration. Company rules were clear for 93%, but 34.5% considered changing companies, while 55.1% were satisfied. External user perception was positive at 58.5%.

Conclusions: The analysis identified positive aspects and areas for improvement in workplace well-being. Safety and fairness in job allocation were well-received, with room for improvement, mostly in promotion transparency. Colleague relationships were positive, emphasizing the importance of transparent communication and employee engagement in building trust and participation. These findings can guide the development of targeted interventions to enhance organizational well-being, fostering employee satisfaction and efficiency.

Key messages:

- The evaluation of organizational climate in this healthcare facility revealed a variety of employee perceptions, highlighting strengths and areas for improvement in workplace well-being.
- Enhancing transparency and communication regarding merit-based promotions within the organization is necessary to foster employee trust and engagement.

Abstract citation ID: ckae144.2287
Do shift-working nurses' work-life quality relate to their physical health and diet quality?

Aydan Yilmaz

A Yilmaz[1], *MN Esin*[2]
[1]Hamidiye Faculty of Nursing, Health Sciences University, Istanbul, Türkiye
[2]Florence Nightingale Faculty of Nursing, Istanbul University-Cerrahpasa, Istanbul, Türkiye
Contact: aydan.yilmaz@sbu.edu.tr

Background: Shift work negatively affects work-related quality of life and this situation causes significant labour force losses and decreased productivity in the society, especially health problems in nurses. This study was conducted to determine the relationship between work-related quality of life, physical health level and nutritional behaviours of nurses working in shifts.

Methods: This descriptive and relationship-seeking study was conducted with 312 nurses selected by quota sampling in Istanbul. Data were collected between December 2022 to July 2023 using the The Professional Quality of Life Scale (ProQOL), Physical Health Questionnaire and Food Consumption Frequency Questionnaire. Descriptive statistics and Pearson correlation tests were conducted on IBM SPSS 25.0. BeBIS 7.1 software were used for calculation diet index.

Results: Compassion Satisfaction (CS), Burnout (B) and Compassion Fatigue (CF) scores of nurses was examined, a relationship was found between CS score and B score ($r=-0.39$ $p < 0.05$) and between B score and CF score ($r = 0.58$ $p < 0.05$). CS score correlated with Cardiovascular Risk Level score ($r=-0.15$ $p < 0.05$) and diet index score ($r = 0.15$ $p < 0.05$). B score correlated with Gastrointestinal Risk Level score ($r = 0.27$ $p < 0.05$) and Cardiovascular Risk Level score ($r = 0.38$ $p < 0.05$). There was a correlation between the score of CF and Gastrointestinal Risk Level score ($r = 0.25$ $p < 0.05$) and Cardiovascular Risk Level score ($r = 0.31$ $p < 0.05$). Daily energy, fibre, vitamin B1 and C, folate, calcium and magnesium intakes of nurses were lower than the recommended.

Conclusions: Research results support that the gastrointestinal and cardiovascular systems have a direct relationship with stress and emotional states. In the policies to be developed within the scope of occupational health nursing practices, it is recommended to carry out studies to improve the physical health and nutritional behaviours of nurses in order to improve their work-related quality of life.

Key messages:

- Nurses are a risky occupational group in terms of burnout. Protection studies should be prioritised to prevent burnout.
- Gastrointestinal and cardiovascular system complaints of nurses should be paid special attention during recruitment and periodic examinations.

Abstract citation ID: ckae144.2288
School-based outdoor education and teacher well-being: the LärMiljö (Learning Environment) - study

Nina Simonsen

N Simonsen[1,2], *N Wackström*[1], *J Ray*[1]
[1]Folkhälsan Research Center, Public Health Research Program, Helsinki, Finland
[2]University of Helsinki, Department of Public Health, Helsinki, Finland
Contact: nina.simonsen-rehn@helsinki.fi

Background: School-based outdoor education (OE) is a teaching method aiming to promote pupils' learning and wellbeing. OE with its action-oriented and cooperative learning approach can inspire teachers to develop their teaching and may also have a positive impact on their work wellbeing. According to self-determination theory, satisfaction or frustration of employees' basic psychological needs - need for autonomy, competence and relatedness - are important facilitators or impediments of work wellbeing. We explored possible associations between OE use and teachers' 1) satisfaction/frustration of basic needs at work and b) work engagement.

Methods: The study, part of the LärMiljö-study, used data collected in 2022 through electronic surveys among teachers in Swedish-language primary schools in Finland; $N = 134$ teachers from 44 schools. Main measures were the 24-item Basic Psychological Need Satisfaction and Need Frustration at Work Scale and 9-item Utrecht Work Engagement Scale. Data was analysed with Mann-Whitney U-tests and Spearman correlation.

Results: The vast majority was female, classroom teachers and had a master's degree. Preliminary findings show that 69% practiced OE (sporadically or regularly) and 31% did not; both groups were similar in terms of teaching experience, age and gender. Teachers using OE had higher autonomy and competence need satisfaction, and lower relatedness need frustration than teachers not using OE ($p < 0.05$). There was no difference in overall work engagement ($p = 0.07$), but OE teachers had higher dedication to work ($p < 0.05$). Satisfaction of basic needs at work was positively, and frustration of needs negatively, associated with work engagement ($p < 0.001$).

Conclusions: Practicing OE appears to have positive associations with teachers' dedication to work and satisfaction of need for autonomy and competence, and a negative association with relatedness frustration. More research is needed to confirm and examine the direction of these associations.

Key messages:

- Outdoor education (OE) may besides pupils' learning and wellbeing also promote teachers' work wellbeing. Work wellbeing among teachers was studied within the framework of self-determination theory.
- Practicing OE seems to be positively associated with teachers' dedication to work, a sub-dimension of work engagement, and satisfaction of the basic needs for autonomy and competence at work.

Abstract citation ID: ckae144.2289
30-month work participation trajectories of employees returning to work with common mental disorders

Alexandra Sikora

A Sikora[1,2], J Almansa Ortiz[2], I Arends[2], U Wegewitz[1], U Bültmann[2]
[1]Division 3 Work and Health, Federal Institute for Occupational Safety and Health, Berlin, Germany
[2]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands
Contact: Sikora.Alexandra@baua.bund.de

Background: Promoting a sustainable return to work (RTW) and work participation (WP) for employees with common mental disorders (CMDs) is a crucial challenge for mental healthcare, organisations, and society at large. To date, work-related factors have only very rarely been examined within RTW trajectory studies. The present study aims to examine 30-month WP trajectories and associated individual, health- and work-related factors of employees on sickness absence due to CMDs in Germany.

Methods: In a prospective cohort study with N = 259 participants, five measurements were conducted at baseline (during the last week of inpatient treatment), and 6, 12, 18 and 30 months later. WP was defined as the proportion of weeks being present at work between two measurement points (self-reported). WP trajectories over 30 months were estimated with Latent Class Growth Analysis (LCGA), and were described according to associated individual, health- and work-related factors.

Results: We extracted four trajectory classes: Class 1 'slowly increasing WP' (19.6%) with a slow but constantly increasing WP over time, and finally reaching nearly 60% of WP; Class 2 'high maintaining WP' (30.3%) with a maintaining high WP of over 80% after RTW until 30 months; Class 3 'highest maintaining WP' (34.7%) with the highest maintaining WP throughout follow-up and reaching nearly 100% WP after RTW; and Class 4 'decreasing WP' (15.4%) with a positive development of WP until 12 months, reaching of about 90% WP, but then decreasing below 60% WP until 30 months. Participants with persistent high WP (Classes 2 and 3, 65.0%) reported better individual-, health- and work-related characteristics at baseline, and more realized work accommodations during RTW.

Conclusions: For the majority of the employees, returning to work resulted in sustainable WP during the 30 months study period. However, about one third of the employees should be given more attention in their complete RTW process from treatment to workplace support.

Key messages:

- Sustainable work participation after returning to work with common mental disorders is a long and complex journey.
- Employees with a better individual, health- and work-related situation at baseline seem to be more likely to achieve a sustainable work participation.

Abstract citation ID: ckae144.2290
Phenotypes of Italian workers with disability: a cluster analysis on workers with multiple sclerosis

Michela Ponzio

M Ponzio[1], E Grange[1], F Di Antonio[1], B Persechino[2], T Manacorda[1], M Inglese[3], P Durando[4,5], MA Battaglia[1,6], G Brichetto[1,7], J Podda[1]
[1]Scientific Research Area, Italian Multiple Sclerosis Foundation, Genoa, Italy
[2]Department of Occupational and Environmental Medicine, Italian Workers' Compensation Authority, Rome, Italy
[3]DINOGMI, University of Genoa, Genoa, Italy
[4]Department of Health Sciences, University of Genoa, Genoa, Italy
[5]Occupational Medicine Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy
[6]Department of Life Science, University of Siena, Siena, Italy
[7]AISM Rehabilitation Service, Italian Multiple Sclerosis Society, Genoa, Italy
Contact: michela.ponzio@aism.it

Background: While job maintaining/reintegrating are clearly complex issues in multiple sclerosis (MS), where many aspects (physical, psychological, relational and personal resources) can play a key role, they offer scope for potential interventions. This study aimed to identify and describe phenotypes of workers with MS considering specific work-related domains such as work-related difficulties, anxiety and depressive symptoms, and coping strategies.

Methods: A cross-sectional online survey on MS workers was conducted in Italy. Hierarchical cluster analysis was performed by the Ward method followed by k-means cluster analysis.

Results: A total of 209 workers with MS were included in the analysis. We identified four phenotypes: phenotype 1 had low work difficulties, low depressive symptoms and mild anxiety, with a moderate tendency to use problem focus and positive attitude and a mild one to use social support as coping strategies (n = 82, 39.2%); phenotype 2 had low-to-mild work difficulties, mild anxiety and low depressive symptoms, with a high tendency to use positive attitude and religion, moderate problem focus and social support, and mild denial (n = 38, 18.7%); phenotype 3 had low-to-mild work difficulties, moderate anxiety and depressive symptoms, with a mild tendency to use problem focus, positive attitude, religion, social support, denial as coping strategies (n = 50, 23.9%); phenotype 4 had mild-to-moderate work difficulties, moderate anxiety and depressive symptoms, with a moderate tendency to use problem focus, positive attitude, and mild social support and denial as coping strategies (n = 39, 18.7%)

Conclusions: This explorative analysis aimed to find distinct workers with MS profiles in a working-age population based on work-related domains such as work-related difficulties, coping strategies, and psychological aspects. This could lead to a better tailoring of the vocational rehabilitation interventions for workers with MS.

Key messages:

- This approach, in which different domains related to work are considered, could help to identify a taxonomy that recognizes distinct and predominant MS worker phenotypes.
- Identification of subgroup MS workers, could result in better tailoring of the vocational rehabilitative interventions for people with MS.

Abstract citation ID: ckae144.2291
Return to work after hip and knee arthroplasty: qualitative outcome from the Netherlands

Nicky Wouters

NT Wouters[1,2,3], KAP Wijnands[1,3,4], I Geilen[1], I van Tuijn[2], B Boonen[2,3], C Gielen[1,3], MGM Schotanus[2,3,5]
[1]UWV, Heerlen, Netherlands
[2]Department of Orthopedic Surgery, Zuyderland Medical Center, Sittard-Geleen, Netherlands
[3]Academic Knowledge Center Work & Health South-East Netherlands, Heerlen, Netherlands
[4]Department of Social Medicine, Care and Public Health Research Institute, Maastricht, Netherlands
[5]Department of Epidemiology, Care and Public Health Research Institute, Maastricht, Netherlands
Contact: nicky.wouters@uwv.nl

Background: Total Hip Arthroplasty (THA) and Total Knee Arthroplasty (TKA) are performed daily worldwide. More younger working-age patients are receiving a THA and/or TKA. Outcomes, including Quality-of-Life (QOL), patient satisfaction and Return-to-Work (RTW) are becoming more important and have implications for healthcare budget and health workforce. Clinical recovery pathways should improve patient outcomes and cost-effective care.

Insight in patient experiences and expectations regarding RTW remains behind. This study aims to gain insight into influenceable factors in the recovery pathway after THA or TKA that could lead to improved care and enhanced patient participation.

Methods: In this single-center qualitative study, performed at Zuyderland Medical Center (Sittard-Geleen, the Netherlands), 12 patients (n = 6 THA; n = 6 TKA) aged under 65 years were approached to participate. During interviews 6-weeks after arthroplasty, this research explored their RTW experiences in both pre-, and postoperative, in- and outpatient settings.

Results: In total, 12 employed patients who received a THA (n = 6, mean age 56 ± 7.4 years; female: n = 4, 66%) or a TKA (n = 6, mean age 61 ± 2.6 years; female n = 3, 50%) participated. Own control regarding RTW and a minimal recovery time after the operation was necessary for all patients. During this time, focus on physical therapy and strengthening was most important. RTW was not expected to be the primary goal during the clinical recovery pathway. The RTW topic was said to belong to the occupational physician (OP) and employer. Patients however knowledge that the type of work should gain importance in the consultation room. Patients missed accessible communication between the orthopedic surgeon and OP.

Conclusions: Overall, patients are satisfied with the current clinical recovery pathway. Intercollegiate communication should be made more accessible. Own control and strengthening self-management in the RTW remain important for all patients.

Key messages:

- Own control and strengthening self-management should have importance in the guidance of working-age patients after THA or TKA.
- Intercollegiate communication should be made more accessible.

DZ. Poster display: Other public health issues

Abstract citation ID: ckae144.2292
Preparing a dataset for new life: cleaning a longitudinal study for new analyses and linkages

Amanda Dylina Morse

A Morse[1], *K Higgins*[1]
[1]Queen's Communities and Place, Queen's University of Belfast, Belfast, UK
Contact: amorse01@qub.ac.uk

Issue: The Belfast Youth Development Study (BYDS) was conducted from 2000-2010, comprising 7 waves of collection. The data contain valuable insights into the health and social lives of adolescents but were stored using inconsistent management practices and lacked a metadata crosswalk describing all variables and their content. Primary challenges to new analysts included shared questions entered using varying notations across waves of collection ("mother" and "yes" in a "mother lives at home" variable), single question responses stored wide across multiple variables, and a need for comprehensive metadata.

Description: Individual questions were un-joined from the linked dataset, cleaned using the tidyverse suite of packages in R, and then left-joined to the primary dataset. Where responses were recorded differently across years, scales were standardised across waves of collection. Questions were arranged in their original order to maintain dataset integrity.

Simultaneously, a crosswalk was created of each question, its old and new variable names, and its response scales. Rows for old variable names and response scales were collapsed into comma-separated values and deduplicated by the new variable names using the dplyr package.

Results: Following this work, the BYDS dataset is ready for new researchers to analyse and describe findings. A large grant has recently been awarded to conduct a new wave of data collection, the analysis of which will be enhanced by the cleaned dataset and its associated metadata.

Lessons: It is feasible and desirable to maintain older datasets through semi-automated practices facilitated through the tidyverse suite of packages in R. Improvements in data management since the initial digitisation of large datasets more than 20 years ago provide a framework for conducting this work.

Key messages:

- The tidyverse suite of packages allow for low-burden cleaning and maintenance of important historical datasets to facilitate their ongoing use and preservation.
- There is value in supporting staff training on simple data management skills in R to support lower burden in data management practices.

Abstract citation ID: ckae144.2293
Trade as a commerical determinant of health: The health impact of a free trade agreement on Wales

Liz Green

L Green[1,5], *L Silva*[1], *L Petchey*[4], *M Douglas*[3,5], *C Mcnamara*[2], *M Fletcher*[1], *T Clemens*[5]
[1]Wales HIA Support Unit, Public Health Wales, Wrexham, UK

[3]Economy and Health, Public Health Scotland, Glasgow, UK
[4]Policy, Public Health Wales, Cardiff, UK
[5]International Health, University of Maastricht, Maastricht, Netherlands
Contact: liz.green@wales.nhs.uk

As a result of the UK's withdrawal from the European Union ('Brexit'), the UK can negotiate its own trade agreements for the first time in over 40 years. This includes the Comprehensive and Progressive Trans-Pacific Partnership Agreement (CPTPP). Public Health Wales undertook a mixed-method Health Impact Assessment (HIA) to assess the potential impact of the CPTPP on health, well-being and inequalities in Wales. It is only the second ever HIA carried out on a free trade agreement (FTA) globally. A literature review on the potential impact of the CPTPP on health was conducted. Qualitative interviews with cross-sectoral representation, such as the environment, were undertaken alongside the development of a community health and demographic profile. The HIA identified significant potential impacts across health determinants, e.g., employment, agricultural production and health care, as well as impacts on population groups, e.g., those on low incomes. The Investor State Dispute Settlement (ISDS) mechanism, economic uncertainty and loss of regulatory alignment were identified as potential pathways for health impacts to affect the population. The HIA highlighted trade as a key commercial determinant of health. The findings have been beneficial in informing policy and decision-makers to prepare for the implementation of the CPTPP and take action to maximise opportunities and prevent potential negative impacts. Communicating HIA evidence that links trade to health has also led to valuable cross-sector and cross-UK engagement and sparked a "rethinking" of trade through a well-being economy lens where health, well-being and sustainability are primary objectives.

This work has demonstrated the value of a HIA approach to FTAs by mobilising a range of evidence through a transparent process, resulting in transferrable learning for others as well providing an entry point for public health to have direct engagement with trade negotiators and those participating in trade discussions.

Key messages:

- Trade agreements are a key commercial determinant of health across health behaviour, policy and economy.
- Multiple population groups are affected by trade agreements both positively and negatively.

Abstract citation ID: ckae144.2294
Unveiling social disparities in later life: Income's Impact on mortality among the elderly in Italy

Luisa Frova

L Frova[1], L Coppola[2], E Grande[1], M Pappagallo[1], I Siciliani[2]
[1]Health and Welfare, Italian National Institute of Statistics, Rome, Italy
[2]Enhancement of the Integrated Registry System, Italian National Institute of Statistics, Rome, Italy
Contact: frova@istat.it

Background: Income is an important predictor of adult mortality, as a proxy of living conditions, capability and access to health services. Previous studies show that mortality decreases by increasing income. In Italy, studies at a national level are missing. This study aims to investigate inequalities in mortality by income in Italy.

Methods: The analysis is based on the integration of the National Population Register (comprising the resident population as of Dec 31, 2018, and deaths in 2019) and the Income Statistical Register (representing perceived income during 2018). This integration enabled the availability of information on age, sex, residence, education, income, and vital status at the individual level for 13 million people aged 65 or above. Individuals were categorized according to their individual disposable income quintiles both before and after disability benefits. Inequalities by income are assessed by mortality rate ratios (MRR) estimated using negative binomial regression models controlling for demographic and socioeconomic features. The study is carried out within the Next Gen EU-funded project "Age-It Ageing well in an ageing society" (PE0000015), NRRF, M4. C2, Intervention 1.3.

Results: Considering income net of disability benefits, lower income levels are associated with higher mortality rates compared to the highest income level, for both sexes. Inequalities are more marked for men. The highest excess was observed for individuals with the lowest income (male MRR=1.65, 95%CI: 1.6-1.71; female MRR=1.43, 95%CI: 1.38-1.48). The excess decreases with increasing income.

Conclusions: The observed relationships between income and mortality are crucial for targeting policies to reduce health inequalities and promote the well-being of the elderly, the goal of which should be to improve access to social and health care and develop supportive policies for the most disadvantaged people. Further research will be devoted to the use of household income for individuals.

Key messages:

- For the elderly, lower income levels are associated with higher mortality, with wider disparities in men.
- The choice of definition of income is essential for an accurate assessment of the association between income and mortality.

Abstract citation ID: ckae144.2295
Smoking, alcohol, substance, technology, and gambling addiction among university students

Ayşe Baran

Contact: abaran88@hotmail.com

Background: University students turn to addictive substances to cope with the anxiety and stress caused by separation from family, adaptation to a new environment, as well as many economic and social problems. This study aimed to examine smoking, alcohol, substance, technology, and gambling addiction among university students.

Methods: The data of this cross-sectional study were collected between February and March 2024. The study population consisted of 23,446 people studying at Ä°nonu University, and the sample size was calculated as 346 based on a smoking rate of 35.6% among university students. A stratified sampling method was adopted according to the faculty of study, and 366 people were approached regarding the study. The independent variables were age, gender, faculty of study, and smoking status, while the dependent variables were alcohol and substance use status. Descriptive data were expressed in numbers and percentages, and a Chi-square test was used in the statistical analysis.

Results: Of the students in the research group, 56.8% were female, 54.4% were 22 years of age or older, 30.1% reported smoking cigarettes, 7.7% reported drinking alcohol in the last 30 days, 39.2% reported using the internet for five hours or more per day, 3% reported playing various casino games on the internet once a week or more, and 1.4% stated that they used substances. There was no statistically significant difference between alcohol and substance use according to smoking status ($p > 0.05$).

Conclusions: Approximately one-third of the students in the research group reported smoking cigarettes, and one-tenth reported alcohol use, which is quite high. The high percentage of students who use the internet for five hours or more per day and the low rate of online gambling should be considered in relation to these addictions.

Key messages:

- Multidimensional interventions and intersectoral cooperation are required to prevent smoking, alcohol, substance use, technology, and gambling addictions among university students.
- In addition, precautions should be taken to protect students against the risks associated with internet addiction and online gaming.

Contact: yosr.ayeedi.93@gmail.com

Background: Tobacco addiction poses a significant global health challenge, contributing to various diseases and premature mortality. The main objective of our work was to describe the epidemiological profile of smokers seeking assistance at the smoking cessation departement of the 'Abderrahmane Mami' hospital.

Methods: We conducted a retrospective study involving smokers who attended the smoking cessation department between January 2020 and December 2023. Data were collected from the consultants' records. The descriptive study was conducted using IBM SPSS 25 software.

Results: The number of consultants was 440 during the years of the study. The study population was predominantly male (75.2%). The average age of the consultants was 45.41 ± 13.9 years [14-89 years]. The education level of the patients was predominantly university-level (42.4%), followed by secondary education (33.6%). Cardiovascular history was the most common (22.42%). More than half of the consultants (n = 279; 63.4%) had tried to quit smoking at least once. More than half of the smokers followed (57.9%) were highly dependent on nicotine (Fagestrom score ≥ 7). The mean score of the hospital anxiety and depression scale was 8.03 ± 5.398 for anxiety and 5.44 ± 5.185 for depression.

Conclusions: Our study provides informations about the epidemiological profile of individuals seeking tobacco cessation support during the study period. The findings underscore the diverse demographic and clinical characteristics of this population. Understanding these profiles can provide information for the development of effective anti-tobacco programs.

Key messages:
- Tailored interventions are essential to meet the diverse needs of people seeking smoking cessation, optimizing the impact on public health.
- Understanding cessation seeker profiles crucial for effective strategies.

Understanding smoking cessation process in Tunisia from 2020 to 2023: description of quit attempts

Yosr Ayedi

K Bebses[1], Y Ayedi[1,2], S Fitouri[1], A Skhiri[1], M Ben Aissa[1], A Fourati[1], Z Nsiri[1], R Hamdi[1], C Harizi[1,2], R Fakhfakh[1,2]
[1]Departement of Epidemiology and Statistics, Abderrahmen Mami Hospital, Ariana, Tunisia
[2]Faculty of Medicine of Tunisia, University Tunis Manar, Tunis, Tunisia
Contact: yosr.ayeedi.93@gmail.com

Background: Many smokers attempt multiple cessation methods before seeking specialist intervention. This study aims to describe these prior cessation attempts and identify relapse factors to enhance support for these individuals.

Methods: Data from 440 patients consulting the Department of Epidemiology Statistics at Abderrahman Mami Hospital from 2020 to 2023 were analyzed. It included information on previous quit attempts, methods used, longest duration of abstinence, number of attempts, reaction to cessation, and reasons for relapse. Statistical description was conducted using IBM SPSS 25.

Results: Among participants, More than half of the smokers had previously attempted to quit smoking 63,4%, with an average of 2 attempts ± 1,7 (0-10 attempts) per patient. The majority of patients (86.8%) quit smoking without using substitution methods. Among those who resorted to substitution, nicotine replacement therapy was the most frequently used method (n = 30; 6.8%). The longest duration of abstinence averaged 8 years. The main reaction to smoking cessation among patients was an improvement in their health (9,1%). The most common reasons for relapse were psychosocial problems (5.5%), followed by relapses during social events (4.3%), and withdrawal symptoms (3%).

Conclusions: This study emphasizes the importance of considering each patient's journey during their smoking cessation process. Analyzing these factors will enable better management of the cessation program with the patient, as well as a deeper understanding of their feedback regarding our program, ensuring long-term cessation success.

Key messages:
- Failed spontaneous quit attempts prior to NRT initiation are prevalent among smoking patients.
- Understanding failed spontaneous cessation attempts can guide the development of more effective strategies.

[5]Faculty of Social Work, University of Iceland, Reykjavik, Iceland
Contact: ieva.reine@rsu.lv

Background: The COVID-19 pandemic has significantly impacted the mental health and wellbeing of older populations across Europe, exacerbating feelings of loneliness and social isolation, known risk factors for poor physical and mental health outcomes. This study aims to understand the extent and implications of these changes in Latvia and Iceland, providing essential insights for targeted public health interventions.

Methods: This comparative study utilized data from two key sources: the Survey of Health, Ageing, and Retirement in Europe (SHARE) for Latvia and the HL20 study for Iceland, focusing on individuals aged 67 and above. Both quantitative surveys were conducted during the pandemic, offering data on health status, loneliness, and social isolation. A novel approach was applied in analyzing older populations to standardize comparisons between the two distinct datasets. This methodological innovation is part of a bilateral EEA initiative FM2021/23 aimed at strengthening research collaboration between Latvia and Iceland. Descriptive statistics and the Pearson Chi-square test were used to compare outcomes between the two countries and within demographic subgroups.

Results: The study revealed stark differences between the two countries: 80% of Latvian older adults reported social isolation compared to 42.7% in Iceland. Similarly, 45% of Latvians experienced loneliness versus 30% of Icelanders. Significant associations were found between social isolation, loneliness, and deteriorating mental and physical health, with worse outcomes noted in socially isolated individuals.

Conclusions: Our findings demonstrate a clear link between social isolation and adverse health outcomes among the older adults, exacerbated by the COVID-19 pandemic. The study supports the need for proactive public health measures in Latvia and Iceland, including the development of community engagement programs and mental health support services tailored to the needs of older adults.

Key messages:
- Study shows significant health impact of social isolation among older adults in Latvia and Iceland, highlighting urgent need for targeted public health interventions.
- Effective public health strategies and innovative digital outreach can mitigate adverse effects of loneliness and isolation observed in older populations.

Loneliness in Baltic-Nordic Older Adults Amid COVID-19

Ieva Reine

I Reine[1,2], M Miķelsone[1], S Tomsone[3], H Guðmundsson[4], A Ivanovs[1], HS Guðmundsson[5], I Koroļeva[1]
[1]Statistics Unit, Riga Stradins University, Riga, Latvia
[2]Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden
[3]Faculty of Rehabilitation, Riga Stradins University, Riga, Latvia
[4]Social Science Research Institute, University of Iceland, Reykjavik, Iceland

[5]Faculty of Social Work, Riga Stradins University, Riga, Latvia
Contact: ieva.reine@rsu.lv

Background: The study investigates loneliness among older adults in the Baltic-Nordic region, particularly in the context of the COVID-19 pandemic. It aims to understand how loneliness varies across cultural and socio-economic contexts in these areas, which is critical for developing public health strategies tailored to the specific needs of older populations.

Methods: We employed a comprehensive comparative analysis, leveraging data from the Survey of Health, Ageing and Retirement in Europe (SHARE) and the HL20 study from Iceland, focusing on individuals aged 67 and above. The study encompassed a diverse sample from Sweden, Denmark, Estonia, Lithuania, Finland, Latvia, and Iceland, totaling 5,313 participants. This research is part of a bilateral EEA FM2021/23 initiative to enhance methodological approaches to analyzing older populations by coding and standardizing variables for comparability across different countries.

Results: Significant regional differences in loneliness were observed. The Baltic regions reported a higher prevalence of loneliness compared to the Nordic countries, which displayed lower levels, attributed to strong social welfare systems and community engagement. Factors such as employment, marital status, and educational attainment varied across regions, affecting loneliness levels.

Conclusions: The findings highlight the importance of considering regional cultural and social contexts in public health interventions aimed at reducing loneliness among older adults. The study underscores the need for targeted strategies that address the unique social dynamics of the Baltic and Nordic regions. Innovative public health actions, such as community engagement programs and policy development, are recommended to alleviate loneliness in these populations.

Key messages:

- Significant regional differences in loneliness in the Baltic-Nordic region underscore the need for tailored public health interventions.
- Employment and social welfare are key factors in mitigating loneliness among older adults, highlighting the importance of socioeconomic support systems.

Catching-Up in Islamabad, Pakistan: Identifying and Reaching Zero-Dose Children Following the COVID-19

Reham Baig

R Baig[1]
[1]PEI, WHO, Islamabad, Pakistan
Contact: rehambaig.md@gmail.com

Background: Routine Immunisation (RI) is critical in mitigating child morbidity and mortality while preventing the spread of infectious diseases. Nevertheless, the COVID-19 pandemic has resulted in considerable disruptions, which have given rise to an unprecedented number of zero-dose (ZD) infants. It has presented formidable obstacles for healthcare systems on an international scale.

Methods: The study employed a retrospective analysis of data obtained from thirteen Supplementary Immunisation Activities (SIAs) that were carried out from 2019 to 2021 to investigate the fluctuations in the documented number of children with ZD. Health authority stakeholder interviews yielded valuable insights about vaccination strategies and obstacles.

Results: An enormous increase in the number of documented ZD minors were identified during the study period. The number of documented ZD minors rose from 3,827 in 2019 to 4,271 in 2020, and then again to 9,620 in 2021. Notwithstanding diligent attempts to immunise ZD children, the vaccination rate persisted at a less-than-ideal 81.24% of documented ZD children in 2021.

Conclusions: As a result of the COVID-19 pandemic, pre-existing obstacles to accessing ZD infants in Islamabad were further intensified. The lessons learned emphasise the significance of community engagement, improved outreach strategies, and fortified healthcare infrastructure in guaranteeing comprehensive immunisation coverage. It is imperative to confront these challenges to reduce the likelihood of subsequent epidemics and protect children's health.

Key messages:

- The spread of COVID-19 among ZD neonates in Islamabad accelerated, prompting calls for improved vaccination programmes.
- The suboptimal ZD vaccination rate in 2021, despite concerted efforts, underscores the criticality for enhanced strategies.

[2]Oral Health Centre of Expertise in Eastern Norway, Oslo, Norway
[3]Department of Public Health and Nursing, Norwegian University of Science and Technology, Norway, Norway
Contact: arnmy@tkmidt.no

Background: Oral diseases and obesity share common risk factors and are highly prevalent. However, the relationships between body mass index (BMI), BMI change and oral health conditions in adults are less studied. In this study, we investigate the associations of long-term obesity and BMI change with risk of poor self-rated oral health among adults.

Methods: This study include individuals aged 29-90 years (57.8 % women, mean age at baseline, HUNT3, was 54.9 years) who participated in the first (HUNT1, 1984-86), second (HUNT2, 1995-97), third (HUNT3, 2006-08) and fourth (HUNT4, 2017-19) survey of the Trondelag Health Study (HUNT). Weight and height were measured at each survey. We estimated average BMI values and BMI change over a 10-year (HUNT2- HUNT3, N = 19,729) and 20-year (HUNT1- HUNT3, N = 14,276) period and linked to their information on oral health status at HUNT4. We employed logistic regression models with adjustment for confounders and computed odds ratio (OR) with 95 % Confidence Interval (CI).

Results: At HUNT4, 1812 (9.2 %) participants rated their oral health as poor or very poor. The multivariable-adjusted ORs for average BMI over 30 kg/m2 were 1.3 (95 % CI: 1.1-1.5) and 1.2 (95 % CI: 1.0-1.5) over a 10-year and 20-year period, respectively, when compared to normal weight. After adjustment for most recent BMI (HUNT4), the associations of long-term obesity with poor self-rated oral health weakened. Compared with stable BMI, both loss and gain in BMI over a 10-year period were associated with increased risk of poor oral health. In the adjusted analysis, we found that a BMI loss of more than 2.5 kg/m2 and a BMI gain of more than 5 kg/m2 was associated with 1.5 times (OR = 1.5, 95 % CI: 1.1-1.9) and 1.3 times (OR = 1.3, 95 % CI: 1.1-1.6) greater risk of poor oral health.

Conclusions: Our findings suggest that individuals with long-term obesity and BMI change have a markedly higher risk of poor self-rated oral health.

Key messages:

- Long-term obesity was associated with increased risk of poor self-rated oral health.
- Compared with stable body mass index (BMI), loss- and gain in BMI were associated with increased risk of poor self-rated oral health.

A Qualitative Study Evaluating the Challenges of Orthopedists and Internists in the Earthquake Zone

İlayda Ayça Ertürk

E Gemici[1], *D Kaş*[2], *F Tosun*[2], *İ Ertürk*[2], *S Dural*[2], *P Ay*[1]
[1]Public Health, Marmara University Medical Faculty, Istanbul, Türkiye
[2]Marmara University Medical Faculty, Istanbul, Türkiye
Contact: papatyailayda@icloud.com

Background: The earthquake centered in Kahramanmaras province, Turkey, on February 6, 2023, with a magnitude of 7.7, resulted in the loss of 53,537 lives and the injury of 107,213 people. This study was conducted to evaluate the challenges and experiences of physicians who provided post-disaster medical care.

Methods: We conducted a qualitative study with orthopedists and internists who had worked in the earthquake zone using in-depth interviews. Participants were selected through snowball sampling. Interviews explored challenges in the disaster zone, obstacles related to healthcare services, and disaster management. Thematic analysis was used.

Results: A total of 13 physicians participated in the study. Data revealed four main themes: disaster management, organizational deficiencies, challenges faced, and logistical issues. Participants indicated that the Ministry of Health didn't have a priori operational emergency action plan, which led to problems in healthcare service delivery. Some physicians complained that they had to serve just as emergency consultants and were not able to carry out tasks compatible with their expertise. Some indicated that they organized the services rather than providing medical care. Almost all encountered a variety of interesting cases and evaluated their experience as significant. Logistical needs were met mostly with the support of non-governmental organizations.

Conclusions: We need to have a priori operational emergency action plan to ensure the effective delivery of healthcare services in the aftermath of a disaster. The Ministry of Health needs to allocate and coordinate healthcare personnel in line with their areas of expertise and prevent service disruptions.

Key messages:

- There is a need to make an operational emergency action plan beforehand to deliver healthcare services effectively following a disaster.
- Physicians should be allocated in line with their specialty of expertise to efficiently address the healthcare needs.

Interrogating the environmental and social correlates of health risk behaviours in West Africa

Chukwuedozie Ajaero

C Ajaero[1], *A Fotso*[2]
[1]Geography, University of Nigeria Nsukka, Nsukka, Nigeria
[2]DEMOSUD-Southern-Demography, Institut National d'études Démographiques, Paris, France
Contact: chukwuedozie.ajaero@unn.edu.ng

Background: Despite the high incidences of health risk behaviors (HRBs) in sub-Saharan Africa, studies on the contextual determinants of HRBs across countries are generally lacking, concentrated on isolated countries and often focus solely on specific health behaviors. Thus, this study investigated the environmental and social correlates of HRBs in West Africa.

Methods: Data was from post-2015 Demographic and Health Surveys in three West African countries of Benin, Mali and Nigeria. A composite outcome variable of health risk behaviors (HRBs) was derived from variables of tobacco smoking, intimate partner violence, overweight/obesity and risky sexual behaviors. The contextual variables were normalized difference vegetation index, precipitation, maximum and minimum temperatures, region of residence and population Density. Data analysis involved descriptive statistics, chi square test, geographical mapping, and multilevel logistic regression.

Results: The engagement in HRBs varied from 42.65% in Nigeria to 42.88% in Benin and 51.06% in Mali as there are spatial variations in the engagement in HRBs within different regions of these countries. There also existed significant variations in HRBs regarding age, education, employment status, wealth index, household size, place of residence, and region of residence in the three countries. In the contextual models of environmental and social factors, population density significantly increased odds of HRBs in the three countries, maximum temperature significantly increased odds of HRBs in Benin and Mali, while precipitation significantly increased odds of HRBs in Nigeria and Mali. Other factors which significantly increased odds of HRBs across the three countries were increase in age, wealth index, households with 9+ persons, and regions of residence.

Conclusions: These findings suggest that among other things, changes in lifestyles regarding the different HRBs should be emphasized in specific contextual situations

Key messages:

- There are variations in engagement in health risk behaviours across the countries.
- Cliamte variables influence engagement in health risk behaviours.
