Vector-borne diseases pose a significant global threat, with approximately 500 million reported cases annually, affecting previously unaffected regions due to climate change and increased international travel. This presentation brings insights from two scoping reviews examining the implementation and operationalization of the International Health Regulations (IHR) in preventing the spread of vector-borne diseases. The first review analysed strategies and policies adopted at continental and national levels and identified four major categories of measures: surveillance and epidemic intelligence, Declaration of Public Health Emergency of International Concern, measures in Points of Entry, and vaccination status. Surveillance systems vary widely across countries, with severe asymmetries in their implementation. The COVID-19 pandemic facilitated the adoption of screening measures and collaboration with airlines and travel agencies, highlighting the importance of early detection and response. An additional review focused on the contribution of IHR to public health action in monitoring and controlling vector-borne diseases. It emphasised the prioritisation of preventive measures related to travel and borders, including vector surveillance. Environmental changes, particularly socio-ecological and climate factors, influence the recurrence of outbreaks, creating the need for enhanced epidemic intelligence. Both reviews underscored the importance of cooperation between institutions and countries in effectively monitoring and controlling vector-borne diseases. Assessing core capacities under the IHR enables readiness levels in outbreak response to be measured, promoting concerted action tailored to each epidemiological context. As the world faces ongoing health challenges, it is imperative for State Parties to refine their core capacities in alignment with the lessons learned from the COVID-19 pandemic, ensuring a robust global response to future infectious disease outbreaks.

The International Health Regulations (IHR), established in 1969 and revised in 2005, represent a binding framework for 196 countries to combat global health threats. Historically, the IHR emerged in response to the need for a collective defence against the spread of infectious diseases. In the present, the IHR provides a legal structure for the World Health Organization (WHO) and its member states to report public health emergencies of international concern, ensuring a coordinated, prompt, and effective response. As we look towards the future, the IHR's role is pivotal in addressing the complexities of global health security. The emergence of novel pathogens, the risk of bioterrorism, and the impact of climate change on disease patterns call for the evolution of the IHR. Such ammendments comprise: increasing clarity on multilevel jurisdiction; defining a pandemic emergency; introducing the concept of quarantine as a public health measure; stressing a compromise and solidarity approach between States Parties; reinforcing the need for bidirectional action between the WHO and States Parties; underlining cargo, as well as passengers, as relevant for public health measures; certificate digitalisation; among others. Strengthening the IHR is essential for a proactive approach to health policy, ensuring preparedness and resilience against any health crisis that may arise, although it remains in great controversy the right balance between the respect of national sovereignty and supranational impositions over national, democratically elected governments. Calling upon this reflection aims to bridge the gap felt in most WHO's member states.

3.X.1. Health literacy in Europe: Building a comparative database for shaping public health policy

Abstract citation ID: ckae144.769

Organised by: Austrian National Public Health Institute (Austria), EUPHA-HL, WHO/Europe, JA PreventNCD
Chair persons: Robert Griebler (Austria), Christopher Le (Norway)
Contact: robert.griebler@goeg.at

Health literacy (HL) is a key determinant of health and a lever for health equity. It refers to the extent to which individuals are able to deal with health-related information, communicate with health professionals, and navigate the health care system to restore, maintain, protect, and improve their health and well-being. It is the result of an interplay between personal motivation, individual competencies and the health information and service environment. HL is strongly related to health behaviors and issues such as obesity, the social determinants of health, and the use of health systems, which have been under pressure since COVID-19. The development and implementation of targeted public health interventions to promote HL in the European Region require reliable and comparable data on population HL to identify the main HL challenges and the most affected population groups. The WHO Action Network on Measuring Population and Organizational Health Literacy (M-POHL) has started monitoring population HL and conducted the first M-POHL Health Literacy Survey (HLS19) in 17 countries in the WHO European Region between 2019 and 2021. In preparation for the 2nd M-POHL Health Literacy Survey (2024-2026; HLS24), the HLS19 instruments were further improved and supplemented by a new measure on mental HL. These instruments are also of interest to the European Joint Action PreventNCD with its specific task on HL and non-communicable diseases (7.4). The workshop will provide insights into the M-POHL HLS24, the largest HL survey in Europe, and the HL instruments used. It consists of four presentations, one describing the M-POHL HLS24 project and three on specific HL instruments used to assess different aspects of HL in the European general population: HLS24-DIGI for digital HL; HLS24-COM-P for communicative HL; HLS24-NAV for navigational HL.

Each presentation will describe the revised item set and results from pretests. We invite the audience to ask questions and to engage in a (cross-cutting) discussion with the presenters. Expected impact: The presentations will provide a comprehensive overview of the advanced family of instruments used in the HLS24 study, their quality, and the expected HL data for Europe. They will provide a deeper understanding of how HL will be measured in the M-POHL HLS24 project.

Key messages:

- The advanced family of HL instruments used in the M-POHL HLS24 project enables comprehensive HL monitoring in Europe.
- The data collected in HLS24 will provide a solid database for shaping public health policy to strengthen population HL and promote health equity in Europe.

Contact: robert.griebler@goeg.at

Background: Inspired by the first European Health Literacy Survey (HLS-EU) and its policy impact, the WHO Action Network on Measuring Population and Organizational Health Literacy (M-POHL) was established in 2018 under the auspices of WHO Europe to monitor and strengthen health literacy (HL) in Europe. The Health Literacy Survey 2019-2021 (HLS19) was the first project of M-POHL, focusing on both general and specific aspects of HL. The follow-up survey (HLS24) builds on this work and will provide even more comprehensive data on HL by including more countries and new aspects of HL. By also focusing on NCDs and prevention, HLS24 is a key partner in the European Joint Action PreventNCD.
Methods: The HLS24 is a cross-sectional study based on nationally representative samples of the adult population (18+) in more than 20 participating countries. The HLS24 core questionnaire includes items on general HL, sociodemographics, health behavior, health status, and health care utilization. Some countries also include questions on prevention and early detection of chronic diseases and health problems. Five optional packages (OPs) enable countries to focus on specific aspects of HL, namely digital, communicative, navigational, vaccination and mental HL.
Results: HLS24 uses a harmonized set of HL instruments that provide a solid database for health policy decisions to strengthen HL and health equity in Europe. In addition to the three OPs on digital, communicative and navigational HL discussed in the following presentations, an 11-item set on vaccination literacy and a 21-item set on mental HL are provided.
Conclusions: Covering NCDs, prevention, digital health, immunization, and mental health, the HLS24 provides important data on current health challenges and highlights the needs of the European

population regarding health information and services upon which policy and action interventions can be based.

Background: Rapid advancement of digital resources for health and healthcare in Europe has widened the scope of opportunities to promote health, but also raises concerns about accessibility and health equity. Measuring digital health literacy (DHL) in populations is critical for assessing digital resource appropriateness in general and specifically among vulnerable populations. The DHL measure used in the M-POHL Health Literacy Survey 2019-2021 (HLS19) in 13 countries showed inadequate DHL in large parts of the population, reflecting a social gradient. As digital resources become increasingly interactive, potentially widening the digital divide, a need to refine the DHL HLS19 tool was evident.
Methods: Building on the HLS19 tool, an additional measure was developed to assess interactive aspects of DHL by representatives from 16 countries in a co-productive way, based on discussions about the diverse digital challenges. The additional scale was to be generic enough to be relevant for all countries, yet specific enough to discern the diverse needs regarding various public health/healthcare service formats across Europe.
Results: The new tool is divided into 2 parts: a scale measuring the skills to access, understand, appraise, and apply digital health information as applied and validated in HLS19, and a new set of items assessing the use and ease of use of interactive digital resources including health promotion apps, digital tools for managing health/medical conditions, navigating the healthcare system, and communicating online with health professionals. The tool has been translated into several languages and is currently undergoing piloting/cognitive testing.
Conclusions: Collaborative work among countries is essential for developing relevant measurement tools on the European level. Just as the technology undergoes rapid change, likewise tools for assessing DHL must be updated acknowledging the diversity of digital resources and needs on country levels.

Background: Communicative health literacy (COM-HL) is important for patients being able to actively participate in communication with health care professionals, such as physicians. The HLS19-COM-P scale was developed for measuring COM-HL in the M-POHL HLS19 survey. However, two items under-discriminated according to the Rasch model and the item set did not sufficiently capture the aspect of appraising health information. Consolidating both a long and short version into a single scale was deemed appropriate. Hence, this study aimed to develop a revised version of the COM-HL scale.
Methods: The revision and development of new items followed a Delphi process. Items that worked well psychometrically in the six-item version of the HLS19-COM-P were kept, and new items concerning appraising information were developed. The revised version of the scale has so far been translated into nine languages (BG, CZ, DE, FR, HU, IT, NO, SK, UA). Challenging translation terms underwent multiple discussions to ensure language consistency. The interpretability of items has been explored in cognitive interviews in six countries (AT, CZ, HU, IT, SK, and UA) so far. Items that were difficult to understand were revised and tested in new interviews. The evaluation of the scale's psychometric properties is scheduled for May and June 2024.
Results: The revised scale consists of eight items - two items for each of the cognitive domains of accessing, understanding, appraising, and applying health information. One item in each of these domains focuses on the interactive aspect of communication. An instruction for translation of terms that were challenging to translate has been developed. Overall, the revised HLS19-COM-P was well accepted in the cognitive interviews. Results from the quantitative testing will be presented.
Conclusions: The adapted HLS24-COM-P scale developed for the M-POHL Health Literacy Survey 2024-2026, is a short and conceptually sound instrument for measuring COM-HL.

Background: European healthcare systems are characterized by a high complexity and intransparency. Finding one's way through the multitude of services requires navigational health literacy (NAV-HL). NAV-HL is defined as the ability to maneuver the healthcare system and deal with information necessary to do so at the system, organizational, and interactive levels. Using a newly developed scale, the European health literacy population survey 2019-2021 (HLS19) measured NAV-HL across multiple countries. To better capture the complexity of the construct and enhance scale validity, the aim was to improve it by generating additional items on the interactive level.

Methods: An international panel of health literacy experts from ten countries generated additional items that specifically covered tasks related to interactions with healthcare professionals. These skills are important for ensuring continuity of healthcare and navigating the healthcare system. The items were generated in an iterative process, translated, and tested in cognitive interviews.

Results: Four items were generated according to the four cognitive domains of the underlying conceptual model. These items concern the proficiency to: a) obtain information from health-care professionals about further healthcare services, b) understand this information and c) assess it in relation to one's own preferences, and d) use it to make decisions about further healthcare. Using cognitive interviews, the four new items have been found to be meaningful and comprehensible. Only minor adjustments were made.

Conclusions: The HLS19-NAV scale has already been successfully applied and validated in eight countries of the HLS19. The new items capturing the interactive level enhance the validity of the existing HLS19-NAV scale. The psychometric properties of the new (sub)scale will be explored.

3.X.2. Integrating trust as a key component of pandemic preparedness and resilience

Abstract citation ID: ckae144.774

Organised by: WHO
Chair persons: Brian Yau (Switzerland), Sandra Machiri (Switzerland)
Contact: byau@who.int

Trust is a key component of pandemic preparedness, which impacts the success of response measures during the public health emergency. Trust is built during preparedness, however the drivers and dimensions of trust are complex and context-specific. What is required is a collaborative, inclusive approach that provides a platform for communities to express their questions and concerns. The proposed workshop will begin with a presentation from a global expert on trust in the content of epidemics and pandemics and the current knowledge about how trust can be built during preparedness. This will be followed by interactive group-work, designed to encourage collaborative discussions and decision-making. Finally, introducing the WHO Hive digital platform that provides a safe space for public health communities to share information and ask questions. Attendees will then reconvene in plenary to discuss these approaches and interventions that can be implemented to build and maintain trust prior to and during an epidemic or pandemic.

This workshop has the following objectives:

1. To demonstrate how trust is an important determinant of successful pandemic response; 2. To enable attendees to explore how the implementation of public health and social measures, infodemic management and digital community partnerships and engagement can build trust during pandemic preparedness for both online and offline communities; 3. To provide opportunity for attendees to workshop how the different features of the Hive digital space can enhance trust building, and to develop actionable strategies for health emergency preparedness, response and resilience.

The workshop will deliver these objectives through an interactive simulation activity. Attendees will be placed into small groups to work through a scenario, having to decide on the actions that need to be taken, considering budget constraints, other health priorities, and the current local context. The teams will co-create actionable strategies for building and maintaining trust. While there is not a one size fits all approach to trust building, this workshop will aim to increase understanding of the drivers and determinants of trust to encourage participants to consider how they can be applied in their local context. It will be interactive and hands-on requiring active participation from participants.

Key messages:

- Trust as a construct is an important component of pandemic preparedness and readiness that impacts on response.
- A multidimensional approach to building and sustaining trust needs to considered across a range of drivers and determinants, where actionable strategies are vital.

3.Y.1. Genomics in EU Health Systems: Navigating the Opportunities and Challenges for Personalized Health

Abstract citation ID: ckae144.775

Organised by: EUPHA-PHG, -EPI
Chair persons: Roberta Pastorino (EUPHA-PHG), Péter Pikó (EUPHA-PHG)
Contact: roberta.pastorino@unicatt.it

The rapid advancements in genomics research offer significant promise for revolutionizing healthcare, potentially reshaping how we approach disease prevention, diagnosis, and treatment. However, unlocking the full potential of genomics requires more than just scientific breakthroughs-it necessitates translating these discoveries into clinical practice. This involves bridging the gap between research and healthcare implementation, addressing challenges such as technical infrastructure, ethical and legal frameworks, healthcare professional competencies, and citizen engagement. As we navigate the evolving landscape of individualized patient care, it becomes increasingly crucial to implement effective risk stratification methodologies and personalized preventive measures. Among these methodologies, polygenic risk scores are gaining prominence. However, the adoption of these innovations necessitates careful consideration of their clinical utility, including their feasibility, cost-effectiveness, and acceptability in diverse healthcare settings. Validating these approaches from multiple perspectives is essential to ensure their effectiveness in real-world clinical practice. Integrating genomic sequencing data with health records presents an invaluable resource that can enhance patient outcomes and drive further research. The creation of infrastructures and initiatives such as those carried out by projects like the European Health Data Space and Genomic Data Infrastructure are fundamental to unleash the enormous potential of data-driven innovation. To date, the implementation of genomics in medical practice varies across European countries, with discrepancies in adoption levels across different aspects of healthcare, including prevention, diagnosis, and personalized treatment. Addressing these disparities and promoting standardized approaches to genomic medicine implementation are crucial steps toward ensuring equitable access and maximizing the benefits of genomics for all individuals across Europe. This workshop aims to provide decision-makers, healthcare professionals and researchers with a comprehensive overview of the state-of-the-art for the adoption of personalized approaches, and of the maturity of genomic medicine practices within different healthcare systems as well outlining the benefits of data accessibility for research. The speakers are coordinators and partners of EU projects as B1MG (Beyond One Million Genomes), Prophet (A PeRsOnalized Prevention roadmap for the future Healthcare), EHDS (European Health Data Space), GDI (European Genomic Data Infrastructure), GoE (Genome of Europe) and CanHeal.

Key messages:

- Genomics has the potential to improve health outcomes.
- Equal access to genomic medicine critical for personalized health. Ensuring equity, while considering feasibility.

The state-of-the-art and barriers for the adoption of personalised prevention in Europe and beyond

Stefania Boccia

S Boccia[1,2], S Farina[1], T Osti[1], L Russo[1], A Maio[1], N Scarsi[1], C Savoia[1], A Taha[1], R Pastorino[1,2]
[1]Department of Life Science and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Woman and Child Health, Fondazione Policlinico Universitario A. Gemel, Rome, Italy
Contact: stefania.boccia@unicatt.it

Personalized prevention is a priority of the European Commission's research agenda, exemplified by the EU-funded project 'a PeRsonalised Prevention roadmap for the future HEalThcare' (PROPHET), a coordination and support action of the International Consortium for Personalized Medicine. It aims to bolster health systems in implementing innovative, sustainable, and high-quality personalized strategies to prevent chronic diseases. In this context, a scoping review was conducted to map personalized preventive approaches (PPA) for chronic diseases and obstacles to their adoption worldwide. The review followed the Arksey-O'Malley guidelines and was conducted from January 2017 to December 2023, on PubMed, Web of Science, Scopus, and grey literature. Eligible studies were primary reports and guidelines, while for the barriers to their adoption we included literature reviews. We included 120 documents on approaches and 34 reviews on barriers. Among the former, 251 PPA were identified: 69% on cancer, 21% on cardiovascular diseases, and 10% on neurological, psychiatric, and metabolic diseases. Furthermore, 27% were on primary prevention, using omic biomarkers to predict disease risk and guide preventive strategies; 27% on secondary prevention, using genomics to guide screening programs; 46% on tertiary prevention, using pharmacogenomics or targeted therapies to prevent disease complications. Among the 34 reviews on barriers, the majority were about the lack of clinical utility evidence and research needs, ethical and legal issues, and limited knowledge among health professionals, citizens, and patients. The majority of the barriers (76%) were referred to primary and secondary prevention, consistent with the low rates of existing approaches in these areas. Ongoing efforts show promise for tailoring prevention strategies, but further research and integration are needed to maximize their potential in improving population health and reducing chronic disease burdens on health systems.

Abstract citation ID: ckae144.777
Implementation of polygenic risk scores in secondary prevention of (breast) cancer

Jeroen van Rooij

J van Rooij[1]
[1]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands
Contact: j.vanrooij@erasmusmc.nl

Utilizing polygenic risk scores to inform secondary prevention of breast cancer via population screening programs is one of the pioneering applications of genomics in public health applications. Over the last decade, polygenic risk scores for breast cancer have been developed and validated in various European populations (AUC ± 0.63, OR per Z unit ± 1.6, depending on the population). In some countries, the polygenic risk score has been integrated with decision modeling tools, such as CanRisk in the Netherlands, and low-level implementation into health and care systems has started. Implementation strategies vary, but generally consider initial implementation into high-risk populations, such as breast cancer families, in specialized clinical setting, such as academic medical centres, or specialized cancer clinics, referring relatives of patients to population screening based on comprehensive risk modelling, including polygenic risk scores. This route may be followed by other disease fields as well. The presentations outlines the current evidence and considerations on breast cancer genetic risk modelling, clinical pilot studies and the outline of step-wise implementation of such models to benefit secondary prevention programs. We start from the perspective of a single hospital, to the needed steps to upscale to national populations, both in diversity of these populations, as the throughput of genetic testing and counselling, until the harmonization and recalibration of various European healthcare models. We draw from examples of the Genotyping on all patients (GOALL), building cancer health platforms (CanHeal) and Genome of Europe (GoE) consortia.

Abstract citation ID: ckae144.778
The 1+Million Genomes Maturity Level Model for Genomics in Healthcare

Astrid Vicente

A Vicente[1]
[1]Department of Health Promotion and NCD Prevention, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
Contact: astrid.vicente@insa.min-saude.pt

The 1+Million Genomes Initiative (1+MG) has been fostering reflection in European countries on their national strategies for genomic medicine, and how these can contribute to research development and improved medical practice. For all citizens to truly benefit from genomic medicine, there must be equitable access across Europe. However, European countries are currently at different stages of implementation of genomics in medical practice. To bridge these gaps, health decision-makers need to understand the maturity of genomic medicine practices in their healthcare systems, to make informed decisions about investment, resources, and practices towards optimized adoption of genomics in healthcare systems. This presentation will focus on the 1+MG Maturity Level Model (MLM), developed in the context of the 1+MG Initiative and B1MG project. This MLM was created as a tool for countries to self-assess the maturity of genomic medicine practices in their healthcare systems, and to define a path to optimization. The MLM content was validated through a Delphi survey with international genomics and public health experts, and a pilot in real-life settings was conducted in eight European countries. The 1+MG MLM pilot provided valuable insights regarding common strengths, weaknesses, and asymmetries across Europe, highlighting the need for national and cross-European investments to close existing gaps, and make personalised medicine accessible to all citizens and patients in Europe.

Abstract citation ID: ckae144.779
Benefits of cross-border access to human genomes at scale for research and healthcare

Serena Scollen

S Scollen[1]
[1]Wellcome Genome Campus, ELIXIR, Hub, Hinxton, UK
Contact: serena.scollen@elixir-europe.org

Genomics data will soon be routinely generated and integrated into national healthcare systems. To maximise the potential of genomic medicine, data should be accessible for research where possible. This is the remit of ELIXIR, an intergovernmental organisation that brings together life science resources from across Europe. Innovative solutions are needed to ensure the validated research findings for disease or preventative medicine are then integrated into healthcare. To tackle this, the 1+MG initiative, a joint initiative of 25 EU countries, the UK, and Norway, aims to enable secure access to genomics and the corresponding clinical data across Europe for better research, personalised healthcare and health policy making. In the design and scale-up phase (B1MG project), recommendations and guidelines to advance towards the deployment of personalised medicine at a European scale have been produced, adopted by 1+MG and developed into a 1+MG framework. This includes guidance on data governance, standards, quality and infrastructure, recommendations on how to approach citizen engagement and a tool for countries to self-assess implementation into healthcare. The European Genomic Data Infrastructure (GDI) project supports the scale-up and sustainability phase of the 1+MG initiative, to deploy infrastructure across 24 countries to support the overall ambition. Recommendations are being used to promote governance and technical interoperability across European initiatives including the European Health Data Space (EHDS), and European Cancer Image Initiative (EUCAIM). The 1+MG will be established as a European Data Infrastructure Consortia in 2025 and will act as an Authorised Participant in the EHDS providing access to a permanent high-quality federated data collection of genomic and health data that will accelerate research, innovation and policy-making facilitating the deployment of genomic medicine across Europe.

3.Y.2. Road traffic injuries, disability burden and implications for compensation schemes in Europe

Abstract citation ID: ckae144.780

Organised by: EUPHA-INJ, -SSWH, -ECO, EuroSafe/IDB network
Chair persons: Maria Papadakaki (EUPHA-INJ), João Vasco Santos (EUPHA-ECO)
Contact: mpapadakaki@hmu.gr

Reducing traffic fatalities and injuries is a complex challenge, but it is one that is of paramount importance for public health and safety worldwide. In recent years, there have been improvements in trauma care and injury prevention efforts, which reduced mortality rates and increased survival after serious injury. However, an increased heterogeneity in recovery times is observed with survivors of road traffic injuries differing in their adjustment compared to other traumas in terms of symptoms' onset, variability and chronicity. The recovery trajectory seems to vary widely with a large percentage of survivors in need of extensive time periods for full recovery. Attention has now been shifted towards the adverse effects of non-fatal injuries on functional, mental health, economic and societal outcomes. The capacity of a person to continue functioning, inability to work, sickness absence and reliance on welfare benefits to compensate for loss of income are some of the injury-related long-term consequences, causing great concern for health and social security systems across Europe, as they have been shown to account for more than one third of total road traffic incident costs. These figures fail to include individuals who sustain “minor” injuries, which do not require hospitalisation, yet still impair their ability to work. Despite the rapidly growing epidemiological and clinical attention, there are still several issues missing from research, policy and practice. A universal definition of recovery after a road traffic injury is still missing, and this has been seen as critical for improved understanding of risk factors of poor recovery as well as improved identification of those in need of welfare benefits. Furthermore, long-term sickness absence and disability following road traffic injury in Europe is still understudied and evidence on the different return to work pathways and compensation schemes is scarce. Evidence is still limited on the context in which return to work occurs, the injury profiles most dependent on long term compensation schemes and the policy settings of injury compensation schemes that impact return to work outcomes post injury. Data availability and data linkage issues often cause misclassification errors when granting disability pensions and this remains unattended long after an injury. Welfare benefits are often poorly connected with the injury or other medical diagnoses and this makes it difficult to assess the contribution of injuries on disability pensions and other welfare benefits, especially in comorbid and multimorbid conditions. The current workshop aims to improve our understanding of the long-term consequences and the challenges faced by those injured in road traffic injuries and aid the development of interventions that seek to enable sustained recovery, and help inform policy and practice of healthcare and injury compensation systems.

Key messages:

- Timely access to quality healthcare, rehabilitation therapies, and assistive technologies can significantly improve outcomes and reduce the strain on social security and compensation systems.

- Ensuring equitable access to social security benefits for injured individuals, requires efficient compensation schemes that recognize the full impact of the disability on individuals' life.

Abstract citation ID: ckae144.781
Health loss after road transport injury – new perspectives

Emilie Friberg

E Friberg[1]
[1]Insurance Medicine, Clinical Neuroscience Department, Karolinska Institutet, Stockholm, Sweden
Contact: Emilie.Friberg@ki.se

Background: Health loss in the road transport system is a major public health problem. Globally, about a fifth of all fatalities within the road transport system are represented by pedestrians, and bicyclists are the group with the highest number of severe injuries in the EU. Here we strive to add new perspectives of health loss in different road user groups examining sickness absence (SA) and disability pension (DP) and in the case of injuries after car crashes also relating them to permanent medical impairment (PMI).
Methods: Several register-based studies were conducted, based on microdata linked at individual level from several Swedish nationwide registers. In one study information about PMI from the insurance company Folksam was also used. In the main analyses we included all working individuals aged 20-59 years injured in a road traffic accident (pedestrians, bicyclists, car occupants, and other road users) in 2015 in Sweden and population-based matched references without any traffic-related injury. Diagnosis specific SA and DP were assessed during 1 year before and 4 years following the accident.
Results: A third of the traffic-related accidents involved bicyclists, 31% car occupants, 16% pedestrian, and 19% were other accidents. The excess SA days/year was elevated for all road user groups the whole study period. Excess SA due to injury diagnoses was 15-35 days/year during the first year following the accident. Among individuals injured in a car crash that reported the injury to Folksam, 2% had a new DP 2 years after the crash, and 8% had injuries resulting in PMI. A distinct trend showed that the proportion granted DP increased with increasing PMI grade.
Conclusions: Sickness absence is a common outcome among individuals injured in the road transport system. Together, these studies highlight the importance of preventing not only fatalities in the road transport system but also non-fatal injuries.

Abstract citation ID: ckae144.782
Statistics on disability pensioners is important for assessing injury burden

Johan Lund

J Lund[1]
[1]Norwegian Association of Public Health, Oslo, Norway
Contact: Johan.lund@nopha.no

Introduction: We have little information about long term effects of injuries resulting in disability. In addition to human suffering and reduced quality of life, these consequences of injuries inflict a heavy burden on the national economy. All persons in Norway aged 16 - 66 years are entitled to disability pension benefits from the National Insurance Administration (NIA) if their working capacity is permanently reduced by at least 50 % due to disease, injury or defect. The burden of injuries in terms of "New disability pensioners" (NDP) related to traffic injuries was assessed in a study for the years 1992-97 and in a follow up study for 2005-12.
Methods: Each year, a number of persons will be registered as NDP in the Disability register of NIA. Between 1992 and 2012 accident types were classified by an additional code, one of them denoting traffic injury. To calculate rates, the number of NDP are related to the number of persons in Norway on the 1st of January minus the number of persons holding a disability pension at that time (risk population) and are shown as NDP pr 100 000 of the risk population.
Results: The rates for NDP due to traffic injuries increased from 16.8 in 1992 to 23.0 in 1997, an average annual increase of 7.4 %. These rates were compared with the mortality rates in the age group 15-64 years due to traffic injuries from 1988-1993. The average time lag between an injury and getting a disability pension is 4 years. These rates were 9.3 in 1988 and 6.4 in 1993, an average annual decrease of 6.2 %. The follow up study for 2005-2017 confirmed more or less this increasing trend in NDP due to traffic injuries.
Conclusions: The rate of NDP due to traffic injuries is increasing while mortality rates for same age group is decreasing. This might reflect that our emergency medicine now saves more and more lives, however many of them ending up as disabled. We need to get valid statistics on disability enabling us to describe the burden of traffic injuries.

Abstract citation ID: ckae144.783
Analysis of traffic injury trends, and strategies for road safety promotion in Lithuania

Birute Strukcinskiene

B Strukcinskiene[1]
[1]Department Public Health, Faculty of Health Sciences, Klaipeda University, Klaipeda, Lithuania
Contact: birute.strukcinskiene@ku.lt

Every year, about 1.3 million people die on the world's roads. The aim of the study was to analyze the mortality trends from traffic injuries, and to discuss strategies for the prevention of road traffic injuries and road safety promotion in Lithuania. A longitudinal study was conducted, and regression analysis was applied. The study showed that, when analyzing the changes in mortality from the main causes of death over 2009-2019, the greatest progress in mortality reduction was observed in the category of deaths from external causes; whereas, the number of deaths from diseases of the circulatory system did not change, and the number of deaths from malignant tumors increased slightly. In Lithuania, the death rate from traffic injuries per 100,000 inhabitants decreased significantly over a 50-year period (1971-2020) (in the whole population, and in the subgroups of men and women). In Lithuania, during the fifty-year period (1971-2020), pedestrian mortality rates decreased significantly in the whole population, and children and adolescents (0-14, 15-19, and 0-19 years). Over 1998-2020, road traffic injury deaths decreased significantly in children age groups 0-14, 15-19, and 0-19. After exploring the preventive strategies used for road safety promotion, it was revealed that the most effective results were achieved, when education, safe environment creation, and legislation with enforcement were used. It was important to create a safe engineering environment, to separate pedestrian and bicycle paths from high-speed traffic on roads, to improve the visibility of road users, to apply measures that reduce driver's fatigue, and to combat the usage of mobile phones while driving. Preventive activities were aimed at alcohol control, speed limitation, education of safe behavior of drivers, promotion of safe cars operation. The usage of safety belts and safety seats, helmets for motorcyclists and cyclists were increased through legislative and educational measures.

Abstract citation ID: ckae144.784
ProtAct-Us from serious injuries with long-term consequences

Werner Leitgeb

W Leitgeb[1], M Papadakaki[2], H Johannsen[3], A Morandi[4], The ProtAct-Us consortium[1]
[1]Vehicle and Road Safety, Virtual Vehicle Research, Graz, Austria
[2]LaHeRS Lab, Department of Social Work, Hellenic Mediterranean University, Heraklion, Greece
[3]Accident Research, Medical University Hannover, Hannover, Germany
[4]Centre for Studies and Research on Road Safety CIRRS, University of Pavia, Pavia, Italy
Contact: Werner.Leitgeb@v2c2.at

Battling serious injuries and long-term consequences in road traffic remains one important issue in the overall goal of resilient future road transport and its Vision Zero. Challenges of increasing personal transport in urban areas coupled with autonomous vehicles and shuttles, new mobility devices and the overall need to ensure the safety of vulnerable road users as well as all types of vehicle occupants' require solid medical background knowledge paired with innovative engineering approaches. EU Horizon Europe is currently funding the ProtAct-Us consortium (2024-2027) that aims at protecting all Road User Groups from serious injury and long-term physical, cognitive and mental health consequences related to road crashes through innovatively interlinked research action between medical and engineering methods and approaches. ProtAct-Us works on the following goals and challenges: i) Medical data correlation, standardisation and classification of long-term consequences of road crashes; ii) Robust and reliable medical, epidemiological and engineering tools like agreed methods to collect information on long-term consequences, upgraded Human Body Models and virtual assessment methods for the extremities, head, neck and face allowing for effective countermeasure development for all road users; iii) Reduction of long-term consequences and related socio-economic cost of road crash related injuries for all road users. The ProtAct-Us solutions will influence new standards in respect of extending current injury codification system with relevant long-term aspects, allowing new physical as well as virtual safety assessment procedures and adaption of rules and regulations to be implemented. Finally, scientifically well-founded suggestion for future implementation into policy, regulatory, and standardization guidelines for an inclusive safety improvement approach for in- as well as post-crash will be provided.

Public-Private Partnerships: A model for injury prevention and safety promotion – Benefitting communities and NGOs

Eva Vaagland

E Vaagland[1]
[1]Norwegian Safety Forum, Oslo, Norway
Contact: eva.vaagland@skafor.org

Injuries are a leading cause of death up to 45years, and 12% of all hospital beds in Norway are dedicated to accident-related treatments. Addressing injuries poses a significant public health challenge, and preventing accidents is crucial for saving money and resources. The Norwegian Act of Public Health mandates that municipalities promote the population's health and well-being, contribute to favourable environmental conditions, and prevent mental and somatic illnesses and injuries. This is echoed in various laws and regulations, providing a supportive framework for injury prevention and safety promotion. However, translating these laws and regulations into effective policies and preventive activities necessitates collaboration across sectors and levels. To meet these demands, a public-private partnership for safety has been established through five-year cooperation agreements between the Ministry of Health, Finance Norway (Association for financial and insurance industry in Norway), and the Norwegian Safety Forum (NSF). As a non-profit organization, NSF is a national advocate for safety, specializing in home and leisure injury prevention, road safety and Safe Community initiatives in Norway.

Program Description: The collaboration aims to reduce accidents and injuries. The agreement secures basic financing for NSF and serves as a platform for knowledge sharing and competence building across sectors. It facilitates seminars and meetings to promote learning among different professions, benefiting municipalities and the public. The collaboration leverages the Ministry's resources, insurance companies' data and knowledge, and NSF's expertise to develop injury prevention programs through dialogue with communities and organizations. This model brings together private-public and NGO perspectives. It also provides enhanced possibilities for coordination on both national and community level, enhancing data and knowledge availability and strengthening capacity for safety promotion.

4.X.1. Health literacy policies – how can they be developed and implemented?

Abstract citation ID: ckae144.786

Organised by: Austrian National Public Health Institute (Austria), M-POHL
Chair persons: Christina Dietscher (Austria), Angelika Schlacher (Austria)
Contact: angelika.schlacher@goeg.at

In Europe and beyond, there is political recognition of health literacy being an important factor for good health and well-being. As health literacy is considered critical to achieving health and as limited health literacy is still a widespread phenomenon, the topic is steadily attracting more attention among policy and decision makers. To meet growing demand from decision makers, a policy guide was initiated by M POHL, the World Health Organization (WHO) Action Network on Measuring Population and Organizational Health Literacy. The guide aims to support awareness-raising, the building of commitment and the implementation of effective policies to improve health literacy. It mainly addresses decision-makers in health policy and administration, but may also inspire researchers and other relevant stakeholders in the health literacy area.

Objectives of the workshop: This skills building seminar seeks to contribute to capacity building and to offer time for exchange and discussion on health literacy policy work. More specifically, the objectives of the workshop are to: - provide an overview on national health literacy policy implementation; - increase the knowledge of participants on what countries are doing already and identify needs for further support; - support participants in reflecting, initiating, developing and implementing effective measures to improve population and organizational health literacy.

Methods of the workshop: The workshop will start off by a presentation introducing the guide "Health literacy policies - how can they be developed and implemented?' and sharing some national experiences in implementing health literacy policies, strategies, and interventions. After these impulses attendees will be divided into groups to enable exchange. A checklist for self-assessment will be provided as a tool to guide the discussion and to identify and address potential challenges in implementing health literacy policies and interventions. The input and identified needs will be captured. They will support M-POHL's continuing efforts to support policy makers and administrators in their work.

Key messages:

- Health literacy is steadily gaining more interest from policy- and decision-makers.
- In this seminar, participants will learn on how evidence-informed policies and practice can be supported.

Abstract citation ID: ckae144.787

A guide for policy and decision makers on health literacy policies

Angelika Schlacher

A Schlacher[1]
[1]Austrian National Public Health Institute, Vienna, Austria
Contact: angelika.schlacher@goeg.at

Supported by supranational organizations such as the WHO or the European Union, governments across the world have begun to work systematically on developing and implementing action plans, strategies and policies to improve the health literacy of their citizens and the health literacy friendliness/responsiveness of health organizations. In 2023, a first project on evidence-based policies and practices was initiated by the WHO Action Network on Measuring Population and Organizational Health Literacy (M-POHL) and financially supported by the Swiss Ministry of Health. In this project a guide on how health literacy policies can be developed and implemented was developed by an international working group. This guide brings together insights from existing literature on national health literacy strategies, action plans and interventions, including an expert snowball search within the M-POHL network and among other partners, experiences and case examples collected from M-POHL members and other countries. Feedback on the guide was collected in interactive webinars with policy representatives and decision-makers and addressed. The structure of the guide follows an adapted version of the Public Health Action Cycle model, assisting step-by-step action on health literacy policy development: situation analysis; agenda setting; developing policies, strategies and interventions; implementation; evaluation and monitoring. Each phase is described, and best practices and recommendations provided. The guide closes with a checklist for self-assessment which follows the structure of this document. It supports reflection on the state of policies in a country. This innovative guide contributes to supporting evidence-informed policies and practice. This can be of interest to experts and practitioners who have data on challenges relating to the health literacy levels of population groups and who wish to develop or adjust their policies, services and communications accordingly.

4.Y.1. Climate trauma, public protest and the ethics of civil disobedience in our warming world

Abstract citation ID: ckae144.788

Organised by: Aletta Jacobs School of Public Health (Nteherlands), ASPHER, EUPHA-LAW, -ENV, -HIA, -PMH, -GH, Faculty of Public Health (UK), GNAPH
Chair persons: Piedad Martin-Olmedo (EUPHA-HIA), Brigit Toebes (Netherlands)
Contact: d.w.patterson@rug.nl

Eco-anxiety, defined as "a chronic fear of environmental dooms," is related to both a direct experience of extreme weather events (e.g., floods, wildfires, hurricanes, droughts) as well as environmental changes. Although it is not yet being addressed as a proper disease, eco-anxiety is being related to symptoms such as obsessive thoughts about the climate and the total destruction of the planet, existential fear and feelings of guilt about one's own carbon footprint, anger, frustration, depression, and anxiety, among others. Eco-anxiety is increasingly reported among children and young people (Hickman et al, Lancet Planetary Health, 2021). Less studied and understood is climate trauma at a societal level resulting from the ever-present, ever-growing threat of climate change.This session aims to facilitate a better understanding of the mechanisms that lead to this symptomatology as well as the reasons for our apparent collective paralysis as a society to act in accordance with the climate threats we face. This analysis will take into account aspects linked to cultural diversity and structural factors that can rationalise the inaction. Particularly following the COVID-19 pandemic, many states have introduced or strengthened laws restricting the right to protest, with implications for public protest about state inaction on climate change. The workshop also aims to address questions such as: Are public protest and civil disobedience rational responses to the climate crisis? Should health professionals protest publicly? How has eco-anxiety been used as a legal defence to criminal charges? How should professional accreditation bodies respond when a member is convicted in a climate protest? Is deregistration appropriate, or should we instead be hastening to revise professional codes of ethics and public health training curriculums to reflect 'the single biggest threat facing humanity'? (WHO, 2021). In the United Kingdom, the UK Health Alliance on Climate Change has urged the General Medical Council 'to be as lenient as the law allows' with health professionals convicted of offences resulting from their protests against damage to nature, the climate, and health. Three expert panellists in mental health, law and ethics will present their perspectives in Pecha Kucha format.

Key messages:

- Climate trauma at societal level may account for our collective paralysis in the face of climate change: yet political, structural and cultural factors must not be overlooked.
- Ethical codes and training curriculums for public health professionals must be updated to reflect the evolving roles of PHP in response to climate change.

Speakers/Panelists:

Jutta Lindert
Hochschule Emden-Leer, Emden, Germany
David Patterson
University of Groningen, Groningen, Netherlands
Farhang Tahzib
Faculty of Public Health, Haywards Heath, UK

4.Y.2. Building inclusive risk communication, community engagement and infodemic management strategies

Abstract citation ID: ckae144.789

Organised by: Ludwig Maximilian University (Germany)
Chair persons: Zeliha Öcek (Germany), Dilek Aslan (Türkiye)
Contact: zoecek@ibe.med.uni-muenchen.de

Public health crises have their most devastating effects on people who are marginalized due to structural vulnerability mechanisms. As a reflection of this phenomenon, the Novel Coronavirus Disease (COVID-19) pandemic as a public health crises has increased the vulnerability of groups such as refugees, asylum-seekers and LGBTQ+ individuals facing discrimination, stigmatisation, displacement, economic instability, risk environments, precarious living and working conditions among others, and health inequities have been further deepened. A critical post-pandemic task is to develop comprehensive crisis response plans that prioritize inclusivity and address diverse needs. Integral to these plans are Risk Communication (RC), Community Engagement (CE), and Infodemic Management (IM) strategies. While international organizations have provided guidelines for RCCE-IM, there is an urgent need to translate these principles into tailored, context-specific strategies that account for the unique circumstances and requirements of diverse groups. The aim of this workshop is to reflect the lessons learned from the COVID-19 pandemic to strengthen the RCCE-IM strategies, using the cases of migrants and LGBTQ+ people, two groups who are intensively influenced by structural vulnerability mechanisms. The first 20 minutes of this workshop will feature four short presentations. First, the concepts of RCCE-IM will be defined, followed by an explanation of why related strategies should differ for vulnerable groups. The second presentation will focus on the issues that LGBTQ+ people faced during the COVID-19 pandemic, as well as their specific RCCE-IM needs. The third and fourth presentations are based on a collective project taking an expert perspective on the RCCE experience with migrants during the COVID-19 pandemic. Firstly, the extent to which the RCCE actions in Munich, Germany, has been able to include asylum-seekers and areas for improvement will be presented. This will be followed by a presentation on recommendations to enhance RCCE of the experts who were working with undocumented migrants, unaccompanied minors, and newly arrived refugees in Malmö, Sweden. In the final part of the workshop, participants will be invited to provide brief recommendations on the operationalization of international RCCE-IM principles across four key thematic areas: 1) Rapid adaptation of RC materials to culture and context, 2) Trust-building in crisis, 3) Navigating sociocultural and linguistic diversity, 4) Addressing LGBTQ+ migrants in RCCE activities.

Key messages:

- Addressing vulnerable groups in (public) health and humanitarian crises using RCCE-IM strategies are needed to leave no one behind.
- To conduct inclusive RCCE-IM activities, cities need to address structural vulnerabilities, identify different needs and context-based strategies, and integrate various sectors and perspectives.

Abstract citation ID: ckae144.790

Addressing vulnerable groups in (public) health and humanitarian crises using RCCE-IM strategies

Dilek Aslan

D Aslan[1]

[1]Department of Public Health, Faculty of Medicine, Hacettepe University, Ankara, Türkiye
Contact: diaslan.dr@gmail.com

Background: Vulnerable groups, including older people, infants and children, women, people with disabilities, migrant populations, individuals with marginalized sexual and gender identities, etc., become more fragile in public health and humanitarian crises. These groups' vulnerability limits their access to health care and other services. Labeling, stigmatization, stereotyping, and other negative consequences contribute to the burden. Concurrent with the motto of the World Health Organization, "Leaving no one behind,' it reminds us of the need for equality and equity-based models to reach these vulnerable groups in such crises.

Methods: Existing scientific literature and perspectives were synthesized.

Results: Novel Coronavirus Disease (COVID-19) contains various experiences. Since the pandemic, the need for interdisciplinary approaches and strategies has become more apparent based on the complexity and intersectionality of the determinants of the crisis. In this regard, Risk Communication (RC), Community Engagement (CE) and Infodemic Management (IM) strategies before, during, and after crises might be used to respond to and mitigate the hazards. Preparation plans before the crisis are almost the most effective intervention. However, "during" and "after" crises need considerable steps of RCCE-IM as well. Listening to the concerns of the vulnerable populations, avoiding discriminatory language, providing correct and timely information, using effective communication strategies, using tools to build resilience, and engaging with the community should be built and/or strengthened among the vulnerable groups.

Conclusions: Addressing structural vulnerabilities with public and global health perspective might provide us with more sustainable and efficient solutions. In this presentation, answers will be provided on how to use RCCE-IM strategies in structural vulnerability and the strengths and weaknesses of the system with the proposed solutions based on the global situation.

Abstract citation ID: ckae144.791

Improving RCCE-IM for LGBTQ+ migrants: Lessons learned from COVID-19 Pandemic

Jorge Gato

J Gato[1,2]

[1]Centre of Psychology, University of Porto, Porto, Portugal
[2]Faculty of Psychology and Education Sciences, University of Porto, Porto, Portugal
Contact: jorgegato@fpce.up.pt

Background: To foster equity during a pandemic event, public health practitioners must be mindful of social and political circumstances that inform poor health. This is especially true for populations who are exposed to several factors that structure health inequity, such as lesbian, gay, bisexual, transgender, or otherwise queer identifying (LGBTQ+) populations. We aim to report on the specific challenges of LGBTQ+ people, including those who belong to the migrant communities, during the COVID-19 pandemic and find out their needs in risk communication (RC), community engagement (CE) and infodemic management (IM).

Methods: We will first review findings of studies conducted in Portugal, UK, Italy, Brazil, Chile, and Sweden, between 2020-2023, in the context of "Project Global Queerantine", then report on the additional challenges that LGBTQ+ people faced when living in migrant communities.

Results: LGBTQ+ individuals perceived their psychological well-being to have been greatly affected by the pandemic. Stressors included fear of the disease itself, and fear of spreading the virus, as well as the negative consequences of adhering to the recommendations of social distancing, which constantly interplayed with the marginalized position of being a LGBTQ+ person. Limited access to the LGBTQ+ community was a common stressor for trans individuals who faced prolonged waiting times for "gender dysphoria" assessment and hormone treatment. The intersectionality of vulnerability mechanisms experienced by LGBTQ+ migrants exacerbated all these issues, as did challenges in accessing and comprehending COVID-19-related information.

Conclusions: During health crises, it is critical for RCCE-IM efforts to consider the increased mental health issues and disruption of social support networks that LGBTQ+ people may face. Strategies and examples of good practices for RCCE-IM that are specifically tailored to LGBTQ+ migrants will be developed in collaboration with the workshop participants.

Risk communication with asylum-seekers: Insights from the COVID-19 Pandemic experience in Munich

Zeliha Öcek

Z Öcek[1,2], *F Link*[1]
[1]Chair of Public Health and Health Services Research, Institute for Medical Information Processing, Munich, Germany
[2]Pettenkofer School of Public Health, Munich, Germany
Contact: zoecek@ibe.med.uni-muenchen.de

Background: The COVID-19 pandemic has created a 'double crisis' for asylum-seekers, whose lives were already in crisis. Many reports indicated the syndemic consequences on asylum seekers' health, underscoring the need for their inclusion in risk communication (RC) and community engagement (CE) and infodemic management (IM) actions. This study aims to describe RCCE experience with asylum seekers in Munich during the COVID-19 pandemic from an expert perspective and thus gain a thorough understanding of the requirements for inclusive RCCE.

Methods: Our qualitative study involved people who conducted COVID-19-related RCCE for asylum-seekers. Volunteers/workers of civil society organizations and health professionals were interviewed using purposeful sampling. After reviewing international guidelines, an interview form was created. The content analysis resulted in themes and categories.

Results: Four of the interviewees were health managers, while 8 were working in civil society organizations. The first category of the results describes the context in which RCCE occurs; syndemic factors (uncertainty; social exclusion and stigma; precarious housing; limited access to healthcare and unmet mental health needs) and pandemic management. The second category includes determinants of RCCE from both the asylum-seeker (trust; risk perception; health literacy; language; culture and gender) and RCCE member (competences; overburden; continuity) standpoint. The third category focuses on various RCCE-IM measures, including their effectiveness and consequences.

Conclusions: Syndemic factors hampered the effective implementation of RCCE for asylum seekers in Munich. RCCE determinants show that pre-crisis actions are necessary for an effective response and individual interactions should accompany community-level activities, particularly for female and marginalised migrants. This study's scope will be expanded by incorporating the IM component.

Abstract citation ID: ckae144.793
Risk communication with migrants: Lessons learned from the COVID-19 Pandemic experience in Malmö

Pia Svensson

P Svensson[1]
[1]Division of Social Medicine and Global Health, Faculty of Medicine, Lund University, Malmö, Germany
Contact: pia.svensson@med.lu.se

Background: During the COVID-19 pandemic, many migrants faced challenges in accessing, comprehending and implementing information, leading to mis- and disinformation and distrust. The pandemic underscored the importance of effective risk communication (RC) and community engagement (CE) that reaches all segments of society, both for managing health effects and preventing the reinforcement of discrimination and stigmatization. This study aims to describe the experience of RCCE targeting migrants in Malmö, Sweden, from an expert perspective. Further, to gain an in-depth understanding of the requirements for inclusive RCCE actions and to identify alternative or complementary strategies based on good local practices.

Methods: Individual interviews were conducted with experts representing civil society and public authorities who were purposely sampled based on their engagement with RCCE targeting migrants. The interview guide was based on a review of international guidelines addressing aspects of RCCE, and analysed with content analysis.

Results: Three key organisations working towards undocumented migrants; unaccompanied minors; and newly arrived refugees, respectively, were included. Findings are synthesized into three key insights: a) RC through trusted sources in safe spaces; b) Understanding migrant living conditions c) Promoting intersectoral collaboration and feedback loops. Experts underscored the importance of cultivating sustainable and relationships with migrant communities to effectively communicate, aiding in compliance and counter distrust. The significance of intersectoral collaboration and communication pathways was highlighted for assessing migrant specific needs and designing appropriate interventions.

Conclusions: Long-term trusting relationship facilitate RC. Embedding sustainability within intersectoral collaboration structures is imperative to facilitate swift mobilization during health crises, foster resilience, and counter health inequities.

5.X.1. Co-designing for policy impact: Belgium's monitoring & evaluation framework for cancer care & control

Abstract citation ID: ckae144.794

Organised by: Sciensano (Belgium), EUPHAnxt, EUPHA-PHPP
Chair persons: Damir Ivankovic (Netherlands)
Contact: Gabrielle.Schittecatte@sciensano.be

Cancer is one of the main public health challenges, and the second leading cause of mortality in the EU. It is Belgium's second leading cause of adult death after circulatory diseases and has been an increasing burden of disease in recent years. Recognizing the urgency of tackling the entire disease pathway, the European Commission (EC) has launched Europe's Beating Cancer Plan (EBCP), a policy-driven strategy, and the Mission on Cancer, a research-focused undertaking. In Belgium, Sciensano's Cancer Centre has been charged with the coordination and implementation of these programs, pioneering the setup of a dedicated structure to coordinate them. While Belgian public, academic, private and non-for-profit entities have been highly involved in these EU initiatives since their launch, there is currently no mechanism to monitor the impact of EBCP's uptake and implementation in Belgium. Moreover, in contrast to the investment and momentum at the European level, the last Belgian Cancer Plan dates from 2008, with its most recent evaluation being published in 2013, highlighting an important gap. To address this gap, the Cancer Centre was asked by the Federal Cabinet to develop a new monitoring and evaluation (M&E) framework for cancer care and control in Belgium. With a view to avoiding traditional top-down approaches, it was decided that the framework would be designed co-creatively, by engaging patients and experts in the field. The aim was to enable the iterative and flexible monitoring of Belgian policies related to the EBCP's implementation, while generating buy-in from stakeholders. To achieve this goal, a modified Delphi process was used, with complementary qualitative data collection in the form of focus group discussions with experts across the cancer continuum. A Steering and Patient Committee were put in place to provide stewardship over the process, and based on their feedback, additional patient workshops were run to ensure M&E priorities for patients were taken into account. The framework will cover the entire spectrum of cancer prevention and control, as well as transversal themes such as inequalities and patient-centeredness. It will also anticipate future evolutions and undergo adjustments when needed. This workshop will use a Pecha Kucha approach, with panelists sharing insights from the Belgian case study. The session will guide the audience through a story of the strengths and pitfalls of co-creating an M&E framework in the field of public health monitoring. Topics covered will include challenges of monitoring cancer care and control policies, approaches taken in Belgium to overcome these challenges, and the importance of involving diverse stakeholders in the process. A moderated discussion will allow participants to share their perspectives and ask questions. Attendees will walk away with a real-world example on how to challenge top-down paradigms of population-level M&E frameworks and identify transferable elements for adaptation in their own settings.

Key messages:

- Europe's Beating Cancer Plan (EBCP) provides opportunities to tackle the second leading cause of disease in the EU but will require innovative approaches to monitor uptake and impact.
- Development of Belgium policy-actionable monitoring & evaluation framework shows how co-creation can challenge top-down paradigms in public health monitoring and assess the uptake and impact of EBCP.

5.X.2. Improving indoor air quality: a public health challenge

Abstract citation ID: ckae144.795

Organised by: K-HEALTHinAIR Consortium
Chair persons: Amy van Grieken (Netherlands), Jose Fermoso (Spain)
Contact: a.vangrieken@erasmusmc.nl

Indoor air quality (IAQ) may have a profound effect on a person's physical and mental health and well-being. The Knowledge for Indoor Air Quality and Health (K-HEALTHinAIR) project (grant no 101057693) is an interdisciplinary European research project that brings together 15 partners across 8 countries to study the sources, determinants and health outcomes related to IAQ. We aim to increase knowledge and provide input for more accurate monitoring and interventions, promoting healthy indoor air quality across several public health settings. The main aim of this workshop is to engage the public health community in the relevance of IAQ as a public health concern. We will share the innovative and new methodologies applied in the K-HEALTHinAIR project to study IAQ and health and discuss opportunities as well as challenges in this field of research to support shared learning. This workshop highlights IAQ pollutant sources and determinants, seasonal variation in IAQ, older people's IAQ and health, and presents the project's open access platform that is developed to share knowledge. We will zoom in on the evidence available for the sources and determinants of exposure to indoor air pollutants. This activity, a systematic review, was fundamental to identify the gaps of knowledge and guide the preparation of data collection tools. It also depicts the main pollutants present in indoor settings and the respective sources and determinants of exposure. Then, one of the 9 public health scenarios studied in the project is presented. We will focus on the first results regarding (determinants of) IAQ variation in primary schools at several locations in Poland. Next, the pilot study in older people living in senior homes in the Netherlands presents first findings of IAQ and health data in this vulnerable population. Finally, the project will deliver an open-access platform aiming to be the one-stop-shop for IAQ Knowledge. The user-profiles identified are presented. At the end, the workshop participants will be up to date on the project's activities, its relevance for public health and the open access platform via which all output will be shared. Participants will leave with increased understanding of public health research needed to further study IAQ and its impact on health and well-being.

Key messages:

- Indoor air quality is a public health concern impacting health and well-being, especially in vulnerable populations such as children and older people.
- The K-HEALTHinAIR project is a multidisciplinary research project in which innovative methodologies are applied to increase knowledge on indoor air quality and health.

Abstract citation ID: ckae144.796
Sources and determinants of exposure to indoor air pollutants in schools and hospitals: a review

Vânia Teófilo

V Teófilo[1], M Clemente[1], S Viegas[1,2], C Martins[1,2]
[1]Occupational and Environmental Health, NOVA National School of Public Health, Lisbon, Portugal
[2]Comprehensive Health Research Center, NOVA National School of Public Health, Lisbon, Portugal
Contact: vhm.teofilo@ensp.unl.pt

Background: Indoor Air Quality (IAQ) is an important determinant of health. This study aimed to review the available scientific evidence about indoor pollutants and determinants of exposure in several settings, in the scope of the K-HEALTHinAIR project.

Methods: The systematic review was performed for the sources, concentrations, and determinants of pollutants in schools in the European region for 2013-2023. Articles were selected for data extraction if they were epidemiological studies, reported primary data for indoor air and pollutant levels, and, identified sources and determinants of exposure.

Results: The main pollutants affecting IAQ in schools and hospitals were carbon dioxide, volatile organic compounds (e.g., formaldehyde, terpenes), particulate matter, nitrogen dioxide, radon, ozone, and carbon monoxide. Besides the outdoor environment, several important indoor sources of emissions were identified such as occupancy, resuspension, cleaning products. Ventilation was the main determinant influencing the indoor levels of pollutants, stressing the importance of good planning, installation, and maintenance of mechanical ventilation systems in buildings. Other determinants were the number of occupants and their activities, and the building characteristics (e.g., type of floor, location, etc).

Conclusions: Results revealed indoor air quality as a public health concern since several pollutants are present in indoor settings. The identification of sources and determinants of exposure is fundamental for determining preventive measures in a public health perspective.

Contact: artur.badyda@pw.edu.pl

Background: Indoor Air Quality (IAQ) in schools is a public health concern, given the vulnerability of children as a demographic group and substantial amount of time that they spend in (highly occupied) classrooms. Conditions specific for school buildings, as well as location and outdoor air quality (OAQ), can adversely affect IAQ and children's health. The aim of this study was to examine the seasonal variation in IAQ and the influence of OAQ herein in primary schools.

Methods: Sampling was carried out in summer and winter in 5 schools in central Poland. A culture-dependent method using impactors was applied to examine the total number of bacteria and fungi. Gas chromatography with flame ionization detector (quartz filters for sampling) was applied to determine concentrations of 16 polycyclic aromatic hydrocarbons (PAHs), crucial for their health impact.

Results: In poorly ventilated classrooms bacteria levels exceeded that of fungi. Bacterial contamination decreased in efficiently ventilated rooms, and before/after the lessons. In summer fungi concentration in indoor air was higher than in winter and reached the level of fungi outdoors. PAHs concentrations (especially those with 4 and more rings, which are biologically active) and the mutagenicity and carcinogenicity equivalents were elevated in winter and related to changes in concentrations in outdoor air.

Conclusions: IAQ in schools depends on a season. Occupants in classrooms are the main source of bacteria, but the type and number of microorganisms also depend on ventilation conditions. PAHs characteristic of coal/wood combustion indicates that in the absence of internal emission sources, external sources most likely affect IAQ in schools in winter.

Indoor Air Quality and health of older people: a pilot study

Amy van Grieken

A van Grieken[1], SC de Leede[1], L Ye[1]
[1]Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands
Contact: a.vangrieken@erasmusmc.nl

Background: Older people often experience one or more chronic conditions, including respiratory conditions. Indoor air quality may (IAQ) may elevate symptoms of respiratory disease such as coughing. Consequently, people may experience a lower Health Related Quality of Life (HR-QoL). The objective of the Rotterdam K-HEALTHinAIR pilot site is to study IAQ and health among elderly: this study presents the design of the study and preliminary baseline results of IAQ and health.

Methods: A observational study is performed among $n = 110$ older people living in the broader Rotterdam-area, the Netherlands, recruited via opportunity sampling, hospitals and senior-residential corporations. Participants provide informed consent to participate in the study. IAQ is assessed near real-time using home sensors. An observation checklist captures environmental characteristics of the home. Participants complete a diary every 3 months and a self-report questionnaire at baseline, 6- and 12-months; measures include Health-Related Quality of Life, well-being and respiratory symptoms.

Preliminary baseline data (n = 30 baseline questionnaires, n = 25 sensors) were analyzed using descriptive statistics and regression analyses.
Results: The mean age was 74.3 (SD: 6.3). Average concentrations were 684 ppm CO2 (SD: 723), PM2.5 was 4.8 µg/m3 (SD: 34.5) and average temperature 19.9 °C (SD:1.6). In total 40.0% participants were experiencing asthma and 43.3% COPD. Participants rated their general well-being 72.6 (SD: 18.6) (0-100). No associations were observed between indicators of IAQ and participant self-rated health and health symptoms in this preliminary dataset.
Conclusions: Future data collection will allow for overtime associations between IAQ and a broad range of health outcomes. In the second and third phase of the study we aim to deepen findings and develop interventions.

K-HEALTHinAIR Open Access Platform: exploring user-profiles

Belen Costa Ruiz

B Costa Ruiz[1]*, L Perez*[1]*, M Ferri*[1]*, C Mediavilla Martinez*[2]*, A Acebes*[2]
[1]Kveloce, Senior Europa S.L., Valencia, Spain
[2]BDS-RD, Eviden Atos Business, Madrid, Spain
Contact: bcosta@kveloce.com

Background: There is a lack of awareness and accessible knowledge of IAQ effects on citizens' health. The K-HEALTHinAIR project is working to provide a one-stop-shop for IAQ knowledge. With this aim, partners are co-designing with representatives of the quadruple helix a unique platform to allocate data, information, and relevant resources to research and foster IAQ in Europe. This platform is envisioned to store in an accessible and friendly manner datasets of concentrations of key indoor air pollutants and health parameters, standardized Key Performance Indicators, indoor location characterization information, IAQ recommendations and regulations and analytical models.
Methods: First, a stakeholders mapping was performed in all project pilot sites to identify the platform potential users. Second, partners identified with stakeholders which information, data and resources of the project would be of interest and how to present them. Findings were summarized in user-profiles according to the quadruple helix (academia, public administration, industry, and general society).
Results: A set of resources had been identified for each user profile. Each of them will be adapted and formatted according to the users' needs before uploading it to the platform. The platform will allow users to access information according to their interest in an accessible a friendly manner. In this sense, a dashboard will be included in the website of the project for accessing the different modules of the platform: data management module and knowledge sharing module. The platform is being co-designed and will be tested in the project scenarios with representatives of the quadruple helix.
Conclusions: The K-HEALTHinAIR Open Access platform aims to be the one-stop-shop for IAQ knowledge.

5.Y.1. Refugees and mental health

Abstract citation ID: ckae144.800

Organised by: EUPHA-MIG
Chair persons: Jutta Lindert (EUPHA-PMH), Sonia Dias (Portugal)
Contact: jutta.lindert@hs-emden-leer.de

Research suggests an elevated risk of mental health conditions (depression, posttraumatic stress disorder, anxiety) among refugees, due to exposure to trauma, displacement, and the challenges of adapting to new environments. Children and adolescents with refugee background face additional challenges, including family disruptions, education interruptions, and uncertain futures. However, the data are heterogeneous and more detailed data are needed. To address this gap, we present data on refugee's mental health and resilience. First, data on resilience and mental health from Germany are presented. These data are adjusted for demographics and suggest that in case data are adjusted to the living situation in the host country the migrant status is less relevant. The second study presents the mental health of refugee adolescents and children in Greece. The third study presents results based on a Portuguese prospective cohort study Perinatal Health in Migrants: Barriers, Incentives, and Outcomes (baMBINO). This study investigates postpartum depression among refugee women in Portugal highlighting the need for access to care. Last, a systematic review and meta-analysis provides data on depression, anxiety and stress of 62,522 refugees from more than 30 countries. This data suggests that life experiences are critical for refugees' mental health. Based on the presentations the audience will be engaged in discussion on how to better early prevent mental health conditions in refugees.

Key messages:

- Mental health of refugees is a Public Health challenge.
- Pre- and post migration experiences impact refugees and migrants mental health conditions.

Abstract citation ID: ckae144.801
Depression, posttraumatic stress of migrants and refugees in Germany – a cross -sectional study

Felix Sisenop

F Sisenop[1]*, J Lindert*[1]
[1]Social Work and Health, University of Health Sciences Emden/Leer, Emden, Germany
Contact: felix.sisenop@hs-emden-leer.de

Background: Research shows associations between migration status and mental health conditions (e.g., depression). Yet, few representative data on migrants' health are available. We aim to provide representative data on depression, and posttraumatic stress (PTSD) among migrants in a representative sample in Northwestern Germany.
Methods: We conducted a longitudinal study with two measurement points using a standardized assessment instrument in a representative sample of 18-65 years olds in Germany. Here we report on the baseline data. To assess socio-demographic characteristics (gender, age, marital status employment status, household income and migration status) we developed a standardized instrument. To assess depression, we used the Patient Health Questionnaire (PHQ-9), to assess PTSD we used the Harvard Trauma Questionnaire (HTQ-5). To investigate associations of migrant status with depression, and PTSD we estimated linear regression models.
Results: The analytical sample for this study includes n = 437 (male: n = 181, female: n = 256) individuals (age: M = 44.48, range: 18-65). In the total sample 15.1% (n = 66) showed symptoms of depression, and 6.5% showed PTSD (n = 26). Depression was more frequent in migrants than in non-migrants (22.1% vs. 13.4%, p = 0.043; 66.7). Crude linear regression models showed statistically significant associations between migration status and depression (B = 1.998, 95% CI:

0.831; 3.165, $p < 0.001$), and PTSD (B = 0.204, 95% CI: 0.085; 0.333, p = 0.002). However, models adjusted for gender, age, marital status employment status, household income and migration status suggested significant associations between migration status and PTSD (B = 0.136, 95% CI: 0.009; 0.263, p = 0.036), but not for depression.

Conclusions: Longitudinal data are needed to better understand trajectories between mental health conditions, PTSD and migration status. Living situation after the migration is of critical importance for mental health of migrants.

Background: Research highlights the mental health challenges faced by children and adolescents from refugee backgrounds due to various risk factors encountered during migration, including exposure to violence, family disruptions, insecure legal status, and educational interruptions. These factors increase the risk of psychological issues and academic difficulties. This study investigates the relationship between mental health and resilience in refugee adolescents in Greece.

Methods: The study focuses on refugee adolescents aged 12-18 from Syria, Iraq, Afghanistan, Somalia, and Ukraine, the countries with the highest numbers of school-age refugees in Greece. Data were collected from 37 refugee children, 37 teachers, 4 parents, and 19 guardians using Poisson sampling. Results are based on responses to the Strengths and Difficulties Questionnaire (SDQ) and the Child Youth Resilience Measure (CYRM), with triangulation of self-completed questionnaires from students, parents/legal guardians, and teachers. Pearson correlation coefficient was employed for analysis.

Results: We present the pairwise Pearson correlation coefficients of students' responses to psychometric tests in relation to those of teachers, along with the corresponding p-values for a two-tailed test of significance. Specifically, cor(SDQst,SDQt)=0.443 (p-value=0.006), cor(SDQst,CYRMt)=-0.341 (p-value=0.039), cor(CYRMst,SDQt)=-0.333, (p-value=0.006), cor(CYRMst,CYRMt)=0.323 (p-value=0.051). All p-values are below 0.05 or very close to it, so we reject (or we are close to) the null hypothesis of no association at 5% significance level for every case. On the contrary, we note that the corresponding coefficients between students and parents/legal guardians are all statistically non-different from 0 at 5% significance level.

Conclusions: Educators exhibit a solid understanding of students' challenges and resilience compared to parents and guardians. These promising findings support further research.

Migration and mental health: the case of postpartum depressive symptoms in Portugal

Henrique Barros

H Barros[1]
[1]Institute of Public Health of the University of Porto, Porto, Portugal
Contact: henrique.barros@ispup.up.pt

Background: Postpartum depression (PPD) affects about 17% of healthy mothers within one year of childbirth. The etiology remains unknown, but PPD is influenced by a combination of genetic, physical, psychosocial, and obstetric factors, migration could influence the risk.

Methods: We analyzed data collected within the scope of baMBINO (Perinatal Health in Migrants: Barriers, Incentives, and Outcomes), a Portuguese prospective cohort study, aimed to investigate the maternity experiences and outcomes of migrant women, defined as foreign-born women, and compared to native women. Among the 5431 women enrolled at delivery, 3006 (55%) were considered eligible for this study and interviewed in their preferred language, within six months of recruitment. The Edinburgh Postnatal Depression Scale (EPDS) was administered during this interview, along with the Migrant-Friendly Maternity Care Questionnaire (MFMCQ).

Results: 2890 (96%) women were included in the analytical sample for this study. Among women included, 1475 (51%) were migrants or refugees. The proportions of women having EPDS scores ≥ 10 were overall greater among migrants than among native women (7.2% vs. 12.4%, $p < 0.001$) and the risk remained higher after multiple adjustment models.

Conclusions: Migration status, poor experience with maternal care and language proficiency increased the risk of PPDS and should be carefully addressed as part of perinatal care.

Refugee mental health - systematic review and meta-analysis

Pallavi Chatarajupalli

P Chatarajupalli[1], *J Lindert*[1]
[1]Social Work and Health, University of Applied Sciences Emden/Leer, Emden, Germany
Contact: pallavi.chatarajupalli@hs-emden-leer.de

Background: Mental health conditions of forcibly displaced persons are unknown as the characteristics of the population change over the years. This study aims to estimate the prevalence rates of mental health conditions among refugees (depression, anxiety and posttraumatic stress).

Methods: We conducted a systematic review using MEDLINE (Ovid), Embase, Web of Science Core Collection (Clarivate), PsycINFO (EBSCO), Sociological Abstracts (ProQuest), and PTSDPubs (ProQuest) published between 1994-2022. We set up clear eligibility criteria and developed a data extraction sheet. The risk of bias of the included studies was assessed using the Effective Public Health Practice Project (EPHPP) quality assessment tool for quantitative studies. Heterogeneity was assessed using I^2 statistics.

Results: The search yielded 4,381 records, of which 171 were included in the full-text review. 54 studies were included in the final review. These 54 studies comprised of 62,522 forcibly displaced populations (49.22% males, 50.78% females). Pooled prevalence rates for anxiety, depression, and PTSD were 36.3% (95% CI 30.0-43.2), 35.9% (95% CI 31.9-41.3), and 35.4% (95% CI 29.0-42.4) respectively.

Conclusions: The prevalence of PTSD, depression and anxiety is significant among forcibly displaced persons. Screening for mental health conditions among these populations might prove beneficial to prevent more severe mental health conditions through the implementation of early intervention strategies.

5.Y.2. Alcohol intoxication among adolescents in Italy, Belgium and The Netherlands

Abstract citation ID: ckae144.805

Organised by: EUPHA-PMH
Chair persons: Johan Bilsen (EUPHA-PMH), Guido Van Hal (Belgium)
Contact: johan.bilsen@vub.be

Excessive drinking behavior poses a significant risk to the health of adolescents and contributes to high social and health costs. It is also well-documented that engaging in risky drinking behavior at a young age increases the likelihood of developing alcohol use disorders and other mental health disorders later in life. Therefore, the timely development of adequate interventions to prevent and reduce such behavior is an important public health task. The initial step here is to gather comprehensive data on the phenomenon. Studying alcohol intoxication data among adolescents is an important source in this context. In the Netherlands, data on alcohol intoxication in adolescents have been routinely collected for several years, leading to a successful transmural framework aimed at supporting these young individuals and their parents. As countries are at varying stages in addressing this issue, the objective of this workshop is to facilitate mutual learning about effective prevention initiatives targeting problematic alcohol use in young people. The workshop will feature presentations from four studies representing three countries: Italy, Belgium, and the Netherlands. Allegra Ferrari from Italy will discuss alcohol-related emergencies among adolescents admitted to an emergency department in Genoa, emphasizing the importance of urgent interventions to mitigate adolescent alcohol use. Hanna van Roozendaal from Belgium will present data from both retrospective and prospective studies on adolescents with acute alcohol intoxication in Antwerp hospitals, exploring the feasibility of follow-up interventions. Louise Pigeaud from the Netherlands will share data from a cohort of individuals under 18 years presented with acute alcohol intoxication symptoms at an emergency department between 2015-2023 to monitor trends in admission characteristics. Finally, Guido van Hal will focus more in depth on the differences and similarities in adolescents accessing emergency care for acute alcohol intoxication in Italy, Belgium and The Netherlands. The workshop will conclude with an open discussion on topics such as the necessary data to be registered for minors with acute alcohol intoxication, the most effective methods for preventing/reducing alcohol intoxication in these age groups, and the potential transferability of the successful Dutch transmural framework to other countries.

Key messages:

- Acute alcohol intoxication and problematic alcohol use in minors can lead to significant alcohol-related issues in adulthood.
- Collecting and analyzing high-quality data can facilitate the development of interventions aimed at reducing and preventing alcohol-related issues in adolescents.

Contact: allegra.ferrari@uantwerpen.be

Background: As a result of underage drinking, adolescents have an increased risk of physical, mental, emotional, and social harm.
Methods: In order to assess the emergencies for alcohol use, data of the emergency department (ED) of San Martino Hospital - the referral acute-care center for adults in Genoa, Northwest Italy - was analyzed retrospectively. 330 records of 320 adolescents visiting the ED between 2014 and 2023 were considered.
Results: The median age of access was 16 (IQR 2), 54.8% were males, 17.4% had foreign nationalities, and the average blood alcohol concentration (BAC) was 1.8 g/L (SD 0.7), with 14.7% testing positive for other substances (6.1% benzodiazepines and 11.2% other drugs). 16.8%, 46.6% and 36.6% were assigned an emergency, urgent, and not-urgent acuity code. 2.8% had a repeated episode, 3.4% had to be removed for inappropriate behavior, 7.8% left spontaneously, 13.1% were hospitalized for additional care (5.5% in the Psychiatry ward). The average length of stay was 1.24 days (SD 5.86). Multivariable logistic regression showed that higher age, an emergency code and the use of other substances were positively associated with hospitalization [ORs 1.74 (95%CI 1.1-2.7), p 0.01; 7.1 (95%CI 2.2-22.4) $p < 0.001$; and 15.6 (95%CI 6.8-35.6) $p < 0.001$, respectively]. Admission in Psychiatry, in particular, was strongly associated with the use of other substances [OR 11.8 (95%CI 3.8-36.6), $p < 0.001$]. Multivariable linear regression showed that, in comparison with other access reasons, accidents and decreased consciousness were associated with higher BAC [beta 0.6 (95%CI 0.1-1.1), p 0.01; beta 0.8 (95%CI 0.3-1.2) $p < 0.001$]. Length of stay, however, was associated with lower BAC [beta -0.2 (95%CI -0.3 -0.01), p 0.04].
Conclusions: In Italy, binge drinking affects 120,000 adolescents aged 11-17. Our findings highlight the harm of this practice and support the need for prompt interventions to reduce the onset and prevalence of adolescent alcohol use.

Abstract citation ID: ckae144.807
Characteristics of adolescents with acute alcohol intoxication in Belgium

Hanna van Roozendaal

Contact: hanna.vanroozendaal@uantwerpen.be

Background: Binge drinking and acute alcohol intoxication (AAI) are common in Belgian adolescents, posing a risk of serious health consequences. To develop cost-effective preventive measures for problematic alcohol use in adolescents in Belgium, more insight into the background of this group is necessary.
Methods: To gain more insight into the prevalence, medical characteristics and context of AAI, a retrospective multicentre hospital chart study was performed on adolescents aged 10 to 18 years with AAI in Antwerp, Belgium from 2015-2021. Furthermore, a prospective intervention study for adolescents with AAI in Antwerp was set up in 2023, of which the first results were not yet known at the time of submission. However, these results will be presented at the conference, if available.
Results: Over the study period, a total of 1032 admissions related to alcohol intoxication occurred in 1016 patients, with a median age of 16.6 years old and a median blood alcohol intoxication (BAC) of

1.95 g/L. There was combined drug use in 10% of the cases. Only 17% of the patients received additional care after admission. These findings did not significantly change over the study period. Multiple linear regression analyses indicated that after correcting for covariates, higher age, no combined drug use and decreased consciousness at admission were associated with more severe AAI cases (higher BAC).

Conclusions: AAI is prevalent among Belgian adolescents. Therefore, better-targeted preventive measures and policies are needed. Our findings could be taken into account when developing preventive measures. However, data addressing the demographics and context of AAI were mostly missing. Therefore, a prospective follow-up study was set up in Antwerp, which started in 2023 and is still ongoing. Furthermore, this study will investigate the feasibility and effectiveness of a follow-up intervention for this group of patients.

Contact: pigeaud@eshpm.eur.nl

Background: Prevent alcohol consumption amongst minors is a major concern for national governments. Collecting comprehensive data on adolescent drinking patterns is crucial for developing effective prevention strategies. Therefore, the aim of this study is to give an overview of demographic and clinical characteristics of adolescents with an acute alcohol intoxication in the Netherlands.

Methods: This study was conducted using a cohort of adolescents aged 14-17 years presenting with acute alcohol intoxication symptoms at the emergency department from 2015-2023. Data were collected at the Reinier de Graaf Gasthuis in Delft in order to monitor trends in admissions for acute alcohol intoxication. Data on patients age, blood alcohol concentration, sex, combined drug use and reason of admission were collected.

Results: A total of 505 patients who presented themselves with symptoms of acute alcohol intoxication at the Reinier de Graaf Gasthuis were included. The mean age of patients was 15.7 years old. The mean blood alcohol concentration was 2.0‰. During the COVID-lockdown period there were statistically significant less admissions with alcohol intoxication. The distribution of sex was nearly equal with 50.3% females and 49.7% males. Combined drug use was present in 13.4% of all cases, with cannabis as the most frequent type of drugs found. The most common known reason for admission was ‘reduced consciousness’ (35.9%).

Conclusions: These findings are relevant for both the central government’s ongoing prevention initiatives and treatment strategies within hospitals. In the future, more countries should evaluate data on adolescent drinking patterns.

[5]IRCCS Ospedale Policlinico San Martino, Genoa, Italy
Contact: guido.vanhal@uantwerpen.be

Background: Excessive drinking among adolescents in Western Europe is prevalent, posing significant health risks and societal costs. Early initiation of alcohol use and binge drinking are associated with adult alcohol use disorders. Collecting comprehensive data on adolescent drinking patterns is crucial for developing effective prevention strategies.

Methods: To gain insight into the demographic and clinical characteristics of acute alcohol intoxication (AAI), we analysed emergency department access data of adolescents aged 14-17 years presenting with AAI symptoms from 2015-2023. Three urban regions were included: the Reinier de Graaf Gasthuis in Delft (The Netherlands), eight combined hospitals in Antwerp (Belgium) and the IRCCS San Martino Hospital in Genoa (Italy).

Results: A total of 1841 patients with symptoms of AAI were included. The mean age of patients in the Netherlands was statistically significant younger than in Italy and Belgium (15.7 compared to 15.9 and 16.0 years old, respectively). Moreover, the blood alcohol concentration was higher in the Netherlands and Belgium compared to Italy (2.0‰ compared to 1.95‰ and 1.8‰ respectively). The distribution of sex was nearly equal in the Netherlands, while statistically significant differences were observed with a higher proportion of males in Italy (54.8%) and Belgium (56.8%). Combined drug use was lower in Belgium with 10.0%, compared to 13.4% in The Netherlands and 14.7% in Italy. The most common reason for admission was ‘reduced consciousness’ in the total population (45.2%).

Conclusions: This is one of the first international studies which combines data on AAI in minors. In the future, efforts should be made to establish a common European database where records of AAI can be stored and analysed more efficiently for prevention purposes.

6.X.1. Disentangling Long-COVID: prevalence, risk factors and impact

Abstract citation ID: ckae144.810

Organised by: Santé Publique France (France), Western University (Canada)
Chair persons: Tatjana Makovski (France), Saverio Stranges (EUPHA-CHR)
Contact: tatjanamakovski@hotmail.com

Background: Prolonged symptoms after the acute SARS-COV2 infection significantly alter daily functioning and work ability for substantial number of people. Application of different long COVID definitions result in variable prevalence estimations, while aetiology of long COVID as well as its impact is insufficiently understood. Our workshop is set to discuss the public health impact of long COVID in the general population, to identify risk factors of developing long COVID, and stimulate dialog to advance adequate health care and public health actions aimed to reduce the impact of this condition.

Objectives and Key Questions: The overall objective is to discuss the public health impact as well as geographic variations across Europe in long COVID prevalence, major risk factors for long COVID and impact on work capacity, accounting for different population-based and hospital study settings. Specifically, the workshop will address the following key questions: 1) what are the challenges in estimating prevalence of long COVID? 2) what are the risk factors of long COVID and some of the most vulnerable population groups? 3) what is a distribution of long COVID in Europe? 4) what is the impact of long COVID on work ability?

Brief Overview: The workshop will include 3 presentations (in combined total duration of 12 min) on challenges for research and practice attributable to variability in defining long COVID, prevalence of long COVID across several European countries, risks factors of long COVID and impact on work ability. Active discussion of 13 min will conclude the session.

Key messages:

- Standardized definitions, such as WHO-PCC definition with severity thresholds would facilitate surveillance of long COVID and advance knowledge on the risk factors related to this condition.
- Understanding better the risk factors and impact of long COVID will inform more adequate screening and therapeutic strategies, and possibly anticipate effects of potential new infectious threats.

Abstract citation ID: ckae144.811
Difference in long COVID prevalence due to different definitions and long COVID related risk factors

Several definitions of long COVID are used in research and practice what challenges epidemiological investigations. Here we present differences in long COVID prevalence accounting for several definitions and concordance between the definitions, as well as the risk factors associated with long COVID. Definitions considered were WHO post-COVID19 condition (PCC) definition with several thresholds (at least low - standard definition, moderate or strong impact on daily activities), NICE1 and NICE2 definitions (reported at least one or at least two symptoms), United States National Centre for Health Statistics, and United Kingdom Office for National Statistics definitions and perceived long COVID. Prevalence of long COVID among French adult population (N = 10 615) in autumn 2022 ranged from 1.2% to 13.4%, conditional of the definition. The concordance between the definitions was at best moderate. Next, on a smaller representative sample of a French adult population (N = 1 813) eight potential risk factors groups for long COVID were assessed in a systematic epidemiological investigation, following a conceptual model. Fifteen factors from seven groups were associated with long COVID including early-defined sociodemographic characteristics, pre-existing chronic conditions, short-term work-related factors, current socioeconomic position, health behaviours, infection-related factors, and perception of COVID-19 severity and long COVID. The likelihood of long COVID was higher for individuals with higher number of diseases and for nineteen out of twenty-six most prevalent dyads and a triad. A more standardized definition would facilitate research and surveillance of long COVID. Furthermore, long COVID should be observed as an interplay of social, medical and contextual factors rather than a mere complication of SARS-COV-2 infection, while patients with multimorbidity may present some of the particularly vulnerable population groups.

The COVID-19 pandemic caused a significant burden in Europe, with over 60% of infected individuals developing Long COVID symptoms. Variations in Long COVID prevalence across countries are linked to individual-level factors, but the influence of population-based country-level characteristics remains unclear. Thus, our objective was to assess how country-level characteristics related to: (i) the way European countries responded to the COVID-19 pandemic, (ii) their population-level health status, (iii) provision and access to healthcare services, (iv) human development, governance, and environmental risk factors, are associated with Long COVID. We used a sample of 4,004 middle-aged and older adults from 27 European countries who, in summer 2021, participated in Corona Survey 2 (from Survey of Health, Ageing and Retirement in Europe) and who reported COVID-19 infection one year prior to the survey. To assess the potential role of country-level characteristics, while controlling for key individual-level factors, we estimated three sequential multilevel random intercept logistic regression models. Approximately 70% of respondents who had COVID-19 also experienced Long COVID symptoms and there were significant cross-country differences in Long COVID rates, ranging from 32% to 89%. About 13% of the total variance in the risk of having Long COVID can be attributed to cross-country differences and the remaining 87% to individual-level factors. The individual-level characteristics also accounted for 6% of the observed cross-country differences in Long COVID rates (compositional effects) while the country-level characteristics further reduced this variance by over 50%. Both individual and country-level factors influence Long COVID occurrence, emphasizing the need for tailored recovery plans, healthcare planning and resource allocation at the national level to address this condition.

Long-COVID19 has been recently associated with long-sick leave and unemployment. We will present recent data obtained by a prospective observational study conducted during the 2nd wave of the pandemic in Italy to assess the time course of Long-COVID19 autonomic syndrome in working age population and its impact on patient's work ability. The patients were consecutively enrolled at the time of their hospital discharge and were followed-up for 1 year. Clinical data and work ability have been collected at 1, 6, and 12 months after hospital discharge in our out-patient clinic. Data on Long-COVID19 autonomic syndrome occurrence in working-age and the effects on work ability will be presented and discussed. Long-COVID19 autonomic syndrome occurred in one in three working-age people and was still evident 6 and 12 months after the acute infection resolution. This was associated with a significant reduction in the work ability. Timely recognition of long-COVID19 autonomic syndrome and its potential impact on work ability represents important steps in the prevention of long-term disabilities among active working adults.

6.X.2. Food Insecurity in Europe: Voices from across Europe

Abstract citation ID: ckae144.814

Organised by: EUPHA-ENV
Chair persons: Christina Lampl (Austria), Anja Simmet (Germany)
Contact: christina.lampl@goeg.at

Food insecurity (FI), "lack of regular access to enough safe and nutritious food for normal growth and development and an active and healthy life", is a global public health issue. The United Nations (UN) have identified achieving food security as a key Sustainable Development Goal (SDG), where all people should "have access to safe, nutritious, and sufficient food all year round." However, disasters related to the consequences of changing climates, pandemics, wars, displacement of populations, high inflation rates, changes in social protection systems, and food system changes challenge the achievement of this SDG. FI persists even in high-income countries including Europe. This workshop session will foster a knowledge, research and experience exchange on the situation of individuals / different population groups in the context of FI in different European countries. Starting with a contribution from Austria, the term food poverty is introduced and considered from a food system perspective / from an equity perspective. The second contribution illuminates the relationships between FI, shopping behaviours and social support among food bank users in Germany during the COVID-19 pandemic. The final third contribution comes from the Netherlands and explores the needs and perceptions regarding healthy eating among people at risk of FI. In all three studies, standardized measurement tools were applied to measure FI but recruiting methods and data collection methods varied considerably between and within the studies. The session enhances the knowledge on FI in Europe from different perspectives.

Key messages:

- Food insecurity does exist in Europe: there is a need for regular, consistent monitoring across European countries.
- Food insecurity involves more than just access to food; it also considers nutritious and climate-friendly options, addressing the link between climate, health, and equity.

Abstract citation ID: ckae144.815
Food poverty as a barrier for a healthy and climate-friendly nutrition in Austria

Christina Lampl

C Lampl[1]*, A Schmidt*[1]*, E Aigner*[2]
[1]Department Climate Resilience and One Health, Austrian National Public Health Institute, Vienna, Austria
[2]Social-Ecological Systems Institute, Leuphana University, Lüneburg, Germany
Contact: christina.lampl@goeg.at

Background: The food system plays a crucial role in promoting healthy and climate-friendly living. One fundamental aspect is accessibility. However, in Austria, there is a lack of systematic and regularly conducted studies on food system accessibility. To address this gap, a comprehensive study on food poverty has been conducted for the first time in Austria.
Methods: We used a mixed methods approach, combining expert workshops, a representative questionnaire survey ($n = 2004$) using the Food Insecurity Experience Scale (FIES), and focus groups ($n = 20$) with affected individuals.
Results: Approximately 12 percent of people living in Austria are affected by moderate and/or severe food poverty. These individuals struggle to afford sufficient quantities and quality of food due to financial constraints or limited access in general. Over four percent experience severe food poverty, leading to skipped meals or even days without food. People affected by food poverty would like to focus more on healthy shopping and quality of food (prioritizing fresh food over cheap high-processed food). The biggest hurdles relate to a lack of financial resources, too little time and a lack of affordable (healthy and climate-friendly) options.
Conclusions: Food poverty is a phenomenon in Austria that has received little attention to date. Public discourse often attributes nutritional problems to information gaps or individual competence, neglecting the impact of structural conditions. Addressing food poverty requires holistic approaches that avoid stigmatization. Recognizing it as a social, health, climate, and agricultural policy concern necessitates robust monitoring and considering the social and environmental aspects of nutrition holistically.

Abstract citation ID: ckae144.816
Food insecurity among food banks users during the COVID-19 pandemic in Germany – what have we learnt and what should we do?

Anja Simmet

A Simmet[1], *N Stroebele-Benschop*[1]
[1]Department of Nutritional Psychology, University of Hohenheim, Hohenheim, Germany
Contact: anja.simmet@uni-hohenheim.de

Background: Before the start of the COVID-19 pandemic in 2019, up to 1.65 million people visited a total of 956 food banks called “Tafel” in Germany. The start of the pandemic and the associated first lockdown led to shortages in commercial food outlets and to considerable restrictions on the range of food banks. The aim of the study “Food INsecurity Among TAfel users” (FINATA) was to investigate the prevalence of food insecurity (FI) and its association with social support and food shopping behaviours among Tafel users during the pandemic.

Methods: A written and/or oral survey was conducted in 2020 and 2021 among a total of 985 Tafel users. In addition to descriptive analyses, regression analyses, stratified for 2020 and 2021, were conducted to investigate associations between FI and the other variables.

Results: Participants of 2020 ($n = 565$) and 2021 ($n = 420$) differed in several socio-demographic characteristics. Whereas the prevalence of moderate FI over the 30 days prior to the survey differed between participants of 2020 (21,6 %) and 2021 (6,6 %), the prevalence of severe FI was almost identical (3,9 % vs. 4,0 %). Variables being significantly ($p < 0{,}05$) associated with moderate/severe FI included being single vs. being married (2020: OR 4,89, 2021: OR 2,69), receiving at least half of food in the household from the Tafel (2020: OR 0,34), low vs. moderate/high social support (2020: OR 2,93), buying food in commercial food outlets at least once/week vs. less often (2021: OR 0,38) and time of travel to the most used commercial food outlet (2021: OR 1,04).

Conclusions: The social safety net during the pandemic failed to enable “all people to have (...) economic access to sufficient (...) food” in Germany. Future studies should investigate the relationship between social support, shopping behaviours and FI at the long-term. Food banks are recommended to introduce measures to improve the social situation of their clients such as cooperating with social cafés and restaurants.

Contact: l.a.van_der_velde@lumc.nl

Background: Healthy eating behaviour is an essential determinant of overall health. This behaviour is generally poor among people at risk of experiencing food insecurity, which may be caused by many factors including perceived higher costs of healthy foods, financial stress, inadequate nutritional knowledge, and inadequate skills required for healthy food preparation. Few studies have examined how these factors influence eating behaviour among people at risk of experiencing food insecurity. We therefore aimed to gain a better understanding of the needs and perceptions regarding healthy eating in this target group.

Methods: We conducted a qualitative exploration with 10 participants at risk of experiencing food insecurity in the Netherlands.

Results and conclusions: The analysis using an inductive approach identified four core factors influencing eating behaviour: Health related topics; Social and cultural influences; Influences by the physical environment; and Financial influences. Overall, participants showed adequate nutrition knowledge. However, eating behaviour was strongly influenced by social factors and physical environmental factors. Perceived barriers for healthy eating behaviour included poor mental health, financial stress, and high food prices. Participants had a generally conscious attitude towards their financial situation, reflected in their strategies to cope with a limited budget. Participants were familiar with several existing resources to reduce food-related financial strain and generally had a positive attitude towards these resources. An exception was the Food Bank, of which the food parcel content was not well appreciated. Proposed interventions to reduce food-related financial strain included facilitating social contacts, increasing healthy food supply in the neighbourhood, and lowering prices of healthy foods. The insights from this study increase understanding of factors influencing eating behaviour of people at risk of food insecurity.

6.Y.1. Defining, measuring, and reducing low-value care in Europe - proposing a new definition and framework

Abstract citation ID: ckae144.818

Organised by: European Observatory on Health Systems and Policies, EU Expert Group on Health Systems Performance Assessment
Chair persons: Dimitra Panteli (Belgium), Kenneth Grech (Malta)
Contact: katharina.achstetter@tu-berlin.de

The EU Expert Group on Health Systems Performance Assessment (HSPA) selected value-based healthcare, with a focus on low-value care, as the work topic for 2023-2024. Against the backdrop of increasing healthcare expenditures and the overall aim to deliver high quality and efficient healthcare, efforts to reduce waste and inefficiencies have long been emerging in health systems worldwide. Value-based healthcare shifts the focus towards improving patient outcomes; the concept of low-value care in particular aims to identify health services that provide little or no health benefits but expose patients to potential harm. The COVID-19 pandemic clearly demonstrated that value-based healthcare is a prerequisite for high-performing health systems and the need to steer resource allocation to those services that maintain or improve health. The reduction in certain elective services observed during the pandemic (e.g. tonsillectomies) indicates that there may be areas for potential dis-investment and reallocation of resources to higher-value care. The pandemic has thereby emphasized the need for identifying and systematizing measurable efforts directed at reducing low-value care. Tackling low-value care can contribute to alleviating health workforce constraints by ensuring that efforts are focused where they are most beneficial, and not on unnecessary services. Engaging and educating the health workforce about low-value care and how to reduce it is a key measure in this direction. What is more, there is increasing awareness about the health sector's considerable environmental footprint. Reducing low-value care would contribute to less greenhouse gas emissions, energy consumption and air pollution from the delivery of health services. Despite intensified efforts to address waste and inefficiencies in healthcare in the last decade, the ability of health systems in Europe to identify and reduce low-value care varies. Through the Expert Group's work, a new comprehensive definition was proposed and a framework to distinguish different types of low-value care was developed as a basis for identifying and tackling low-value care in EU Member States. Indicators to measure low-value care as well as measures to reduce it were collected. This workshop aims to present the findings of the Expert Groups work on low-value care and to discuss them with conference participants to both raise awareness and identify priority elements for future activities. After a brief introduction on the definition, framework, obstacles and solutions, the panelists will share their views and experiences, followed by a facilitated discussion with the audience.

Key messages:

- A comprehensive definition of low-value care and an accompanying framework for categorizing and identifying low-value care is proposed.
- Country experiences with indicators to measure low-value care and strategies to reduce it, as well as related methodological obstacles, offer substantial opportunities for cross-country learning.

Abstract citation ID: ckae144.819

Defining, measuring, and reducing low-value care – proposing a new comprehensive definition and framework

Katharina Achstetter

6.Y.2. AI and health care: what are the capabilities and limitations?

Abstract citation ID: ckae144.820

Organised by: The Commonwealth Fund (USA)
Chair persons: Evan Gumas (USA), Reginald Williams (USA)
Contact: eg@cmwf.org

With the rapid advancement of artificial intelligence (AI) technologies and their implementation in health care, there is a critical need to explore the different applications and implications of AI. This workshop seeks to look at different aspects of AI, both potential applications for AI technology in health, public opinions of use of AI in health care, and the reality of implementing AI in different contexts. Understanding health care approaches to AI from different countries is a unique opportunity for shared learning of innovations across various sectors of health care and patient engagement in order to most effectively engage this emerging field. AI, in whichever form it may be incorporated into health care, has the opportunity to impart meaningful, innovative change, but understanding this new technology comes with important questions. This session will dive into research on AI in various areas of health care by 1) looking at different ways AI is being harnessed in health care; 2) discussing lessons which can be learned and adapted from other countries; 3) discussing promising solutions and approaches to implementing AI in health care; 4) discussing the limitations or concerns of integrating AI in health care.

The panel will be composed of 1 moderator and 2 panelists. Panelists are experts in their fields, established researchers and practitioners, and alumni of the Harkness Fellowship from Germany and the United Kingdom. A moderator will briefly frame the discussion for the audience and introduce the speakers and their presentations before leading an interactive, engaging question and answer portion. The coherence of this panel lays in its theme of leveraging AI to enhance healthcare delivery and understanding ways we can work across countries to foster ethical, equitable AI technologies that revolutionize healthcare practices with the ultimate goal of improving patient outcomes and health system efficiencies. Dr. Saira Ghafur from the U.K. will begin by presenting her research on evidence-based reasons for implementing AI in health care and Dr. Benedikt Simon from Germany will close out by discussing his work in AI in Germany and the challenges that have prevented robust integration. Each panelist will speak for roughly 8-10 minutes, with about 5 minutes reserved for moderator and audience questions.

Key messages:

- Sharing cross-country experiences and research enables us to better understand how AI can impact health care.
- In weighing both the benefits and challenges or limitations of implementing AI, we can best understand effective approaches to utilizing AI in health care.

Abstract citation ID: ckae144.821
Evidence for AI in healthcare

[3]Digital Health, Prova Health, London, UK
Contact: saira.ghafur13@imperial.ac.uk

In healthcare, novel AI solutions are being created to address some of the biggest challenges in the prognosis, diagnosis, and treatment of disease, as well as clinician workflows and service improvement. The emergence of generative AI presents a compelling opportunity to revolutionize diagnostics, treatment planning, medical research, and patient engagement. The hypothesized uses of generative AI are broad, ranging from medical education, providing information to patients, generating synthetic patient data for the validation of AI tools, to the analysis of continuous data from wearables to detect early signs of disease. Adoption of digital solutions and AI in healthcare is slower than in other industries. The majority of clinicians don't have direct experience with AI technologies, only a quarter have recommended a digital therapeutic, and less than a fifth have prescribed one. Safety, quality and confidence can be built through appropriate governance, testing, careful implementation and appropriate clinical use. There is a responsibility for AI developers, health systems and providers, as well as regulators, to create clear expectations for evidence and solutions. AI solutions require unique model evidence (evidence for the underlying algorithm) and solution evidence (evidence for the product in which the algorithm is embedded). Models will need validation first on internal and then on external datasets (internal and external validation). This will indicate how accurate and reliable the model is, but will be limited to the dataset that a client has access to. By examining ways to evaluate evidence for AI in healthcare, we can develop a better understanding of how best to use AI to its most appropriate advantages.

Abstract citation ID: ckae144.822
Challenges to implementing AI in health care

Benedikt Simon

B Simon[1,2]
[1]Integrated and Digital Care, Asklepios, Hamburg, Germany
[2]Harkness Fellow, The Commonwealth Fund, New York, USA
Contact: be.simon@asklepios.com

Germany, renowned for its robust healthcare system, finds itself at the early stages of AI integration. This is a reality for many European countries, emphasizing that, despite general technological prowess, AI adoption remains in its absolute infancy. However, in Germany there are areas where AI shows promise, notably in fields like radiology. Beyond such niche applications though, Germany grapples with a significant challenge - the scarcity of robust data essential for meaningful AI utilization, particularly in the realm of public health. While these insights are specific to the German context, understanding the intricate hurdles impeding widespread AI implementation is a meaningful takeaway for countries around the world. In order to effectively leverage new technologies, there is an acute need for advancements in data infrastructure and governance to unlock the full potential of AI in healthcare. Overcoming barriers and charting a path towards a future where AI serves as a transformative force in German healthcare, could one day lead to enhanced system efficiencies and patient experiences, but for now we have to be thoughtful about the realities of implementing AI within current existing health system infrastructure.

7.X.1. Providing BoD estimates on a regional level – necessity in assessing health inequalities

Abstract citation ID: ckae144.823

Organised by: European Burden of Disease Network, EUPHA-CHR, -PHMR
Chair persons: Elena von der Lippe (Germany), Sarah Cuschieri (Malta)
Contact: vonderLippeE@rki.de

Burden of disease indicators, such as Disability-adjusted life years (DALY), Years lost due to disability (YLD) and Years lost due to death (YLL) have become standard indicators in public health reporting systems. Due to the combination of morbidity and mortality, the DALY provides valuable information on the burden due to specific diseases. These tools are employed by policymakers to devise intervention programs with the objective of enhancing the collective health of the population. Studies at the subnational level offer a greater added value to the public health information systems. Identifying variations in health outcomes and disease burden across different regions is a key factor when introducing targeted interventions and allocating resources. Health inequalities persist also in countries with good health systems and well-developed welfare state. There are notable contrasts in the political, economic and social environments across Europe. Moreover, the European countries are at different stages of the epidemiological transition, which encompasses a range of factors influencing health and modifiable risk behaviours. These differences are determined by socioeconomic inequalities at national and sub-national level, such as municipalities, counties and others. It is therefore imperative to provide BoD indicators at the most possible detailed regional-level and to link this information with further indicators such as deprivation indexes or Gini coefficients. Obtaining regional-level data for BoD analysis and health inequalities is not straightforward and can pose many challenges. Data availability is usually scarce and may involve significant resources in collecting it. Data quality and data completeness can also pose challenges in the reporting systems, which can result in under-reporting of certain diseases and overlooking health problems in the population. Also, countries with smaller populations are confronted with the challenge of a limited number of cases, which poses difficulties in obtaining regional estimates. The following workshop presents examples from European BoD studies, that have analysed health inequalities at regional level. The first presentation shows a country comparison study of the overall YLL and their association with socioeconomic and geographical inequalities. The second is from an Estonian study, representing a country with a small population that has developed its own methodology for assessing regional health issues. The third presentation from the German BoD study presents results on 96 spatial planning regions, which have been combined with the German index of socioeconomic deprivation. The final presentation brings example from Norway, where the association between YLL and education and income is examined at municipality level.

Key messages:

- By comparing BoD estimates at the regional level, policymakers and public health officials can identify areas with higher disease burdens, indicating potential health inequalities.

- Linking information on BoD indicators with data on regional and socioeconomic inequalities is essential when monitoring developments and tailoring strategies in public health outcomes.

Background: Health inequalities have been linked to reduced life expectations. This study aimed to investigate regional variations in all-cause years of life lost (YLLs) in European Economic Area (EEA) countries prior to the COVID-19 pandemic.

Methods: Demographic data were extracted from Eurostat for 1390 small regions 32 EEA countries. Age-standardised sex specific YLL rates per 100,000 population in 2019 were estimated for EEA regions (Eurostat NUTS level 3) using methodologies derived from the Global Burden of Disease study. Relative spatial disparities were evaluated using the Gini coefficient (GC) and absolute spatial disparities assessed using the slope index of inequality (SII).

Results: Between EEA countries, relative geographical inequality in age-standardized YLL rates was higher than within them, slightly more so for males (GC = 16.96% [95% CI = 16.26-17.65]) than females (14.22% [13.62-14.82]). Among females, the UK (11.21% [95% CI 10.11-12.30]), Greece, and Croatia had the highest relative spatial inequality, while Ireland (3.37% [2.26-4.48]), Slovakia, and the Netherlands had the lowest. For males, Belgium (10.76% [9.34-12.17]), the UK, and Croatia exhibited the highest relative spatial inequality, while Ireland (1.99% [1.18-2.81]), Lithuania, and Slovakia had the lowest. Germany had the largest absolute geographical inequality in YLLs among females (SII=16.86% [16.28 to 17.44]), followed by Estonia and the UK. Among males, Estonia had the largest absolute spatial inequality (36.60% [-10.88 to 84.07]), followed by Latvia and Hungary. Ireland had the lowest absolute spatial inequality for both females and males.

Conclusions: Relative and absolute disparities in premature mortality rates are evident across regions of the EEA, both within countries and across the entire region. These findings offer insights for national and local stakeholders, aiding them in customising public health interventions to target spatial health disparities.

Abstract citation ID: ckae144.825
Addressing Regional Health Disparities: Estonia's Approach to Burden of Disease Studies

Maria Lepnurm

M Lepnurm[1], J Idavain[1]
[1]Department of Health Statistics, National Institute for Health Development, Tallinn, Estonia
Contact: maria.lepnurm@tai.ee

Background: Estonia, a small country defined by NUTS2 regions, faces challenges in assessing health disparities across its different counties when using global health data such as the Global Burden of Disease (GBD). Recognizing this limitation, Estonia initiated independent burden of disease studies in Estonia since 2013, with the findings being biennially published through the health statistics database of the National Institute for Health Development. The objective of this research is to assess the strengths and limitations inherent in various methods when calculating the years of life lost due to premature mortality (YLLs).

Methods: The approach to assess the burden of disease in Estonia differs somewhat from the Global Burden of Disease (GBD) methodology. One key distinction lies in our utilization of a national life expectancy table and our presentation of results at the LAU1 regional level. These burden of disease studies utilize region-specific life tables supplied by Statistics Estonia, categorized by county and gender, to compute Years of Life Lost (YLLs), offering an opportunity to pinpoint and tackle regional health issues.

Results: Since the calculation of YLL (Years of Life Lost) in these past studies has relied upon Estonia's regionalized life tables, categorized by county and gender, the results exhibit substantial disparities when juxtaposed with the Global Burden of Disease study conducted by the Institute for Health Metrics and Evaluation (IHME).

Conclusions: This research aims to delve deeper into these variations, examining the challenges related to methodology, the availability, and the quality of data, and most importantly, knowledge translation. Our own burden of disease studies empowers us to formulate informed policy recommendations precisely tailored to the distinctive needs of each county, thereby facilitating targeted interventions, and driving improvements in overall public health outcomes.

Burden of disease and socioeconomic deprivation in Germany – regional patterns and variations

Annelene Wengler

A Wengler[1], A Rommel[1], M Porst[1], J Leddin[1], A Anton[1], E von der Lippe[1]
[1]Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: WenglerA@rki.de

Within the scope of the BURDEN 2020 project (Burden of disease in Germany at the National and Regional Level) carried out by Robert Koch Institute (RKI) in collaboration with the German Environmental Agency and AOK Scientific Institute, burden of disease estimates for Germany and its regions become available for the first time. The national estimates of YLL, YLD and DALY are provided not only stratified by age and sex, but also by detailed regional level (96 spatial planning regions). The regional estimates provide valuable information and support the evidence-based decisions in health policies aiming at reducing the burden of disease in the country. To facilitate further the interpretation and usability of these estimates, the provided indicators were linked to the regional information on deprivation. For this purpose, the German index of socioeconomic deprivation (GISD) was used. The index was developed at the RKI and the last revised version was published in 2022. It is based on nine indicators which reflect the three subdimensions of deprivation: education, employment, and income. That is why GISD is a very suitable index for evaluating regional health disparities. Connecting both informations on BoD and deprivation, gives deeper insides in the regional differences within the country. Some diseases exhibit east/west differences, while others show north/south patterns or rural/urban distinctions. These differences reflect the variation in the prevention and health care needs for the

different diseases in Germany. The results underline the necessity to study the regional inequalities separately for each disease. Different health conditions are connected to variations in settings and outline different needs in intervention programs and allocation of means.

All-cause Years of life lost due to death at municipality level in Norway. Association to educational attainment and median income

Carl Baravelli

C Baravelli[1], *H Breivik*[1], *I Forthun*[1], *AK Skrindo Knudsen*[1], *TT Nguyen*[1]
[1]Norwegian Institute of Public Health, University of Oslo, Oslo, Norway
Contact: CarlMichael.Baravelli@fhi.no

Background: Norway, with 5.5 million people spread across 356 municipalities, has pursued an active policy to reduce social and geographical health inequalities. Despite, studies find significant health disparities linked to socioeconomic factors at the individual-level, although evidence at larger geographical-levels has been mixed. We used a key burden of disease (BoD) metric, Years of Life Lost (YLL), to examine spatial health inequities among Norwegian municipalities and their association with socioeconomic factors.
Methods: We analysed data from all residents in Norwegian municipalities with over 1000 inhabitants as of January 1, 2019. Data was sourced from the National Population Register and Statistics Norway. All-cause YLL were calculated based on age-specific aspirational life expectancy obtained from GBD 2019. Deprivation was measured using educational attainment and median income, categorized into quartiles. Geographical maps illustrating municipality-level all-cause age-standardised YLL rates for males and females were generated. Negative binomial regression models assessed associations between socioeconomic factors and YLL rates, adjusting for age, sex, and an index of centralisation.
Results: High-deprivation municipalities exhibited a 9% higher YLL rate in terms of education (Incidence Rate Ratio [IRR] = 1.09, 95% Confidence Interval [CI] = 1.01-1.17) and a 10% higher YLL rate in terms of income (IRR = 1.10, 95% CI = 1.02-1.08) compared to the least deprived, translating to absolute differences of 1391 and 1466 YLL per 100,000 population, respectively. Additionally, we discuss the potential expansion of this study to incorporate cause-specific outcomes and other BoD metrics based on previous county-level analyses.
Conclusions: Our study demonstrates the feasibility of using BoD methods to assess geographical deprivation and premature mortality at the municipality level, providing valuable insights for public health policy targeted at small administrative areas.

7.X.2. Planetary Health: metaphorical visualizations of transdisciplinary working in practice

Abstract citation ID: ckae144.828

Organised by: EUPHA-PHPP, -ENV, -HSR, EUPHAnxt, EHMA, WHO/Europe
Chair persons: Marleen Bekker (EUPHA-PHPP), Marija Jevtic (EUPHA-ENV)
Contact: marleen.bekker@wur.nl

Across public health and healthcare practices, we signal low awareness and little urgency for Planetary Health among health professionals as well as lacking or lagging implementation of planned policies. Planetary health requires a ‘just do it’ mentality with a transdisciplinary and reflection-in-action approach. There is a need for a bottom up movement, but HOW to get started and HOW to persevere against all odds? This 25 minute pecha kaucha session is aimed at facilitating transdisciplinary learning for planetary health action. We will start with a brief introduction to the concept of Planetary Health, followed by two short presentations on two metaphorical work processes underlying the startup of a flowering community garden and the preparations for a delicious Italian lasagna. The second half of the session is dedicated to a creative exercise with the audience, generating multiple metaphors in small groups using picture cards, paper drawings. We finalize this session by collaboratively building a visualised sea with transdisciplinary waves of metaphorical innovations that, instead of litter and pollution, make our beaches and shores stronger foundations protective of our planetary life.

Key messages:

- Planetary health requires a ‘just do it’ mentality with a transdisciplinary reflection-in-action approach.
- Metaphorical reasoning visualizes social reality and boosts Planetary health mentality, community spirit and transdisciplinary action.

Abstract citation ID: ckae144.829

Planetary health as a paradigm shift towards health and well-being

Marija Jevtic

M Jevtic[1,2]
[1]Faculty of Medicine, University of Novi Sad, NIJZ, Vojvodina, Serbia
[2]Environmental Health and Occupational Health Research Centre, Université Libre de Bruxelles, Brussels, Belgium
Contact: marija.jevtic@uns.ac.rs

Planetary health is a concept that focuses not only on human health but wider - on the health of our planet. Health is not only a privilege of human beings. Planetary health emphasizes the interconnected nature of human health and environmental health. This also makes a shift in the direction from human anthropocentricity to a more fair approach - health of the whole planet. Human well-being is dependent on the health of the planet, including clean air, water, and food sources. Paradigm shift towards planetary health promotes a holistic view of health that encompasses social, economic, and environmental factors. It considers the complex interactions between humans, animals, plants, and ecosystems. Planetary health insists on a preventative approach by addressing root causes such as pollution, climate change, and biodiversity loss. We should be aware of human responsibility linked to terrible symptoms of our Planet like heat waves, fires, droughts, floods... Planetary health approaches underline the importance of sustainable practices that protect the environment, promoting human health, but also actions to achieve that. By adopting sustainable lifestyles, industries, and policies, we can ensure the well-being of current and future generations. Planetary health calls for global collaboration, interconnecting nature, environment and human health challenges. By prioritizing planetary health, we show that we can be less selfish and that we respect nature and the environment. Planetary health insists on a paradigm shift towards a more integrated and sustainable approach using social and nature sciences in a holistic approach. But, we should also use Planetary health concept as a call for peace, which is a condition for all other achievements.

Abstract citation ID: ckae144.830
Community gardening: metaphorical reconstruction of transformative health governance

Marleen Bekker

M Bekker[1]
[1]Health and Society Group, Wageningen University, Wageningen, Netherlands
Contact: marleen.bekker@wur.nl

Transdisciplinary working has been defined by the inclusion of non-academic stakeholders in the process of knowledge production. While theoretical, phenomenological and experimental dimensions have been described in the literature, Rigolot proposes transdisciplinarity as a 'way of being' that stretches beyond professional life. The promise of transdisciplinarity however does not always meet the expectations in practice. How to get started, maintain and overcome barriers requires guidance. In an action-oriented evaluation research study we explored this dimension in the Dutch All about Health collaborative platform, which since 2014 facilitates a continuous development of bottom up health initiatives, networks, alliances and other forms of collaboration and learning. From our case studies we developed the Transformative Health Governance model. The model shows the ongoing and reciprocal connections between the actions, the context and intermediate results that were verified in a survey among 103 platform participants. Five types of returns are also building blocks that increase the chance of real (yet hardly measurable) increasing health benefits. They reinforce each other in a continuous process of ideation, integrative approach, innovation, implementation, and impact. The context provides for acceleration or deceleration of that process. With the help of a cartoonist we translated our model into an ongoing cycle of community gardening and maintenance. This metaphor makes the intangible of underlying social processes more tangible, providing a bit more grip on the building blocks, timing and time aspects, as well as deeper understanding the role and necessity of conflict and explicit conflict engagement rather than management. Moreover the cartoon elicits recognition, acknowledgement and spirit to continue their rowing against the systems-invoked tide for better health. It serves as a concrete aid to transdisciplinary working towards planetary health.

Abstract citation ID: ckae144.831
Applying a Planetary Health approach in the European urban context: Lessons from Preparing Traditional Lasagna

Chiara Cadeddu

C Cadeddu[1]
[1]Erasmus School of Health Policy and Management, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: cadeddu@eshpm.eur.nl

Lasagna is a quintessential Italian dish, renowned worldwide. The most traditional version is "alla Bolognese", which requires a complex preparation process involving careful attention to mixing ingredients and layering to achieve the final delicious result. The images depicting the preparation steps of this typical Italian dish will be used to inspire participants to creatively reflect on how to implement a transdisciplinary approach to address a planetary health issue, such as heatwaves, in a European urban context.

The presentation will be structured as follows: 1. Identification of current problems; 2. Stakeholder analysis; 3. Possible solutions; 4. Barriers and limitations.

The first phase will focus on selecting quality ingredients, analogous to analyzing the urban map of the city, the presence of green areas, identifying vulnerable residents, mapping transportation, etc. The second phase will identify all relevant stakeholders to be involved in creating transdisciplinary solutions for the city, paralleling the proper mixing of lasagna ingredients. The third phase will propose various solutions to be applied, taking into account the inputs and viewpoints of the involved stakeholders, showcasing best practices already adopted, and comparing them to different variations of lasagna alla Bolognese. The final phase will present barriers and limitations to implementing such an approach in a European urban context (e.g., costs, historical monuments, lack of stakeholder collaboration), drawing parallels to challenges in preparing lasagna, such as ingredient unavailability, oven issues, or overcooking. Through this original modality, participants will learn about the process of implementing a planetary health approach to one of the major climate change issues affecting the European landscape.

7.Y.1. Health Literacy in a multi-modal world: innovation challenges

Abstract citation ID: ckae144.832

Organised by: HeLiCA, EUPHA-HP, Freiburg University of Education (Germany), IPC of Coimbra (Portugal)
Chair persons: Luís Saboga-Nunes (EUPHA-HP), Sukran Peker (Türkiye)
Contact: saboga.nunes@gmail.com

Good Governance, Healthy Cities and Health Literacy (HL) (The Shanghai Declaration, WHO 2016) are presented as the three pillars of Health Promotion. In order to pursue these pillars as a global strategy to ensure that citizens can make healthy choices, there is a need to explore innovative ways that are accessible and affordable to all, that will ensure that all have the right to health. In this workshop five presentations will trigger a discussion that is proposed to be developed around the consequences of innovating from the health literacy perspective: Floriane Silvestri from Portugal, will focus on health literacy and health coaching as a node towards health promotion; Juliana Bertani from Basil will address Health literacy & somatic education from a salutogenic self-resource critical health intervention; Alcina Ilharco will focus on mental health and the health literacy of university students; Paula Vital will consider the role of social prescription multi-modal approach and Sukran Peker from Turkey will present a qualitative study of the relationship between health information and behaviors. The discussion that will follow these presentations is aimed at providing new perspectives on the topic of health literacy with participants interaction and networking.

Key messages:

- Innovative ways to bring health promotion into effectiveness needs to be established from health literacy focused initiatives.

- Salutogenesis is a structural paradigm to drive innovative mechanisms to help improve wellbeing and quality of life by health literacy innovative approaches.

Abstract citation ID: ckae144.833
Health coaching: the node of health literacy & health promotion

Floriane Silvestri

F Silvestri[1], *P Vital*[1], *L Saboga-Nunes*[2], *U Bittlingmayer*[2]
[1]HeLiCA, Portugal
[2]HeLiCA, Institute of Sociology, University of Education, Freiburg, Germany
Contact: florianesilvestri@esdrm.ipsantarem.pt

Introduction: To achieve sustainable health behaviors and outcomes to move from a precarious health situation to good health, people need to be supported in health literacy in behavior change that ensure interventions' success. As a non-clinical approach, health coaching aims to increase a person's levels of self-efficacy, confidence and resilience, by promoting the sense of coherence. This communication aims to identify the benefits that health coaching as a salutogenic approach can trigger.

Methods: The work is structured in a narrative review of literature and the lived experience of the authors in health coaching.

Results: The published research on health coaching and the systematic professional experience of the authors highlight: (1) the anchoring of health coaching in the salutogenic model and in the person-centered approach focused on individual characteristics and needs in driving healthy behaviors; (2) health coaching as a collaborative relationship with chronically ill people and people at risk of developing illness; (3) the role of health coaching as a sense of coherence (SOC) promoter; (4) health coaching as a new profession in the healthcare ecosystem (e.g. NHS, UK), cooperating with multidisciplinary teams.

Discussion: From A.Antonovsky's model approach to health, the SOC stands out and constitutes one of the basic theories in health coaching interventions, by strengthening the person's capabilities of comprehensibility, manageability, and meaningfulness. As an emerging profession, with ethical and a growing research foundation, it is facilitated by trained professionals in managing and monitoring health behavior change.

Conclusions: Health coaching aims to bring relevance, meaning and strategy to a person's behavioral change. Health coaching demonstrates positive effects on several health parameters by supporting the implementation of health literacy development and empowering people to trigger sustainable changes that lead to healthier lifestyles.

Health literacy & somatic education: a salutogenic self-resource critical health intervention

Juliana Bertani

J Bertani[1,2]
[1]Pontifical Catholic University of São Paulo, Sao Paolo, Brazil
[2]HeLiCA, Sao Paolo, Brazil
Contact: julianaabertani@gmail.com

Issue: Non-communicable diseases (NCDs), such as musculoskeletal conditions, cause severe functional limitations. Therapeutic practices in this field have employed a theoretical-practical framework with a pathogenic and mechanistic bias. However, the causes of these NCD's are also related to biopsychosocial factors. Therefore, a critical theoretical-practical approach, such as Somatic Education, becomes relevant as it introduces a subjective experience to an educational praxis, modifying the meaning processes in human movement experience in a complimentary approach to the pathogenic perspective.

Description of the problem: There is a perceptual poverty in movement experience, which dissociates doing from feeling. Somatic practices aim to foster movement awareness (perception) and autonomy (self-regulation), placing the individual as a valuable resource, strengthening the capacity for understanding, reflection and habitus change. This presentation will focus on the following research questions: Can Somatic Education, as a critical intervention of the body, contribute to increased levels of health literacy? Can somatic practices contribute to sustainable health development? Is it possible to create a new meaningful process in human movement experience through this practice incrementing its salutogenic emphasis?

Results/Effects: Somatic practices foster integrative approaches of health, promoting subjective bodily experience (interface between doing, thinking and feeling). Integrative progress can urge the embodiment of health literacy, encouraging more active and awareness of individuals related to their well-being, contributing to sustainable health development. Moreover, subjective bodily experience transforms the process of meaning in movement experience.

Lessons: Somatic practices enhance NCDs prevention and education, increasing health literacy rates through innovative conceptual foundations.

Abstract citation ID: ckae144.835
Promoting mental health in higher education students: a pilot study

Luís Saboga-Nunes

A Ilharco[1], *M Pocinho*[1], *L Saboga-Nunes*[1]
[1]Coimbra Health School, Polytechnique Institute of Coimbra, Coimbra, Portugal
Contact: saboga.nunes@gmail.com

Introduction: The mental health and well-being of higher education students is a relevant topic today, given the high prevalence of mental disorders and their increasing trend. Therefore, it is imperative to develop health education programs that aim to develop strategies to promote psychological well-being and reduce suffering in this population.

Objectives: To develop and implement a mental health promotion program, with interventions based on Yoga/meditation and Auriculotherapy, and evaluate its impact on the mental health of higher education students.

Methodology: Pretest-posttest design, with assessment before (T0), after the intervention (T1) and with a three-month follow-up (T2). Evaluation with the Portuguese version of the Mental Health Inventory (Pais-Ribeiro, 2001), and physiological assessment (heart rate, respiratory rate and blood pressure). 22 students participated in the intervention, randomly divided into two groups: Yoga/meditation group (GY) and Auriculotherapy group (GA), each with 11 students.

Results: The physiological parameters evaluated showed, in all sessions, a decrease in averages, regardless of the technique implemented. In the assessment at T0 and T1, it was found that there was a significant decrease in the Distress ($p = 0.037$) and Anxiety ($p = 0.031$) dimensions. In the evaluation over time (T0, T1 and T2), it was found, regardless of the technique implemented, that the intervention had a positive effect on the mental health of the students.

Discussion: The results point to the importance of developing mental health promotion programs in higher education.

Abstract citation ID: ckae144.836
Health Promotion and the case of social prescription of laughter

Paula Vital

P Vital[1], F Silvestri[2], L Saboga-Nunes[3]
[1]São José Local Health Unit, Hp, Lisbon, Portugal
[2]Rio Maior Sports School, Polytechnic Institute of Santarém, Santarém, Portugal
[3]HeLiCA, University of Education, Freiburg, Germany
Contact: apaulavital@gmail.com

Introduction: The use of laughter to change lifestyle and promote active and successful ageing is an area of interest within the scope of health promotion. The positive effects of laughter practices occur throughout the life cycle. That is why "laughing" has been identified and indicated as a human activity of social prescription promoting healthy lifestyles. This communication aims to (1) identify the benefits for health, health promotion, well-being, and healthy lifestyle of using laughter activities and practices, (2) identify "laughing" as a social prescription activity that promotes a healthy lifestyle.

Methods: This work is structured in a narrative review of the literature and the authors' lived experience as professionals in the well-being area.

Results: Studies show that laughing and using laughter-inducing approaches have immediate effects on the person who experiences them (e.g. increased general well-being, reduced cortisol levels) with benefits for the immune system and cardiovascular health. Daily practices that are structured and systematic interventions that induce laughter were revealed to have lasting and durable effects. Studies also highlighted the effectiveness of laughter and its important role in improving communication in healthcare professional-patient encounters.

Discussion: Several behaviors are associated with well-being, happiness and positive affect, but the one that is accessible to all people and with the most immediate effects is laughter. Daily practices, structured and systematic interventions that induce laughter are part of non-pharmacological approaches that promote health and well-being. The principles underlying laughter practices are aligned with the Sustainable Development Goals, namely goal 3 (Health), goal 4 (Education) and goal 16 (Peace).

Abstract citation ID: ckae144.837
Promoting health information and healthy behaviors: Results from a qualitative study

Sukran Peker

S Peker[1], A Topuzoğlu[2], S Hıdıroğlu[1], O Tanrıöver[3], L Saboga-Nunes[4], D Save[1]
[1]Department of Public Health, Marmara University School of Medicine, Istanbul, Türkiye
[2]FM, Izmir, Türkiye
[3]Department of Medical Education, Marmara University School of Medicine, Istanbul, Türkiye
[4]HeLiCA, University of Education, Freiburg, Germany
Contact: sukranpeker16@gmail.com

Background and aim: Healthy living behaviors can prevent many chronic diseases. This study aimed to explore qualitative perceptions and behaviors about healthy lifestyles in a district's residents.

Methods: This qualitative research was conducted through in-depth interviews with 24 participants aged 28 to 63 in Türkiye.

Results: Of the 24 participants, six were men. The themes were daily routines; health information-seeking behavior, beliefs, motivation for healthy living, dietary habits, daily movement, psychological relaxation, unhealthy behaviors, facilitators, and barriers. Individuals' daily routines were shaped by caregiving duties or work. Health information was preferred from professionals, TV, family health history, and the Internet. Male participants lacked the need to seek health information. Also, some participants believed that diseases are unavoidable and incurable. People with growing children or a family member with a serious illness like cancer often report practicing healthy behaviors. Participants have different healthy eating patterns, including organic eating, home cooking, regular meals, more fruits and vegetables, increased water intake, avoiding late-night eating, and steering clear of packaged foods, salt, and sugar. Many participants walked regularly for physical and mental health; they also expressed avoiding negative people and engaging in hobbies and social activities to maintain psychological well-being. Smoking participants had attempted to quit smoking. Some participants said that adding salt to their food before tasting. Factors cited as hindering healthy behaviors included lack of time, financial constraints, and cultural reasons.

Conclusions: Despite awareness of healthy living, many participants struggle to implement it due to lack of motivation, busy work schedules, social and physical environments, and economic factors. Multisectoral collaboration to create environments that support healthy behaviors can improve public health.

7.Y.2. Solidarity and public health teaching and practice in the age of new normal

Abstract citation ID: ckae144.838

Organised by: ASPHER
Chair persons: Nadav Davidovitch (Israel), Robert Otok (ASPHER)
Contact: nadavd@bgu.ac.il

This workshop will address the concept and topic of solidarity as it pertains to public health (PH). The objectives of the workshop are: • To explore what is understood by solidarity in the context of PH; • To consider the PH scenarios in which solidarity may be an important construct; • To consider how solidarity is understood by PH experts and practitioners, and • To profile investigate how solidarity is represented in educational and training programme in PH.

Solidarity is a social determinant of health. It is proven as a crucial factor in achieving PH objectives such as: compliance with vaccination campaigns; donations of bodily samples to biobanks; or refraining from polluting. It can be defined as a cost taken upon oneself for the sake of a group with which one identifies (Prainsack and Buyx 2017). As PH is about achieving health objectives through public participation, solidarity can be seen as the kernel of PH practice. In an era with emerging PH threats, from pandemics to climate crises, the importance of understanding the many meanings and uses of solidarity is essential to PH practitioners. There is much more in solidarity than meets the eye. Solidarity is largely a mystification of a collective identity, a boundary-making mechanism that draw the line between 'us' and 'them', and most importantly, it is the generator of what is understood as 'public'. Facing increasing challenges in PH, solidarity is a concept to be thoroughly apprehended. Is there one solidarity, or rather multiple solidarities? What are the referent publics of different solidarities and how do they interact?

Can be a global solidarity? Is solidarity a normative or descriptive concept? Is solidarity the outcome or the generator of pro-social behaviour. These are questions that will be discussed in this round table workshop session. Curious to learn about PH views on solidarity, we conducted structured interviews with PH experts to ascertain views on solidarity as a key concept in PH; whether the concept should be incorporated into PH education programme, and if so, how best to do that. Preliminary findings suggest that all interviewees agreed that solidarity is a key concept in PH but when asked to define solidarity, provided diverse answers. They acknowledged that solidarity should be taught in different stages of PH education, but admitted that it rarely appears in current curricula. Many interviewees stated that solidarity may be culturally and politically determined and should be discussed through case studies and guest lectures as well as theory. The added value of this workshop is to raise awareness about the importance of the concept of solidarity and its importance in PH education and training programmes. The workshop will run as a Round table discussion, in which each panellist will make a short presentation on a specific subject, which will then be discussed between panel members and audience.

Key messages:

- Solidarity is considered a key concept for the practice of public health, yet has been constantly contested as too vague and even too political.
- Presenting key challenges facing the teaching of solidarity as competence in public health; its conceptual ambiguities and cultural differences and the different uses of solidarity as a value and tool.

Speakers/Panelists:
Farhang Tahzib
Faculty of Public Health, Haywards heath, UK
Mary Codd
University College Dublin, Dublin, Ireland

9.X.1. Protecting the mental health of healthcare workers: evidence, policy and implementation challenges

Abstract citation ID: ckae144.839

Organised by: EUPHA-HCW, WHO Collaborating Center for Health Workforce Policies and Planning, European Observatory on Health Systems and Policies, WHO/Europe
Chair persons: Ellen Kuhlmann (EUPHA-HCW), Tiago Correia (Portugal)
Contact: e.kuhlmann@em.uni-frankfurt.de

Background: There is growing evidence that highlights increasing stress levels and declining mental health among the global healthcare workforce, exacerbated by challenges within workplace environments, labour market and policy frameworks. These conditions place additional strain on an already vulnerable healthcare workforce and consequently threaten the stability of health systems as a whole, given the escalating challenges in retaining, recruiting and reactivating healthcare workers. Although the problems are evident, awareness is increasing and international organisations such as the WHO have advanced policy recommendations, comprehensive and context-specific interventions effectively addressing these problems at varying levels are missing.

Objectives: This innovative workshop offers a platform for bridging the gap between research evidence and policy interventions, stimulating policy learning and knowledge exchange across countries. The session provides an overview of existing knowledge and engages representatives of academia as well as national policymaking, and international organisations to critically discuss challenges as well as good practice experiences with a focus on implementation and problem-solving. The following major questions will be explored: What evidence is available regarding the mental health and wellbeing needs of the healthcare workforce? How are different countries responding to these needs and supporting healthcare workers more effectively? What are some best practice cases focusing on improving mental health support for healthcare workers across various groups, considering diverse needs, gender-inclusiveness, and minority groups? Finally, how can evidence-based policymaking be improved, and how can the implementation of these policies be advanced in a more effective manner? Thesession will encourage critical debate and identify major policy recommendations, focusing on governance and implementation strategies. In the second half of the session, the panel will engage the audience in an interactive discussion to explore novel solutions that prioritise the wellbeing of healthcare workers and effectively address the healthcare workforce crisis in a more person-centred and 'humanised' manner. The workshop supports cross-country learning and networking opportunities.

Key messages:

- Mental health and wellbeing of the healthcare workforce is crucial for health system resilience and needs stronger advocacy for coordinated multi-level governance action.
- Establish a health system and governance approach together with comprehensive monitoring and qualitative comparative workforce studies to identify transformational policies in contextual settings.

Abstract citation ID: ckae144.840
Where should health system investments be made to protect the mental health of healthcare workers?

Gemma Williams

G Williams[1]
[1]European Observatory on Health Systems and Policies, London, UK
Contact: G.A.Williams@lse.ac.uk

Background: This study explores trends and work-related determinants of mental health and wellbeing among health and care workers in Europe since the COVID-19 pandemic. The aim is to determine where investments can best be made to protect and support mental health and wellbeing among health and care workers to improve retention and recruitment.

Methods: Data are analysed from the National Health Service staff survey in England and the Health Service Executive 'Your Opinion Counts' survey in Ireland to explore trends in mental health and wellbeing and burnout. Evidence is then taken from a series of

European Observatory policy briefs, based on expert-led literature reviews, to explore determinants of poor mental health and wellbeing and to identify potential areas for investment.

Results: Rates of burnout and poor mental health and wellbeing have increased in England and Ireland since the start of the pandemic among all professional groups. Workplace-based factors are important determinants of poor mental health and wellbeing, and can be grouped into: macro-level structural factors such as staff shortages, poor working conditions and low pay; meso-level organisational factors including poor leadership, and insufficient education, training and support; micro-level individual factors such as insufficient self-care or not seeking support. However, determinants at the micro-level, especially seeking support from others, are largely shaped by structural or organisational factors.

Conclusions: Increased financing to address structural and organisational determinants of mental health and wellbeing contributes to improved patient care, better staff experience, lower rates of absenteeism, and enhanced recruitment and retention. It is therefore one of the best health system investments that can be made.

Mental health support for healthcare workers: what is it about governance and policy implementation

Michelle Falkenbach

M Falkenbach[1], E Kuhlmann[2,5], MG Brinzac[3], T Correia[4,5], M Panagioti[6], M-I Ungureanu[3,5]

[1]European Observatory on Health Systems and Policies, Brussels, Belgium
[2]Institute for Economics, Labour and Culture, Goethe-University Frankfurt, Frankfurt, Germany
[3]Department of Public Health, Babeș-Bolyai University, Clu-Napoca, Romania
[4]IHMT, Universidade Nova de Lisboa, Lisbon, Portugal
[5]WHO Collaborating Center for Health Workforce, Lisbon, Portugal
[6]Division of Population Health, Health Service, University of Manchester, Manchester, UK
Contact: michfalk@umich.edu

Background: We adopt a health system and governance perspective to address the mental health needs of healthcare workers, considering the nature of interventions and the levels and actors involved in governance. The aim is to move the debate forward by identifying governance gaps hampering the implementation of health workforce policies and exploring strategies to effectively increase mental health support.

Methods: A qualitative comparative methodology is applied based on a case study design utilising a multi-level intersectoral governance matrix. The assessment matrix comprises four key categories: health policy and data, social policy and psycho-social conditions, organisation of work, and job and professional conditions. We conducted a rapid assessment of healthcare workforce developments in the European context, drawing on secondary sources and country experts. The country sample comprises Germany, Portugal, Romania, Switzerland and the United Kingdom.

Results: Awareness of mental health threats among healthcare workers increased, but policy discourse is driven by service delivery and labour market demands. The attention to healthcare workers' needs is stronger on the international level especially supported by WHO action, and weakest at national/regional levels. Although organisations and professions demonstrate varying degrees of activity, their efforts are scattered and lack sustainability. Similar challenges were identified across healthcare systems, including limited action, disconnected actors, missing coordination, and a lack of attention to governance gaps and system weaknesses.

Conclusions: There are similar problems across countries. Mental health policy is driven by labour market needs and ignores research evidence and the individual needs. Successful mental health policy implementation needs multi-level governance and coherent coordination mechanisms, and generally greater attention to the 'human side' of the healthcare workforce.

9.X.2. Activating the ASPHER-WHO Public Health Core Curriculum: Interprofessional Skills

Abstract citation ID: ckae144.842

Organised by: ASPHER, Faculty of Public Health (UK)
Chair persons: Alison Mc Callum (UK), Judit Simon (Austria)
Contact: alison.mccallum@ed.ac.uk

The updated ASPHER-WHO Public Health Core Curriculum builds on ASPHER's previous work on Competencies for Public Health Professionals (2006-2020), reflects the changing needs of our population and planet and public health professionals.

The key objectives of this workshop are to: - Share the updated ASPHER core curriculum for public health; - Illustrate examples of public health challenges that young professionals have championed for inclusion; - Share the Faculty of Public Health (UK)'s work on Fair training as a case study on operationalising public health leadership on equality, diversity and inclusion and demonstrating the core competencies in action.

A curricular content survey of member schools and programmes yielded responses from 60 schools, with > 500 submissions of detailed. subject curricula. These have been compiled into 36 Subject Areas in four Domains, namely: (1) Core Subject Areas in Public Health: (2) Subject-specific Areas in Public Health;(3) Core Cross-curricular Subject Areas; and (4) Core Interdisciplinary Professional Skills in PH. The development process was guided and grounded by the expertise and passion of young public health professionals. They are helping us make the core curriculum fit for purpose for the near future and provide them with the skills required to be a competent member of a supportive public health team in an ever changing world. This Workshop will profile selected Subject Areas from each Domain using real life challenges facing WHO European Region to show how the core curriculum integrates research, theory and practice to help build those essential interdisciplinary skills. The examples will focus on Economics in Public Health (Domain 1); Public Health and Criminal Justice; (Domain 2); Health Literacy and Infodemiology, Mental Health and Wellbeing (Domain 3); and Integrative Learning in Action; Communication Skills; Advocacy, Negotiation; Collaborations and Partnerships; and Leadership, Management and Implementation Science (Domain 4). Discussions for each of the Subject Areas will be led by an expert in the area. We will also illustrate an example of these competencies in action, how they are helping shine a light on the challenges we face in creating that supportive team and environment and how the potential for collaboration helps us to capitalise on the expertise available in some schools and programmes for the benefit of all.

Key messages:

- Learning interdisciplinary skills are essential for effective public health analysis, advocacy and action.
- Collaboration across countries, schools, professions and generations can create transformational change.

9.Y.1. Breaking down silos: Maximizing the impact of different EU funding schemes in health

Abstract citation ID: ckae144.843

Organised by: EUPHAnxt, EUPHA-PHMR, Sciensano (Belgium)
Chair persons: Nienke Schutte (Belgium)
Contact: Nienke.Schutte@sciensano.be

The European Commission (EC) has established various funding schemes to support large health initiatives, such as EU4Health, Horizon Europe, and Digital Europe. These initiatives aim to support research and innovation in order to tackle different health challenges faced by EU member states, improve the health and well-being in European citizens and invest in resilient health systems Funding can come in different forms such as grants, subsidies, loans, prizes, and procurements and is managed by different Directorates General of the European Commission. The EC offers a wealth of financial resources, enabling health scientists to conduct cutting-edge research. However, to make the full potential of the EC funding programmes it is essential to achieve interactions and synergies. Thematic interactions consider the underlying policies of specific actions, striving to connect projects focused on related topics rather than letting them work in isolation, and transferring results from one to another. Implementation interactions involve the sequential or cumulative funding of one or multiple projects. Moreover, the abundance of financial sources poses the possibility for duplication of efforts and redundancy among the various programmes. In addition, complexities in rules and guidelines pose challenges for researchers to fund their long term research projects through cumulative funding. To avoid redundancy and tackle health issues efficiently, it is essential to ensure collaboration and coordination across funding schemes to effectively address both overarching and specific health topics. The aim of this roundtable is to share with the audience the different funding mechanisms provided by the European Commission, explore barriers and challenges to fostering collaborative innovation through the funding programs, and demonstrate best practices for optimizing synergies across different programs. This round table gathers panelists from a variety of backgrounds covering the European Commission, national health institutes, NGOs and SMEs.

Key messages:

- The European Commission provides diverse and rich funding schemes supporting health research and innovation to tackle European health challenges.
- Complexities in rules and guidelines pose challenges and combined efforts of both the European Commission and research communities can foster collaborative innovation across the funding schemes.

Speakers/Panelists:
Jinane Ghattas

9.Y.2. Leveraging GenAI and Deep Learning for the Analysis of Public Health Data: A Global Perspective

Abstract citation ID: ckae144.844

Organised by: Conduent
Chair persons: Dianna Lydiard (USA), Tarun Khatri (Canada)
Contact: dianna.lydiard@conduent.com

The evolution from Artificial Intelligence (AI) to Generative Artificial Intelligence (Gen AI) represents a significant advancement in technological capabilities and applications. Advancements in computing power, algorithmic complexity, and data availability have enabled Gen AI to exhibit broader cognitive abilities such as reasoning, problem-solving, and learning across diverse domains. Private sector investment and innovation is advancing capability in this space at a rapid pace, trending toward a complete paradigm shift towards machines capable of autonomously adapting and learning in dynamic environments, promising profound impacts across industries from education and finance to healthcare and beyond. Yet harnessing the power of GenAI remains out of reach for most public health entities. Questions like “How to start” and “What to do”, let alone concerns regarding cost, security, and ethics, often thwart an agency from endeavoring to even begin their journey to the program improvement they visualize through the lens and promise of AI. Conduent’s longstanding presence and pioneering work in AI across various sectors, has led to a simple, underlying philosophy: we leverage Gen AI technologies to assist and enable humans to improve business processes. Instead of developing Gen AI technologies ourselves, we focus our efforts on making advanced technologies accessible to our clients and enabling them to achieve their outcomes.

This session focuses on accessibility and enablement for public health agencies looking to jump start their journey to AI and evolve their public health programs with the use of Gen AI, covering topics such as: • The evolution of GenAI in the private sector; • Visualizing objectives in public health outcomes and improved business processes; • What to do about data; • Using human intelligence to drive machine learning; • Managing security, ethics, and equity; • Roadmap your Journey to Gen AI.

For Conduent, Gen AI is not intended to replace humans but to harness its potential to support and empower humans in creating innovative, additive opportunities that enhance business process outcomes. In the public health space, its impact is immense and far reaching. Let's shift from "How do I start" to tackling the questions that improve programs and their outcomes. So how will you optimize your program with Gen AI? Let's get started.

Key messages:

- Private sector Gen AI capability is expanding at a rapid pace yet many public health agencies are struggling just to start. Conduent offers an informed perspective to jump start your Gen AI journey.
- Accessibility and enablement for public health agencies looking to jump start their journey to AI and evolve their public health programs with the use of GenAI.

Speakers/Panelists:

Mark Marostica
Conduent Public Health Solutions, Florham Park, USA
Dianna Lydiard
Conduent, Florham Park, USA
Tarun Khatri
Conduent, Burlington, Canada

10.X.2. Strengthening primary health care through best practice transfer: the CIRCE-JA approach

Abstract citation ID: ckae144.845

Organised by: CIRCE-JA Consortium, EC
Chair persons: Loukianos Gatzoulis (Belgium), Elena Petelos (EUPHA-HTA, EUPHA-GH)
Contact: anam.carriazo@juntadeandalucia.es

Primary health care (PHC) is a fundamental component of resilient, strong, and sustainable health systems. The main aim of PHC is to address people's health in a high-quality comprehensive system approach, ensuring person-centred and integrated care across their lifespan, which includes their physical, mental and social well-being. Following the COVID-19 pandemic, health systems' strengthening has become a global public health and European public health priority, and an overarching objective of the EU4Health programme. In Feb 2023, the three-year Joint Action on the transfer of best praCtices In pRimary CarE (CIRCE-JA) was launched. Its overall objective is to effectively transfer and implement six identified PHC best practices (BPs) across EU Member States (MS), with scientifically robust evidence-based approach, to ensure sound transferability methodology. Critically, it aims to increase MS capacity to deploy innovative care models in PHC and to effectively support health system transformation at this level of care. CIRCE-JA is a collaborative effort with 14 MS participating, bringing together 48 entities, to initially transfer the identified BPs into 42 new implementation sites, whilst at the same time generate all the necessary tools to facilitate uptake and evidence-informed decision-making across all MS. This implementation is based on the alignment of key BP characteristics to meet the local healthcare needs and priorities and match them with national and regional policies. It aims to facilitate integration of public health priorities to PHC practice, and to support the reorganization of services, for strong health promotion focus, synergies with community care, and better coordination of care. During this session key aspects will be discussed using the Pecha Kucha style, to inform the audience about current progress and CIRCE-JA using short stories, also on EU policies and priorities, and the EU4Health support for PHC and public health integration. What is urgently needed at EU-level when it comes to health systems' strengthening in the post-COVID-19 period and why is PHC critical in this respect? How can the CIRCE-JA developments inform the ongoing transfer and future efforts for the selected BPs in terms of a robust scientifically evidence-based approach? How does the policy dialogue CIRCE-JA is establishing locally, nationally, regionally, supports not only the JA's sustainability, but all future implementation efforts for PHC?

Finally, a brief interaction with the audience will take a place to allow attendees to discuss on key priorities and challenges in their own settings and practice, including the barriers and difficulties that they have initially identifies in the implementation efforts. The output of this interaction will also inform the initial steps towards the establishment of the final deliverable of CIRCE-JA, i.e., the European Primary Healthcare Observatory, to sit on the European Commission's Health Policy Platform.

Key messages:

- Health systems' strengthening necessitates strong PHC. CIRCE-JA delivers state-of-the-art tools and brokers policy dialogue to achieve it across Europe.
- Several barriers and issues that facilitate the transferring process have been identified in the first implementation of this European initiative.

Speakers/Panelists:

Christos Lionis
CSFM & HSR-PH Lab, Faculty of Medicine, University of Crete, Heraklion, Greece
Ana M Carriazo
Regional Ministry of Health and Families of Andalusia, Seville, Spain

10.Y.1. Energy poverty and public health: insights from the European WELLBASED project

Abstract citation ID: ckae144.846

Organised by: WELLBASED Consortium
Chair persons: Amy van Grieken (Netherlands)
Contact: a.vangrieken@erasmusmc.nl

Rising rates of energy poverty in Europe, affecting 11% of households, are a serious public health concern. Being unable to afford basic energy needs can impact both mental and physical health and well-being. The WELLBASED project is a European research project (grant no 945097) in which 19 partners across 10 countries develop, implement and evaluate comprehensive urban programs to tackle energy poverty. We aim to support public health practice by understanding determinants and impacts of energy poverty and develop solutions for policy and practice. This workshop's main aim is to engage the public health community in the relevance of energy poverty for public health. The workshop participants are introduced to the WELLBASED project and methods used. Two pilot sites will share their story about the implementation of the WELLBASED interventions. Next, findings from the evaluation of the programs on health, well-being and energy poverty across all pilot sites are presented. Implications for policy and practice are shared with the audience. After the workshop, participants are informed about the implications of energy poverty for health, understanding its relevance for public health action.

Key messages:

- The WELLBASED project provides a framework to fight energy poverty and promote health and well-being based on studies in six European cities.
- Energy poverty is a public health challenge that requires a health-in-all-policies approach with local evidence-based urban programs.

Abstract citation ID: ckae144.847
Valencia and the Right to Energy approach

Belen Costa Ruiz

B Costa Ruiz[1], A Zea[2], J Valls[2], N Garcia-Lepetit[3], P Jordá[2]
[1]Kveloce, Senior Europa S.L., Valencia, Spain
[2]Fundación València Clima i Energia, Valencia, Spain
[3]Las Naves Foundation, Valencia, Spain
Contact: bcosta@kveloce.com

Background: Valencian (Spain) vulnerable households are suffering both winter and summer energy poverty. An increasing number of families have difficulties paying energy bills and are being forced to cut consumption, consequently reducing their well-being and quality of life. This study presents the development and implementation of the Right to Energy urban program in the Valencia pilot city, as part of the larger European WELLBASED project.

Methods: The interventions were designed based on the social ecological model, aiming at impacting the different layers influencing individuals' health, following co-creation sessions with 6-9 stakeholders from policy, citizens and practice. Implementation efforts were monitored using administration of participation. The experience of the Energy Office was also valuable for the design and implementation phase.

Results: The program consisted of bill optimization and advice, socio-energetic audit at home and the installation of an efficiency kit. On top of that, the Valencia pilot has created the Citizen School for the Right to Energy [CSRE] to empower households and improve their health through education activities. In total, 130 vulnerable households with different profiles were supported. The CSRE has carried out 28 workshops to train people in energy and health topics: energy rights, healthy diet, mental health, sleep quality or preparation for heat waves. These were an opportunity to share experiences among participants, fighting stigmatization and isolation by creating a community. The CSRE has also organized capacity-building sessions for professionals who can identify energy poverty such as healthcare and social workers, teachers or NGO's.

Conclusions: Energy poverty, both winter and summer, is a major public health issue that impacts people's health. The CSRE is an innovative way to tackle it and promote the Right to Energy across society by supporting and training people to improve their wellbeing.

Abstract citation ID: ckae144.848
Transitions in heating systems and impact on perceived wellbeing: a qualitative study

Hande Barlin

H Barlin[1]
[1]Department of Economics, Gebze Technical University, Gebze/Kocaeli, Türkiye
Contact: hbarlin@gtu.edu.tr

Background: as part of the larger European WELLBASED project an urban program focusing on transitions in heating to tackle energy poverty, is implemented in 4 disadvantaged, predominantly Roma neighborhoods of Edirne, Türkiye. These neighborhoods have high levels of vulnerability, aid dependency, and energy poverty. This study investigated the impact on perceived wellbeing of implementing the heating system transition.

Methods: A qualitative methodology was applied; data was collected through semi-structured in-depth interviews among participants in the intervention group of the larger WELLBASED evaluation study. Diversity was ensured regarding gender, age, education level, and working status. Participants were 13 individuals from 13 households in which energy-efficient heating systems were installed. Interviews were audio-recorded, transcript verbatim and coded; thematic analysis was conducted.

Results: 3 main themes and 7 sub-themes (st) emerged in the preliminary analysis with regard to impact on well-being: perceived changes in living conditions (st: physical changes, financial implications, domestic burden), perceived effects on health (st. mental health, physical health), and expectations versus reality (st. insulation, efficiency). Experiences differed as per housing condition, type of energy used, usage proficiency, and income level.

Conclusions: Energy efficient heating system transition to tackle energy poverty at homes may not be sufficient to realize impact on perceived wellbeing. Housing conditions (ie. insulation), supported energy sources and management of expectations need to be considered as part of the program.

Abstract citation ID: ckae144.849
Impact of the WELLBASED urban programs on health, well-being, and energy poverty

Amy van Grieken

A van Grieken[1], M Stevens[1], B Costa-Ruiz[2], JJ Martínez[3], M Barbagelata[4], A Pilotto[4,5], J Redon[6]
[1]Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

[5]Department of Interdisciplinary Medicine, University of Bari Aldo Moro, Bari, Italy
[6]INCLIVA, Valencia, Spain
Contact: a.vangrieken@erasmusmc.nl

Background: The WELLBASED project developed and implemented urban programs across six pilot sites to tackle energy poverty. This study aimed to evaluate these programs' effectiveness on a broad range of health, well-being, and energy poverty indicators.
Methods: a controlled study was performed in six European pilot sites. Participants in the intervention condition receive the 12-month WELLBASED urban program. Participants were recruited via different methods and provided informed consent to participate in the 18-month study. Self-report questionnaires were completed at baseline, 6-, 12 and 18 months in both research conditions. In the intervention group, monthly health monitoring of e.g. heart rate and blood pressure, and continuous monitoring of indoor CO2, temperature and humidity were performed. Descriptive statistics and regression analyses are performed to assess the impact of the urban programs on health, well-being and energy poverty-indicators
Results: In the baseline sample ($n = 1350$; $n = 661$ intervention group, $n = 689$ control group) the mean age was 49 years (SD 16), 15.6% was >65 years, 65% were women, and 42% was married. At baseline people reported not feeling comfortable warm in winter (58%) or cool in summer (70%), 43% reported damp or leak. Preliminary findings at 6-month follow-up indicate changes in HR-QoL, subjective well-being and depression/anxiety differ strongly per pilot site location ($p < 0.01$). In summer 2024 all data will be available for analysis.
Conclusions: the comprehensive urban programs developed in the WELLBASED project may support public health to tackle energy and improve health and well-being of vulnerable citizens.

10.Y.2. Unlocking innovation: trustworthy co-creation for tackling complex public health challenges

Abstract citation ID: ckae144.850

Organised by: Health CASCADE
Chair persons: Vinayak Anand-Kumar (Germany), Sebastien Chastin (UK)
Contact: danielle.agnello@gcu.ac.uk

Background: Public health interventions often have limited effects, with few achieving large-scale implementation. Moreover, these interventions frequently fail to replicate their effects in real-world settings, possibly due to an overemphasis on generating universal knowledge through theory building and testing in controlled conditions. An alternative approach involves developing interventions within specific contexts, fostering collaborative knowledge generation, and establishing equitable partnerships. Co-creation offers a transformative strategy for addressing complex public health issues by generating real-world solutions. However, utilizing co-creation in public health presents challenges, including a lack of guidance on implementation and evaluation in public health settings. This underscores the need to integrate real-world co-creation with rigorous research to establish a reliable methodology grounded in both scientific evidence and participatory principles.
Workshop: This Pecha Kucha-style workshop will explore the essence of an evidence-based co-creation methodology developed through rigorous research by the European-funded H2020 Marie Sklodowska-Curie Innovative Training Network, Health CASCADE, and its partners. Emphasizing the significance of fostering innovative solutions to public health challenges, the workshop will provide key considerations for designing co-creation projects. It will also examine the role of enabling technologies in optimizing hybrid intelligence for effective co-creation, highlighting their contribution to collaboration enhancement. Perspectives from co-creators will be presented to offer unique insights into their experience of the co-creation process. Additionally, the workshop will elucidate the adaptation of co-creation processes within the Danish context, exploring collaborative efforts across sectors and shedding light on cross-sectoral cooperation intricacies. A moderated panel discussion will conclude the workshop, facilitating deeper engagement with the presented topics. Delegates will gain insight into applying co-creation in health promotion and behaviour change research, navigating prevalent challenges through Health CASCADE's systematic approach, and discovering strategies for fostering effective and inclusive co-creation. They will also acquire strategies and resources to overcome potential obstacles, fostering more effective and inclusive approaches to complex public health challenges.
Key messages:
- Co-creation presents a powerful approach to addressing complex public health challenges by fostering collaboration, creativity, and inclusivity across diverse stakeholders and communities.
- Effective and trustworthy implementation of co-creation requires an understanding of its principles and methods, enabling technologies, and strong partnerships across sectors and institutions.

Abstract citation ID: ckae144.851
Co-creation in public health: innovations and considerations

Danielle Agnello
School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
Contact: danielle.agnello@gcu.ac.uk

Danielle will delve into the essence of co-creation and its application in navigating the complexities of public health challenges. Delegates will gain insights into how co-creation fosters innovative solutions and discover key considerations essential when designing co-creation projects. Join us to explore the transformative potential of co-creation in addressing the pressing issues of public health.

Abstract citation ID: ckae144.852
Harnessing technology for co-creation: maximizing the collaborative potential

Quentin Loisel
School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
Contact: quentin.loisel@gcu.ac.uk

Quentin will introduce the role of enabling technologies in maximizing hybrid intelligence for effective co-creation. This presentation sheds light on how technological advancements, particularly artificial intelligence, shape the co-creation landscape, emphasizing their pivotal contribution to enhancing collaboration. Through Quentin's insights, delegates will understand how technology can optimize the co-creation process, facilitating communication, data integration, and collective problem-solving. Explore the transformative power of technology in driving innovative co-creation initiatives and unlocking new possibilities for collaboration in addressing complex challenges.

Abstract citation ID: ckae144.853
Navigating co-creation dynamics: lessons from Denmark

Knud Ryom
Department of Public Health, Aarhus University, Aarhus, Denmark
Contact: knudryom@ph.au.dk

Knud will delve into the adaptation of co-creation processes within the Danish context. Drawing from extensive experience Knud will explore collaborative initiatives with both the private/civil sector and municipalities, offering insights into the intricacies of cross-sectoral cooperation. Delegates will gain valuable perspectives on navigating diverse stakeholders and fostering effective partnerships in co-creation endeavours. Don't miss this opportunity to learn from Denmark's innovative approach to collaborative problem-solving and community engagement.

Abstract citation ID: ckae144.854
Voices from the co-creators: perspectives on collaborative innovation

Lauren McCaffrey
School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
Contact: lauren.mccaffrey@gcu.ac.uk

Lauren will offer firsthand accounts from co-creators in Scotland involved in the development of an intervention targeting sedentary behaviour in adults. This presentation provides a unique insight into the co-creation process, highlighting the collaborative journey, challenges encountered, and successes achieved. Don't miss this opportunity to explore real-world experiences and lessons learned from those immersed in the co-creation of interventions.

5. Poster Walks

1.R. Poster walk: Public health policy and politics

Abstract citation ID: ckae144.855
Social Cohesion in Different Periods of the Pandemic: What Works in Reducing COVID-19 Mortality

Ying-Chih Chuang

Y Chuang[1]
[1]School of Public Health, Taipei Medical University, Taipei, Taiwan
Contact: yingchih@tmu.edu.tw

Background: Inconsistent results were reported regarding the effects of social cohesion dimensions on COVID-19 mortality rate (MR). Most studies have indicated that trust in civil services, but not participating in social activities, reduces COVID-19 MR, possibly because of the highly contagious nature of this disease. In this study, we investigated how the effects of various dimensions of social cohesion on COVID-19 MR vary across different phases of the pandemic.

Methods: This longitudinal study was conducted using data from 86 countries that participated in the 2017-2020 World Values Survey. The measures of social cohesion were identified by aggregating survey responses to the country level. COVID-19 MR was calculated-using data from the European Centre for Disease Prevention and Control-separately for three distinct periods during the pandemic (January 2021-June 2022). A factor analysis was conducted to identify the dimensions of social cohesion, and negative binomial regression models were constructed to analyze data for each period.

Results: The factor analysis revealed three dimensions of social cohesion: social participation and inclusion, health service equality, and trust in civil services and democracy. Our findings suggest that each dimension of social cohesion uniquely affected COVID-19 outcomes in different periods of the pandemic. Trust in civil services and a positive attitude toward democracy are strongly associated with a low COVID-19 MR. However, this association was observed only in the early and middle stages of the pandemic. By contrast, our study demonstrated that in the late stage of the pandemic, increased social participation and inclusion helped combat COVID-19.

Conclusions: This study underscores the importance of collective cohesion and solidarity in mobilizing public responses against pandemic situations. This study emphasizes that preventive or regulatory interventions should be tailored to different phases of a pandemic.

Key messages:

- COVID-19 mortality rate was negatively associated with trust in civil services during the early two periods and with social participation and social inclusion during the late period of the pandemic.
- This study emphasizes that preventive or regulatory interventions should be tailored to different phases of a pandemic.

Abstract citation ID: ckae144.856
15 years of the Colorrectal Cancer Screening Programme. Decreasing inequalities

Isabel Idigoras Rubio

I Idigoras Rubio[1,2], *I Portillo*[1,2], *I Sainz de Rozas*[1], *M Ijalba*[3], *D Aguilar*[3]
[1]The Basque Health Service, The Basque Health Department, Bilbao, Spain
[2]Health Research Institute, Biobizkaia, Barakaldo, Spain
[3]OSI Ezkerraldea Enkarterri Cruces, The Basque Health Department, Barakaldo, Spain
Contact: isabel.idigorasrubio@osakidetza.eus

Background: The Colorectal Cancer (CRC) Screening Programme approved in 2008 by the Regional Parliament and carried out in 2009 a pilot study inviting to residents 50-69 years old (586,700), through a biennial Faecal Immunochemical Test (FIT), colonoscopy in FIT positive. The Programme Coordinating Centre sends FIT by post and involves Primary Care and Endoscopy departments in process and results control. In 2013, 100% coverage was reached, and in 2023 more than 80% were invited more than 6 times. However, inequalities in participation were detected: by age, gender, deprivation and vulnerability. Since 2014, different strategies have been carried out in order to decrease with the commitment of authorities, researchers and associations.

Objectives: To describe strategies and results to decrease inequalities in participation

Results: From the pilot participation rate increased ($p < 0.001$) 58.1% to 72.0% in 2023. Inequalities by gender (69.4 men vs

74.4% women) and deprivation index were detected (55.7/1000 lower vs high 41.0/1000). The non-adherence to colonoscopy was 5% along the period. Training, and communication campaigns developed. 2016-2017 special recruitment for imprisoned and mental health patients increasing participation rate (9.3 to 97.1%). In 2021 and ongoing: thanks to Resilience Funds (European Union), strategies were implemented: SMS specific by sex, research health literacy, studying CRC behavior by sex in FIT sensitivity 85.4% (CI95% 84.2-86.7) in men and 80.9% (CI95% (79. -82.6) in women $p < 0.001$

Conclusions: The governance and involvement of professionals, researchers and patient associations crucial to decrease inequalities. The Basque Programme achieved one of the highest participation rate. Investment in reducing barriers will probably impact on the reduction of incidence and mortality.

Key messages:

- A population based CRC Screening Programme reduces incidence and mortality on participants.
- Intervention to increase participation reduces inequities and is crucial on Public Health policies.

Abstract citation ID: ckae144.857
About the need for a Swiss digital health 'Sistine Chapel' – lessons from 25 years of health policy

Federica Zavattaro

F Zavattaro[1,2], F Gille[1,2]
[1]Digital Society Initiative, University of Zurich, Zurich, Switzerland
[2]Implementation Science in Healthcare, University of Zurich, Zurich, Switzerland
Contact: federica.zavattaro@uzh.ch

Background: The Swiss government's 'DigiSanté' program 2025-2034 aims to address Switzerland's delay in digitising its healthcare system. Public and professionals' trust is central for the implementation of digital health initiatives and partially based on past experiences with the digital health system. To inform DigiSanté, it is crucial to analyse the evolution of the socio-political discourse surrounding health data sharing in Switzerland in the past 25 years to identify the main obstacles encountered and lessons learned during this period.

Methods: We designed a multi-method study comprising a policy analysis of 65 Swiss policies on health data sharing from 1998 to 2023; scoping review of 250 editorials; sentiment analysis of 400 news articles from six major Swiss newspapers; and thematic analysis of transcripts from 11 online interviews with key stakeholders.

Results: We identified 32 key policy milestones in Swiss health data sharing, with the COVID-19 pandemic emerging as a trigger for present policymakers' awareness of health data's potential and the need for healthcare system digitization. The troubled implementation of the Electronic Patient Dossier (EPD) and its negative narrative are identified as more central in eroding long-term public trust than scandals. Primary obstacles to implementation of the EPD include misaligned stakeholders' interests, slow policy processes, lack of professional support, low public awareness, and technical interoperability issues. Future strategies involve increasing actors' involvement to establish a common vision and strategy and improving public communication.

Conclusions: The present socio-political discourse on health data sharing in Switzerland is shaped by past negative experiences with the EPD, compounded by additional scandals. To cultivate public trust, stakeholders should collaborate to align interests and ensure all parties work cooperatively toward common goals.

Key messages:

- National and international scandals marginally affect public trust compared to the impact of the negative narrative surrounding the slow EPD implementation.
- Misalignment of stakeholder interests is the main barrier to implementing health data sharing initiatives, causing delays and trust erosion.

Abstract citation ID: ckae144.858
Changing the environment: Removing HFSS items in prominent areas of stores in Nottinghamshire

Olivia Brown

O Brown[1,2], T Langley[1,2], R Murray[1,2], I Bogdanovica[1,2], M Bains[1]
[1]Population and Lifespan Science, University of Nottingham, Nottingham, UK
[2]Spectrum Consortium, Edinburgh, UK
Contact: Olivia.brown1@nottingham.ac.uk

This study examines the change in exposure to high-fat, salt, or sugar products (HFSS) after the implementation of a policy restricting the placement of HFSS items in prime locations in England that came into legislation in October 2022. 132 observations were conducted in 2022 and 2023, using a food environment survey. Supermarkets (SM), chain convenience stores (CSS), and independent convenience stores (ICS) were observed in the highest and lowest socioeconomic districts (SED) in Nottinghamshire. Descriptive statistics were used to analyse changes in exposures in prime locations by product category, the policy's inclusion criteria, the Food Standard Agency's Nutrient Profile Score (NPS), and the Nova classification. Exposure defined as is the presence of a product at a prime location in stores. A decrease in exposure to restricted products in both SED in SM and CCS was observed. No notable changes were observed in the ICS due to their exemption from the policy. In all SM, the observed exposure to products restricted by the policy was reduced from 39% to 14%. The study found that the policy was successful in reducing exposure to high-sugar products such as biscuits and chocolate. NPS and NOVA showed that exposure rates were notably higher in less healthy and ultra-processed food (UPF) categories compared to the exposure to products restricted due to the policy's exemption criteria. Exposure to alcohol products increased after the policy's implementation, with a 20-percentage point increase in alcohol exposure in all SM checkout areas. The study suggests that the policy may have narrowed the differences in environments between the SEDs, highlighted by the findings in the ICS, whereby exposure to less healthy products was higher in the lower SED. The policy also created an opportunity for the alcohol industry to increase its exposure. Shortfalls in the policy's design were identified through the use of the NPS and Nova classification system.

Key messages:

- Despite the equitable outcomes in socioeconomic districts, loopholes in policy design allow the alcohol industry to exploit prime locations and undermine health objectives.
- Policy success is evident in HFSS reduction; however, continued exposure to HFSS items exempt from the policy, and UPF products highlight policy design flaws that undermine health objectives.

Abstract citation ID: ckae144.859
Tobacco Industry CSR activities in Poland between 2020-2023

Paulina Dera

P Dera[1,3], M Banach[2], J Majchrzak[2], Ł Balwicki[3]
[1]First Doctoral School, Medical University of Gdansk, Gdansk, Poland
[2]Faculty of Medicine, Medical University of Gdansk, Gdansk, Poland
[3]Department of Public Health and Social Medicine, Medical University of Gdansk, Gdansk, Poland
Contact: poldera@gumed.edu.pl

Background: The tobacco industry has undergone a significant transformation in its approach towards Corporate Social Responsibility (CSR) activities. Once primarily associated with controversy and criticism due to the health risks associated with tobacco consumption, many tobacco companies have begun to embrace CSR initiatives as a means to mitigate these concerns and demonstrate their commitment to broader societal well-being.

Methods: Methods were based on the Global Tobacco Industry Interference Index. Between 1 January 2020 and 31 March 2023 scoping review of legal basis, Polish media websites, Polish government and local government websites, also social media of tobacco industry companies has been done by four reviewers searching separately.

Results: Between 2020 and 2023 several tobacco companies supported public schools (organized workshops, offered internships, and demonstrated the production processes). In 2022, the National Revenue Administration signed an agreement with Philip Morris Polska, among other companies, under the Cooperation Program. The objective of the Program is to initiate collaborative measures that promote compliance with tax regulations. At the end of 2021, the National Revenue Administration took patronage over the Business Center Club social campaign entitled 'Coming together to fight the illicit trade in tobacco products'. Moreover, in March 2023 the General Police Headquarters started cooperation with BAT and JTI in the field of combating illegal production and trade in tobacco products, as well as disclosing and eliminating tobacco products from illegal sources from economic circulation.

Conclusions: In Poland, which currently has no specific regulation constraining tobacco industry lobbying, implementation of the provisions of WHO FCTC Article 5.3 is needed to limit interactions between the government and the tobacco industry. Government and public schools should not accept any support from the tobacco industry.

Key messages:

- The government should have regulatory measures to manage its interactions with the tobacco industry, emphasizing the importance of refraining from accepting industry assistance.
- Implementation of WHO FCTC Article 5.3 of is needed to limit interactions between the government and the tobacco industry.

Review of national rare disease strategies: innovation driving change

Valerie Power

V Power[1], *M Norris*[1], *D Swanton*[1], *E Reidy*[1,2], *S Spillane*[1], *M Ryan*[1,3], *M O'Neill*[1]

[1]Health Technology Assessment Directorate, Health Information and Quality Authority, Dublin, Ireland

[2]School of Pharmacy, University College Cork, Cork, Ireland

[3]Department of Pharmacology and Therapeutics, Trinity College Dublin, Dublin, Ireland

Contact: vpower@hiqa.ie

Background: A rare disease affects fewer than 5 in 10,000 people. More than 6,000 known rare diseases affect up to 6% of the European population. A national rare disease strategy sets out a country's plan to reduce disease burden and improve quality of care for people with rare diseases. This review, requested by the Department of Health in Ireland to inform a new national strategy, described national rare disease strategies in 13 selected countries.

Methods: Strategies published from 2013 to 2023 were identified via online searches for Austria, Australia, Denmark, England, Finland, France, Germany, Ireland, the Netherlands, Northern Ireland, Portugal, Scotland and Wales. National representatives were contacted to confirm the identified resources. Data were extracted for the domains of: aims, priorities, implementation, governance and funding models. Descriptive analysis and narrative synthesis was undertaken.

Results: Improving treatment and coordination of care was a common overall aim. Priorities noted in all strategies were: screening and diagnosis; access to healthcare and coordination of services; rare disease research; and patient representation and empowerment. Implementation details varied to reflect the national context and time of strategy development. More recently-developed strategies included more precise actions and greater emphasis on innovations in genomics than older strategies. Strategies were developed, implemented, monitored and evaluated via combinations of newly-established bodies and or existing health authorities. Six countries did not specify a funding model or dedicated budget for strategy implementation.

Conclusions: National rare disease strategy contents and implementation approaches varied between countries and reflected innovations over time. This review will inform the development of Ireland's new national rare disease strategy.

Key messages:

- This review provided insights into national rare disease strategies over a 10-year period.
- The findings will inform strategy development in Ireland, and are relevant to other countries.

[3]Institute of Health, Institute of Virology, Charité-Universitätsmedizin Berlin, Berlin, Germany

[4]Department of Culture, Media and Psychology, Macromedia University of Applied Sciences, Frankfurt, Germany

Contact: theresa.dicks@unimedizin-mainz.de

Background: The SARS-CoV-2 pandemic required rapid and effective policy responses from governments worldwide, especially in the realm of public health. Due to the global impact of the pandemic, it is important to compare country-specific approaches. A systematic analysis of the role and institutionalization of different bodies of scientific policy advice during the pandemic was conducted to gain insights into scientific policy advice structures and to inform future solutions.

Methods: We contacted the governments of 35 democratic countries about the role and institutionalization of bodies of scientific advisory advice during the pandemic. Data collection took place between September 2023 and March 2024. We analyzed primary data provided by the governments by qualitative systematic document analysis.

Results: We received feedback from 25 countries within the research period (including 19 European countries). The results were divided into three main categories: (1) temporality, (2) structure, function, & composition, and (3) transparency. Further sub-categories emerged that helped to compare and classify the countries' approaches, such as initiation, financing, selection, expertise, and diversity of members, systematics of documentation. For example, some used existing structures from ministries, research institutions or the private sector while others were entirely newly established. National bodies of scientific policy advice mostly developed ad hoc, were temporary, and showed several differences between countries.

Conclusions: Different types of bodies of scientific policy advice were identified in terms of e.g. initiation, function, expertise, and

institutionalization. The results demonstrate a significant variation regarding the role and impact of scientific policy advice during the SARS-CoV-2 pandemic. Our study can help to identify essential aspects of scientific policy advice and to formulate recommendations for future health crises.

Key messages:
- The innovative methodological approach and the data which was collected from 25 countries give new insights into an important field of research.
- National bodies of scientific policy advice mostly developed ad hoc, were temporary, and showed several structural differences between countries.

Abstract citation ID: ckae144.862
Factors for sustainable cross-sector collaboration for health equity: a Dutch qualitative study

Celeste Coolen

CM Coolen[1], YMR Vendrig-de Punder[1], C Hugen[1], M Jambroes[1], CBM Kamphuis[2], E Ruijer[3]
[1]Global Public Health and Bioethics, UMC Utrecht, Utrecht, Netherlands
[2]Interdisciplinary Social Science, University of Utrecht, Utrecht, Netherlands
[3]Utrecht School of Governance, University of Utrecht, Utrecht, Netherlands
Contact: c.m.coolen@umcutrecht.nl

Background: Cross-sectoral collaboration between healthcare and the social domain is necessary to address the complexity of health inequity. However, this collaboration is often unsustainable in the long-term, for example due to temporary budgets and professionals changing jobs. We explored the factors that facilitate or restrain sustainable cross-sectoral collaboration by applying an interdisciplinary theoretical lens combining insights from relevant frameworks from governance, interprofessional learning and health policy. Following, we applied the framework in an 'Integrated Community Approach' in two Dutch cities (Utrecht and Amersfoort).

Methods: A qualitative research was conducted, involving 32 semi-structured interviews with professionals involved in an 'Integrated Community Approach' in the two Dutch cities in 2022 and 2023. Participants worked at various levels of the municipality, or as a local professional in the medical or social domain in the community. Thematic analysis and a deductive approach were employed- based on the theoretical framework.

Results: We identified nine components as important for sustainable cross-sectoral collaboration. Whether these components acted as facilitator or barrier varied between participants, depending on their position and organizational context. The nine components could be summarized into three main mechanisms: 1) the foundation for collaboration, which is dependent on having a shared vision and the competencies to engage residents; 2) a pre-condition, which is having support at management level and having the right resources; 3) support, which is provided by data and flexibility.

Conclusions: Long-term cross-sectoral collaboration is important, complex and depends on various interconnected factors. To improve cross-sectoral collaboration in the long term, it is necessary to disentangle each theme and conduct in-depth analysis of each one individually to facilitate deeper understanding of the context and problem.

Key messages:
- Collaboration between medical and social sectors is challenging, yet significance is clear. While the start is evident, sustaining the 'how' is unclear.
- The opportunities and obstacles of cross-domain collaboration vary among stakeholders, influenced by both their organization and position within it.

Abstract citation ID: ckae144.863
The impact of tobacco retailers density reduction on smoking status of Belgian adults

Sarah Croes

S Croes[1], L Guariguata[1], B Devleesschauwer[1,2], V Gorasso[1]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Ghent, Belgium
Contact: sarah.croes@sciensano.be

Background: Smoking being one of most impactful risk factors for causing non-communicable diseases (NCD) and consequently attributable death, represents an enormous public health issue. New policy interventions aimed at reducing smoking prevalence are planned in the Belgian Tobacco Free Generation plan. Within the plan, it is aimed to reduce the number of outlets that sell tobacco products, as a higher tobacco retail density (TRD) is believed to be linked to higher smoking prevalence. Using health impact assessment (HIA), this study aims to evaluate the policy before it is set in place.

Methods: For this intervention a 17% reduction in density was estimated according to the scoping review would be associated with an 0.39 percentage point reduction in prevalence. The Potential Impact Fraction (PIF) was calculated to assess the change in proportion of current smokers. Time series and projections of the Belgium Health Interview Survey provided data on the smoking status from 1997 untill 2040. The relative risk were retrived from the Global Burden of Disease 2021 study. Using data from the Belgian Burden of Disease Study, the avoidable burden was estimated.

Results: The policy is expected to reduce the density by 17 % by 2025, which results in a PIF for lung cancer of 0.92%, decreasing to 0.82% in 2040. The smoking prevalence would decrease from 12.62% to 12.23%. We estimated that this intervention would avoid the burden of more than 300 lung cancer cases and around 100 deaths in 2040.

Conclusions: The HIA in this study suggests that reducing TRD has a potential to contribute to achieving the objectives in Tobacco Free Generation plan. However, it should be noted that the impact is rather small, lower than 1% for most diseases. In addition, the actual impact may vary depending on the specific implementation of the policy and future smoking trends. Further research is needed to refine the effect size estimate based on the actual policy intervention details.

Key messages:
- Reducing tobacco retail density can reduce the burden of smoking.
- Modeling limitations need further research to refine HIA results.

Abstract citation ID: ckae144.864
Strengthening public health professionals in policymaking in the Eastern WHO European region

Julian Hein

J Hein[1,3], M Verschuuren[1], E Aragon De Leon[2]
[1]EUPHA
[2]Country Health Policies and Systems, WHO/Europe, Copenhagen, Denmark
[3]Health & Society Group, Wageningen University, Wageningen, Netherlands
Contact: julianhein@gmx.de

Background: The collaborative research between EUPHA and WHO aimed to explore factors impacting public health professionals' (PHP) involvement in health policy processes in the Eastern WHO European Region, addressing barriers, enablers, and capacity-building needs.

Methods: Utilizing a mixed methodology, the study employed document analysis, scoping review, and interviews to triangulate data, with the document analysis focusing on 4 published Essential Public Health Operations Self-Assessment Reports, the scoping review analysing 15 key articles, and 5 semi-structured interviews providing additional insight from key country stakeholders.

Results: Core findings revealed significant barriers impeding PHPs' participation in policy processes. Among others, these included limited intersectoral collaboration, shortage of skilled public health (PH) personnel, financial resource constraints and inadequate governance structures. Conversely, several enablers were identified, such as a positive trend in increased intersectoral collaboration and innovative governance structures during Covid-19, the development of more trained PHPs and the utilization of International Health Organisations. The two main capacity building needs reported were the importance of modernizing PH education and promoting intersectoral collaboration.

Conclusions: This study offers a preliminary overview of how PHPs' involvement in health policy processes in these countries can be enhanced: More intersectoral collaboration, updated PH education curricula and trainings, and governance re-design building on positive trends seen during the pandemic. Following actions are recommended: Creation of an international platform for cross-sectoral PH communication & exchange, direct support for universities and PH researchers, development of comprehensive PH trainings, assistance in forming or strengthening national public health associations and identification & sharing of effective local governance practices.

Key messages:

- This research identifies barriers to PHPs’ participation in Eastern WHO European Region's health policy processes, while highlighting enablers like increased collaboration during Covid-19 to build on.
- Recommendations to harness the enablers include clear actions such as creating an international public health platform for interaction and exchange or build-up of national public health associations.

Abstract citation ID: ckae144.865
Decision-making under pressure: ethical considerations in COVID-19 policy making in Switzerland

Caroline Brall

C Brall[1]
[1]Ethics and Policy Lab, MCID, University of Bern, Bern, Switzerland
Contact: Caroline.brall@unibe.ch

Background: Policy making and science were deeply intertwined during the COVID-19 pandemic, particularly in justifying health policy measures with ethical considerations being at the core of decision-making trade-offs. However, not much is known about the actual ethical challenges encountered by policy makers and scientists involved in policy advice. This study aims to explore the ethical challenges in COVID-19-related political decision-making as perceived by Swiss policy makers and scientists involved in policy making, the role of ethics advice, and what can be learned for future public health crises.

Methods: Thirteen qualitative expert interviews were conducted with policy makers and scientists involved in COVID-19 policy decisions in Switzerland at regional and national levels. We used inductive thematic content analysis to analyse the interviews.

Results: Key ethical challenges included making trade-offs between common vs. individual good and economic welfare vs. health of the population, proportionality of policy measures, and public capacity to handle uncertainty. Opinions varied on the sufficiency of ethical considerations on the policy level. Constraints included a lack of time in the fast-paced dynamic of the pandemic, ethics as a complex subject area, its overlap with law, too much focus on few topics such as vaccination-related questions, and individual character traits, such as the dominance of medical professionals over ethicists. While ethics support was deemed adequately present in the decision-making process, there were calls for more ethics training, involvement of the public in the discourse, and for accompanying communication to build trust among the population for the future.

Conclusions: The study offers empirical insights into the ethical considerations of COVID-19 policy making in practice in Switzerland, providing a basis to enhance ethics support for future crises also in other countries.

Key messages:

- This study uncovers the key ethical considerations in Swiss COVID-19 policy making, emphasizing constraints to sufficient ethical discussions.
- Enhanced ethics training and greater public engagement is needed in future health crises to build trust and improve decision-making in future health crises.

Abstract citation ID: ckae144.866
Heterogeneous courses of cardiovascular disease incidence in Europe 2000-2019 – what are the causes?

Susanne Stolpe

S Stolpe[1], *S Stolpe*[1]
[1]Centre for Clinical Epidemiology, University Hospital Essen, Essen, Germany
Contact: susanne.stolpe@uk-essen.de

Background: Data from the Global Burden of Disease (GBD) project distributed by the Institute for health metrics and evaluation (IHME) include incidence and prevalence data for almost all countries in the world. In course of own research, the data on cardiovascular disease (CVD) incidence in Western European countries were analysed and revealed great variation in the course of CVD incidence, that is difficult to interpret. We want to present the different courses of CVD incidence for selected countries and discuss possible reasons for this diversity with the audience.

Methods: GBD data on CVD incidence and mortality for 25 European countries from 2000-2019 for men and women were to graphically display courses of CVD incidence for visual analysis.

Results: The course of CVD incidence in Western Europe is country-specific - and, within a country, even sex-specific. Yet, in many countries besides the Baltic states and Czechia, CVD incidence reaches a minimum in 2010, increasing afterwards again. Different patterns of incident courses were visible:

a) wave-shaped courses which increase e.g. in Austria, Belgium, France and in males in Finland only, but decrease for both sexes Germany, Norway, Portugal and Poland, and in males in Denmark

b) u-shaped courses in Spain, Great Britain, France, Italy, and for Finnish and Dutch females

c) linearly increasing for both sexes in Czechia, the Baltic states and in Swiss males

d) linearly decreasing for women Norway, Belgium, Denmark and Austria.

Conclusions: The patterns of CVD incidence in Europe are multitude and country-specific even between sexes, reaching a minimum in 2010 in most countries. The validity of analyses combining these different patterns for regional analyses of CVD incidence such as in GBD reports do not take account for this diversity. Unless these differences can be explained by country-specific prevention or risk factor profile, the validity of data on CVD incidence seems to be limited.

Key messages:

- CVD incidence in Europe between 2000 and 2019 is country-specific changing and very heterogeneous.
- Analyses summarizing data for (Western/Eastern) Europe will miss this heterogeneity and might come to invalid conclusions regarding the development of CVD incidence.

Abstract citation ID: ckae144.867
Knowledge, attitudes and practices of Italian general practitioners on food supplements

Diana Menis

M Driutti[1,2], *F Cozzarin*[2], *S Celotto*[3,4], *L Arnoldo*[2,5], *L Brunelli*[2,5], *D Menis*[2]
[1]SOC Istituto di Igiene ed Epidemiologia Valut, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy
[2]Dipartimento di Medicina, Università degli Studi di Udine, Udine, Italy
[3]Medico di Medicina Generale, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy
[4]Società Italiana di Medicina Generale, Florence, Italy
[5]SOC Accreditamento, Qualità e Rischio Clinico, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy
Contact: menis.diana@spes.uniud.it

Background: Food supplements are widely used, but they can be dangerous if used inappropriately, as they often interaction with patients' treatment. Their misuse has public health and patient out-of-pocket expenditure implications; general practitioners (GPs) play a central role in managing patient safety. This study aims to investigate the knowledge, attitudes and practices (KAP) of Italian GPs' toward the use of food supplements.
Methods: From March to April 2024, an online survey was conducted via the EU-Survey platform among Italian GPs invited through their professional organization. The 62-question survey, adapted from a tool used among pharmacists, comprises two sections: A) KAP questions (28 true/false, 34 on a 5-point Likert scale) and B) socio-demographic questions (i.e. age, sex, years of experience, urban/extra-urban environment). Survey reliability was evaluated using Cronbach alfa and responses were analysed to look for differences between sub groups using Kruskal Wallis Test.
Results: 202 GPs participated in the survey, 46.0% were male, 53.5% female and 0.5% non-binary, with a mean age of 47±2 years. The majority (70.3%) came from an urban environment and 54.9% worked in group medicine. Only 53.5% of GPs showed an adequate knowledge of the topic (more than 60% of correct answers), with a mean of 18 correct answers. The overall reliability of the test was evaluated as acceptable (alfa>0.7). The 99.5% of GPs interview agreed (score 4 or more on the Likert scale) that they have an important role in food supplements prescription and 98% are involved in life styles counselling activities, but only 66.3% felt they have adequate formation on the topic. No statistically significant differences between population groups were found ($p < 0.05$).
Conclusions: Although GPs have recognized their key role in prescribing food supplements, there seem to be a general lack of knowledge on the subject that requires targeted educational interventions to ensure patient safety.
Key messages:

- Food supplements are often taken by patients because they are under the impression that these products are always and completely safe.
- Clinical recommendations for the use of food supplements are much more limited than their actual use.

Abstract citation ID: ckae144.868
A Delphi method approach to consensus - based translation of 'Second Victim' definition into German

Hannah Roesner

H Roesner[1,2], *V Klemm*[1,2], *R Strametz*[1,2]
[1]RheinMain UAS, Wiesbaden, Germany
[2]Wiesbaden Institute for Healthcare Economics and Patient Safety, Wiesbaden, Germany
Contact: hannah.roesner@hs-rm.de

Background: Healthcare providers involved in unanticipated adverse patient events, unintentional healthcare errors, or patient injuries, and who become negatively impacted, are defined as 'Second Victims'. The term Second Victim has gained substantial attention since its inception around 2000, yet lacks a standardized definition in the German context. This study addresses this gap by proposing a consensus-based translation of the term into German, aiming to foster understanding and facilitate research comparability.
Methods: A Delphi method approach was employed, engaging a panel of German-speaking, clinically and scientifically active Second Victim experts. The study was conducted using an online survey and commenced with the reference of the consensus- and evidence-based definition from the European Researchers' Network Working on Second Victim (ERNST) published in 2022.
Results: Nine out of eleven invited experts participated in the study, contributing to a robust consensus-building process. Through three Delphi rounds, a consensus rate of 90% was attained for the translation of the international definition of a Second Victim. The resulting definition provides a comprehensive understanding of the term within the German context.
Conclusions: This Delphi study establishes a formal consensus among recognized experts, delivering a German-language, evidence-based definition of the term Second Victim. It serves as a crucial foundation for understanding and further researching the Second Victim phenomenon within the German-speaking healthcare community.
Key messages:

- Consensus-based German translation of Second Victim enhances clarity in healthcare discourse.
- Delphi method with German experts yields unified definition, promoting the coherence of patient safety research.

Abstract citation ID: ckae144.869
Does staffing impact health and work conditions of staff in long-term care homes?: a scoping review

Michaella Miller

M Miller[1], *P Hopwood*[1], *P Haghighi*[1], *E Littler*[1], *A Davis*[1], *Y Al Momani*[1], *E MacEachen*[1]
[1]University of Waterloo, Waterloo, Canada
Contact: m29mille@uwaterloo.ca

Background: Long-Term Care (LTC) homes are highly regulated and task oriented, with demanding work and insufficient resources. Chronic underfunding of the sector, coupled with increased complexity of care, has deteriorated working conditions, resulting in precarious employment, intensified and stressful work, and decreased job satisfaction. These work conditions have contributed to severe staffing shortages of healthcare workers globally. To meet increased labour demands, OECD countries on average will need to increase the proportion of overall employment dedicated to LTC by 32% over the next decade. While reviews of literature have examined the association between staffing and care outcomes for residents in LTC, they have not examined how staffing structures affect the healthcare staff themselves. This scoping review asks: How does staffing impact the health of staff and working conditions in LTC?

Methods: A scoping review of empirical peer reviewed and grey literature was conducted to examine the association between LTC staffing practices and how they impact working conditions and the health and well-being of staff. PubMed, CINHAL, and Scopus databases were searched for relevant articles published within the past 10 years.

Results: Searches yielded 3994 unique articles, which were independently screened by pairs of reviewers. Preliminary results highlight that staffing levels are not optimized for healthy, sustainable work conditions. The level of staff, their skill mix, and ratios all impact the ability to provide care. In circumstances where there is inadequate staffing, care workers are more likely to experience stress, burnout, job dissatisfaction, and increased injury and illness.

Conclusions: Staffing practices shape working conditions which impact healthcare workers own health outcomes. To facilitate a strong LTC workforce, working conditions and occupational health need to be a priority in improvement initiatives.

Key messages:

- With extreme staffing shortages challenging the healthcare sector, this review highlights the need for heightened attention to the impact of staffing practices on the healthcare workforce.
- Improving working conditions and attuning to the needs of the workforce, ultimately improves quality of care.

Abstract citation ID: ckae144.870

Assessment of adults' misconceptions for Human papilloma virus through development of an instrument

Selva Dilan Golbasi Koc

SD Golbasi Koc[1]*, D Oktar*[1]*, E Salis*[1]*, S Metintas*[1]*, MF Onsuz*[1]
[1]Public Health Department, Eskisehir Osmangazi University, Eskisehir, Türkiye
Contact: selvadilangolbasi@gmail.com

Background: Misconceptions, myths, and conspiracy theories surrounding Human papilloma virus (HPV) are prevalent and diverse. To comprehensively address these misconceptions about HPV, the HPV Misconceptions Scale (HPV-MS) was developed and implemented, which supports public health initiatives aimed at combating HPV-related diseases.

Methods: This methodological and cross-sectional study collected data from May 2 to June 28, 2022, involving two sequential participant groups, starting with 150 and expanding to 471 individuals. The survey, which collected demographic data, HPV-MS responses, variables thought to be associated with HPV-MS scores, and knowledge levels using the HPV Knowledge Scale (HPV-KS), was distributed via social networks and analyzed using SPSS and JASP.

Results: The HPV-MS, which includes 26 items and explains 46.8% of the variance, demonstrated substantial reliability with a Cronbach's alpha of 0.691. The scores ranged from 2 to 20, with a median score of 14. Higher HPV-MS scores, indicating fewer misconceptions, were associated with younger age, higher education levels, absence of a family history of cervical cancer, and greater knowledge about HPV. Analysis revealed that HPV-KS scores were significant predictors of HPV-MS outcomes, even when controlling for other variables.

Conclusions: HPV-KS scores significantly predicted HPV-MS outcomes, highlighting the importance of knowledge in reducing misconceptions. Additionally, the HPV-MS effectively identifies widespread misconceptions about HPV, which is crucial for designing targeted educational measures. The wider use of this tool could help refine strategies to address HPV-related misconceptions across diverse populations.

Key messages:

- HPV-KS scores were significant predictors of HPV-MS outcomes, even when controlling for other variables, highlighting the importance of knowledge in reducing misconceptions about HPV.
- The HPV-MS effectively identifies widespread misconceptions about HPV, which is important for designing targeted educational measures.

Ready or not? The state of emergency preparedness among Italian Public Health medical residents

Nunzio Zotti

N Zotti[1]*, S Guicciardi*[2]*, F Di Serafino*[1]*, R Mimmo*[3]*, A Sanna*[4]*, G Granvillano*[5]*, A Iagnemma*[6]*, C Rizzo*[1]*, S Tafuri*[7]*, WG*[8]
[1]Translational Research and NTMS, University of Pisa, Pisa, Italy
[2]Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy
[3]Public Health Science, University of Turin, Turin, Italy
[4]Post Graduate School of Public Health, University of Siena, Siena, Italy
[5]Medical and Surgical Sciences, University of Catania, Catania, Italy
[6]Life, Health and Environmental Sciences, University of L'Aquila, L'Aquila, Italy
[7]Interdisciplinary of Medicine, University, Bari, Italy
[8]Medical Residents' Council, Italian Society of Hygiene, Preventive Medicine and Public Health, SItI, Italy
Contact: nunzio.zotti@gmail.com

Background: Italy frequently experiences major events like earthquakes, floods, and migrant shipwrecks, reflecting global concerns that also include climate change, pandemics, and wars. This study aims to assess the role of public health experts and the current state of Italian post-degree Public Health schools in addressing these challenges.

Methods: In June 2023, a cross-sectional online survey was administered to all Italian Public Health residents enrolled in the Italian Society of Hygiene, Preventive Medicine, and Public Health (SItI). The survey investigated the availability and frequency of training and updates related to emergencies, measured the interest and perceived importance of these topics among residents, examined the impact of the COVID-19 pandemic on their awareness, and identified their primary sources of information in the subject.

Results: Out of 289 respondents, a significant majority (86.2%) acknowledging the importance of being trained in emergency management and 74.4% expressed interest in topic ($p < 0.001$). A 90.1% of residents indicated a lack of dedicated courses and 93.1% reported an absence of specialized master's programs ($p < 0.001$). There was a strong correlation between recognizing the importance of the topic and the desire to attend specialized conferences ($p < 0.001$). The COVID-19 pandemic had a noticeable impact: 24.6% recognized the importance of the topic pre-pandemic, while 50.9% raised awareness during ($p < 0.001$).

Conclusions: The findings highlight a critical gap in the training of public health professionals in Italy, particularly in the domain of emergency preparedness and management. There is a pressing need to establish enhanced, uniform training programs across different public health training networks in Italy. Implementing such programs would ensure a more robust and effective response to future emergencies, thereby safeguarding public health and improving outcomes during crises.

Key messages:

- Significant gap in specialized training and awareness among health professionals.
- Urgent need for emergency preparedness training in public health.

Abstract citation ID: ckae144.872
How do palliative care clinicians use their emotions during end-of-life encounters?

Katrien Moens

K Moens[1]*, J Bilsen*[2]*, S Zambrano*[1]
[1]Institute of Social and Preventive Medicine, Universität Bern, Bern, Switzerland
[2]Mental Health and Wellbeing Research Group, Vrije Universiteit Brussel, Brussels, Belgium
Contact: katrien.moens@unibe.ch

Background: Palliative care clinicians are regularly exposed to emotionally laden end-of-life care situations. Until now, the use of their emotions during palliative care consultations has remained understudied. We aimed to develop a theory to understand how palliative care clinicians use their emotions.

Methods: Qualitative data were collected via individual interviews held with different types of palliative care clinicians across the world (countries were selected based on their Quality of Death Index ranking). We used a social constructivist grounded theory approach to analyze the data using a constant comparative method.

Results: We held interviews with 21 palliative care clinicians (5 nurses, 11 physicians, 2 psychologists, and 3 social workers) from 10 different countries. Fourteen were female. Participants' average age was 46 and they had 14 or more years of palliative care experience. The mean length of the interviews was 52 minutes. The process of using emotions could be characterized as follows: first, a difficult end-of-life encounter (e.g. ethical dilemmas or conflicts) would trigger a strong emotion in clinicians. Second, clinicians become aware of the specific emotion via its physical or psychological cues. Third, an assessment of the appropriateness of the use of the emotion follows, in which facilitators and barriers (e.g. the level of emotion skills, the view on emotions, or the feeling of safety in the team) interplay, influencing the clinician to act upon a specific emotion or not. Finally, with a specific intent (e.g. to build connection, stimulate patients and relatives to express their feelings, or clarify a point of view) the clinician shares, shows, or expresses the emotion.

Conclusions: We found that the strong emotions clinicians experience can be used as a valuable resource to provide palliative care. We also identified key steps to aid clinicians reflect on the appropriateness of using certain emotions in patient care.

Key messages:

- Palliative care clinicians' emotions can be considered as tools to support palliative care provision.
- The developed theory shows potential to explore its applicability in other professions that are also regularly confronted with emotionally charged situations.

Abstract citation ID: ckae144.873
Incentives to attract and retain physicians to underserved areas - a case study from Portugal

Sara Alidina

S Alidina[1]*, I Fronteira*[2]*, J Cortes*[2]
[1]Human Resources Management for Health, Central Administration of the Health System, Lisbon, Portugal
[2]Comprehensive Health Research Centre, NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
Contact: salidina@acss.min-saude.pt

Issue: Physician shortages in underserved areas are a common challenge for governments and policymakers worldwide, including in Europe. Meanwhile, a knowledge gap exists on effective measures to address the issue.

Description: According to WHO Europe, one of ten actions to strengthen the healthcare workforce is to develop strategies to attract and retain health workers in rural and remote areas. Portugal faces geographical asymmetries in the distribution of physicians, and difficulties in retaining them in certain areas of the country. This case study seeks to describe and analyse the impact of an incentives package introduced in 2015 that aimed to attract and retain physicians in underserved areas. Financial incentives data was gathered via a national health human resources information system. Non-financial incentives data was reported by health institutions through an online form. Document analysis was conducted to understand the scope of the incentives package and its amendments.

Results: The incentives package implemented in Portugal effectively deployed physicians to underserved areas, since it led to a fourteen-fold increase in physicians settling in underserved areas. In terms of retention, an average of 59% of the physicians that took up the incentives package are still practicing in the same underserved area. However, the difference between the retention levels of physicians under the incentives package and those not covered is minimal. To further reduce health inequities and achieve universal health coverage, a need exists to review the financial and non-financial incentives to better suit physicians' needs and expectations, as well as those of the National Health Service.

Lessons: The incentives package introduced in Portugal makes it clear that flexibility in the design of attraction and retention measures is crucial. It requires a long-term commitment and a recognition that each intervention should be assessed and adapted to local circumstances and context.

Key messages:

- The incentives package introduced in Portugal attracted physicians to underserved areas and led to a fourteen-fold increase in physicians settling in underserved areas.
- More than half of the physicians are still practicing in the same underserved health institution but the difference in retention against those not covered by the incentives package is minimal.

Abstract citation ID: ckae144.874
Strengthening the quality of primary healthcare services and interdisciplinary collaboration

Cecilie Nørby Lyhne

C Lyhne[1]
[1]Public Health, Aarhus University, Department of Public Health, Aarhus, Denmark
Contact: cnth@ph.au.dk

Background: Political organisations stress the need for preventive strategies to reduce the amount of avoidable hospital admissions, i.e. admissions that could have been avoided given timely and adequate care in the primary healthcare setting. Interdisciplinary collaboration has been suggested as a means to prevent hospitalizations, but effective implementation remains a challenge. Thus, there is a need for evidence-based strategies to prevent avoidable admissions and support interdisciplinary collaboration. The aim was to develop an evidence-based framework for preventive and coordinated interventions strengthening the quality of primary healthcare services and supporting interdisciplinary collaboration.

Methods: The project consists of three sub-studies: 1) a mixed methods systematic review following the JBI methodology; 2) a focus group study with primary healthcare providers in the Central Denmark Region, including general practitioners, physiotherapists, occupational therapists, home care providers, registered nurses and nurse specialists; and 3) a study using participatory design, where a framework for coordinated interventions were developed based on the results from study 1 and 2, supported by all stakeholders.

Results: Findings suggest that some hospitalizations can be prevented by intervening on mental factors, e.g., through trustful relations, and social factors, e.g., living situation. Also, a strong collaboration between healthcare providers from different disciplines and healthcare services is needed to improve the care pathway and prevent hospitalization. The collaboration may be strengthened if the health providers share a common language regarding the citizens' health status.

Conclusions: Stakeholders at all levels should be informed about the relevance of considering mental, social and physical factors to improve the quality and responsiveness of primary healthcare services and to develop initiatives to support interdisciplinary collaboration.

Key messages:

- By focusing on the whole person, it could be possible to provide more person-centred care through interdisciplinary collaboration and ultimately to prevent some admissions.
- Well-established primary healthcare services are important to provide person-centred care through interdisciplinary collaboration.

Abstract citation ID: ckae144.875
Interaction between alcohol intake and employment status changes on mortality among young workers

Heejoo Park

H Park[1], *B Yun*[2,3], *J Oh*[1], *J Sim*[2], *J Lee*[1], *J Yoon*[2,3,4]

[3]Institute for Occupational Health, Yonsei University College of Medicine, Seoul, South Korea
[4]Institute for Innovation in Digital Healthcare, Yonsei University Health System, Seoul, South Korea
Contact: hjpark106@yuhs.ac

Background: To investigate the impact of changes in employment status and their interaction with alcohol consumption on health outcomes among young workers. This study aims to explore how employment fluctuations, periodic unemployment, and economic activity levels influence the health of economically active individuals, focusing particularly on the synergistic effects that these employment changes may have when combined with alcohol consumption.

Methods: We conducted a retrospective cohort study using data from the Korean National Health Insurance Service database. The study included individuals aged 25-44 years who underwent health check-ups between 2009 and 2010. We categorized changes in employment status into three groups: continuously employed, economically active with employment fluctuations, and periodically unemployed. We estimated adjusted hazard ratios and 95% confidence intervals using multivariable Cox proportional hazard models to assess the impact of changes in employment status on the risk of all-cause mortality. The relative excess risk due to interaction, a widely accepted indicator of additive interaction, was used to assess the interaction between alcohol consumption and changes in employment status.

Results: Changes in employment status significantly increased the risk of all-cause mortality in both men and women in the economically active with employment fluctuations and periodically unemployed groups compared with the continuously employed group. The synergistic effect of alcohol consumption and changes in employment status on the risk of all-cause mortality was significant only among men.

Conclusions: The findings of this study indicate that changes in employment status, particularly when combined with alcohol consumption, significantly affect all-cause mortality among young workers.

Key messages:

- Employment status fluctuations combined with alcohol consumption significantly increase all-cause mortality risks among young workers, especially men.
- This study emphasizes the urgent need for targeted interventions that address the combined impact of employment and lifestyle factors on public health.

Abstract citation ID: ckae144.876
Future proof competencies for nurses working in primary care; a mixed methods study

Renate Wit

RF Wit[1,2], *K de Groot*[1,3], *EHML de Bruijn*[1], *RS Batenburg*[1,2], *AL Francke*[1,4]
[1]NIVEL, Utrecht, Netherlands
[2]Department of Sociology, Radboud University, Nijmegen, Netherlands
[3]Thebe Wijkverpleging, Tilburg, Netherlands
[4]Department of Public and Occupational Health, Amsterdam University Medical Centre and Vrije Universiteit Amsterdam, Amsterdam, Netherlands
Contact: r.wit@nivel.nl

Background: Healthcare services, also those provided by nurses, are challenged by the increasing care demands of an ageing population and people with chronic conditions. To improve care efficiency and quality, now and in the future, nurses must have competencies regarding self-management support of patients, electronic communication, preventive care, and engaging relatives in care. This study aimed to assess primary care registered nurses' (RNs) time allocation to these competencies and their perceived needs for further development of these competencies.

Methods: A mixed methods design was used, involving a nationwide survey ($n = 303$) and focus groups (12 participants), both with RNs working in community care services or general practitioners (GPs) practices. Survey data were analysed descriptively, and focus group transcripts underwent qualitative thematic analysis.

Results: The majority of RNs invest significant time in client self-management support (90%), preventive care (82%), and involving relatives in care (74%). RNs also recognized an increasing demand for these competencies in the future and the need to motivate patients and relatives to self-manage their health. Furthermore, RNs reported that competencies regarding electronic communication skills will become extra important in the future, yet currently only 37% dedicate substantial time to this. RNs face challenges in effectively utilizing electronic communication with patients and thus need opportunities to improve digital skills. Additionally, RNs desire enhanced collaboration with other healthcare professionals, such as GPs and medical specialists.

Conclusions: RNs' limited time allocation and perceived inadequacy in electronic patient communication, underscore the importance of targeted training in this area, and prioritizing this by healthcare organizations. In addition, fostering collaboration between nursing staff and other healthcare professionals could support future proof nursing in primary care.

Key messages:

- Nurses demonstrate resilience in addressing healthcare challenges, emphasizing client care, prevention and family engagement.
- Training nurses in competencies for electronic communication with patients is essential to meet the anticipated increase in demand for this aspect in their practice.

Abstract citation ID: ckae144.877
Let's Get Walking: Establishing Workplace Walking Groups in a regional Public Health Department

Ciara Kelly

C Kelly[1], *G O'Kane*[2], *D Edwards*[2], *J Lee*[2], *D McCrossan*[2], *L Smith*[2], *W Farmer*[3], *C Conlan*[2], *U Fallon*[2], *F Cooney*[2]
[1]National Health Service Improvement, Public Health, HSE, Dublin, Ireland
[2]Department of Public Health HSE Dublin and Midlands, Dr Steevens' Hospital, Dublin, Ireland
[3]Trinity College Dublin, Dublin, Ireland
Contact: kellyc42@tcd.ie

Maintaining staff health and wellbeing (HWB) is an ongoing priority for the Department of Public Health HSE Dublin and Midlands (PHD). This is particularly important in the context of an ongoing programme of reform for Public Health in Ireland. To support this priority, in November 2023 a pilot Workplace Walking Groups initiative was established to increase workplace physical activity and build team relationships. The initiative was designed following staff feedback on team HWB initiatives in September 2023. The Model for Improvement (which includes the Plan-Do-Study-Act cycle) was used to take a structured quality improvement approach to the development and evaluation of the 4-week pilot, led by the PHD HWB Committee. Staff joined across 3 sites. Lunchtime walks were arranged for 1-2 days per week. WhatsApp groups and email supported group communication. Quantitative data on registration and attendance were collected via Microsoft Excel. A virtual focus group was arranged to gather participant feedback, which was analysed into themes. Group registration ($n = 10$, $n = 9$, $n = 5$) and weekly attendance varied by site ($n = 10$, $n = 9$, $n = 5$). Key benefits noted by participants included physical activity, building relationships with colleagues, and getting fresh air. The main barrier was the impact of work schedules on attendance. There was broad support for re-establishment of Workplace Walking Groups for 2024. This pilot Workplace Walking Groups initiative achieved its dual aim of increasing physical activity and social connection among staff. Learning from this pilot informed the launch of a 3-month Walking Groups term for Spring 2024. The initiative is now established practice and is a component of the Department's blended working policy, being a feature of on-site working days.

Key messages:

- Our successful pilot Workplace Walking Groups project has translated into a sustainable health and well-being initiative for staff, during a time of ongoing reform across Public Health in Ireland.
- A structured approach to designing and implementing staff health promotion initiatives is crucial to support the cycle of learning and improvement, and to sustain change over time.

Achieving integrated care through clusters of co-occurring diseases for people with multimorbidity

Thomas Beaney

T Beaney[1], *J Clarke*[1], *T Woodcock*[1], *M Barahona*[1], *A Majeed*[1], *P Aylin*[1]
[1]Imperial College London, London, UK
Contact: Thomas.beaney@imperial.ac.uk

Background: People with multimorbidity are often seen in many different specialist health services, resulting in fragmented care. Conventional services are designed around specialties based on anatomical systems, rather than diseases that occur together. We examined whether organising services around clusters of co-occurring diseases would lead to fewer interactions with unique services and so improve integrated care.

Methods: We used the Clinical Practice Research Datalink, a nationally representative sample of primary care data in England, including all patients registered on 1st January 2015 with multimorbidity (two or more of 212 long-term conditions (LTCs)). We used the assignment of 212 LTCs to 15 clusters of co-occurring diseases, derived from our earlier work. For each patient, we calculated the number of interactions with different specialists, under both the existing specialty-based model, and the hypothetical cluster-based model, under the assumption that a patient required review for each LTC.

Results: Of 6,200,973 patients with multimorbidity, the mean age was 53 years, with a median (interquartile range) of 8 (5 - 11) LTCs per person. There was considerable variation in the assignment of diseases comparing 15 clusters versus 15 specialties. Under the existing model, 409,708 (6.6%) patients interacted with only one specialty, and under the hypothetical cluster model, 584,446 (9.4%) patients interacted with only one cluster. On average, patients interacted with 3.66 specialties versus 3.30 hypothetical clusters ($p < 0.001$ for difference).

Conclusions: Health services designed around clusters of co-occurring diseases might lead patients to interact with fewer different services and so experience less fragmented care. Further work is needed to understand which specialties collaborating, and how, would have the greatest impact on improving integrated care.

Key messages:

- Health services designed around clusters of co-occurring diseases led to a small reduction in the number of interactions with different services per year.
- Designing services around clusters of co-occurring diseases might reduce fragmented care for people with multimorbidity.

Abstract citation ID: ckae144.879

How common is emergency department as a death place in Portugal and who is more likely to die there?

Beatriz Sanguedo

B Sanguedo[1], *B Gomes*[1,2], *S Lopes*[3]
[1]Faculty of Medicine, University of Coimbra, Coimbra, Portugal
[2]King's College London, Cicely Saunders Institute of Palliative Care, Policy & Rehabilitation, London, UK
[3]NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
Contact: beatriz.sanguedo@uc.pt

Background: Most people would prefer to die at home but most die in hospitals or other healthcare settings. Some of the latter deaths may have taken place in Emergency Departments (EDs), as EDs are a major hospital gateway. However, EDs have not been consistently categorised as a place of death (PoD) across countries. Portugal is an exception. This study aimed to examine trends in deaths at EDs in Portugal from 2015 to 2021, identifying who is more likely to die at the ED.

Methods: We obtained national death certificate data on PoD for 2015 to 2021 from the the Portuguese General-Directorate for Health. We analysed the percentage of deaths taking place at the ED by sex, age group (0-17y, 18-49y, 50-69y, 70-79y, ≥80y), underlying cause of death (cancer, dementia, and other causes) and year of death.

Results: 804.971 people died in Portugal from 2015-2021 (50.1% male; 0.4% aged 0-17y, 58.0% aged ≥80y; 23.3% died from cancer, 5.6% from dementia, and 71.1% from other causes). Of these, 13.2% died at the ED. The percentage of ED deaths was higher in female (13.7% vs. 12.8% in male), in adults (13.3% vs. 9.0% in children), in those dying from dementia (15.7% compared to 9.6% in cancer and 14.3% in other causes). The percentage of ED deaths rose from 10.6% in 2015 to 14.3% in 2021, increasing steadily over time (average 0.6 percentual points per year, representing 1069 additional deaths per year).

Conclusions: One in every ten deaths in Portugal happens at ED and this is increasing. Patients with non-cancer conditions are more likely to die at the ED, in particular those dying from dementia. To understand if this reality compares with other countries, we are developing a pioneering international classification of place of death which includes the ED. Funding: European Research Council (agreement nr. 948609).

Key messages:

- Emergency department (ED) is a significant PoD in Portugal and has increased from 10.6% to 14.3% (2015-2021). Non-cancer patients, especially those with dementia, more likely to die at ED.
- This study highlights the need for an international place of death classification to compare emergency department death trends across countries.

Abstract citation ID: ckae144.880
The Effect of Multidisciplinary Care on Polypharmacy in Advanced Cancer Patients near the End of Life

Yun-Yi Chen

YC Kao[1], YY Chen[1,2], KC Lin[1], HC Chang[2]
[1]National Yang Ming Chiao Tung University, Taipei, Taiwan
[2]Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan
Contact: yunyichen@nycu.edu.tw

Objectives: Multidisciplinary Team (MDT) aims to integrate cancer patient care plans and provide holistic care to improve clinical outcomes and quality of life. However, there is a lack of empirical evidence regarding the effect of MDT on polypharmacy in advanced cancer patients near the end of life, which warrants further investigation.

Methods: This retrospective cohort study utilizes the National Health Insurance Research Database (NHIRD), Taiwan Cancer Registry, and Cause of Death Statistics, provided by the Health and Welfare Data Science Center (HWDC), Ministry of Health and Welfare (MOHW). The study subjects were patients who were diagnosed with stage III or IV cancer, aged 65 or above, experienced recurrence or metastasis, and who died between 2014 and 2020. Propensity score matching (PSM) was employed, followed by analysis using the Generalized Estimating Equation (GEE) to examine the differences in the risk of polypharmacy in the last 30 days before death. In addition, to confirm the robustness of the results, we conducted two different sensitivity tests: the first way is to use different ages as sample selection criteria and only include people who died over 75 years old as study subjects; the second way is to use conditional logistic regression models as a multivariate statistical method.

Results: There were 35537 samples before matching, including 4942 who received MDT care and 30595 who did not. After 1:1 matching, 9884 patients were finally included in the analysis. The prevalence of polypharmacy significantly decreased during the study period from 59.90% to 58.80% ($p = 0.03$; trend test). When examined through different PIM criteria, patients who received care from MDT exhibited a lower risk of polypharmacy (OR = 0.91, 95% CI = 0.84-0.98).

Conclusions: Advanced cancer patients who received care from MDT during the end-of-life period had a significantly lower risk of polypharmacy.

Key messages:

- The prevalence of polypharmacy significantly decreased during the study period from 2014 to 2020 among advanced cancer patients.
- Advanced cancer patients who received care from MDT during the end-of-life period had a significantly lower risk of polypharmacy.

Abstract citation ID: ckae144.881
Performance and trend of core measures among oral cancer patients: A population-based cohort study

Yun-Yi Chen

ZC Wang[1], YY Chen[1,2]
[1]National Yang Ming Chiao Tung University, Taipei, Taiwan
[2]Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan
Contact: yunyichen@nycu.edu.tw

Objectives: This study explores the performance and trend of core measures, which were established as evidence-based indicators to assess and improve the quality of care for oral cancer patients.

Methods: This retrospective cohort study uses the National Health Insurance Research Database (NHIRD), Taiwan Cancer Registry, and Cause of Death Statistics, provided by the Health and Welfare Data Science Center (HWDC), Ministry of Health and Welfare (MOHW). The study population was adult patients hospitalized for oral cancer surgery with stage I-IV between 2014 and 2021. The trend tests and the generalized linear mixed model (GLMM) were applied.

Results: A total of 23392 oral cancer patients were enrolled. The core measure set used in this study included five indicators (two process-related and three outcome-related indicators). Process indicators' mean achievement rates significantly increased from 82.6% to 85.7% ($p = 0.018$, trend test). On the other hand, most patients demonstrated good achievement rates to the outcome indicators (98.9% to 99.3%) ($p = 0.218$, trend test). Overall indicators' 100% achievement rate increased over time from 62.9% in 2014 to 66.2% in 2021 ($p < 0.001$, trend test). Subgroup analyses were performed by age, stage, and comorbidity score. The analysis of the GLMM revealed that the 100% achievement to overall indicators was positively associated with age<45, not-low socioeconomic status, body mass index ≥ 24, squamous cell carcinoma, recent treatment year, treated with surgery only, negative surgical margins, and receiving care in a high-volume hospital (all $p < 0.01$).

Conclusions: The results highlight a significant measurable improvement in the quality of oral cancer care. However, there is still room for enhancement in process indicator performance.

Key messages:

- The results highlight a significant measurable improvement in the quality of oral cancer care.
- There is still room for enhancement in process indicator performance.

Abstract citation ID: ckae144.882
Patient and healthcare provider perspectives on a digital first general practice: mixed-method study

Anke Versluis

A Versluis[1], RF Willemsen[1], NH Chavannes[1], JJ Aardoom[1]
[1]Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands
Contact: a.versluis@lumc.nl

Background: General practitioners (GPs) are facing an increased workload as a result of an aging population and a growing prevalence of chronic diseases. Utilizing eHealth may help to enhance healthcare accessibility and reduce costs. A digital platform was developed that integrates eHealth into the organizational aspects of general practices. This study aims to provide insight into the experiences of patients and healthcare professionals with this new, digital way of working.

Methods: A mixed-method study was conducted in three Dutch general practices working with the digital platform. The digital platform focuses on digital communication and remote healthcare delivery in primary care. Primary outcomes included acceptability, the implementation process, suggestions for improvement, and facilitators and barriers for future implementation. Patient perspectives were identified through online questionnaires and focus groups, and healthcare professionals' experiences were explored through in-depth interviews.

Results: Five focus groups and ten in-depth interviews were held. The questionnaires were completed by 616 patients. Patient acceptability of the care concept was high (M = 3.9, SD = 1.0; on a scale from 1-5) and they were satisfied with received care (M = 30.1, SD = 3.4; on a scale from 8-32). Regarding the perceived quality of consults, patients were positive about the longer duration of physical consults (i.e., 20 instead of 10 minutes). Some participants indicated a less personal doctor-patient relationship, because care was provided by various GPs.

Conclusions: Overall, patients and healthcare professionals were positive about the digital platform. The study gives insights into how to improve the care concept, e.g., how to enhance the doctor-patient relationship.

Key messages:

- Digital first general practices that integrate eHealth into the practice's organizational aspects of are considered acceptable by patients and healthcare professionals.
- Digital first general practices can help to improve healthcare accessibility for both patients and healthcare professionals.

Abstract citation ID: ckae144.883
Impact of bundled payments on healthcare use and costs for cardiovascular diseases in the Netherlands

Jesper Dros

JT Dros[1,2,3], CE van Dijk[2], RA Verheij[1,2,3], I Bos[1], BR Meijboom[3]
[1]Learning Health Systems, NIVEL, Utrecht, Netherlands
[2]Funds and Analysis of Healthcare Costs, National Health Care Institute, Diemen, Netherlands
[3]Tranzo, Tilburg University, Tilburg, Netherlands
Contact: j.dros@nivel.nl

Background: Bundled payments for patients with cardiovascular diseases (CVD) aim to enhance primary care utilization in the Netherlands. This study assesses changes in healthcare utilization patterns and costs for CVD between 2015 and 2019, while investigating the potential association with bundled payment adoption.

Methods: We studied patients at very high risk for CVD using routinely recorded nationwide healthcare data. Multilevel logistic- and gamma regressions were conducted to assess healthcare utilizations patterns between 2015 and 2019, and the impact of bundled payments on the likelihood of receiving medical specialist care and the height of associated costs.

Results: The odds of medical specialist involvement declined over time for the 148,876 patients included in our study. This decline was significantly associated with practices' use of bundled payments. Medical specialist costs did also significantly decrease between 2015 and 2019, and patients in practices with the highest level of bundled payments had significantly lower medical specialist costs. When general practice costs were included however, healthcare costs per patient stayed the same, both over time and stratified by use of bundled payments.

Conclusions: Our findings suggest an association between bundled payments and specialized healthcare use, potentially facilitating the transition to primary care. While we found no evidence for costs savings, our findings do support a reduction in spending growth.

Key messages:

- We evaluated the impact of bundled payments as a means to facilitate integrated care, and found that bundled payments were associated with lower uptake of specialized medical care.
- We found no cost savings were found, but findings do support reduced spending growth.

Abstract citation ID: ckae144.884
Ethical Dilemmas in Home Palliative Care

Gila Yakov

G Yakov[1], I Halevi Hochwald[2], M Weiss[3], R Sabar[3]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Afula, Israel
[2]Nursing, The Max Stern Yezreel Valley College, Afula, Israel
[3]Sabar Health, Netanya, Israel
Contact: gilayak@gmail.com

Background: In the past two decades, there has been a noticeable shift towards home-based care, reflecting the broader trend among OECD countries to prioritize a comprehensive approach to health and well-being. This approach emphasizes preventive and proactive measures, often relying on home-based care delivered by multidisciplinary teams providing both curative and palliative care. However, the unique nature of providing care in a home environment raises ethical questions among healthcare providers, necessitating high levels of attentiveness and sensitivity from the caregiving team to address them effectively.

Research Objectives: This study aims to identify ethical challenges encountered by a multidisciplinary team, as perceived by managers of an organization offering home palliative services in Israel.

Methods: A qualitative study was conducted, involving interviews with nine key managers to explore prevalent ethical issues in delivering home-based care.

Findings: Thematic analysis unveiled common ethical dilemmas in providing Home Palliative Care. These dilemmas include balancing patient preferences with professional obligations, addressing the needs of both patients and their families, navigating caregiver-patient relationships, understanding patients' cultural backgrounds, and advocating for home care as the preferred option while considering alternative treatment approaches.

Conclusions: Home palliative care poses ethical dilemmas for caregiving teams. It's imperative for organizations in the home care sector to devise strategies aimed at assisting teams in navigating these challenges while upholding the autonomy and dignity of patients within their home environment.

Key messages:

- Home-based care faces ethical challenges, requiring strategies to balance patient preferences and professional duties.
- Ethical home hospice care needs strategies that respect patient autonomy and dignity.

Abstract citation ID: ckae144.885
Scoping the EU's health impact in the Southern Neighbourhood: Building resilience and trust

Majd Alshoufi

K Perehudoff[1,2]
[1]Law Centre for Health and Life, University of Amsterdam, Amsterdam, Netherlands
[2]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands
Contact: m.alshoufi@uva.nl

Background: The European Neighborhood Policy (ENP) focuses on security, migration, and economic stability. Strengthening health systems can contribute to these aims by building local resilience and institutions; however, little is known about the EU's health policy and impacts in the Southern Neighborhood (Syria, Lebanon, Jordan, Palestine, Egypt, Libya, Tunisia, Algeria, Morocco). This paper examines the role of health in the ENP and what is known about the health-related impacts of EU actions in this region.

Methods: This is a qualitative case study of the EU's ENP commitments, outcomes, and impacts (2004-2024) in nine middle-income Southern Neighborhood countries. A scoping review of empirical evidence included 5 scholarly databases and grey literature published. Retrieved publications and the ENP documents were thematically analysed with WHO's health systems building blocks and the alignment between the ENP and practice was assessed.

Results: ENP health actions have evolved from public health and selected communicable diseases (2004), to health service delivery, vaccine supply, and occupational health (2021). The review included 19 publications (2004-2024). Publications most often addressed the financing (n = 14 papers) and service delivery (n = 9) aspects of health systems (not mutually exclusive), and only once addressed workforce and health information. Publications addressed mostly intentional EU health actions in the region; 4 papers reported unintentional effects.

Conclusions: The limited scope of health actions in the ENPs suggests health may be instrumentalised to pursue the EU's security and stability goals. The type of EU health actions reported most often in the literature were consistent with the ENP health priorities. There is no systematic evaluation of the impacts of the EU's health-related commitments in the ENPs. To build resilience and trust in the region, future EU action should support a range of WHO building blocks and mitigate potential negative effects.

Key messages:

- The EU's health commitments in the European Neighborhood Policy evolved from public health & communicable diseases (2004), to health service delivery, vaccine supply, & occupational health (2021).
- There is no systematic empirical evaluation of the impacts of the EU's health-related commitments in the European Neighborhood Policy.

Abstract citation ID: ckae144.886
The effect of team-model on healthcare usage and treatment levels among people with type 2 diabetes

Marja-Leena Lamidi

M Lamidi[1,2], *K Wikström*[1,3], *H Tirkkonen*[2], *P Rautiainen*[2], *M Laaninen*[2], *T Laatikainen*[1,2,3]
[1]Institute of Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio, Finland
[2]Wellbeing Services County of North Karelia, Joensuu, Finland
[3]THL, Helsinki, Finland
Contact: marja-leena.lamidi@uef.fi

Background: In North Karelia Finland, a team-based service model was implemented in some municipalities' primary healthcare (PHC) centers during 2020. In this team-model, a healthcare customer contacts a nurse who initiates the service process immediately. Nurses can also consult or direct customers to other healthcare professionals and arrange physical appointments if needed. The aims of the model are improved customer and personnel experience and satisfaction, and improved quality and effectiveness of care. We assess the effect of this team-model on treatment levels, measurement activity, and health care usage among patients with type 2 diabetes (T2D).

Methods: Patients with T2D were identified using the ICD-10 code E11 from the regional electronic health records. The data include all patients diagnosed by 2016 who were alive and residing in North Karelia in 2023 (N = 6312). Diabetes-related contacts with nurses or doctors in outpatient PHC and specialized healthcare (SHC) were considered, along with measurement activity and levels of glycated hemoglobin (HbA1c) and low-density lipoproteins (LDL) between the years 2017 and 2022. Annual differences between areas were analyzed using logistic and linear mixed models.

Results: In 2017, patients' mean age was 66 and age range 20-93. The proportion of men was 55% and 45% resided in team-model areas in 2023. The team-model increased T2D-related outpatient PHC remote contact with nurses for a couple of years. But eventually they decreased to a lower level than before. Additionally, the team-model reduced the number of other contacts. An increased difference between areas in measurement activity on HbA1c and LDL levels was also observed. But the difference between areas in proportion of those who achieved treatment targets stayed unchanged.

Conclusions: In the long-term, the team-model reduced the number of T2D-related contacts and increased the measurement activity of HbA1c and LDL, but it had no effect on treatment levels.

Key messages:

- Team-based service models might potentially reduce service use in the long term.
- More research and evidence are needed on the effectiveness and cost-effectiveness of team-based service models.

[5]School of Population and Global Health, McGill University, Montreal, Canada
Contact: viktoria.gastens@unifr.ch

Background: Improving blood pressure (BP) control is of major importance among patients with diabetes, due to their high risk of micro- and macrovascular complications. Community-based models of care with the involvement of pharmacists and other nonphysician healthcare providers can help manage hypertension. We aimed to estimate the effectiveness of pharmacist interventions, alone or in collaboration, on BP among outpatients with diabetes and hypertension.

Methods: We conducted systematic searches of randomized controlled trials assessing the effect of pharmacist interventions on BP among outpatients with hypertension and diabetes compared to usual care. The outcome was the systolic and diastolic BP change or BP control. We performed a meta-analysis with random effects models and results are presented by mean difference along with relative 95% CI.We will perform subgroup analyses for the types and intensity (duration, frequeny) of pharmacist interventions, patients' characteristics, and healthcare settings. The protocol was registered in PROSPERO (CRD42021279751) and published in an open-access peer-reviewed journal.

Results: Out of 2048 study records identified by electronic database searching, we included 9 studies, with 5067 participants, published between 2008 and 2022. These studies were conducted mainly in North America (n = 5; other regions: n = 4). The intervention was led by the pharmacist in 78% of the studies and in collaboration with other healthcare providers in 22%. Pharmacist intervention included patient education in 67%, healthcare providers education in 11% of studies and feedback to healthcare providers in 44% of the studies. Systolic and diastolic BP were reduced after pharmacist intervention by -5.6 mmHg (95% CI: -10.6 to -0.6) and -4.1 mmHg (95% CI: -7.1 to -1.2) respectively. Additional analyses will be presented at the congress.

Conclusions: Pharmacist interventions improve blood pressure control in hypertensive diabetic outpatients.

Key messages:

- Recent hypertension guidelines recommend pharmacist involvement in hypertension care management.
- This systematic review provide updated evidence on the effect of pharmacist interventions on hypertension management of patients with diabetes.

Standardizing Primary Health Care in Italy: Operational Guidelines for Community Health Houses

Alice Borghini

M Scotellaro[1], AR Cornio[2,1], A Borghini[1], E Carini[1], M Iodice[1], M Cosentino[1], CV Sposato[1], M Rinaldi[1], M Verrengia[1], D Mantoan[1]
[1]Telemedicine, Agenas, Rome, Italy
[2]Department of Public Health and Pediatric Sciences, Turin, Italy
Contact: borghini@agenas.it

Background: In response to Italy's demographic changes and increasing chronic disease burden, there has been a need to standardize Primary Health Care (PHC) through Community Health Houses (CHHs). This study addresses the gap in a unified approach by developing operational guidelines using a consensus-based method among a national Experts Panel, aiming to enhance the effectiveness and integration of healthcare services across the country.

Methods: A multidisciplinary and multiprofessional workgroup was formed, including stakeholders from various health professions and Italian regions, to develop these guidelines that could integrate different health professional skills. The consensus process involved a series of online and face-to-face meetings, utilizing a modified Delphi method. This approach ensured that diverse expert opinions were harmonized and that the guidelines were relevant to different geographic contexts and healthcare settings.

Results: Through iterative rounds of consultation and revision, the workgroup reached a consensus on key aspects of PHC delivery. These included procedures, digital health tools integration and definition of various roles within the CHHs. Preliminary feedback from pilot implementations has shown improvements in accessibility, care continuity, and patient satisfaction, indicating effective adaptation of the guidelines to local contexts in line with the territorial healthcare Italian reform ratified by Ministerial Decree n. 77/2022.

Conclusions: The consensus-driven development of CHHs guidelines represents a significant advancement in Italy's health policy, promoting a more integrated and efficient healthcare system. These guidelines are anticipated to form the cornerstone of Italy's strategy to cope with its public health challenges, particularly in managing chronic diseases and aging populations. Future work will focus on national rollout and continuous improvement of these guidelines based on ongoing evaluation and feedback.

Key messages:

- Consensus-based guidelines for Italy's CHHs enhance PHC delivery, improving accessibility and patient satisfaction across the Country.
- Italy's new PHC guidelines, developed through expert consensus, set a foundation for a unified, efficient healthcare system to address chronic disease and aging.

Governance and health system reform: a case study of new health regions in Ireland, 2018-2023

Carlos Bruen

K Schulmann[1], C Bruen[1], S Parker[1], R Siersbaek[1], L Mac Conghail[1,2], S Burke[1]
[1]Trinity College Dublin, Dublin, Ireland
[2]Health Service Executive, Dublin, Ireland
Contact: carlos.bruen@gmail.com

Background: While the significance of good governance is recognised within health systems research, its role in health system reform is underexplored. This research focuses on the establishment of new decentralised regional health structures in Ireland in the period 2018-2023, examining how aspects of governance impacted the decentralisation reform process, from policy design through to implementation.

Methods: The research applied a qualitative, multi-method approach involving analysis of official documents relevant to the regional decentralisation process, and 12 semi-structured interviews with key informants from across the health sector. The research applies the TAPIC framework for health governance as its analytic framework and the data is analysed using thematic analysis.

Results: Deficiencies in accountability arrangements, poor transparency within the system and vis-à-vis external stakeholders, and a lack of clarity of roles and responsibilities for various process and key decisions related to the reform were identified as undermining progress at various stages of Ireland's decentralisation reform process. An underlying distrust between key institutional actors was identified. These findings are grounded in complex social, cultural, and political and institutional developments in Ireland's history. Also of note is the interwovenness of the five TAPIC domains and the importance of engaging with the complexity and relationality intrinsic to health system reform processes to achieve the aim(s) of the reform in question.

Conclusions: Large scale health system reform is a complex process and its governance presents distinct challenges and opportunities for stakeholders. To understand and address these, critical analysis of the historical context surrounding the policy reform and the institutional relationships at its core are needed.

Key messages:

- Governance plays a crucial if overlooked role in health systems reform. Effective governance arrangements are central to the successful design and implementation of reform initiatives.
- Ensuring a strong link between policy design and implementation processes is crucial to the success of health systems reform.

Alarm fatigue and sleep quality in healthcare workers

Lukasz Rypicz

L Rypicz[1], I Witczak[1], M Supinova[2], HP Salehi[3], O Jarabicova[4]
[1]Division of Public Health, Wroclaw Medical University, Wrocław, Poland
[2]Department of Nursing, Slovak Medical University, Banská Bystrica, Slovakia
[3]Department of Biomedical, Industrial and Human Factors Engineering, Wright State University, Dayton, USA
[4]Department of Nursing, Jan Evangelista Purkyne University, Ústí nad Labem, Czechia
Contact: lukasz.rypicz@umw.edu.pl

Background: Alarm fatigue, a prevalent issue in medical settings, arises when healthcare professionals are exposed to an overwhelming number of clinical alarms, leading to desensitization and decreased responsiveness. The constant alertness required due to medical device alarms in hospitals can severely disrupt the quality of sleep for medical personnel. This study aims to demonstrate whether there is a relationship between alarm fatigue and sleep quality in medical staff. For the research project, it was decided to carry out the study in three European neighbouring countries: Poland, Slovakia and the Czech Republic

Methods: The the survey was carried out in three European countries: Poland, Slovakia, and the Czechia from June to July 2023. The study was attended by a total of 756 participants. The study used: a socio-demographic metric; Alarm Fatigue Assessment Questionnaire and The Pittsburgh Sleep Quality Index to evaluates sleep quality.

Results: Among the 756 survey participants, 603 (79.76%) had poor sleep quality (6-21 PSQI points), 147 (19.44%) had good sleep quality (0-5 PSQI points), and 6 (0.79%) did not answer. The analysis of sleep quality scores for participating countries shows that sleep problems were significantly higher in Slovakia and Poland than in the Czech Republic. Alarm fatigue levels were determined for respondents in every country in this study. The statistical difference between countries is significant. In Slovakia and Poland, the levels of alarm fatigue caused by medical devices were significantly higher than in the Czech Republic. With regards to sleep quality, there is a positive correlation between alarm fatigue and sleep problems. A statistically significant positive correlation was obtained for all three countries.

Conclusions: The study found that workers in the health system are exposed to alarm fatigue, and that this in turn can reduce sleep quality. The consequences of this may be reflected in patient safety.

Key messages:

- The results of the study clearly indicate that quality of work should be ensured by developing protocols for managing medical device alarms.
- Combatting alarm fatigue among medical personnel is vital for public health as it reduces medical errors caused by sleep deprivation.

Public trust in national electronic health record systems: A scoping review of qualitative studies

Kimon Papadopoulos

K Papadopoulos[1,2], *V von Wyl*[1,2], *F Gille*[1,2]
[1]Institute for Implementation Science, University of Zurich, Zurich, Switzerland
[2]Digital Society Initiative, University of Zurich, Zurich, Switzerland
Contact: kimon.papadopoulos@uzh.ch

Background: Having public trust in national electronic health record systems (EHRs) is essential for the successful implementation of electronic health records within a country's healthcare system. Without trust, people are less likely to consent to sharing their health data through an EHR and government stakeholders will have difficulties promoting uptake and facilitation of EHRs. Research investigating public trust in EHRs is limited, however. In response, we conducted a scoping review in order to gain clarity on the influences and themes behind public trust in EHRs, which can support the implementation of EHRs.

Methods: We reviewed 27 qualitative studies focusing on public trust in EHRs. Studies were identified between January 2022 and June 2022 and were ascertained using an inclusive search method and guided by the PRISMA-ScR checklist. In an iterative process, conceptual themes were derived, and detail the promoters and outcomes of public trust in EHRs.

Results: Three major themes that describe the promoters of public trust in EHRs and two major themes that detail the outcomes once public trust in EHRs exists were ascertained from the literature. Additional findings bring forth the consequential role of healthcare actors in the public trust building process.

Conclusions: Results show comprehension, autonomy, and data protection are key concepts that help build and consolidate public trust in EHRs, while the public and the healthcare system benefit from public trust in EHRs. Furthermore, health system actors can be supportive or detrimental to the implementation of EHRs. Their effect is dependent on their activities within the health care system and how the public perceives those activities. Based on: Papadopoulos K, von Wyl V, Gille F. What is public trust in national electronic health record systems? A scoping review of qualitative research studies from 1995 to 2021. DIGITAL HEALTH. 2024;10. doi:10.1177/20552076241228024

Key messages:

- This research clarifies the conceptualizations that make up the trust relationship between the public and EHRs.
- The findings can assist researchers, policymakers, and other health system actors in attaining a better understanding of the intricacies of public trust in EHRs.

Levels of adherence to the Planetary Health Diet of current diets in Italian adults

Giuseppe Grosso

G Grosso[1,2], *M Tucci*[3], *J Godos*[1,2], *D Martini*[3]
[1]Department of Biomedical and Biotechnological Sciences, University of Catania, Catania, Italy
[2]Center for Human Nutrition and Mediterranean Foods, University of Catania, Catania, Italy
[3]Department of Food, Environmental and Nutritional Sciences, University of Milan, Milan, Italy
Contact: giuseppe.grosso@unict.it

Despite the efforts in the direction towards the identification of healthy and sustainable diets, little is known about the environmental impact associated with current diets. The aim of this study was to validate the application of the Planetary Health Diet Index (PHDI) to dietary habits currently adopted in a sample of adults living in southern Italy and background variables associated. Dietary intake from nearly 2000 individuals was assessed through a validated 110-item food frequency questionnaire. The PHDI was applied by considering the energy contribution of 16 different components with a gradual scoring system. For the estimation of the environmental impact, carbon and water footprint data for food commodities were extracted from the SU-EATABLE LIFE database and matched with the FFQ items. An energy-adjusted linear association between the PHDI scores and the majority of food groups included in the analysis was found; when considering the level of food processing, ultra-processed food consumption was inversely associated with PHDI scores. Among nutrients, PHDI scores were directly associated with fiber, antioxidant vitamins, potassium, plant-derived omega-3 poly-unsaturated fats, and inversely with sodium, total, saturated, mono- and poly-unsaturated fats, cholesterol, and protein. A significant difference in carbon and water footprint was observed across quartiles of PHDI scores as well as a linear direct association. After adjustment for potential confounding factors, 1-point increase in the PHDI score was associated with lower likelihood of being overweight or obese (OR = 0.99, 95% CI: 0.98-0.99). A linear inverse association between PHDI scores and waist and hip circumferences and, partially, with BMI but not with body weight was found. In conclusion, the PHDI seems to properly identify an environmentally friendly diet with a good nutritional quality.

Key messages:

- An environmental-friendly dietary pattern resulted also having a good nutritional profile.
- Adherence to the Planetary Health Diet is associated with parameters of central obesity.

Abstract citation ID: ckae144.893
Establishing a healthy and sustainable diet in diabetes management: a social marketing approach

Rogerio Ribeiro

RT Ribeiro[1,2], M Mourre[3,4], L Ribeiro[1], D Nascimento do Ó[1], A Charvet[5], MJ Sequeira[1], E Dupont[6], JF Raposo[1]

[4]Université Gustave Eiffel, Paris, France
[5]French Diabetes Federation, Paris, France
[6]IDF Europe, Brussels, Belgium
Contact: rogerio.ribeiro@apdp.pt

Background: In recent years, there has been evidence that diets based on plant-based products have positive results in the management of type 2 diabetes (T2D). However, their adoption remains low.

Objectives: To evaluate and understand food consumption of people with T2D; and to define priority groups for intervention using a social marketing approach.

Methodology: An online questionnaire was developed and applied to 832 adults with T2D living in Portugal and France. The questionnaire included the collection of socio-demographic data, health data, as well as data on food consumption, eating habits, awareness and attitudes towards the consumption of plant-based foods. Finally, hands-on food workshops were organized to convey practical knowledge on plant-based food cooking.

Results: Regarding eating habits, 11% of participants have already excluded or would like to exclude meat products, and 37% would like to consume them in smaller quantities. 35% of the participants intend to increase the intake of plant-based products. The most well-known diets among the participants were the Mediterranean diet (80%) and Low Carb diet (51%). Regarding the Planetary diet, 86% of the participants expressed low or no knowledge. Regarding the consumption of plant-based foods, 61% of participants view them as a desirable and suitable option for people with diabetes. Furthermore, the planetary diet is among the least often recommended by healthcare professionals (1%). The clustering of participants originated five main groups, with two being highlighted as particularly relevant for intervention, namely through knowledge or practical support.

Conclusions: Overall, participants with T2D seem to have a positive attitude towards increasing the consumption of plant-based products and decreasing the consumption of meat products. Social marketing profiling identified specific clusters which constitute priority target groups for support in shifting to healthier and sustainable diets.

Key messages:

- Social marketing profiling identified specific clusters which constitute priority target groups to support the shift towards plant-based/planetary diets.
- Hands-on food workshops were shown to be effective in conveying practical knowledge and motivation about plant-based diets.

Predicting Obesity via Deep Learning: The Role of Chrononutrition

Luigi Palla

L Di Traglia[1], A Vestri[1], L Palla[1]
[1]Department Public Health and Infectious Diseases, University of Rome La Sapienza, Rome, Italy
Contact: luigi.palla@uniroma1.it

Background: Obesity is a significant public health challenge, prompting the need for assessing effective tools for its monitoring and prevention. Chrononutrition investigates the role of timing, regularity and frequency of food intake on body metabolism and health. Here we aim to check if data on the distribution of calorie intake in the day may improve BMI prediction as compared to using only data on total day intake.

Methods: We apply deep learning on chrononutritional data on calorie intake over 6 daily timeslots from a nationally representative cross-sectional survey sample of the Italian population (INRAN-SCAI 2005/2006) comprising 2313 Italian adults 18-64 ys old with 3 day diet diaries. In particular, we implemented three deep neural network models, varying network configurations and feature selection. The 1st includes 18 (6 for each day diary) chrononutritional variables and the 3 day total intakes, beside age and sex; the 2nd includes age, sex and the 18 chrononutritional variables only; the 3rd uses age, sex and the 3 day totals only. We applied Early Stopping to limit overfitting. Optimization was conducted using the Adam algorithm, minimizing the mean squared error (RMSE), while mean absolute error (MAE) was the primary performance indicator.

Results: The results highlight that Model 3 outperformed the other models with MAE=2.514 and RMSE=3.476, indicating that for the purpose of predicting obesity, information on the time-of-day distribution of calorie intake is not increasing predictive ability of BMI on top of age, sex and total calorie intake in the day.

Conclusions: Additional use of day-time intake information worsened prediction of BMI via deep learning using this cross sectional Italian survey. However the error made is still sizeable and warrants the inclusion of other variables; our results don’t rule out the role of chrononutrition on metabolic health which may act through other biological mechanisms related to specific nutrients.

Key messages:

- Chrononutrition data don’t improve BMI prediction over total calorie intake data in a cross-setional representative sample of the Italian population.
- Deep learning approach to BMI prediction shows the importance of targeted selection of features in public health nutrition.

Abstract citation ID: ckae144.895
Effectiveness of pictorial-warning intervention to reduce consumption of sugar-sweetened-beverages

Kumar Mishra

A Afreen[1], S Patnaik[1]
[1]Community Medicine, Apollo Institute of Medical Sciences & Research, Hyderabad, India
Contact: drguru1990@gmail.com

Background & Aims: Limited research have looked at pictorial-health-warnings (PHW) for sugar- sweetened beverages (SSB), despite the potential for behaviour change that pictorial warnings on tobacco products hold. This study aimed to examine how visual warnings impacted parents’ decisions to buy SSB for their children.

Materials and methods: All residents dwelling in the communities and local vendors available were subjected to a ten-week multi-strategy intervention by randomized stepped-wedge controlled trial to support the introduction of PHW labels. Stepped implementation of a two-week PHW intervention was delivered in a randomly selected order at one-week intervals. Follow-up data were collected for all three sectors two weeks following the completion of the PHW intervention in the third sector. The trial outcome was determined by comparing the overall perception change towards SSB among parents between the baseline and follow-up periods for three sectors combined. Secondary outcomes included reactions to the trial labels, attitudes toward SSB, and intentions to serve their child SSB.

Results: PHW led to a 30 % (-37.12%, -22.37%) reduction in purchases of SSB, along with lower intentions to serve SSB to children, higher thoughtfulness about the harms of SSB, more perceived control of healthy eating decisions, stronger negative emotional reactions, lower perceived healthfulness of SSB for their child, and greater injunctive norms to limit SSB for their child (all $p < 0.05$). No differences by sector or within sector were found between pre and post-intervention in the appeal of SSB or perceived tastiness of SSB (all $p > 0.05$). Nearly 53% of participants reported being more in control of making healthy eating decisions.

Conclusions: Warnings on SSB are a promising policy approach to reduce sugary drink purchasing. This evidence will support the health service adoption of implementation strategies to support PHW labels across the entire country.

Key messages:

- Warnings on SSB are a promising policy approach to reduce sugary drink purchasing.
- Support the health service adoption of implementation strategies to support PHW labels across the entire country.

Abstract citation ID: ckae144.896
Association between bisphenol A exposure and cardiometabolic outcomes: a longitudinal approach

Sofia Almeida Costa

SA Costa[1,2], *M Severo*[1,3], *C Lopes*[1,2,4], *D Torres*[1,2,5]
[1]EPIUnit - Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal
[2]Laboratório ITR, Universidade do Porto, Porto, Portugal

[4]Department Ciências Saúde Pública e Forenses, Edu Med, Faculdade de Medicina da Universidade do Porto, Porto, Portugal
[5]Faculdad de Ciências da Nutrição e Alimentação, Universidade do Porto, Porto, Portugal
Contact: sacosta@ispup.up.pt

Background: Increased cardiometabolic risk is associated with abnormalities in blood biomarkers profile and adiposity measurements. Some substances found in the food matrix or the environment, called endocrine-disrupting chemicals, may impair cardiometabolic health in the yearly and later stages of life. Bisphenol A (BPA) is a food contaminant that migrates from food contact materials and may act as an endocrine disruptor, negatively affecting human health. The present work aims to assess the longitudinal association between BPA exposure and cardiometabolic outcomes.

Methods: Data from the four waves of the Portuguese population-based birth cohort Generation XXI were used ($n = 3138$). Dietary data were collected by 3-d food diaries, using the FoodEx2 classification system to describe the reported foods. BPA daily exposure was estimated using a random forest model, combining dietary information with urinary BPA measured in 24-h urine from a subsample, used to predict the remaining sample's BPA exposure. The generalised least squares model was used to test the associations between BPA and cardiometabolic outcomes.

Results: Blood insulin and HOMA-IR presented a significant longitudinal association with BPA daily exposure after adjustment for important variables and energy (0.06 SD(0.03, 0.09); 0.05 SD(0.02, 0.08) respectively). The same findings were observed for fat mass and waist circumference (0.03 SD(0.01, 0.06); 0.06 SD(0.04, 0.08), respectively). For z-BMI, a significant cross-sectional and longitudinal association was found (0.03 SD(0.01, 0.04); 0.02 SD(0.00, 0.04), respectively).

Conclusions: This was the first study assessing the association between BPA exposure and health outcomes from childhood to adolescence. We found an association between BPA exposure and an increased blood insulin level, insulin resistance, fat mass percentage, waist circumference and z-score of body mass index. Our results point to the need to reduce exposure to BPA in the early stages of life.

Key messages:

- BPA exposure was estimated using direct and indirect methods.
- BPA can impair cardiometabolic outcomes from the early stages of life, such as higher blood insulin level, insulin resistance, fat mass, waist circumference, and body mass index.

Abstract citation ID: ckae144.897
Dietary inflammatory potential: a comprehensive approach to the inclusion of flavonoids

Sofia Almeida Costa

S Martins[1,2,3], *D Correia*[1,2,3], *C Carvalho*[1,2,4], *SA Costa*[1,2,3], *C Lopes*[1,2,3], *D Torres*[1,2,4]
[1]EPIUnit - Institute of Public Health, University of Porto, Porto, Portugal
[2]Lab Integrative and Translational Research, University of Porto, Porto, Portugal
[3]Department of Public Health, Faculty of Medicine, University of Porto, Porto, Portugal
[4]Faculty of Nutrition and Food Science, University of Porto, Porto, Portugal
Contact: sacosta@ispup.up.pt

The Dietary Inflammatory Index (DII) has been widely used to estimate dietary inflammation. However, most studies do not consider the six classes of flavonoids (6F) included in the original DII. This study aimed to develop two new tools, the Complete-DIP (CDIP) and Short-DIP (SDIP), to estimate the Energy-adjusted Dietary Inflammatory Potential (DIP) in adults while exploring the benefit of including the 6F. An open-access reference population (RP) was created from the Global Dietary Database (GDD) to calculate DIP. CDIP considered 38 food parameters (FP), whereas SDIP excluded the 6F and considered 32 FP. CDIP and SDIP were estimated for 3501 participants aged 18-84 from the IAN-AF. FP intake z-scores were calculated using FPs from the RP. Centred percentiles were multiplied by the FP's inflammatory effects (IE) to obtain FP-specific DIP, which were then summed to achieve the individual DIP. IE were retrieved from the literature. Lower DIP values indicated more anti-inflammatory diets. Linear regressions assessed the association between sociodemographic factors and diet quality (measured with the Healthy Eating Index (HEI)) with DIP. Pearson's test evaluated the correlation between CDIP and SDIP. The mean and standard deviation for CDIP and SDIP were 0.00±2.17 and 0.02±1.74, respectively. Men had more pro-inflammatory diets than women using CDIP ($\beta = 0.354$[95%CI:0.209,0.499]), but this effect was not statistically significant when using the SDIP. Older adults had more anti-inflammatory diets than adults (CDIP: β=-0.668 [95%CI:-0.850,-0.486]; SDIP: β=-0.548[95%CI:-0.529,-0.076]). Participants with lower diet quality (Q1 of HEI vs Q4) had higher DIP (CDIP: $\beta = 2.309$[95%CI:2.116,2.502]; SDIP: $\beta = 2.185$ [95%CI:2.037,2.334]). A very strong correlation between the CDIP and the SDIP was observed ($r = 0.94$). Results suggest that CDIP and SDIP may be equally successful in estimating dietary inflammation. However, the advantage of adding the 6F to evaluate the DIP needs further research.

Key messages:

- This study created two open-access energy-adjusted dietary inflammatory potentials (DIP), with and without flavonoids.
- Results suggest that flavonoids may not be essential for accurate DIP estimations.

Abstract citation ID: ckae144.898
Correlates of food insecurity among university students in a low socioeconomic area

Henri Dehove

H Dehove[1], M Mofakhami[2], C Julia[1,3], S Peneau[1], A Bellicha[1]
[1]Nutritional Epidemiology Research Team, CRESS, University Sorbonne Paris Nord, INSERM, INRAE, CNAM, Bobigny, France
[2]Interdisciplinary Institute of Social Issues, CEET, University Sorbonne Paris Nord, Aubervilliers, France
[3]Public Health Department, Avicenne Hospital, Assistance Publique des Hôpitaux de Paris, Bobigny, France
Contact: henri.dehove@eren.smbh.univ-paris13.fr

Background: The prevalence of food insecurity (FI) is high and suggested to be growing among university students, with potential detrimental effects on their health status and academic performances. This cross-sectional study aims to identify the socioeconomic, demographic and lifestyle factors associated with FI among university students in a disadvantaged area.

Methods: An anonymous online survey was conducted from Nov 2022 to Jan 2023 among students enrolled at University Sorbonne Paris Nord, located in a low socioeconomic area in France. FI was assessed with one question distinguishing 2 levels of FI: quantitative (i.e. not having enough to eat) and qualitative (i.e. not having the desired food). This abstract focused on quantitative FI. To improve the representativeness of the sample compared to the total student population of the university, sample weights were used according to gender, study level and speciality, whether they were undergoing initial training or not, or obtained their baccalaureate abroad or not. Multivariable multinomial logistic regression models were used to identify factors associated with FI.

Results: A total of 5068 students provided valid answers (20% of the target population), 66% of whom were women, and 12% and 36% reported quantitative and qualitative FI, respectively. Being a man, an undergraduate, having obtained a baccalaureate abroad, not living in the family home, not receiving food from family, having no household food-heating facilities, reporting financial difficulties, relying on food charity and eating alone on a regular basis were positively associated with quantitative FI ($P < 0.0001$). Those reporting quantitative FI were more likely to report academic difficulties.

Conclusions: This study shows a high prevalence of FI in this student population and identifies several associated factors. Identifying students at greater risk of FI is an important first step to design and evaluate public health interventions.

Key messages:
- The different socio-economic backgrounds of university students imply important food insecurity disparities among them.
- University students present several factors associated with food insecurity, which should be considered when addressing food insecurity in this population.

Abstract citation ID: ckae144.899
A Review of Lifestyle Interventions in Weight Loss Programs for Community-Based Psychiatric Patients

Giulia Picardo

G Picardo[1], C Donnoli[1], G Liotta[1]
[1]Deparment of Biomedicine and Prevention, University of Rome, Tor Vergata, Rome, Italy
Contact: picardogiulia@gmail.com

Background: Psychiatric patients face aggravated physical health issues and reduced life expectancy, primarily due to premature cardiovascular diseases. The intricate relationship between lifestyle factors, illness, and psychotropic medications contributes to this phenomenon. The focus of this research is to evaluate weight management interventions for individuals with Severe Mental Disorders through a comprehensive scoping review, focusing on diverse study designs, outcomes, and their clinical implications.

Methods: 20 studies were analyzed to understand the effectiveness of interventions and characteristics, such as duration, delivery, and professional involvement. Assessment criteria included weight modifications, BMI changes, and metabolic measures like blood pressure and lipid profiles.

Results: The total number of participants included in the 20 studies evaluated was 3886. All trials included individuals of all genders. The studies included patients with a weighted mean age of 44.37 ($SD = 4.72$) and a mean BMI of 34.7 kg/m2 ($SD = 3.56$). Varied interventions, mostly conducted in the US, showed promising weight reduction and cardiovascular risk management results among psychiatric patients. However, disparate methods used in the studies hindered the evaluation of outcomes. The studies which yielded more interesting results included Gaughran F. et al, 2017 who showed improvements in HDL cholesterol and metabolic indicators, (HR 0.085; 95% CI:0.007-0.16), and Bartels S. et al, 2015 who reported that 51% of participants achieved clinically significant reduction in overall cardiovascular risk.

Conclusions: Although interventions displayed potential benefits for beneficiaries, the lack of standardized protocols and non-uniform endpoints poses challenges in effectively addressing weight-related concerns in psychiatric patients. Clear guidelines and standardized assessments are necessary to implement psychiatric patients' weight management interventions.

Key messages:
- The health issues and reduced life expectancy of psychiatric patients is a major health burden. The mean BMI of 34.7 kg/m2, indicating a prevalence of Obese individuals needs to be addressed.
- Psychotropic medications are associated with increase in weight. More effort in increasing awareness and including mandatory nutritional educational classes when prescribing these drugs is needed.

Abstract citation ID: ckae144.900
Veggies4myHeart – educational project to promote vegetable knowledge and consumption in preschoolers

Sara Simões Dias

R Novo[1], J Edra[2], L Vieito[1], S Simões Dias[1,2], M Lages[1], MP Guarino[1,2], C Braga-Pontes[1,2]
[1]ciTechCare, Polytechnic University of Leiria, Leiria, Portugal

Vegetable consumption among children is below recommended. Given the critical role of vegetable consumption in health promotion, it is essential to identify effective strategies to promote this intake. The Veggies4myHeart project aims to increase vegetable knowledge and consumption in preschool children through nutrition education strategies (NES). Veggies4myHeart is a prospective longitudinal study with children aged 2 to 6 years who attend preschools in the Leiria district. A questionnaire was applied to the parents to characterize the sample. NES were used: children's story, digital game, vegetable-themed sticker booklet and the food wheel. The intervention consisted of 5 food education sessions, each focusing on one selected vegetable (lettuce, carrot, red cabbage, cucumber, and tomato). Sessions to assess knowledge and consumption of vegetables were held pre-and post-intervention. Knowledge was evaluated through a taxonomic categorization questionnaire. Consumption was assessed by recording the number of portions of each vegetable consumed. Wilcoxon test was used to compare pre-and post-intervention vegetable knowledge and consumption. ANOVA test was used to compare NES. Between 2018 and 2024, 649 children (52,5% female, mean age 4,36 ± 0,942) from 17 preschools participated. After the intervention, there was a statistically significant increase in vegetable knowledge ($p < 0{,}001$) and a statistically significant increase in the consumption of vegetables ($p < 0{,}001$). There are statistically significant differences between NES, with the digital game having greater vegetable knowledge ($p < 0{,}001$) and consumption ($p < 0{,}001$) than the others. The Veggies4myHeart project effectively increased vegetable knowledge and consumption in preschoolers. It is essential to continue the intervention to promote consumption and familiarity with vegetables, as well as the involvement of parents and preschool teachers, due to their prominent role as models for acquiring healthy eating habits.

Key messages:

- The NES used proved useful, contributing to increased knowledge and consumption of vegetables.
- The Veggies4myHeart project is an asset for preschool-aged children to become familiar with vegetables.

Abstract citation ID: ckae144.901
Potential reformulation of food products two years after implementation of Nutri-Score in Belgium

Maria Salve Vasquez

MS Vasquez[1], *S Vandevijvere*[1]
[1]Health Information, Sciensano, Brussels, Belgium
Contact: MariaSalve.Vasquez@sciensano.be

Background: Nutri-score is a front of pack labeling system that provides consumers with simplified information of the nutritional quality of food products. It is based on a five color (green to red) or letter (A to E) scheme that grades the quality of the product using an algorithm that takes into account the energy, sugar, saturated fats, salt, fiber, protein content, and percent of fruits and vegetables. In Belgium, Nutri-score was implemented on a voluntary basis in April 2019. This study aims to explore reformulation of products with Nutri-score by comparing their nutrient content and Nutri-score distribution in 2019 and 2021.

Methods: Product data from one of the major retailers was used in the analysis. Similar products in 2019 and 2021 with matched barcodes were used. Descriptive statistics were computed and statistical analyses such as the signed rank test and the McNemars test were performed to respectively evaluate the changes in the nutrient content and Nutri-score. The tests were conducted at 5% level of significance.

Results: From the matched sample of 668 products, about 55% had a Nutri-score of A and B in both 2019 and 2021. The proportion of food products with Nutri-Score of A/B and of D/E was not significantly different after two years of Nutri-Score implementation. Results showed a significant decrease in the median energy content of dairy, sauces, and meat products and in the median sugar content of dairy and fruit and vegetable products. There was a significant increase in the median fiber content of the dairy, meat products, and non-alcoholic beverages. For all food groups, the salt content of the products in 2019 and 2021 was not significantly different.

Conclusions: This two-year interval analysis described the changes in the classification and reformulation of the products with Nutri-score. Favorable changes in the nutrient quality of the product profiles reveals improvement in their reformulation.

Key messages:

- In this analysis, changes has been observed in the nutrient content of food products between 2019 and 2021.
- Producers or manufacturers should continue working on commitments to enhance the nutritional quality of the products delivered to consumers.

Abstract citation ID: ckae144.902
Impact of the COVID-19 pandemic on lifestyle's behaviours of school-aged children in Portugal

Ana Rito

A Rito[1], *I Figueira*[2], *S Mendes*[2], *M Buoncristiano*[3], *J Williams*[3]
[1]WHO Collaborating Center for Nutrition and Childhood Obesity, National Institute of Health-INSA, Lisbon, Portugal
[2]Centre for Studies and Research in Social Dynamics and Health, Lisbon, Portugal
[3]Special Initiative on Noncommunicable Disease, WHO/Europe, Copenhagen, Denmark
Contact: rito.anaisabel@gmail.com

Background: COVID-19 pandemic impacted children's daily routines. Based on this, WHO Collaborating Centre for Nutrition and Childhood Obesity in collaboration with WHO Regional Office for Europe coordinated the study about the impact of COVID-19 on lifestyle's behaviours of school-age children in Europe, where 17 Member States participated, including Portugal.

Methods: Cross-sectional study was conducted within the sixth round of COSI Portugal, following a WHO common methodological protocol, during 2021-2022 school year. A national representative sample of families with children 6-8 years old were included and asked to report on variables comparing two periods: pre and during the COVID-19 pandemic.

Results: 5139 families participated. 11.4% reported a worsening of their perceived wealth and the percentage of fathers and mothers working full- or part-time decreased (74.6% to 68.7% and 70.6% to 59.6%, respectively) during pandemic. Children's consumption of sweets (19.4%), savoury snacks (13.8%), fruit (11.9%) and vegetables (7.1%) increased, and sugary soft drinks (13.8%) decreased during pandemic. Family behaviours with the highest increases during pandemic were "eating together as a family" (35.4%), "cooking meals together with your child" (33.6%), "buying food in large quantities" (33.6%) and "eating home-cooked meals" (29.1%). Approximately, one in four parents reported children's physical activity decreased and almost one in two reported an increase in recreational screen time. Parents who perceived their child as overweight during pandemic doubled (f7.9% to 14.6%). Children's well-being behaviours that worsened more during pandemic were "having fun with friends" (44.3%), "got on well at school" (27.9%), "feel full of energy" (23.8%) and "feel fit and well" (22.2%).

Conclusions: These observations underscore the need to "build back better" post-pandemic with a focus on preventing and controlling childhood obesity and its determinants.

Key messages:

- Portuguese children experienced negative impacts of the pandemic in their lifestyle behaviours, particularly on their physical health and well-being, with a report of a poorer socioeconomic situation.
- This study and its findings give us a first-of-its-kind view into the physical and mental outcomes of the pandemic on school-aged children with a focus on the long-term, high-risk disease of obesity

Socio-economic gradients in urban green space access and respiratory health

Daniel Szabó

D Szabó[1], *H Pikhart*[1,2], *M Bobák*[1,2], *A Kšiňan*[1]
[1]RECETOX, Masaryk University, Brno, Czechia
[2]Department of Epidemiology and Public Health, University College London, London, UK
Contact: daniel.szabo@recetox.muni.cz

Background: This study investigates social disparities as one of the drivers influencing the access to green spaces and exposure to natural environments, potentially exacerbating disparities in respiratory health in children.

Methods: Longitudinal ELSPAC birth cohort study data included 4384 complete case participants born in cities of Brno and Znojmo, examined throughout the years 1990-2010. Estimates on socio-economic status (SES) scores of children's parents and their education were used as socio-economical predictors. Tree cover density (TCD) calculated as mean canopy closure percentage in the individual walking distance neighbourhoods and the ownership and accessibility of a garden were used as indicators of green space accessibility. Multiple logistic regression models were employed to estimate odds ratios for predictors of respiratory health outcomes, controlling for several confounders.

Results: Parents' SES was found to be positively associated with neighbourhood TCD, and this effect was even more pronounced for garden owners. Higher tree cover was then significantly negatively associated with development of acute bronchitis (OR 0.88, CI 95 % 0.84-0.94 for 1 SD of tree cover), while not having a garden (OR 1.81, CI 95 % 1.42-2.33) and living in area with lower tree cover (OR continuously decreasing from 1.88 to 1.68 for lowest and highest quartile respectively) was significantly associated with progression of acute bronchitis into chronic bronchitis in a fully adjusted model. Vice versa, higher tree cover was statistically significantly positively associated with development of allergic rhinitis (OR 1.09, CI 95 % 1.03-1.15), suggesting viability of the novel method of estimation of individual neighbourhood greenness.

Conclusions: The results suggest protective effect of access to urban green spaces against adverse respiratory outcomes in children. The socially uneven distribution of access emphasizes the importance of urban policies in promoting urban health. #NGEU

Key messages:

- There is a significant protective effect of access to green spaces against respiratory diseases and their progression.
- There's an unequal, but varied distribution of access to green spaces, and social gradient in health, highlighting the importance of urban green space distributive politics.

Abstract citation ID: ckae144.904
Thermal inequality and heat-related adaptive capacity: A systematic review

S Claire Slesinski

SC Slesinski[1,2], *F Matthies-Wiesler*[1], *S Breitner-Busch*[1,2], *G Gussmann*[3], *C Bunge*[3], *A Schneider*[1]
[1]Institute of Epidemiology, Helmholtz Munich, Neuherberg, Germany
[2]Faculty of Medicine, Ludwig Maximilians Universität München, Munich, Germany
[3]German Environment Agency, Dessau-Roßlau, Germany
Contact: sandraclaire.slesinski@helmholtz-munich.de

Background: Extreme heat is an important public health concern. Heat stress exposure and related adaptive capacity are not equally distributed across social groups, generating thermal inequality. We implemented a systematic review to answer the question: In the general population, what is the effect of social disadvantage on exposure to subjective and objective heat stress and adaptive capacity to prevent/reduce exposure to heat stress?

Methods: We searched for peer-reviewed journal articles published between 2005 and 2024. Screening and data extraction were conducted by one reviewer, with a second screening and extracting 10% for comparison. Synthesis included identification and description of specific social groups unequally exposed to heat stress and with lower adaptive capacity as well as a narrative description of the evidence and identification of research gaps.

Results: We identified 114 relevant publications. 53% included evidence on objective heat stress, 19% subjective heat stress, and 58% adaptive capacity. Nearly half came from North America (47%), 24% from Asia, and 17% from Europe. Publishing increased over time, from 0 articles in 2005 to 20 articles in 2023. Most studies considered socioeconomic status (SES) (87%), while fewer focused on race/ethnicity or other social factors. Across global regions, lower-SES populations, immigrants, and racial/ethnic minorities are generally more exposed to heat stress and have lower adaptive capacity, and lower-SES and minority neighborhoods are generally hotter and less green. Most studies of objective heat stress use imprecise measures, such as land surface temperature, which are not representative of experienced temperatures.

Conclusions: This review summarizes the available evidence on inequalities in heat stress exposure and adaptive capacity for the first time and identifies important research gaps related to heat stress measurement and social factors beyond SES.

Key messages:

- Heat stress exposure and related adaptive capacity are not equally distributed across social groups, generating thermal inequality.
- Social inequalities must be considered during climate change adaptation planning.

Abstract citation ID: ckae144.905
The association between traffic noise and self-rated health within the German National Cohort (NAKO)

S Claire Slesinski

S Slesinski[1,2], *K Wolf*[1], *S Zhuang*[3], *T Lakes*[3], *G Bolte*[4], *A Peters*[1,2], *A Schneider*[1]
[1]Institute of Epidemiology, Helmholtz Munich, Neuherberg, Germany
[2]Faculty of Medicine, LMU Munich, Munich, Germany
[3]Department of Geography, Humboldt University, Berlin, Germany
[4]Institute of Public Health and Nursing Research, University of Bremen, Bremen, Germany
Contact: scslesinski@gmail.com

Objectives: Traffic noise can cause stress and disturb sleep, impacting health in many ways. However, few large studies on this topic exist. We investigated the association between traffic noise and self-rated health (SRH) within the German National Cohort (NAKO).

Methods: NAKO enrolled >200,000 adults ages 20-74 at 18 sites in Germany. We used logistic regression to test whether 1) annual mean 24-hour ambient traffic noise levels at or above 55 dB(A) within a 10-meter residential buffer and 2) subjectively reported nighttime traffic noise annoyance were associated with higher odds of reporting fair/poor SRH. We calculated these associations within the full sample, stratified by sex, and stratified by age group

(≤39 years, 40-59 years, ≥60 years). We adjusted for study site, age, sex, marital status, education level, and migration background.

Results: Among participants without missing data (n = 121,232), moderate annoyance was associated with 1.27 higher odds (95% CI 1.21-1.32) and strong annoyance with 1.75 higher odds (95% CI 1.65-1.84) of fair/poor SRH, while annual mean noise ≥55 dB (A) was associated with 1.07 higher odds (95% CI 1.03-1.12). Females who reported strong annoyance had especially high odds of fair/poor SRH (OR 1.81, 95% CI 1.69-1.95), as did those aged 40-59 years who reported high annoyance (OR 1.78, 95% CI 1.66-1.92). Those 39 and under had no significant increase in odds of fair/poor SRH if they reported moderate annoyance or if they were exposed to ≥ 55 dB(A) annual mean noise. In single exposure models, noise annoyance and objectively measured noise were both significantly associated with higher odds of reporting fair/poor SRH, but in combined models, the effect of objectively measured noise became insignificant while the effect of annoyance remained strongly significant.

Conclusions: These findings confirm that traffic noise is an important public health issue. Further analyses on most affected populations should inform noise protection policies.

Key messages:

- Higher levels of traffic noise are associated with worse self-rated health.
- Ambient noise is an important public health issue for which more research is needed.

Heat-related risk in outdoor workers in the context of climate change: a systematic review

Maria Francesca Rossi

MF Rossi[1], A Pulvirenti[1], R Leone[1], MR Gualano[2], I Borrelli[1], PE Santoro[1], U Moscato[1]
[1]Università Cattolica del Sacro Cuore, Rome, Italy
[2]Unicamillus, Rome, Italy
Contact: mariafrancesca.rossi01@icatt.it

Background: Climate change is one of the paramount challenges in the current global health setting. From an occupational health perspective, outdoor workers are amongst the most vulnerable populations to climate change and heat-related risk. A systematic review was performed, aiming to assess heat-related health outcomes in outdoor workers.

Methods: The research query was structured using the Population, Intervention, Comparison and Outcome (PICO) model, and including synonyms and Medical Subject Headings (MeSH) terms for the following keywords: "outdoor workers", "climate change", and "occupational risk". The systematic review was performed following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statements, screening three databases (PubMed, Web of Science, and Scopus).

Results: After duplicate removal and title and abstract screening, the final screening by full-text resulted in 10 included studies. The included studies were performed mostly on construction (included in 5 studies, 50.0%) and agriculture (in 5 studies, 50.0%) workers. Eight studies (80.0%) had a majority of male workers, while one (10.0%) had a majority of female workers, and one study (10.0%) did not report on the gender ratio. Four of the included studies (40.0%) reported a high prevalence of heat-related symptoms, ranging from 64.0% to 90.3% of workers. Three studies (30.0%) showcased a prevalence of heat-related symptoms in less than 50% of workers (ranging from 11.6% to 47.5%). Three studies (30.0%) evaluated odds ratio, highlighting an increased odds ratio of heat-related symptoms in outdoor workers.

Conclusions: This systematic review highlights heat-related stress in outdoor workers as an important occupational risk. Mitigation and prevention strategies should be developed and implemented at a company, national, and supra-national level, to ensure the safety and wellbeing of outdoor workers worldwide.

Key messages:

- A systematic review was performed to assess risks related to climate change in outdoor workers. Heat-related symptoms were reported with a high prevalence, ranging from 64.0% to 90.3% of workers.
- Mitigation and prevention strategies should be developed and implemented at a company, national, and supra-national level, to ensure the safety and wellbeing of outdoor workers worldwide.

Accounting for adaptation when projecting climate change impacts on health: a review of methods

Kai Wan

R Cordiner[1], K Wan[2], S Hajat[2], H Macintyre[1,3]
[1]Centre for Climate and Health Security, UK Health Security Agency, Chilton, UK
[2]Centre on Climate Change and Planetary Health, LSHTM, London, UK
[3]School of Geography Earth and Environmental Sciences, University of Birmingham, Birmingham, UK
Contact: Kai.Wan@lshtm.ac.uk

Exposure to high and low temperatures can cause harm to health. Temperature related health effects are likely to increase in the future, due to global warming, unless populations can adapt to a warming environment. Adaptation occurs through multiple mechanisms, however, the amount that populations may adapt to rising temperatures is unclear. There are currently a variety of methods used to include adaptation in projections, but it is unclear how underlying assumptions are made and whether they are based on evidence. With increasing interest from decisionmakers around implementation of adaptation strategies, an important step in responding to climate change will be to understand how adaptation can statistically be incorporated when estimating future health burdens. A systematic scoping review was conducted to identify all quantitative methods to include adaptation in studies projecting future temperature-related health impacts under climate change. Approaches employed in studies were coded into methodological categories. Advantages and disadvantages of each method were also explored, along with the empirical basis for model assumptions. Eight methodological categories were identified from the included fifty-nine studies. More recent methods of including adaptation in projections use a combination of approaches or modelling adaptation based on specific adaptation strategies or socioeconomic conditions. The most used approaches in the literature to model adaptation are heat threshold shifts and reductions in the exposure-response slope. Just under 20% of studies were categorised as using an empirical basis for statistical assumptions. Including adaptation in projections considerably reduced the projected temperature-mortality burden in the future. Researchers should ensure that all future impact assessments include adaptation uncertainty in projections and assumptions are based on empirical evidence where possible.

Key messages:

- Including adaptation in future projections considerably affects temperature-related mortality numbers.
- All future impact assessments should include adaptation uncertainty and assumptions should be based on evidence where possible.

Introduction: Hospitals face a dual challenge with climate change (CC): reducing emissions and preparing for its impacts. The main objective of this study was to evaluate the knowledge, behaviours, and practices (KBP) of health workers (HWs) in French hospitals regarding CC and environmental sustainability (ES). The secondary objectives were to understand their expectations and identify associated factors with the KBP of HWs.

Methods: A multicenter cross-sectional KBP study was carried out among HWs of six French hospitals from June 2021 to December 2022. A structured questionnaire was designed and consisted of five parts: i) participant characteristics, ii) CC knowledge and perceptions, iii) behaviours, iv) practices concerning ES actions, and v) expectations. A multilevel logistic regression model assessed associations between HWs' KBP and both individual and hospital characteristics.

Results: Out of 57034 HWs, 4552 (8.0%) participated in the study. Only 15.4% identified the activities with the greatest environmental impact. On a scale of 1 (Not a priority) to 10 (High priority), the average median rating attributed to commitment to ecological transformation in their hospitals was 5.0/10. Among the participants, 1079 (23.7%) had already initiated at least one ES action. To implement ES-related projects, main barriers were reported including lack of dedicated time (40.4%), hierarchical support (32.5%), methodological support (28.9%), and training access (23.7%). The presence of a sustainable development steering committee, especially active for over 5 years, positively correlated with better information for HWs (ORa=1.78 [1.29-2.45]), better knowledge (ORa=1.83 [1.32-2.53]), and more ES actions initiated (ORa=1.74 [1.33-2.29]).

Conclusions: French HWs demonstrate a commitment to making their hospitals more environmentally sustainable. Some drivers and barriers were identified to further support these essential transformations.

Key messages:

- First national study on knowledge, behaviours, practices, and expectations on climate change and environmental sustainability among French health workers.
- Among the drivers to strengthen dynamics within hospitals, the need for training among French health workers and institutional support has been identified.

Abstract citation ID: ckae144.909
A systematic review of health outcomes of public transport use by older adults

Omer Dilian

O Dilian[1], *C Beckers*[2], *N Davidovitch*[3], *K Martens*[1]
[1]Faculty of Architecture and Town Planning, Technion - Israel Institute of Technology, Haifa, Israel
[2]Faculty of Sciences, Ghent University, Ghent, Belgium
[3]School of Public Health, Ben Gurion University of The Negev, Be'er Sheba, Israel
Contact: Dilian.omer@campus.technion.ac.il

Background and Aim: Public transport use has been linked to several health benefits in the general population, and is crucial for older adults' mobility, due to an age-related decline in mobility, and particularly the ability to use other transport modes. The objective of this systematic review is to determine what is known about the physical and mental health outcomes of public transport use by older adults and to identify remaining gaps in the literature.

Methods: Five electronic databases were searched in April 2023, with an update in January 2024: Pubmed, Scopus, Web of Science, Ageline and Transport Research International Documentation (TRID). Included were studies that were in English, contained a measure of public transport use as exposure, and any health outcome, including mental or physical health, physical or cognitive function, morbidity, or mortality, among people aged $\geq$ 60 years.

Results: Of a total of 2247 unique records that were screened, the full text of 20 was assessed for eligibility and 11 were identified as eligible. Citation search identified two additional studies, amounting to a total of 13 included studies. Significant health outcomes described in assessed studies were decreased obesity and depressive symptoms, and to a lesser extent increased gait speed and cognitive function.

Conclusions: Initial evidence suggests a positive impact of public transport use on obesity, depressive symptoms, gait and cognitive function, although available research was limited in context and methodology. Further research should focus on determining causality between public transport use and health, and be conducted in more diverse contexts. Transport and urban planners, as well as policymakers, should consider the implications of public transport on the health and independence of older adults.

Key messages:

- Public transport use is linked to reduced obesity and depression among older adults. Links with other health outcomes were reported in several studies, but evidence is scarce.
- Current research is limited in terms of quantity, scope, and design. Future research should be conducted in wider contexts, encompass a broader range of health outcomes, and address reverse causality.

Abstract citation ID: ckae144.910
Outdoor living environment and cardiovascular disease risk: results from a Swedish cohort

Pauline Rebouillat

P Rebouillat[1], *K Mattisson*[1], *G Gefenaite*[2], *P Nilsson*[3,4], *J Björk*[1,5]
[1]Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden

[3]Department of Clinical Sciences, Lund University, Lund, Sweden
[4]Department of Internal Medicine, Skåne University Hospital, Malmö, Sweden
[5]Clinical Studies Sweden, Forum South, Skåne University Hospital, Lund, Sweden
Contact: pauline.rebouillat@med.lu.se

Cardiovascular disease (CVD) is the leading cause of mortality and morbidity worldwide. While sociodemographic, dietary and lifestyle factors have been well documented in relation to CVD, environmental factors have been less studied. However, considering the ongoing biodiversity, climate, and health crises, it is imperative to better understand the interplay between the environment and health. This study aimed to examine the associations between green qualities of the residential environment and CVD. The Malmö Diet and Cancer study is a prospective cohort initiated in the 1990s in the city of Malmö (southern Sweden). At baseline, participants were invited to a health screening, including extensive questionnaires about socioeconomic conditions, lifestyle and diet, clinical examination and blood sampling. The residential coordinates of the participants at baseline were linked to the Scania Outdoor Environment Database comprising scores for a range of perceived qualities of the neighbourhood outdoor environment. Three greenness-related dimensions (serene, natural, diverse) were selected for this substudy. Information on incidence of CVD until 2019 was retrieved from Swedish registers. Adjusted Cox proportional hazards models were used to estimate associations between green-related qualities and cardiovascular diseases (major adverse coronary events). Approximately 27000 participants were included, of which 60% were women. The average age at baseline was 58 years old (±8). Mean follow-up was 20 years (±7) and 4318 cases of major adverse coronary events were identified. Preliminary results suggest that several sociodemographic and lifestyle factors, as well as some aspects of neighbourhood greenness, were associated to increased cardiovascular incidence. Neighbourhood greenness might play a role in major adverse coronary events incidence. Further investigation on underlying mechanisms is required.

Key messages:

- Identifying environmental risk factors for cardiovascular disease is of importance for public health.
- Neighbourhood greenness might play a role in cardiovascular disease incidence, and underlying mechanisms need to be investigated further.

Abstract citation ID: ckae144.911
Effect of sustainable food habits on gut microbiota diversity: A pilot study

Annika Tillander

A Tillander[1,2]*, O Halling Ullberg*[2]*, S Toivanen*[2,3]*, K Bälter*[2,4]
[1]Computer and Information Science, Linköping University, Linköping, Sweden
[2]School of Health, Care and Social Welfare, Mälardalen University, Västerås, Sweden
[3]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
[4]Department of Medical Epidemiology and Biostatistics, Karolinska Institute, Stockholm, Sweden
Contact: annika.tillander@liu.se

Background: To reach climate goals, sustainable food habits are needed and a plant-based diet is more climate-friendly. However, analyses of food products show that the highest levels of pesticide residues have been found in vegetables, fruits and cereal. Further, pesticide residues have been seen to decrease microbiota diversity. Since microbiota diversity is linked to human health, understanding these dynamics is crucial. This study aimed to evaluate the effect of sustainable food habits on gut microbiota diversity.

Methods: An 8-week intervention study on sustainable food habits with participants randomized into three groups and assigned to different diets; climate friendly ($n = 8$), organic ($n = 9$) and control group ($n = 9$). Data was collected at baseline, at 4 weeks, and at 8 weeks and included a comprehensive meal questionnaire (Meal-Q), urine samples for pesticide analysis, and fecal samples for gut microbiota diversity. As intervention the groups attended four educational sessions about their specific diet. Linear mixed-effects models were used for data analyses.

Results: There was no indication of adverse effects of a climate friendly diet ($p = 0.79$) or an organic diet ($p = 0.32$) on gut microbiota diversity compared to the control group. Pesticide residues that showed negative effects on gut microbiota diversity were mepiquat ($p < 0.05$) and chlormequat ($p < 0.05$). The single food items that had adverse effects on gut microbiota diversity was Lemonade ($p < 0.05$), Juice ($p < 0.05$), and Brie cheese ($p < 0.05$).

Conclusions: Despite its small sample size, this study provides valuable insights, supported by an 8-week longitudinal design and comprehensive monitoring of dietary habits. Notably, both climate-friendly and organic diets showed trends toward increased gut microbiota diversity over time. These findings need to be confirmed in future studies with longer durations and larger sample size.

Key messages:

- A climate-friendly diet not only benefits planetary health but also holds potential for individual health improvements.
- Increased intake of plant-based items did not reduce gut microbiota diversity.

Blue crab (Callinectes sapidus) is one of the last reported invasive species that have colonized the Italian coasts, in particular the lagoons of the northern Adriatic Sea. Their massive presence is compromising shellfish farming, causing a serious economic crisis among the valley populations. To limit the economic damage, blue crabs have been introduced as human food in the Italian markets. This study aimed to evaluate the microbiological contamination of blue crab as potential risk to human health. From July 2023 to April 2024, 72 blue crabs were collected in coastal lagoons and 5-6 nm from the coast of the Emilia Romagna Region. Microbiological analysis revealed Shewanella algae as one of the most commonly identified microorganisms (18/72, 25%). Shewanella was isolated on Chromagar Vibrio^{TM} and TCBS after an enrichment step in Alkaline Saline Peptone Water. Colony morphology, Gram stain, and biochemical tests (oxidase, catalase) sustained Shewanella identification, later confirmed by MALDI-TOF MS (MALDI Biotyper$^{®}$ Sirius, Bruker Daltonics). S. algae is a Gram-negative, rod-shaped, aerobic microorganism widely distributed in seawater, freshwater, and soil. In humans, it is considered an opportunistic pathogen, especially in people with impaired immune systems. Shewanellosis has been strongly associated with seawater exposure and typically arises in hot months. Clinical manifestations include skin and soft tissue infections, otitis media, keratitis, biliary tract infections, vertebral discitis, and bloodstream infections. Notably, in the last years, S. algae infections have increased globally, even in healthy young people. The present study suggests blue crabs as a potential source of S. algae throughout the year. The increasing identification of S. algae in marine waters worldwide, as well as in marine-derived foods like blue crabs, underscores the growing importance of S. algae as an emerging pathogen and its impact on public health.

Key messages:

- Shewanella algae is an opportunistic pathogen, increasingly isolated in marine water and seafood.
- Blue crab is an invasive species that has recently conolonised the Italian coasts.

Abstract citation ID: ckae144.913
Scanning the horizon- environmental health indicator surveillance

Aoife O'Connell

A O'Connell[1], M Casey[1], B Cosgrove[1]
[1]Department of Public Health MidWest, HSE, Limerick, Ireland
Contact: aoife.oconnell5@hse.ie

Aim: This work aimed to conduct a comprehensive literature review with narrative synthesis of evidence in relation to the surveillance of environmental health indicators by Public Health agencies internationally. This will strengthen the All-Hazards approach to Health Protection in Ireland.

Methods: The project proposal was registered on PROSPERO. Preferred Reporting Systems for Systematic Review and Meta-Analysis (PRISMA) guidelines were followed. A systematic search was conducted across five databases. In addition, relevant websites, reference lists and the grey literature were searched. Data were extracted following TIDieR-PHP guidelines. Risk of bias was considered and quality appraisal was performed using SANRA and AGREE-HS tools. A narrative synthesis of the evidence was completed.

Results: 12 papers were included in the final review. Four were narrative review articles describing European and worldwide initiatives and the remaining eight described a single health system. Only three papers were deemed high quality. The number of indicators monitored varied widely from one in Italy to over 400 in the USA. The most established programmes described the use of a framework such as Drivers-Pressures-States-Exposures-Effects-Actions (DPSEEA) and indicator selection criteria were applied. The papers described a variety of public health actions arising from the surveillance of environmental health indicators. The knowledge provided by this review can inform the implementation process. Establishment of a project team, and beginning with monitoring one domain is suggested. Air quality is the most frequently monitored domain internationally. The DPSEEA framework is recommended, and Briggs' indicator selection criteria should be applied to any indicator under consideration. The system should measure both hazard and outcome measures. Finally, meaningful public health action should result from the monitoring.

Key messages:
- Environmental health indicator surveillance is essential to all-hazards health protection.
- Few public health agencies internationally are systematically monitoring environmental health outcomes.

Abstract citation ID: ckae144.914
Taxing animal-based food products: A qualitative framing analysis of the media debate in Germany

Anna Leibinger

A Leibinger[1,2], KS Moerschel[1,2], A Hagge[1,2], B Hawkins[3], P von Philipsborn[1,2]
[1]Chair of Public Health, LMU Munich, Munich, Germany
[2]Pettenkofer School of Public Health, Munich, Germany
[3]MRC Epidemiology Unit, University of Cambridge, Cambridge, Germany
Contact: anna.leibinger@ibe.med.uni-muenchen.de

Background: In most high-income countries, consumption of animal-based food products exceeds levels recommended for health and environmental reasons. Although taxes can reduce the consumption of animal-based products, they are politically controversial. In recent years, various tax models and motivations for these have been discussed. Our study seeks to identify key arguments and policy actors in the German media debate on the taxation of animal-based products, shedding light on emerging narrative frames surrounding tax models and motivations.

Methods: We conducted a qualitative analysis of German media coverage on taxes and levies influencing the price of animal-based foods. We analyzed 488 articles from 10 national newspapers and eight trade press journals published between February 2019 and July 2023. Employing an inductive approach, we identified the actors involved in the debate and common frames and arguments around various tax proposals.

Results: We found broad consensus on a need for change due to inadequate animal welfare conditions, while environmental and health arguments are more contested. Significant debate surrounds the suitability of taxation as the preferred policy instrument. Furthermore, doubts are raised about a tax's effectiveness and appropriate revenue allocation. Framing of the tax often emphasizes potential negative impacts on domestic production and product affordability. Additionally, concerns about various unintended consequences and the overall unpopularity of taxation emerge as prominent themes.

Conclusions: The taxation of animal-based products for health and environmental reasons is still highly contested in the media debate in Germany. Many, but not all arguments commonly raised against such taxes may be considered spurious from an evidence-based public health perspective. Proponents of such taxes may seek to address existing concerns through appropriate policy design and communication strategies.

Key messages:
- Taxation of animal-based foods may help to align consumption with levels recommended for health and environmental reasons, but adoption and implementation is hindered by political controversy.
- Objections common in the public debate on such taxes could be addressed with appropriate policy design alleviating justified concerns, and with communication strategies countering spurious arguments.

Abstract citation ID: ckae144.915
Air Pollution Reduces the Individuals' Life Satisfaction Through Health Impairment

Mary Abed Al Ahad

M Abed Al Ahad[1]
[1]School of Geography and Sustainable Development, University of St Andrews, St Andrews, UK
Contact: maaa1@st-andrews.ac.uk

Background: The impact of air pollution on individuals' happiness and life satisfaction (LS), and its relationship to other factors became the focus of recent research. Though, the underlying mechanism of how air pollution impacts LS remains unclear. In this study, we examined the direct and indirect effect of air pollution on individuals' LS through health mediation.

Methods: We used longitudinal individual-level data from "Understanding-Society: the UK Household-Longitudinal Study" on 59,492 individuals with 347,377 repeated responses across 11 years (2009-2019) that was linked to yearly concentrations of NO2, SO2, and particulate-matter (PM10, PM2.5) pollution. Generalized structural equation models with multilevel ordered-logistic regression were used to examine the direct effect of air pollution on LS and the indirect effect from health impairment.

Results: Higher concentrations of NO2 (coefficient = 0.009, 95%CI = 0.007,0.012, $p < 0.001$), SO2 (coefficient = 0.025, 95%CI = 0.017,0.034, $p < 0.001$), PM10 (coefficient = 0.019, 95%CI = 0.013, 0.025, $p < 0.001$), and PM2.5 (coefficient = 0.025, 95%CI = 0.017,0.033, $p < 0.001$) pollutants were associated with poorer health, while poorer health was associated with reduced LS (coefficient = -0.605, 95%CI = -0.614,-0.595, $p < 0.001$). Mediation path analysis showed that air pollution impacted individuals' LS directly and indirectly. The percent of total effect mediated through health was 44.03% for NO2, 73.95% for SO2, 49.88% for PM10, and 45.42% for PM2.5 and the ratio of indirect to direct effect was 0.79 for NO2, 2.84 for SO2, 0.99 for PM10, and 0.83 for PM2.5.

Conclusions: Health plays a major mediating role in the relationship between air pollution and LS. To alleviate the impact of air pollution on LS, future strategies should focus on health promotion besides reducing air pollution emissions.

Key messages:

- Air pollution is related to lower life satisfaction directly and indirectly through health impairment.
- Strategies and policies aiming at reducing air pollution emissions and better health would improve the individual's life satisfaction and lower the mental health burden.

Abstract citation ID: ckae144.916
A selective diesel vehicle ban's impact on NO2 concentrations in Munich: a quasi-experimental study

Anna Leibinger

A Leibinger[1,2], *E Rehfuess*[1,2], *J Burns*[1,2,3]
[1]Chair of Public Health and Health Services Research, LMU Munich, Munich, Germany
[2]Pettenkofer School of Public Health, Munich, Germany
[3]Professorship of Public Health and Prevention, Technical University of Munich, Munich, Germany
Contact: anna.leibinger@ibe.med.uni-muenchen.de

Background: The European Union's current NO2 concentration limit of 40 µg/m^3 is regularly exceeded in Munich, Germany. This limit is likely to be reduced towards the WHO recommended target of 10 µg/m^3. In response, the city enacted a selective ban on older diesel vehicles, specifically those categorized as Euro 4 or older, within the current low-emission zone in February 2023. Our study examined how Munich's selective ban on diesel vehicles impacted NO2 levels, concentrating on the six-month period after its introduction.

Methods: We employed a synthetic control approach in the primary analysis and a controlled interrupted time series approach in the secondary analysis. These quasi-experimental methods establish a 'counterfactual' no-intervention scenario, allowing for comparison with the actual observed scenario and estimation of the impact of the intervention. Historical data from monitoring stations within and outside the low-emission zone from 2014 to 2022 were utilized as controls, while potential confounders were considered.

Results: NO2 concentrations within Munich's low-emission zone decreased across the study period. Effects of the selective diesel vehicle ban at monitoring stations within the low-emission zone were minimal, with wide confidence intervals indicating uncertainty. At Landshuter Allee, the average intervention effect was -2.67 µg/m3 (95%-CI = [-12.72; 7.38]), at Stachus it was -2.74 µg/m3 (95%-CI = [-9.91; 4.42]) and at Lothstrasse, it was -1.03 µg/m3 (95%-CI = [-7.75; 5.69]). The secondary analysis confirms these findings.

Conclusions: Munich's selective diesel vehicle ban had limited effects in reducing NO2 concentrations. Factors such as its narrow focus on Euro 4 diesel vehicles, numerous exemptions, and unclear enforcement may explain this outcome. Comprehensive strategies and continuous monitoring and evaluation are crucial for effectively addressing urban air pollution and protecting public health.

Key messages:

- Munich's selective diesel vehicle ban had minimal effects on reducing NO2 levels, possibly due to its narrow scope, many exemptions, and unclear enforcement.
- Current guidelines and court rulings signal the need for more effective solutions beyond selective bans, emphasizing the importance of well-designed interventions and rigorous evaluation.

Sickness absence patterns during the COVID-19 pandemic among Finnish public sector employees

Eija Haukka

E Haukka[1], *M Joensuu*[1], *J Kausto*[1], *T Oksanen*[2], *J Vahtera*[3], *M Kivimäki*[4], *J Ervasti*[1]
[1]Finnish Institute of Occupational Health, Helsinki, Finland
[2]University of Eastern Finland, Kuopio, Finland
[3]University of Turku, Turku, Finland
[4]University of Helsinki, Helsinki, Finland
Contact: eija.haukka@ttl.fi

Background: The patterns of sickness absence (SA), that is, the clustering of differing lengths of episodes and total number of days absent, have not been examined. We examined these SA patterns and factors associated with the patterns during the COVID-19 pandemic.

Methods: We used survey data from employees of four large Finnish cities in 2020 linked with SA data in 2021 retrieved from employer registers (n = 39 791). SA patterns were defined through cluster analysis (K-means) including number of SA days, short (1-9 days), and long (10-365 days) SA episodes within one year. The associations of employee and work characteristics in 2020 with SA clusters in 2021 were analysed with multinomial regression.

Results: Four SA patterns (=clusters) were identified: 1) Optimal SA pattern (n = 31 320, 79%), 2) Recurring short SA episodes (n = 5149, 13%), 3) Recurring long SA episodes (n = 2964, 7%), and 4) Very high levels of SA with long episodes (n = 358, 1%). Compared to optimal SA pattern, female gender, higher body mass index, former smoking, abstinence from alcohol, not being in high occupational socioeconomic position, on-site work during COVID-19, and COVID-19 infection were associated with all suboptimal SA patterns. Recurring short SA episodes were more likely in younger employees (odds ratio=0.98, 95% confidence interval 0.97-0.98), those with a temporary job (1.10, 1.00-1.20), current smokers (1.34, 1.21-1.48), those using passive commute modes (1.03, 1.01-1.05 [car]; 1.02, 1.00-1.04 [public transport]), and those who had experienced a team reorganization due to COVID-19 (1.27, 1.10-1.46). The two most adverse SA patterns were more likely among older employees, and less likely among those cycling to work (0.91, 0.84-0.98; 0.97, 0.95-0.99).

Conclusions: We identified three differential suboptimal SA patterns. Compared to the optimal SA pattern, several individual-level risk factors, but also some COVID-19 related factors were found to associate with suboptimal SA patterns.

Key messages:

- We identified three suboptimal sickness absence patterns during COVID-19 pandemic.

- Individual characteristics, but also COVID-19 related factors were associated with the observed sickness absence patterns.

A scoping review on sociodemographic inequalities in breast cancer screening attendance in Germany

Núria Pedrós Barnils

N Pedrós Barnils[1,2], *V Härtling*[1], *H Singh*[1], *U Haug*[2], *B Schüz*[1,2]
[1]Prevention and Health Promotion, Bremen University, Bremen, Germany
[2]Digital Public Health, LeibnizScience Campus, Bremen, Germany
Contact: nupedros@uni-bremen.de

Background: Organized breast cancer screening (BCS) programs are effective measures among women aged 50-69 for preventing the fifth cause of death in Germany. However, still participation rates have not yet reached EU standards. It is unclear which and how sociodemographic factors are related to BCS attendance. This scoping review aims to identify sociodemographic inequalities in BCS attendance among 50-69-year-old women following implementing the Organized Screening Program in Germany.

Methods: Following PRISMA guidelines, we searched the Web of Science, Scopus, MEDLINE, PsycINFO, and CINAHL. We included primary studies with a quantitative study design and reviews examining BCS attendance among women aged 50-69 with data from 2005 onwards in Germany. Harvest plots depicting effect size direction for the different identified sociodemographic inequalities were developed.

Results: We screened 476 titles and abstracts and 33 full texts. In total, 27 records were analysed, 14 were national reports, and 13 peer-reviewed articles. Eight sociodemographic variables were identified and summarised in the harvest plots: age, education, income, migration status, type of district, employment status, partnership cohabitation and health insurance. Older women, women with lower incomes and migration backgrounds who live in rural areas and lack private insurance, respond more favourably to BCS invitations. However, from a lifetime perspective, these associations only hold for migration background, are reversed for income and urban residency, and are complemented by partner cohabitation. Finally, women living in the federal states of Lower Saxony, Saxony, Mecklenburg-Western Pomerania, Saxony-Anhalt, and Thuringia showed higher attendance rates in the last two years.

Conclusions: High-quality research is needed to identify women at higher risk of not attending BCS in Germany, particularly as the overall attendance rate still falls below European standards.

Key messages:

- High-quality research is needed to identify women at higher risk of not attending BCS in Germany, particularly as the overall attendance rate still falls below European standards.
- Women without migration background, high income, living in rural areas, and not cohabitating with their partners are at higher risk of never attending BCS in Germany.

[2]Center for Child Health, Center for Child Health, Rome, Italy
[3]Research & EU Projects, Deep Blue S.r.l., Rome, Italy
[4]Italian National Committee for UNICEF, UNICEF, Rome, Italy
Contact: francesca.zambri@iss.it

Background: In recent years, there has been a focus on the role of fathers in childcare within public debates and social policies. Maternity, paternity, and parental leaves are essential tools for active father involvement in family life. The study aims to describe the fathers and mothers' perspective about the use of two types of leave (paternity and parental) by fathers.

Methods: As part of the European project 4E (Early, Equal, Engaged, Empathetic) PARENT (CERV-2022-DAPHNE No. 101095956), a cross-sectional study was carried out using an online questionnaire addressed to parents between August and December 2023.

Results: A total of 3,811 mothers and 720 fathers participated. Sixty percent of mothers and 57% of fathers came from the North, with the majority having a high level of education (74% and 58%, respectively). Seventy-three percent of fathers reported using paternity leave, with most cases from the public welfare system (59%). Overall, most of mothers (91%) and fathers (89%) do not consider the current duration of leave adequate nor do they agree with the traditional division of family roles. Additionally, 69% of mothers and 72% of fathers believe that fathers should have more leave, but also that mothers need more months for breastfeeding. The logistic model shows that for fathers: low education level (ORadj 0.34, 95% CI 0.13-0.86), living in the Center (ORadj 0.49, 95% CI 0.28-0.87) and Southern Italy (ORadj 0.32, 95% CI 0.15-0.64), and acceptance of traditional family role division (ORadj 0.30, 95% CI 0.14-0.65) reduce the likelihood of using paternity leave. Similar results were observed in case of mothers' responses. Furthermore, living in Southern Italy reduces the likelihood of using parental leave for both fathers (ORadj 0.24, 95% CI 0.09-0.69) and mothers (ORadj 0.67, 95% CI 0.49-0.92).

Key messages:

- Maternity, paternity, and parental leaves are crucial for facilitating active father participation in family life.
- It is important to implement inclusive policies that ensure equitable access to paternity and parental leave, thereby promoting active father involvement in childcare.

Abstract citation ID: ckae144.920
Co-creation of migrant health interventions in Portugal: Insights from the VO(I)CES project

Ana Gama

MJ Marques[1,2], *A Seyfulayeva*[1], *S Hamwi*[1], *AS Machado*[1], *A Gama*[1,2], *R Osbourne*[3], *S Dias*[1,2]
[1]Public Health Research Centre, NOVA National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[2]Comprehensive Health Research Center, REAL, NOVA University Lisbon, Lisbon, Portugal
[3]Centre for Global Health and Equity, Swinburne University of Technology, Hawthorn, VIC, Australia
Contact: ana.gama@ensp.unl.pt

Background: International migration is increasing both globally and in Europe, highlighting the need for responsive interventions that cater to the diverse needs and strengths of migrants. Although genuine involvement of stakeholders in the design and implementation of interventions is vital to enhance their relevance, responsiveness, and ownership, co-created migrant health interventions remain limited. This study aims to address this gap by collaboratively developing health literacy interventions with meaningful involvement from migrants and professionals from both the social and health sectors.

Methods: As part of the VO(I)CES project, twelve idea-generation workshops were conducted in Portugal, applying the Ophelia (Optimising Health Literacy and Access) process, engaging over 70 stakeholders (migrants, social and healthcare professionals). To guide discussions, these workshops used case vignettes developed from 16 health literacy profiles that were identified in a previous study among 1,126 migrants. The discussions aimed at eliciting detailed insights into the potential actions that are responsive to migrants' challenges.

Results: Several key interventions were identified by the stakeholders, including the enhancement of cultural and linguistic training for healthcare providers, the use of community health agents/mediators to improve service delivery and community engagement, and the creation and dissemination of multilingual, multi-format health information materials. Specific interventions for groups experiencing increased vulnerabilities such as pregnant women were also proposed, alongside suggestions for creating citizen spaces and improving digital skills among healthcare staff.

Conclusions: The co-creation approach facilitated the development of tailored context-specific interventions that are anticipated to enhance health literacy, improve healthcare accessibility, and promote health equity for migrants.

Key messages:

- Ideas Generation Workshops provide a platform for a wide range of groups to have their say and know their voice is being heard.
- Co-creation tailors interventions to diverse needs, avoiding a one-size-fits-all approach.

Abstract citation ID: ckae144.921
Identification of different types of nicotine product users: results from a cluster analysis

Iris Kramer

I Kramer[1], *NA van Westen-Lagerweij*[1], *E Cornelissen*[1], *N Lize*[1], *EPC Hopman*[1], *EA Croes*[1]
[1]Tobacco Control, Trimbos Institute, Utrecht, Netherlands
Contact: ikramer@trimbos.nl

Background: Smoking cessation interventions often target people that use nicotine products as one homogenous group. However, heterogeneity exists among people who smoke and/or use e-cigarettes. The aim of the current study was to characterize clusters of nicotine product users based on their use and motives.

Methods: The study included 2000 people who smoke and/or use e-cigarettes aged $\geq$18 years in the Netherlands. Respondents were recruited from a large survey-panel between August and October 2023. The questionnaire consisted of questions on demographics, product use/frequency, and motives to use nicotine products and motives to quit. A cluster analysis was used to identify the number and nature of subgroups reporting similar product behavior and/or motives. Analyses were weighted to correct for imbalances between the survey sample and the population of the Netherlands.

Results: Four clusters were identified. Cluster 1 'socially-influenced smoker' (13%) had a greater proportion of men, participants indicated using a variety of products and often try a product if they have seen other people using it. Cluster 2 'party smoker' (5%) was characterized by participants being young, mostly smoke during a social event, and indicated that drinking alcohol is a reason to smoke/use a nicotine product. Participants in cluster 3 'coping-driven smoker' (43%) were more often women, use nicotine products to reduce stress, to relax and regulate mood. Cluster 4 'Inveterate smoker' (39%) mainly contained participants of older age and endorsed smoking due to pleasure and habit and see smoking as part of their identity. The socially-influenced smoker had the highest intention to quit (67%), and the inveterate smoker the lowest (35%). Among all clusters, improving health was reported as most important reason to stop using nicotine products.

Discussion: Classifying nicotine product users into subgroups based on their use and motives could lead to more appropriate smoking cessation interventions.

Key messages:

- People who use nicotine products are not a homogenous group, but can be divided into different clusters based on their product use and motives.
- Classifying people that use nicotine products into subgroups based on their use and motives could lead to more appropriate smoking cessation interventions.

Abstract citation ID: ckae144.922
Physical activity promotion in Aged care: a participatory approach

Annika Frahsa

A Frahsa[1], *LS Hahn*[2], *A Thiel*[2]
[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland
[2]Institute of Sport Science, University of Tuebingen, Tübingen, Germany
Contact: annika.frahsa@ispm.unibe.ch

Introduction: Aged care facilities (ACF) constitute an increasingly important, yet challenging setting for health promotion - given it is a highly sedentary pseudo-total institution characterized by structured daily routines within a paradigm of care for residents perceived as fragile and vulnerable. A participatory approach with residents, significant others, staff, and management might be a promising pathway to address intrapersonal, sociocultural, organizational, environmental, and political determinants of physical activity in this specific context. We will present processes and results from a research project, funded by the German Ministry of Health (2019-2023), on physical activity promotion in ACFs.

Methods: Our co-creation approach involved residents, significant others, staff, and management from seven nursing homes in Southern Germany. Methods included 800hrs on-site observations, semi-structured interviews ($n = 31$), Photovoice ($n = 27$ participants, $n = 169$ photos), as well as future workshops ($n = 14$) for intervention co-development ($n = 14$) and co-evaluation workshops ($n = 7$). Data analysis used reflexive thematic analysis with MaxQDA20.

Results: Implemented interventions ($n = 57$) addressed individual, social, environmental, and organizational factors. Activity promotion was integrated into care concepts and mission statements, staff work descriptions, as well as informal internal routines. Of the interventions implemented, 33% were rated as more successful, 43% as successful, and 19% as less successful than anticipated.

Conclusions: Participation can initiate structural and cultural change towards physical activity. However, the analyses also emphasized the critical role of staff training, along with the involvement of significant others and external service providers, as essential components for achieving sustainable change.

Key messages:

- Participatory approaches integrate physical activity into aged care, fostering cultural shifts for resident well-being.
- Success requires staff training, engaging residents' support networks, balancing empowerment with protection.

Abstract citation ID: ckae144.923
Changes of lifestyle and mental health among COVID-19 situation: resident-centered health promotion

Takeo Shibata

T Shibata[1], *M Koyano*[2], *C Hiraga*[2], *Y Shimizu*[3]
[1]Department of Health Management, Tokai University, Kanagawa, Japan
[2]Yuzawa Town, Niigata, Japan
[3]Graduate School of Nursing, Tokyo Women's Medical University, Tokyo, Japan
Contact: takeo.shibata10@gmail.com

Background: Yuzawa town, located in the Niigata prefecture of Japan, is famous for its hot springs and ski resorts. A sustainable action plan for resident-centered regional health promotion (Yuzawa family health plan) was initiated in 2002. Surveys have been conducted every five years. This study aims to evaluate changes of their habits and mental health status between in 2017 and in 2022.

Methods: The survey of Yuzawa family health plan was conducted in 2017 and in 2022. Questionnaires were composed with living alone, living with marriage partner, living with son or daughter, living with grandchildren, living with brother or sister, health consciousness, attention to health, health concern, awakening in a morning, clockwork life, fitness habits, smoking, taking alcohol, anxiety, loneliness, consultation, resolve suffering, economic problem, handle stress, taking a rest, risk breaching, communication, life satisfaction, talking with family, job at home, intercommunion with friends, greeting with neighbors, relationship with neighbors, occupations, good sleep, taking breakfast, nutritional balance, mastication status, confirmation of food compositions, exercise habits, yearly health check-up, dental check-up, brushing teeth habits, and sleep satisfactions. Chi square tests were used to evaluate changes between in 2017 and in 2022. This study was approved by the ethics committee of Tokyo Women's Medical University.

Results: Passive smoking, intercommunions with neighborhood and friends, exercises, and Salt reduction awareness reduced in 2022. Talking with family, taking a rest, attention to health, clockwork life, and sleep satisfactions increased.

Conclusions: Many changes were shown between in 2017 and in 2022. Because elderly has been able to use a mobile phone, loneliness was not increased. But numbers of elderly living alone have been increased from 2002. Health promotion programs giving health information for elderly is needed.

Key messages:

- Many lifestyle changes were shown between in 2017 and in 2022.
- Passive smoking reduced. Taking a rest and attention to health increased.

[7]Public Health, Université de Montréal, Montréal, Canada
Contact: ariane.belanger-gravel@com.ulaval.ca

Background: The World Health Organization highlighted the need to better integrate behavioural science in the field of public health. Based on the theoretical domains framework, this study examined correlates of public health practitioners' use of behavioural science principles to plan public health actions aim at promoting physical activity and healthy eating.

Methods: This study adopted a cross-sectional design. A convenience sample of 160 public health practitioners were recruited from different public health agencies (non-profit organizations, governmental and para-governmental agencies). They were asked to complete a survey questionnaire online and self-reported their use of behavioural science to plan health promotion interventions. Regression analyses were conducted to examine correlates of behaviour and behavioural intentions. All analyses were controlled for sex, number of years of experience in public health and the type of organization they work for.

Results: Skills (OR = 4.1, 95%CI: 1.3, 13.5) and intentions/goals (OR = 9.2, 95%CI: 2.3, 36.1) were the two domains significantly associated with the use of behavioural science. Perceived capacity to overcome the fact that none of their colleagues rely on behavioural sciences in their organization (OR = 7.2, 95%CI: 1.7, 30.3) was also associated with behaviour. Knowledge (OR = 8.6, 95%CI: 1.9, 39.1) and beliefs about consequences (OR = 4.0, 95%CI: 1.1, 14.7) were in turn associated with intentions/goals.

Conclusions: This unique study provides important insights for the development of future knowledge transfer activities aim at supporting positive attitudes and motivations toward the use of behavioural science as well as developing competencies and a normative use of behavioural science. The development of a strong knowledge basis would also need to be a core component of trainings to support the integration of behavioural science in public health to design physical active lifestyles and healthy eating interventions.

Key messages:

- Increasing knowledge and skills in behavioural sciences is a key for a better integration in public health practices.
- Changes in norms and attitudes toward the use of behavioural sciences will also support a better uptake.

Abstract citation ID: ckae144.925
Understanding compliance with smoke-free environments: a realist review

Sophie Jooren

SJA Jooren[1,2], *H Garritsen*[2], *S Troelstra*[2], *MC Willemsen*[1,2], *M Jansen*[3], *J Bommelé*[2]
[1]Department of Health Promotion, Maastricht University, Maastricht, Netherlands
[2]Dutch Expertise Centre for Tobacco Control, Trimbos Institute, Utrecht, Netherlands
[3]Department of Health Services Research, Maastricht University, Maastricht, Netherlands
Contact: s.jooren@maastrichtuniversity.nl

Background: Local governments increasingly implement outdoor smoke-free environments to decrease adolescent smoking and denormalize smoking behavior. Recent research indicates that compliance with smoke-free outdoor spaces is often lacking. We examined compliance with outdoor smoke-free environments and examined the mechanisms that affect compliance in different contexts.

Methods: We performed a realist review, an exploratory approach that synthesizes existing evidence into a program theory that links elements of compliance with outdoor smoke-free environments with specific mechanisms and outcomes. A search was performed in PubMed, Web of Science, Embase, and PsycINFO, resulting in 25 relevant English language articles.

Preliminary results: Our analysis showed that the kind of enforcement (voluntary or enforcement with sanction options etc.) influences smokers' compliance. Additionally, how implementation of the smoke-free environment was done (with supporting signs, size of the environment, attention for smoking cessation etc.) also influenced smokers' compliance. For instance, with the implementation of an outdoor smoke-free environment (context), smokers get used to non-smoking. They are reminded they can quit smoking at any time (mechanism), leading to more compliance (outcome). If however, their social environment continues smoking (context), they are more inclined to keep smoking (mechanism), which leads to less compliance (outcome).

Conclusions: Compliance of smokers with smoke-free outdoor environments is influenced by the type of enforcement and the type of outdoor smoke-free environment. These mechanisms are important to understand so that policymakers may consider smokers' reactions and are better able to anticipate upon them.

Key messages:

- Type of enforcement and type of implementation influence compliance with smoke-free outdoor environments.
- This realist review helps policymakers consider smokers' reactions while implementing smoke-free environments.

Abstract citation ID: ckae144.926
International survey of young adults' opinions on tobacco endgame measures & e-cigarette regulations

John Gannon

J Gannon[1,2]*, S Forberger*[1]*, Y Bar-Zeev*[1]*, M Cattaruzza*[1]*, B Kilibarda*[1]*, M Jongenelis*[1]*, E Cosgrave*[1]*, N Sinha*[1]*, M Gonzalez*[1]*, Z Kabir*[2]
[1]Tobacco Control Working Group, WFPHA, Geneva, Switzerland
[2]School of Public Health, University College Cork, Cork, Ireland
Contact: john.gannon03@gmail.com

In the last decade, while tobacco consumption has decreased, there has been a significant rise in e-cigarette usage particularly among young people. Tobacco-free generations and other endgame strategies are being considered in several countries, moving from tobacco control towards ending the tobacco epidemic. This online survey of 18-34-year-olds evaluated opinions on potential endgame measures and e-cigarette regulations, to generate evidence to inform policy decisions. The survey was developed with input from the World Federation of Public Health Associations and Tobacco-Free Ireland, asking participants about support (yes/no) for 20 endgame measures in 4 domains and attitudes towards e-cigarettes. Utilising convenience sampling, the survey was distributed through international networks. Of 295 responses in 34 countries, 72% were never smokers and 56% were never e-cigarette users. 31% were aware of tobacco endgame. 68% supported increasing tobacco purchasing age to 21. 70% supported restricting tobacco sales to a limited number of licenced shops. 73% supported reducing nicotine content in cigarettes. 74% supported tobacco companies having to pay for health costs from smoking. 73% would like to see tobacco-free generation legislation in their country, but only 31% expected it would be successful. Regarding e-cigarettes, they were judged as more desirable than cigarettes mostly due to different flavours and visual appearance (both 74%). They were perceived to be an important health risk (82%) and as or more addictive than cigarettes (78%). 65% believed overall harms from e-cigarettes outweigh benefits for society. 86% felt they should be subjected to the same advertising restrictions as cigarettes and 66% supported increasing their cost. There was strong support for various tobacco endgame measures and tobacco-free generation legislation in this 18-34-year-old cohort. The majority recognised health risks of e-cigarettes and favoured stricter regulation of these products.

Key messages:

- An international survey of 295 young adults in 34 countries demonstrated strong support for various tobacco endgame measures including tobacco-free generation legislation.
- For e-cigarettes, there was wide acknowledgement of addictiveness and health risk, and support for increased education and warnings, lower nicotine content and reduced advertising and availability.

Students' attitudes towards and willingness to intervene in partner violence against women in Sweden

Maria Wemrell

K Svalin[1]*, M Wemrell*[2,3]*, A-K Ivert*[1]
[1]Department of Criminology, Malmö University, Malmö, Sweden
[2]Department of Social Work, Linnaeus University, Växjö, Sweden
[3]Unit for Social Epidemiology, Lund University, Malmö, Sweden
Contact: maria.wemrell@lnu.se

Intimate partner violence against women (IPVAW) is a global public health problem, shown to be related to gender equality and to attitudes towards IPVAW. In Sweden, however, the reported prevalence of IPVAW is high, despite high levels of gender equality and a clear condemnation of such violence on the societal level. This phenomenon has been referred to as The Nordic paradox. One potential explanation for this paradox is that gender equality measures at the public level are not necessarily comparable to gender equality at a private level. One way to find out more about this is to investigate attitudes towards IPVAW at an individual level, which has so far been done to a limited extent in a Swedish context. In the current study, the aim was to investigate different aspects of attitudes to IPVAW (perceived acceptability, perceived severity, victim-blaming and ambivalent sexism) among university students in Sweden, and whether those attitudes were related to studentś willingness to intervene in cases of IPVAW. Any gender differences related to IPVAW attitudes and willingness to intervene were also examined. The respondents ($n = 656$, ≥ 18 years old) were recruited from three different universities and represented different scientific fields (e.g. social, behavioral, and technical sciences). Most of the respondents were undergraduate students and the majority were women (81%). The results showed that the students had rather non-accepting attitudes towards IPVAW overall, but viewed victims as to some extent responsible of the violence they are subjected to. There were no gender differences regarding willingness to intervene in cases of IPVAW, and attitudes to IPVAW were related to willingness to intervene. There were both similarities and differences between male and female students, in terms of how attitudes were linked to willingness to intervene. The presentation will discuss the results and their implications for future research, policy and practice.

Key messages:

- Increased knowledge on attitudes towards IPVAW in Sweden may shed light on the Nordic paradox.
- While non-accepting attitudes were found overall, gender differences and tendencies towards victim-blaming were identified.

Abstract citation ID: ckae144.928
Citizen needs towards personalised medicine and genetic testing: results from a European survey

Martina Porcelli

M Porcelli[1]*, F Beccia*[1]*, FA Causio*[1]*, L Proto*[1]*, DM Tona*[1]*, M Di Pumpo*[1]*, C Van El*[2]*, GE Calabrò*[1]*, R Pastorino*[1]*, S Boccia*[1]
[1]Department of Life Sciences and Public Health, Catholic University of Sacred Heart, Rome, Italy
[2]Department of Human Genetics, Amsterdam UMC, Amsterdam, Netherlands
Contact: porcellimartina96@gmail.com

Introduction: Personalised Medicine (PM) aims to tailor diagnostic and therapeutic pathways for patients. Despite technological advancements in this field, public awareness of PM remains limited, representing a barrier to its clinical integration.

Methods: We conducted a survey across eight European Countries (France, Germany, Hungary, Italy, Netherlands, Poland, Romania, Spain) via the private platform YouGov, in April 2023. Our web questionnaire explored knowledge of PM, willingness to embrace it, and trust in information delivered by mass media.

Results: Of 6,581 respondents, approximately 42% lacked sufficient knowledge of PM and genetic testing, while 36.3% found information about the topic not easily accessible. Healthcare providers were the most trusted source of information (according to 80% of responders), followed by educational institutions (71.4%). Education, age, and gender significantly influenced the acceptance of PM and

mass media trust, highlighting the association between high education level, readiness to embrace PM, and high trust in academic sources of information. Additionally, age, gender, and geographical location influenced the perception of PM and genetic tests in various ways across Europe. Despite the geographical differences, 63.2% of respondents want to know more about PM, and 60% support its implementation in clinical practice.

Conclusions: Although the growing interest in PM genetic, and -omics technologies, large sections of the population still lack access to information and understanding, indicating a disconnection between technological advancements and public awareness. The study emphasizes the importance of providing focused citizen engagement initiatives to implement PM approaches. Citizen participation in defining personalised diagnostic and therapeutic pathways is vital to empower individuals and enable them to make informed health choices.

Key messages:

- Understanding European citizens' attitudes and needs regarding Personalised Medicine is crucial for creating policies and facilitating access to new technologies and treatments.
- Despite limited knowledge, European Citizen recognize the importance of Personalised Medicine for their health, seek further understanding, and place trust in Academic Sources of Information.

Abstract citation ID: ckae144.929
Sociodemographic inequalities in smoking cessation: a population survey from Flanders, Belgium

Marie Vermote

M Vermote[1]*, P Debognies*[2]*, S Demarest*[1]*, E Braekman*[1]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Vlaams Instituut Gezond Leven, Brussels, Belgium
Contact: marie.vermote@sciensano.be

Background: Flanders' decline in daily tobacco use will not reach the aim of a 5% prevalence by 2040. A faster reduction necessitates, especially among low-educated and socially vulnerable groups, as in these groups the decline goes slower. Towards future smoking cessation interventions within these specific target groups, this study examined prevalence and sociodemographic inequalities in different indicators of smoking cessation in Flanders.

Methods: Data from the 2022 Prevention Barometer, a probability-based survey from Flanders, were used ($N = 4011$, 18+). Prevalence in ever smokers was calculated overall and by age, sex, educational attainment, making ends meet and employment status. Daily smokers reported their past-year quit smoking attempts, upcoming-year quit smoking intentions and intentions to use cessation aids. Former smokers reported successful cessation and use of cessation aids. Multivariate logistic regressions, including all demographic variables, aimed to uncover inequalities.

Results: Quit smoking attempts in daily smokers (26.5%) were lower for low education (vs. middle and high education). Quit smoking intentions in daily smokers (41.0%) were lower for low vs. middle and low vs. high education. Daily smokers had lower intentions to use cessation aids (48.5%) when having difficulties in making ends meet. Among ever smokers, being older, having high education (vs. middle and low education), having no difficulties in making ends meet and being retired (vs. working and not working) was associated with higher odds for successful quitting (73.2%). Among former smokers, people being retired (vs. working and not working) had higher odds of using cessation aids (15.3%).

Conclusions: Low educated daily smokers are less likely to quit smoking. Former smokers limitedly use cessation aids to quit smoking and the use varies regarding one's sociodemographic profile. Encouraging quit attempts and equitable access to cessation aids are public health priorities.

Key messages:

- Low-educated smokers in Flanders face barriers in quitting, highlighting the need for targeted cessation support.
- Socioeconomic disparities impact cessation aid utilization, underlining the importance of equitable access to aid for all demographics.

Abstract citation ID: ckae144.930
Non-health-targeted promotions and step counts of smartphone-based mall walking program users

Yoko Matsuoka

Y Matsuoka[1]*, H Yoshida*[1]*, M Hanazato*[1,2]
[1]Center for Preventive Medical Sciences, Chiba University, Chiba, Japan
[2]Design Research Institute, Chiba University, Chiba, Japan
Contact: y-matsuoka@umin.ac.jp

Background: The COVID-19 pandemic changed lifestyles and raised concerns regarding physical inactivity among adults. Mobile health interventions for physical activity may be a potential solution. However, the effects may diminish over time. This study investigated whether incorporating non-health-targeted promotions into an existing mobile health-walking program could stimulate users to walk.

Methods: We used nationwide cohort data of smartphone users participating in a shopping mall walking program in Japan. We focused on existing users registered in the program until October 31, 2022. A Japanese anime tie-in promotion was conducted by the shopping mall company from December 3 to 25, 2022, offering additional rewards alongside the regular program. We collected step count records of existing users 1 month before and after (November 1 to December 2, 2022, and December 26, 2022 to January 31, 2023, respectively), and during the promotion period. Propensity score matching was applied to ensure balance in the baseline characteristics of existing users in terms of gender, age, and pre-promotion program participation frequency. Next, we analyzed the association between participation in the promotion program and the average daily step counts during and after the promotional period using mixed effects models for repeated measures, while adjusting for the same covariates.

Results: Among the 18,156 users included in the study, 13,386 (73.7%) were women, with a mean (SD) age of 45.2 (12.7) years, and a mean (SD) pre-promotion program participation frequency of 9.7 (9.6) per month. During the promotion period, the participants walked 87 (95% CI: 50-125) more steps per day than non-participants, after adjusting for covariates. No clear association was observed 1 month post-promotion.

Conclusions: These findings indicate that non-health-targeted promotions may be short-term motivators for existing app users to walk. Ongoing monitoring is necessary to assess the long-term impact.

Key messages:

- Mobile health intervention effects may diminish over time.
- A non-health-related promotion could stimulate existing mall walking program app users to increase their daily step count temporarily.

Abstract citation ID: ckae144.931

Cost per kilogram weight-lost - Lifestyle change program at the Public Health Institute in Croatia

Jasmina Kovačević

J Kovačević[1], D Zombori[1]
[1]Public Health Institute of Pozega Slavonia County, Pozega, Croatia
Contact: dr.jasminakovacevic@gmail.com

According to the 2019 European Health Survey, 42% and 23% of the Croatian adult population were affected by overweight or obesity, respectively. Counselling services are available in some Public Health Institutes for free or paid out-of-pocket. The estimated cost per kilogram lost in programs in Europe and the USA ranges from 100-340€, with a justifiable cost estimation for a weight loss intervention being 120-210€. Aim was to demonstrate the cost of losing one kilogram by analysing necessary initial material and human resources, including equipping counselling centres, and estimating the cost of continuous implementation. In the year 2023, 47 participants (31F,10M) with a BMI higher than 30 kg/m2 enrolled in the three-month free Program in the County Public Health Institute in Pozega. The program consisted of personalized assessment, habit change plan, education, counselling and follow-up. An analysis of the minimal required equipment and working hours of physician and a nurse (contracted gross hourly wage rates) was conducted. The main outcome measure was the cost of one kilogram lost by participants at the end of the Program. Program was completed by 41 (22F, 9M) participants (87.2%). Their initial BMI ranged from 30.3 to 47.4 kg/m2. Collectively, they lost 323.2 kg (1.3-24.4kg), with an average of 7.9 kg or 7.4% (1.7-19.8%) of their initial weight lost. The estimated total cost of medical, IT and office equipment, was 9363€. The human resources cost was 9509€, with a specialist and nurse spending 249 and 116 hours, respectively (27.6€/hour and 13€/hour). The initial cost per kilogram lost, including the prerequisites for the work of the counselling centre, was 58.4€. The continuous program cost with equipment already in place is estimated at 27.9€ per kilogram lost. We have shown that the lifestyle management program in the Croatia without extra cost to patients delivers results with a cost of 27.9€ per kilogram weight-lost in continuous implementation.

Key messages:

- The significant impact of obesity on premature mortality and healthcare systems calls for the systematic implementation of effective weight management programs that are available to patients for free.
- It is possible to implement effective weight management program in Croatia without extra cost to patients for 27.9 € per kilogram weight-lost.

Abstract citation ID: ckae144.932

Consumer Preferences for Health Services Offered by Health Insurance Companies in Germany

Raphael Schilling

R Schilling[1,2], M Pavlova[1], A Karaman[2]
[1]Department of Health Services Research, Maastricht University, Maastricht, Netherlands
[2]Core Business Operations, Deloitte Consulting GmbH, Düsseldorf, Germany
Contact: schillingraphael1@gmail.com

German health insurance companies increasingly strive to position themselves as health partners to their customers to improve customers' health and contain costs. However, there is uncertainty about customers' preferences for health services offered by health insurance companies. Therefore, this paper studies consumer preferences for health services that are or could be provided by health insurance companies in Germany. An online survey was conducted using two stated preference techniques to collect and analyze the data (namely, rating and ranking of health services considered by insurance companies). A sample of 880 German health insurance customers between 18 and 65 years old filled out the online questionnaire, of which 860 submitted complete responses. Ordinal logistic regression analysis was used for the rating and ranking. Preliminary examinations, care management, and health programs were the three health services most important to the respondents. The results suggest that people want their health insurance to support them with preventive health services that offer direct therapeutic value and not just informational, economic, access-related, or convenience-related benefits. These preferences for health services are homogeneous for most subgroups of the population, implying that health insurance companies could consider an overall strategy to address these preferences for all clients by focusing on the important health services.

Key messages:

- People value health services provided by health insurers that offer direct therapeutic value over those that offer only informational, economic, access or convenience benefits.
- As preferences are homogeneous across the population, insurers could consider an overall strategy by focusing on the important health services.

Abstract citation ID: ckae144.933

Cost-effectiveness of respiratory syncytial virus adjuvanted vaccine in Portuguese aged $\geq$ 60 years

Lefteris Zarkadoulas

L Zarkadoulas[1], P Bota[2], F Silva[2], A Coelho[2], R Castanheira[2]
[1]GSK, Wavre, Belgium
[2]GSK, Lisbon, Portugal
Contact: eleftherios.x.zarkadoulas@gsk.com

Background: Respiratory syncytial virus (RSV) infections are one of the leading causes of lower respiratory tract disease among adults aged ≥60 years in Europe. This study aims to assess the potential public health impact of the RSVPreF3 OA adjuvanted vaccine, the first approved preventive intervention for the older adult population in Portugal.

Methods: A monthly-cycle static Markov model was developed to assess RSVPreF3 OA adjuvanted vaccine impact on adults aged 60 years and older in Portugal. A single dose of RSVPreF3 OA adjuvanted vaccine was compared to no-vaccination over a three-year time-horizon. The model captures lower respiratory tract disease (LRTD) RSV cases, hospitalizations, deaths, and healthcare resource utilization. Data inputs were based on local published literature, supplemented by the best available data when local information was lacking.

Results: Based on preliminary analysis considering 75% vaccine coverage, model outputs estimate that RSVPreF3 OA adjuvanted vaccine can prevent 71,433 LRTD cases requiring medical attendance, 11,067 hospitalizations, 1,793 intensive care unit admissions and 1,003 deaths. The model estimates that 32 adults need to be vaccinated to avoid one RSV LRTD case, 207 adults need to be vaccinated to avoid one hospitalization and 2,283 adults need to be vaccinated to avoid one death. The incremental cost-effectiveness ratio was estimated at 9,541€, hence the RSVPreF3 OA adjuvanted vaccine is cost-effective compared to no vaccination.

Conclusions: The results demonstrate a strong preventive impact of the RSVPreF3 OA adjuvanted vaccine on health outcomes and healthcare resource utilization in adults $\geq$60 years, leading to a significant public health benefit. This result emphasizes the importance of preventing RSV to preserve the health and well-being of Portugal's older adults. In addition, data from ongoing studies may enhance precision and extensive sensitivity analyses validate the robustness of the model's input assumptions.

Key messages:

- This study shows the robust evidence of RSVPreF3 OA adjuvanted vaccine to improve public health by preventing thousands of hospitalizations and deaths among $\geq$60 years, in Portugal.
- Vaccinating adults aged $\geq$ 60 years with RSVPreF3 OA adjuvanted vaccine in Portugal is a cost-effective strategy.

Abstract citation ID: ckae144.934
Decision-analytic modelling of costs & benefits of adding sigmoidoscopy to CRC screening in Germany

Kathrin Krueger

K Krueger[1,2], *K Schaubert*[1], *M Brinkmann*[3], *W Schramm*[4], *M Dreier*[1], *C Krauth*[1,2]
[1]Institute for Epidemiology, Hannover Medical School, Hanover, Germany
[2]Center for Health Economics Research Hannover, Hanover, Germany
[3]Institute for General Medicine, Hannover Medical School, Hanover, Germany
[4]GECKO Institute of Medicine, Heilbronn University of Applied Sciences and Arts, Heilbronn, Germany
Contact: krueger.kathrin@mh-hannover.de

Background: In Germany, a colorectal cancer (CRC) screening programme is in place that entitles individuals to a stool test or colonoscopy. However, less than half of those eligible participate. The inclusion of an additional screening option, such as the evidence-based sigmoidoscopy, could lead to a higher overall participation rate, but also to individuals preferring the additional option to the more effective colonoscopy. The objective of this modelling study is to estimate the impact of offering sigmoidoscopy as an additional option for CRC screening in Germany.

Methods: A life-time mathematical model (Markov model) is developed to analyse the long-term effects of the additional offer of sigmoidoscopy on benefits (prevalence, mortality, health-related quality of life (HRQoL)), costs, and cost-effectiveness. The model is based on systematic literature reviews and real-world healthcare data. It incorporates disease development, sensitivity and specificity of the options, compliance rates, survival probabilities and background mortality. A discrete choice experiment (DCE) was conducted to estimate the future uptake of the options (stool test, colonoscopy, sigmoidoscopy, no screening) based on stated preferences of $n = 666$ individuals.

Results: Adding sigmoidoscopy leads to greater effectiveness of the CRC screening programme in terms of increased screening participation, increased adenoma detection, decreased disease-specific mortality, and improved discounted HRQoL. However, it also incurs higher costs. The incremental cost-effectiveness ratios (ICER) for men and women are €507 per quality-adjusted life year gained (QALYg) and €74 per QALYg, respectively.

Conclusions: The results indicate that the inclusion of sigmoidoscopy in the German CRC screening programme would be cost-effective and that sigmoidoscopy should be piloted in practice. The expanded programme has the potential to enhance the program's effectiveness, improve health outcomes, and reduce the burden of CRC.

Key messages:

- Expanding the CRC screening programme may increase overall participation, resulting in higher costs, but also greater effectiveness in detecting more adenomas, reducing mortality, improving HRQoL.
- Introducing sigmoidoscopy in Germany appears cost-effective and justifies practical piloting to enhance CRC screening efficacy and health outcomes.

[6]Department of Preventive Medicine, Korea University, Seoul, South Korea
[7]Institute for Future Public Health, Graduate School of Public Health, Seoul, South Korea
Contact: jdlvalue@gmail.com

Purpose: As the number of cancer survivors increases, addressing their unmet supportive care needs (USCNs) has become crucial. This study aimed to evaluate the influence of financial toxicity on USCNs and identify comprehensive factors associated with USCNs among adults' cancer survivors.

Methods: A cross-sectional survey using convenience sampling from the 2022 Korean Population Census. Data were collected online between November 17 and December 15, 2022. The study included 1,038 cancer survivors aged 19 years or older who had completed primary treatment. Multivariable logistic regression was analyzed to identify factors associated with USCNs.

Results: Two-thirds (65.7%) of cancer survivors experienced severe financial toxicity, correlating with high unmet supportive care needs. Among those who reported a severe financial burden, a substantial 170 out of 187 respondents, or approximately 90.9%, were identified as having high unmet supportive care needs. Cancer survivors had the highest needs in the order of 'management of psychological symptoms' and 'coping and emotional needs'. Cancer survivors diagnosed between 5 and 10 years ago were found to be less likely to report unmet supportive care needs compared to those diagnosed more recently, with an odds ratio of 0.14. Additionally, breast cancer survivors and individuals who were unemployed at the time of diagnosis had a higher likelihood of experiencing unmet supportive care needs, with adjusted odds ratios of 1.68 (95% confidence interval: 1.088-2.603) and 1.80 (95% CI: 1.125-2.891), respectively.

Conclusions: Cancer survivors with moderate to severe financial distress were more likely to be at risk of experiencing a high level of unmet supportive care needs. Coping and emotional needs are the most important concerns among the unmet needs of cancer survivors regardless of the time since cancer diagnosis.

Key messages:

- Cancer survivors in South Korea with moderate to severe financial distress are twice as likely to face a high level of unmet supportive care needs.
- The most significant unmet supportive care needs among South Korean cancer survivors relate to coping and emotional support, highlighting the need for enhanced mental health services.

Abstract citation ID: ckae144.936
Unequal cannabis use among European adolescents: the mediating role of perceived access and risk

Julian Perelman

J Perelman[1,3], *M Ribeiro*[2], *J Alves*[1,3], *C Palladino*[4]
[1]Nova National School of Public Health, Nova University of Lisbon, Lisbon, Portugal
[2]Baixo-Mondego Health Center Group ACES, Aveiro, Portugal
[3]Comprehensive Health Research Center, Nova University of Lisbon, Lisbon, Portugal
[4]Research Institute for Medicines, Lisbon University, Lisbon, Portugal
Contact: jperelman@ensp.unl.pt

Introduction: Cannabis use among adolescents is a public health concern, because of its association with the use of other illicit drugs, mental health disorders, and social problems. Most studies show that adolescents from low socioeconomic status (SE) background are more likely to use cannabis, but the causes of SE inequalities remain to be understood. We test whether access and risk perceptions of cannabis use among disadvantaged adolescents explain the SE gradient.

Objectives: The aim of this study was to measure the mediating effect of access perception and risk perception on the association between SE status and cannabis use among European adolescents in 2019.

Methods: A cross-sectional, observational, analytical study was conducted, among 16-year-old students, based on data from the European School Survey Project on Alcohol and Drugs (ESPAD) in 2019. The outcome was cannabis use (experimental, regular, and problematic) and the exposure was SE status (parental education and subjective social status). Mediating variables were perceived accessibility and perceived risk of cannabis use. We used logistic regressions, where the odds ratio (OR) reduction measures the part of the association explained by the mediators.

Results: Regular and problematic cannabis use was significantly more prevalent among adolescents with a lower SE background (low parental education and low subjective social status, $p < 0{,}001$). This relationship remained significant after adjustment for perceived access and risk, and the modification of ORs was of a small magnitude (a non-significant reduction of the association).

Conclusions: Perceived accessibility and risk showed a weak mediating effect of the association between SE background and cannabis use. Consequently, these factors cannot be considered as major explanations for the higher use among worse-off adolescents. Reinforcing information or imposing stronger barriers in access may not help reduces SE inequalities in cannabis consumption.

Key messages:

- Perceived accessibility and risk hardly explain the association between socioeconomic background and cannabis use among European adolescents.
- Reinforcing information or imposing stronger barriers in access may not help reduces socioeconomic inequalities in cannabis use.

Abstract citation ID: ckae144.937
New evidence on household financial protection against out-of-pocket payments for health in Poland

Marzena Tambor

M Tambor[1], *M Pavlova*[2]
[1]Health Economics and Social Security Department, Institute of Public Health, Jagiellonian University, Cracow, Poland
[2]Department of Health Services Research, Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands
Contact: marzena.tambor@uj.edu.pl

Background: Protecting households against financial hardship when using health care is an integral element of universal health coverage. Previous analysis showed that in Poland, catastrophic spending on health is more common than in many European countries. Over the last decade, several measures were undertaken to reduce the burden of out-of-pocket payments for households in Poland.

Methods: The study aimed to assess financial protection in Poland using the indicators of catastrophic and impoverishing health spending. It relies on the methodology developed by the WHO Region Office for Europe. Catastrophic expenditure is defined as out-of-pocket payments that are greater than 40% of household capacity to pay. The study uses data from the Polish household budget surveys in 2013-2021.

Results: The incidence of catastrophic health spending remained relatively constant over the years analyzed, with 9% of households affected. Only in the first year of the COVID-19 pandemic (2020) it reached nearly 10%, although overall household out-of-pocket expenditure declined that year. The share of households impoverished or further impoverished due to out-of-pocket payments decreased from 4% in 2013 to 3% in 2021. Payments on medicines are the main driver of catastrophic spending, particularly among poorer households, although their role has diminished over time. Household's available resources, gender, age, education, disability status, residence place, number of children, and household's main source of income are significantly associated with catastrophic health payments.

Conclusions: Despite the implemented policies, household financial protection against out-of-pocket payments in Poland did not improve significantly between 2013 and 2021. Available evidence should be used to design well-tailored measures to reduce the burden of out-of-pocket payments, targeting the most vulnerable population groups and specific healthcare areas.

Key messages:

- Household financial protection against out-of-pocket payments in Poland did not improve significantly between 2013 and 2021.
- Out-of-pocket payments for medicines are the main cause of financial hardship for Polish households.

Abstract citation ID: ckae144.938
Geographical variation in prostate cancer testing explained by socio-economic position in Stockholm

Balram Rai

B Rai[1], *M Clements*[1]
[1]Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden
Contact: balram.rai@ki.se

Background: Prostate cancer screening using prostate-specific antigen (PSA) testing is controversial but remains prevalent in many countries. Despite its prevalence there is little information in Sweden or globally on the spatial heterogeneity in PSA testing. This study aims to describe the spatio-temporal variation in PSA testing in the Stockholm region specifically at the municipality and small area level. Additionally, it aims to quantify the extent to which socio-economic position (SEP) indicators such as education, income, and country of birth explain the observed variation in PSA testing.

Methods: A retrospective population-based register study was conducted, encompassing men aged 40 years and older residing in the Stockholm region from 2007 to 2016. Utilizing spatial smoothing techniques, we calculated the age-standardised proportion of men undergoing PSA testing prior to any prostate cancer diagnosis within each area for every calendar year. Furthermore, we used Bayesian logistic regression models with spatial random effects to estimate the individual-level association between PSA testing and socio-economic position. The proportion of variance in PSA testing explained by various measures of SEP was also estimated at both the municipality and small area levels.

Results: Significant geographical disparities in PSA testing were observed across small areas within Stockholm. The proportion of variance explained in PSA testing at the small area level was highest for income (32.6%), followed by education (9.7%) and country of birth (7.4%). Incorporating all SEP measures led to a higher proportion of explained variance at the small area level (41.6%) compared to the municipality level (24.8%).

Conclusions: PSA testing was significantly associated with various socio-economic indicators and some of the spatial variation could be explained by SEP. It would be useful to ascertain whether similar patterns are observed in other regions or countries.

Key messages:

- The findings suggested widespread and consistent opportunistic prostate cancer screening practices within the Stockholm region, raising concerns regarding potential overdiagnosis and overtreatment.
- The socio-economic differences in prostate cancer screening could partially explain the differences in cancer incidence and mortality.

Health selection in three cohorts of outmigrants, return migrants and non-migrants

Marcelo Urquia

M Urquia[1], *G Detillieux*[1], *S Debbarman*[1]
[1]Manitoba Centre for Health Policy, University of Manitoba, Winnipeg, Canada
Contact: marcelo.urquia@umanitoba.ca

Background: The two main hypotheses behind the healthy migrant effect are selection of healthier migrants and the salmon bias. However, these hypotheses have not been thoroughly and simultaneously investigated in distinct cohorts due to data limitations.

Methods: Linking national and provincial immigration registers with health care utilization datasets at the Manitoba Centre for Health Policy, we assembled a cohort of 816,185 adults who resided in Manitoba, Canada and were followed up for at least one year between 1985 to 2023 to outmigration, return migration or death. We included three subcohorts of international immigrants (16.4%), interprovincial migrants (10.8%) and all other Manitobans (AOM) (72.8%). Within each subcohort, we matched ‘stayers’ who never migrated, outmigrants and returnees on sex, birth year and place of residence and compared their hospitalization rates and Charlson and Elixhauser comorbidity scores 1-year before outmigration and 1-year after return migration.

Results: Outmigrants had lower hospitalization rates than stayers among AOM [Adjusted Relative Rate (RR): 0.80; 95% confidence interval (CI): 0.78, 0.82] and in the other two subcohorts. Comorbidity scores were also consistently lower among outmigrants compared to stayers in all three subcohorts, even after restricting to hospitalized cases. Outmigrants whose destination was another country were healthier than those who migrated to other provinces. Returnees had better health status than stayers upon return in the AOM subcohort only but lower than those who did not return at the time of outmigration in all three subcohorts.

Conclusions: Contrary to common belief, health selection is not restricted to international immigrants but also among interprovincial migrants and the local population. Migration dynamics may bias comparisons between population subgroups.

Key messages:

- Migration is not only associated with positive health selection among international immigrants but also among interprovincial migrants and the local population.
- Selective migration may represent a source of bias in health-related population-based studies.

Polish midwives’ experiences of providing maternity care to Ukrainian women in Poland

Ilona Nenko

I Nenko[1], *B Baranowska*[2], *B Szlendak*[2], *N Sahraoui*[3], *M Węgrzynowska*[2]
[1]Jagiellonian University, Cracow, Poland
[2]Department of Midwifery, Centre of Postgraduate Medical Education, Warsaw, Poland
[3]Centre for Sociological and Political Research, Paris, France
Contact: ilona.nenko@uj.edu.pl

Background: Migrants’ health has attracted the attention of researchers for many years, particularly from the perspective of barriers in access to healthcare systems. Providing high quality care to migrants and refugees, especially in contexts of significant and sudden arrivals, may be particularly challenging.

Aim: The aim of our research was to learn about the experiences and strategies of midwives providing maternity care for Ukrainian migrant women in Poland after the outbreak of the full-scale war in Ukraine.

Methods: Five focus group interviews with 32 midwives providing maternity care in Poland were conducted. The interviews were thematically analysed.

Results: Healthcare personnel experiences a number of barriers to the provision of high-quality care to the migrant population. Polish midwives expressed mainly experience of two groups of barriers on: (1) individual and interpersonal, (2) management and organization levels. Firstly, at the individual and interpersonal level midwives experienced: fear for life and well-being related to the threat of war in a neighbouring country, depleting resources and post-pandemic fatigue, language barriers, lack of knowledge on caring for woman fleeing the war. Secondly, at the management and organizational level midwives experienced: lack of organizational support, interpreting services and documentation in any other language than Polish. In the first months after the outbreak of the full-scale war in Ukraine, most strategies to improve the provision of maternity care for women fleeing the war took the form of grassroots initiatives by the staff of individual care units.

Conclusions: The Polish health care services need systemic solutions prepared jointly by state and local authorities and considering the voices of midwives to support the provision of high-quality care to migrant population.

Key messages:

- Midwives were left to their own devices.
- Midwives need better preparation for providing high-quality care to migrant population.

Abstract citation ID: ckae144.941
Uptake of cervical screening and acceptability of HPV self-sampling in Irish Traveller women

Patricia Fitzpatrick

A O'Flynn[1], P Fitzpatrick[1], R Jalal[1], K Frazer[2], R Joye[2], MB Collins[3], L Kavanagh[3], T McCarthy[4], M McEnery[4], P Fox[2]

[2]School of Nursing, Midwifery & Health Systems, University College Dublin, Dublin, Ireland
[3]Pavee Point, Traveller & Roma Centre, Dublin, Ireland
[4]National Cancer Control Programme, HSE, Dublin, Ireland
Contact: patricia.fitzpatrick@ucd.ie

Introduction: Irish Travellers are a minority ethnic group. The 2010 All-Ireland Traveller Health Study noted the life expectancy of Traveller women was 11 years shorter than women in the general population. Coverage of the CervicalCheck, the Irish cervical screening programme, is 78.7% overall, however, there is no recently published data on the attendance of Traveller women. This study sought to determine participation by eligible Traveller women in CervicalCheck and the acceptability of HPV self-sampling.

Methodology: A face-to-face cross-sectional survey, adapted from the National Cancer Control Programme's 2022 National Survey on Cancer Awareness, was disseminated to Irish Travellers via Primary Health Care Travellers Project peer researchers, following ethical approval, May to December 2023.

Results: 451 Travellers participated; 286 (63.4%) were female. Of these, 178 (62.2%) were in the eligible age group for cervical screening. 134 (75.3%) advised they had received an invitation to screening; 121 (68% of all eligible; 90% of all receiving an invitation) advised they had attended at least once (regular attenders 88 (49.4%); 27 (15.2%) irregular attenders). Of all responders in the screening eligible age group, 36 (20.2%) reported HPV self-sampling as acceptable; 18 (50%) of these were non or irregular attenders at screening. Similar proportions of 25-45 year-olds (20.4%) and 46-65 year-olds (20%) reported HPV self-sampling as acceptable.

Conclusions: Irish Traveller women face barriers to accessing mainstream health services. Uptake of cervical screening overall is lower compared to the general population in this study; one issue may be unreliable postal service to Travellers and non-receipt of invitations. While the overall acceptability of HPV self-sampling was low at 20.2%, half of those who would self-sample did not attend or attended irregularly. HPV self-sampling has the potential to improve cervical screening rates among Traveller women.

Key messages:

- Irish Traveller women's uptake of cervical screening is lower than general population.
- HPV self sampling has potential to improve cervical screening rates in Travellers.

Abstract citation ID: ckae144.942
Patients' experiences of racism in German inpatient healthcare

Regina Brunnett

R Brunnett[1], K Meshkova[1]
[1]Health Sciences, University of Applied Sciences, Fulda, Germany
Contact: Regina.Brunnett@gw.hs-fulda.de

Background: Racism is recognised as a social determinant of health. An evolving concern in research and policymaking has been the impact of racism in the healthcare system, particularly regarding the quality of healthcare and barriers for healthcare. Little is known about patients' experiences of racism in hospitals and rehabilitation facilities in Germany and their coping strategies in dealing with racism.

Methods: As part of a joint project on racism in healthcare (RiGeV) funded by the Federal Ministry of Education and Research, twenty qualitative interviews and two group discussions with patients and their next of kin about their experiences in hospitals and rehabilitation facilities were conducted and analysed using the documentary method. Ethical approval for this study was obtained from the Ethics Committee of Fulda University of Applied Sciences.

Results: Interviews with patients and their next of kin revealed that the most significant experiences of racism in hospitals are attributions of dramatisation and exaggeration of pain, embedded in a general perception of not being taken seriously and/or being ignored. Patients try to avoid such experiences that compromise their trust and sense of security, as well as the quality of treatment they receive. Healthcare for refugees is impacted by structural barriers (AsylBLg) which jeopardise the healing process and represent a considerable psychosocial burden.

Conclusions: Recommendations for policies and practice include a mission statement for non-discriminatory treatment and the sanctioning of racism within healthcare institutions. A complaints office should manage implementation and offer support for affected patients. The topic of racism must be addressed in the training and further education of doctors and healthcare professionals. Patient trust in a safe and high-quality form of healthcare should be strengthened by addressing their complaints. Health care for refugees has to be improved.

Key messages:

- Racism in German inpatient healthcare represents a considerable psychosocial burden for patients and impairs the quality of treatment they receive.
- Policies for reducing racism inpatient healthcare have to be implemented.

Abstract citation ID: ckae144.943
Can health communication improve newly settled refugees' health literacy? A quasi-experimental study

Maissa Al-Adhami

M Al-Adhami[1], N Durbeej[1], A Daryani[1], E Larsson[2], J Wångdahl[3], R Salari[1]
[1]Department of Public Health & Nursing Sciences, Uppsala University, Uppsala, Sweden
[2]Department of Global Public Health, Karolinska Institutet, Stockholm, Sweden
[3]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden
Contact: maissa.aladhami@uu.se

Structural and contextual factors such as limited work opportunities, inadequate housing options and discrimination negatively affect the health and well-being of newly settled refugee migrants in European countries. In Sweden, health promotion initiatives aiming at strengthening health, resilience and integration have been tried out within the Introduction Program for refugee migrants. The main component of these interventions has been educational activities in the form of health communication. Generally evaluated from the perspectives of participants and course leaders, longitudinal evaluations remain rare. The current study aimed to compare the effectiveness of a regular and an extended civic orientation course with added health communication and examine whether the latter would improve self-rated health and psychological well-being, health literacy and social capital among newly settled refugee migrants in Sweden. Pre- and post-assessment questionnaires were collected from the intervention group receiving the extended course ($n = 143$) and a control group receiving the regular course ($n = 173$). Linear mixed models and chi-square analyses showed a significant increase with a small effect size (0.21) in health literacy in the intervention group. However, there were no significant changes in general self-rated health, psychological well-being or emotional and practical support. The findings indicate that added health communication embedded in the civic orientation course can increase health literacy. However, further longitudinal studies are needed to confirm the sustainability of the observed change in health literacy and its translation into long-term advances in health and integration.

Key messages:

- Added health communication provided within the Introduction Program for refugee migrants can increase health literacy.
- Increased health literacy may be beneficial for newly settled refugees as it is linked to improved health-seeking behavior, better health outcomes and empowerment.

Abstract citation ID: ckae144.944
Cultural filters in processing information on COVID vaccines among minoritized groups in London, UK

Tahreem Chaudhry

T Chaudhry[1], D Zenner[1], P Tum[1], F Morrow[1], K Kielmann[2]
[1]Wolfson Institute of Population Health, Queen Mary University of London, London, UK
[2]Institute of Tropical Medicine, Antwerp, Belgium
Contact: wpw111@qmul.ac.uk

Introduction: Vaccination coverage among minoritized groups, including migrants, is low in the United Kingdom. Cultural factors are often cited as barriers, yet the broader impact of minoritization on vaccine acceptance remains understudied. We explored the intersection of culture with individual, familial, and systemic factors in shaping trust and perceptions of COVID-19 vaccines in East London, UK.

Methods: We conducted focus group discussions (n = 6) and interviews (n = 19) with individuals from minoritized backgrounds in East London to elicit their perceptions and experiences of COVID-19 and the vaccination programme. Thematic analysis was used to identify individual, social, and systemic factors influencing the processing of perceived value of information on COVID vaccines.

Findings: Culture was rarely cited as an explicit barrier to vaccine uptake. Instead, participants' linked their perceived vulnerability and immunity to COVID-19 with age, sex and health status. Information about COVID vaccines was processed and acted upon in the context of gendered family dynamics and support. Community identity, gatekeepers and social networks further influenced the perceived legitimacy of information received. Some participants voiced how their minoritized status shaped trust/mistrust in the national health system's and government's delivery of the COVID-19 information and vaccination campaigns

Conclusions: Unpacking cultural filters is crucial for addressing vaccine-related information barriers in minoritized groups. Going beyond mere language translation, tailored communication materials should address social enablers and systemic barriers. Further, closer collaboration between community gatekeepers and healthcare professionals to facilitate optimal use of these materials is needed to improve vaccine uptake.

Key messages:

- Culture should not be assumed to be the main factor contributing to non-adherence and non-uptake of public health vaccine.
- Vaccine uptake can be improved by healthcare workers and key community gate-keepers working collaboratively with minoritized groups.

Factors influencing protective gear use in crisis-affected Afghanistan during COVID-19

Jung-Won Lee

JW Lee[1], YJ Kim[1], KB Kim[2], JW Noh[3]
[1]Health Administration, Yonsei University Graduate School, Wonju-si, Gangwon-do, South Korea
[2]International Healthcare Administration, Catholic University of Daegu, Daegu, South Korea
[3]Health Administration, Yonsei University, Wonju-si, Gangwon-do, South Korea
Contact: jwlee8269@naver.com

Background: Afghanistan has faced considerable challenges in healthcare delivery during the COVID-19 pandemic. These challenges were compounded by limited health literacy, shortages of skilled health workers, and fragile health infrastructure, which increased the country's double burden of disease. The World Health Organization (WHO) recommended the use of masks as part of a comprehensive strategy to mitigate the spread of SARS-CoV-2. Nevertheless, research on mask-wearing practices in Afghanistan is limited. This study aims to investigate the factors influencing the wearing of protective gear, including masks, during the COVID-19 pandemic in Afghanistan.

Methods: This study analyzed 16,058 households from the 2020 Afghanistan Multi-Sector Needs Assessment (MSNA) survey data. This survey was conducted between August and September 2020 by the Racial and Ethnic Approaches to Community Health (REACH) Initiative. Sampling weighted multivariable binary logistic regression analysis was performed.

Results: Recent internally displaced persons (IDPs) and returnees in Afghanistan were more likely to wear protective gear to prevent COVID-19 compared to non-recent IDPs. Factors such as household sizes, household income, knowledge of humanitarian support, and the distance to healthcare facilities were significantly associated with the likelihood of wearing protective gear.

Conclusions: The study suggests that certain factors place crisis-affected populations in Afghanistan at high risk in COVID-19 preventive behaviors, especially in wearing protective gear. The findings in this study indicate that public health interventions should focus on improving healthcare accessibility and enhancing information dissemination while considering socioeconomic factors. Additionally, this study highlights the need for access to personal protective gear during outbreaks of infectious disease, such as the COVID-19 pandemic.

Key messages:

- Socioeconomic factors and accessibility on health services and information can affect COVID-19 preventive behaviors in crisis-affected populations.
- This study can inform public health professionals to develop adequate interventions during infectious disease outbreaks.

Abstract citation ID: ckae144.946
Vaccine-preventable diseases in migrants to Europe: a systematic review

Beatriz Morais

B Morais[1], R Halliday[1], A Deal[1,2], O Bouaddi[1], J Carter[1], F Knights[1], SE Hayward[1], S Hargreaves[1]
[1]Migrant Health Research Group, St George's University of London, London, UK
[2]Faculty of Public Health and Policy, LSHTM, London, UK
Contact: bmorais@sgul.ac.uk

Migrant populations in Europe are at increased risk of under-immunisation and therefore likely to be at high risk of vaccine-preventable diseases (VPD), yet the relationship between migration and VPD incidence is not fully understood. This study aimed to explore the prevalence of VPDs in migrant populations in Europe and to define at-risk groups. Following PRISMA guidelines, Embase, MEDLINE and Global Health were searched for peer-reviewed papers published from 1st January 2010. Inclusion criteria comprised primary research on VPD cases (measles, mumps, rubella, diphtheria, pertussis, tetanus) among migrants to/within EU/EEA and Switzerland. We defined migrants as foreign-born nationals. Forty-seven eligible studies from 15 EU/EEA countries and Switzerland were included, with a total of 1357 migrant VPD cases reported. Analysis revealed 1357 migrant cases across measles (28 publications; 926 cases), pertussis (9; 267 cases), mumps (9; 107 cases), diphtheria (11; 67 cases), rubella (2; 6 cases imported from Romania and Pakistan), tetanus (2; 2 cases). Over-representation of measles cases was observed among migrant children and adolescents, predominantly from the WHO Europe region (particularly Bulgaria, Bosnia and Herzegovina and Serbia). Migrants of East African origin were over-represented among diphtheria cases. This study underscores the association between migration and VPD cases in EU/EEA and Switzerland, establishing a clear association between European migrant children and adolescents in measles outbreaks, and adult migrants from East Africa in diphtheria cases. This study suggests strengthening systems for targeted catch-up vaccination for migrants is imperative upon arrival in European countries to align them with national schedules, alongside the need to improve data collection and surveillance systems to inform effective public health interventions.

Key messages:

- Migrant populations in Europe face heightened risk of vaccine-preventable diseases and need to be better incorporated into catch-up vaccination initiatives on arrival.
- Improved data collection and surveillance systems are crucial for informing effective public health interventions targeting migrant populations.

Abstract citation ID: ckae144.947
Comparison of perinatal hospital services of women living in Roma settlements in Slovenia

Tatjana Krajnc Nikolic

T Krajnc Nikolić[1], *K Rostohar*[2], *M Ranfl*[1]
[1]RU Murska Sobota, NIJZ, Murska Sobota, Slovenia
[2]Health Data Centre, NIJZ, Ljubljana, Slovenia
Contact: tatjana.krajnc-nikolic@nijz.si

Background: Women living in Roma settlements in Slovenia had worse perinatal health indicators comparing with women from the rest of population. They gave more births in younger age and used fewer preventive services and later in pregnancy. Roma children had higher chances to be born earlier and with lower birth weight. We explored the differences in provided hospital services between pregnant Roma and the rest of female population in Slovenia.

Methods: We identified the female inhabitants of Roma settlements from the national registry of population and separated from the rest of the population data. Health indicators were provided from the national health register - Perinatal Information System for the years from 2018 to 2022. The frequency statistics, ANOVA and comparison of column proportion tests were used ($p\text{-value} < 0.005$, 95% CI) to compare the differences in categories of services in those two groups.

Results: Statistically significant differences were found in several hospital services comparing treatments of pregnant females from Roma settlements comparing to the rest of female population. Women from Roma settlements had higher ratio of gynecologic history without remarks, fewer treatments and less prevention investigations in prenatal period and higher ratio of natural start of delivery. In addition, by Roma females was used less medication during delivery, less episiotomies and fewer caesarean section were performed.

Conclusions: There are significant differences in provision of hospital services between female inhabitants of Roma settlements and the rest of population. Some of them could be explained by younger average age of delivery in Roma, but additional research would bring more light in possible impact of socio-economic and cultural determinants on both the use and provision of health services.

Key messages:

- There are differences in provided health services between Roma women and the rest of female population. In depth research of prenatal and hospital services would bring additional explanations.
- Considering the health inequalities which start by birth, targeted and tailored actions to improve health of Roma women and their new-borns are appropriate and necessary.

Abstract citation ID: ckae144.948
Educational and employment for adults with a history of migration and foster care in Finland

Maili Malin

M Malin[1], *J Miettinen*[2], *J Anand*[2], *N Joubert*[2], *E Batbaatar*[2]
[1]Social Security and Services, National Institute of Health and Welfare, Helsinki, Finland
[2]Department of Social Sciences, University of Eastern Finland, Kuopio, Finland
Contact: maili.malin@thl.fi

Several studies document the adverse educational prospects for both immigrant-origin as well as out of home placed children and youth. Few studies have examined the educational and employment outcomes of migrant-origin young adults with a history of out-of-home care (OHC), which is the aim of our study. Methods. We studied all subjects born in 1976 to 1995 abroad and immigrated to Finland as underage persons prior to 2010 ($N = 20\,037$), comparing them to children born in Finland to foreign born parents ($N = 3198$) and a matched random sample of host population ($N = 23\,187$) according to register data 1991 to 2015. We formed OHC alumni and non-OHC alumni groups among refugee-origin born abroad and in Finland, non-refugee-origin born abroad and in Finland as well as native Finns group. Logistic regression analysis was used in which age of the child in the first placement, number of placements and the type of the first place were adjusted. Results.Minors both with refugee and non-refugee background born in Finland were more likely than native Finns to be placed in OHC. A history of OHC predicted less chance of degrees completed and being employed compared to non-OHC peers in all study groups. Refugee background born abroad having history in OHC had lower educational and employment outcomes as young adults compared to other OHC groups. Education made difference since immigrant background having OHC history and post-compulsory degree had two times higher likelihood of being employed. The first OHC during teenage years decreased odds for post-compulsory education but increased odds for employment. Multiple placements in OHC decreased a youth's chances of completing degrees and employment

Key messages:

- Education made difference since persons with OHC history and degrees done had two times higher likelihood of being employed.
- Refugee origin OHC alumni were in the most vulnerable position with less degrees and less employment, and thus they need any support in their studies.

Abstract citation ID: ckae144.949
Prevalence of Mental health and Receipt of Services in Latino Immigrants Living in Philadelphia

Brigitte Guariglia

B Guariglia[1,2], Y Yamasaki[2], C Perez[2], C Zumaeta-Castillo[2], M Lazo[2], L Bakely[2], A Martinez-Donate[2]
[1]School of Public Health, Temple University, Philadelphia, USA
[2]Dornsife School of Public Health, Drexel University, Philadelphia, USA
Contact: brigitteguariglia@gmail.com

Background and Purpose: Research shows that Latino populations are less likely to seek formal mental health services, these attitudes combined with difficulty finding affordable services impact the ability to receive a mental health diagnosis. This project examines mental health symptoms, utilization of mental health services, and socio-ecological barriers to receive mental health services among Latino immigrants, including region of origin, health insurance, immigration status, and English proficiency.

Methods: Data was collected between 2021-2022 by Drexel University's CRISOL lab using a cross-sectional respondent-driven sample survey of Latinos born outside the U.S. mainland and residing in Philadelphia. The final sample included 420 Latino/a/e immigrants. Descriptive statistics and bivariate associations using Chi-square analyses were computed.

Outcomes: The findings revealed that 29.1% of the surveyed individuals exhibited signs of Depression, 36.1% experienced symptoms of Anxiety, 8.7% showed signs of PTSD, and 43.4% possessed one or more mental health conditions. The findings show that country of origin ($p<.01$), health insurance ($p<.05$), immigration status ($p<.01$), and language proficiency ($p<.001$) are significantly associated with whether an individual has received mental health services in the past year or in their lifetime. Of the survey population, only 39.5% of individuals with one or more mental issues had received mental health services in their lifetime.

Conclusions: Interventions to increase access to mental health services for Latino communities are needed. Solutions addressing disparities in access to mental health services must address systemic, cultural, and language barriers.

Key messages:

- Region of origin, health insurance, immigration status, and English proficiency impact the utilization of mental health services.
- Immigrant populations face stressors that increase the risk for mental health disease and experience multiple barriers to access mental health services.

Abstract citation ID: ckae144.950
Diagnoses of mental health disorders among Norwegian youth and young adults with immigrant parents

Naima Said Sheikh

NS Sheikh[1], ML Straiton[2], MK Kjøllesdal[1]
[1]Institute of Public Health Science, Norwegian University of Life Science, Ås, Norway
[2]Mental Health and Suicide, Norwegian Institute of Public Health, Oslo, Norway
Contact: naima.said.sheikh@nmbu.no

Introduction: Adolescence and early adulthood are associated with an increase in mental health problems. Migration is also a risk factor for mental disorders. Yet, there is a notable gap in research concerning the mental well-being of descendants of immigrants. This study investigates the risk of a diagnosis of a mental health disorder among those aged 16-30 years, born in Norway with at least one immigrant parent.

Methods: Data were sourced from the Medical Birth Registry of Norway, the Norwegian Patient Register, and Statistics Norway. Cox proportional hazard regressions were used to estimate hazard ratios (HR) of being diagnosed with different mental disorders, in total and by parental region of origin, compared to individuals of Norwegian background. Analyses were adjusted for sex, year of birth, and parental education.

Results: Individuals with two immigrant parents had a lower risk of most mental disorder diagnoses, while those of one immigrant parent had a higher risk. With the exception of schizophrenia, individuals with two immigrant parents had a lower risk of most mental disorder diagnoses compared to those with Norwegian-born parents. The HR for the risk of a diagnosis of anxiety for those with two immigrant parents was: 0.79 [95% CI 0.76 - 0.81], with immigrant mother: 1.07 [95% CI 1.04-1.10], with immigrant father: 1.28 [95% CI 1.24 -1.30]. Similarly, for depression, two immigrant parents: 0.85 [95% CI 0.82-0.88], immigrant mother: 1.13 [95% CI 1.09 - 1.17], immigrant father: 1.31 (95% CI 1.28-1.37). Bipolar disorders, two immigrant parents: 0.67 [95% CI 0.60-0.76], immigrant mother: 1.19 [95% CI 1.07 - 1.31], immigrant father: 1.47 [95% CI 1.35-1.61]. The pattern was relatively consistent across parental regions of origin.

Conclusions: Those with one immigrant parent are more likely to use specialist mental health services, while those with two immigrant parents are not. These need special attention in adulthood.

Key messages:

- Differences in risk of diagnosis for mental disorders could be due to differences in the utilization of mental health services.
- Early prevention of mental health issues seems to be especially important among children and youth raised in families with one immigrant parent.

[5]WHO Collab Centre for Research and Training, University of Verona, Verona, Italy
[6]Department de Ciências da Saúde Pública e Forenses, Faculty of Medicine, University of Porto, Porto, Portugal
Contact: raquelmt100@gmail.com

Background: The ADVANCE project aims to address mental health disparities among people in a situation of vulnerability in Europe. Through a co-creation approach, workshops were conducted to devise stigma prevention strategies during the implementation of mental health promotion interventions for migrant populations in Italy and Denmark.

Methods: The methodology involved two rounds of scenario-based workshops, a participatory method that elicit expert opinions to solve local problems and anticipate future ones. Round 1 included two separate workshops with (1) end-users and umbrella organizations, and (2) healthcare practitioners and decision-makers, to ensure diverse perspectives and minimize the impact of power imbalances. Participants brainstormed strategies to minimize stigma and optimize the intervention scenario. In Round 2, a mixed-group workshop was held to refine the strategies. Workshops occurred in Copenhagen and Verona in March 2024. Content analysis of the data was carried out.

Results: In Denmark, discussions emphasized tailored presentation of the intervention promoting shared experiences and normalizing mental health challenges, language sensitivity, participation through self-identification, and attention to relational aspects in intervention delivery to combat stigma effectively and enhance acceptability and engagement with the intervention. In Italy, proposed strategies included group exercises to raise awareness and promote open dialogue about cultural differences, language barriers, and discrimination. Discussions also considered the intersectionality of stigma, including factors like gender, socioeconomic status, and sexual orientation. Common themes included language sensitivity, facilitator training, and inclusive and safe spaces.

Conclusions: Scenario-based workshops can be a valuable tool to facilitate the co-creation of stigma-prevention strategies while involving all stakeholders in promoting effective mental health interventions.

Key messages:

- Co-creation approach fostered stakeholder collaboration, yielding tailored strategies that promote inclusivity, acceptability and engagement with mental health interventions for migrant populations.
- Context-specific approaches that emphasize trust, confidentiality and cultural sensitivity were prioritised to tackle stigma when implementing interventions and promoting mental health equity.

Contact: florencewongnaah@yahoo.com

Background: Cervical cancer remains prevalent in sub-Saharan Africa (SSA). Despite global efforts to eliminate this disease, its incidence continues to rise due to barriers in screening, vaccination, and treatment access. While studies address access barriers, little has explored inequality, often limited to single countries. Here, we examine socioeconomic inequalities in cervical cancer screening in SSA.

Methods: Data from the Demographic and Health Surveys of 10 SSA countries was used for the analysis. We stratified the study by wealth index and educational attainment as a measure of socioeconomic status. Socioeconomic status inequalities in cervical cancer screening were constructed using concentration curves. We then computed the concentration index to quantify socioeconomic inequality. To examine the factors associated with high socioeconomic inequality in cervical cancer screening, a decomposition analysis was conducted.

Results: Concentration curves showed screening uptake skewed towards the wealthy and educated across all countries, reflected by positive concentration indices (CIX=0.21; p-value<0.0001) except in Burkina Faso and Mauritius. Decomposition analysis revealed significant positive concentration indices for women with complete secondary (CIX=0.74) and higher education (CIX=0.91), those in the richest wealth index (CIX=0.35), separated women (CIX=0.08), currently working women (CIX=0.02), as well as those who were exposed to reading newspaper/magazine (CIX=0.19), listening to radio (CIX=0.10), and watching TV (CIX=0.44).

Conclusions: Cervical cancer screening in SSA exhibits pro-rich and pro-higher educational inequalities. Urgent interventions are needed to restructure existing screening programs to prioritize accessibility and inclusion, particularly for women from poorer households and with a lower level of education. These findings are vital for policymakers and public health practitioners to address cervical cancer screening disparities in SSA.

Key messages:

- Addressing socioeconomic inequalities in cervical cancer screening is crucial for improving public health in sub-Saharan Africa.
- Combatting socioeconomic disparities in cervical cancer screening is critical for achieving health equity in sub-Saharan Africa.

Abstract citation ID: ckae144.953

Inequalities in Primary Care Provision in Gwangju Metropolitan City, South Korea

Yerin Choi

Y Choi[1], S Kweon[1,2,3], M Baek[1]

[1]Gwangju Institute for Public Health and Equity, Gwangju, South Korea
[2]Department of Preventive Medicine, Chonnam National University Medical School, Hwasun-gun, South Korea
[3]Gwangju-Jeonnam Regional Cancer Center, Chonnam National University Hwasun Hospital, Hwasun-gun, South Korea
Contact: yerin2132@icloud.com

Background: Primary care clinics play a crucial role in community health promotion by facilitating early disease detection and management. The number of these clinics in Gwangju Metropolitan City increased from 931 in 2000 to 2,400 in 2022, but this growth was not evenly distributed within the city. This study aims to examine the spatial inequalities in the distribution of clinics in Gwangju Metropolitan City.

Methods: This study utilized local administrative licensing data on medical institutions classified as clinics. To estimate healthcare resource imbalances, Lorenz curves and Gini indices for the number of clinics per 100,000 individuals and per square kilometer were calculated by district.

Results: The number of primary care clinics per 1,000 individuals or per square kilometer was highest in Dong-gu and Seo-gu, while Gwangsan-gu had relatively fewer facilities. In particular, Buk-gu, Seo-gu, and Nam-gu had more than 40% of areas with a high number of healthcare facilities relative to population or area, whereas less than 50% of Gwangsan-gu fell into the lower tier in these categories. The Gini index, used to measure the geographical inequality of healthcare facility distribution, showed a slight improvement from

2000 to 2023. However, Seo-gu and Buk-gu exhibited different trends compared to other districts.

Conclusions: Geographical disparities in the distribution of primary care clinics in Gwangju Metropolitan City have slightly improved since 2000, but show different patterns by district. Addressing healthcare imbalances is essential for enhancing health equity, requiring multifaceted efforts to mitigate disparities and improve medical service accessibility in underserved areas.

Key messages:

- Significant disparities exist in the distribution of primary care clinics across Gwangju, with higher densities in Dong-gu and Seo-gu, and fewer facilities in Gwangsan-gu.
- The Gini index for clinic distribution has improved since 2000, but disparities remain, particularly in Seo-gu and Buk-gu. Continued efforts are essential to reduce healthcare inequalities further.

Gender stereotypes in Ukrainian healthcare: results of the mixed methods study

Mariia Samko

A Boiko[1], M Peresada[1], M Duda[1], P Pavlenko[2], B Hinchey[1], N Avaliani[1], E Polomoshnova[1], D Elkins[1], M Samko[1], A Tokar[1]
[1]USAID Health Reform Support, Kyiv, Ukraine
[2]Office of Health USAID Regional Mission to Ukraine, Kyiv, Ukraine
Contact: msamko@hrs.net.ua

Background: A good interpersonal patient-provider relationship is crucial for quality care, still patients frequently perceive interface as discriminatory and marginalizing, reinforcing societal gender roles and hindering healthcare quality. This becomes even more critical for healthcare systems with limited resources and prolonged emergencies, such as Ukraine during the COVID-19 pandemic and full-scale war. We explore gender stereotypes of healthcare workers in Ukraine.

Methods: This mixed-methods study was conducted in August-September 2022, and included: 1)16 online focus group discussions with 93 healthcare workers; 2)survey conducted face-to-face with 1,529 physicians and 502 nurses; modified Nijmegen Gender Awareness in Medicine Scale questionnaire was used. Qualitative data was transcribed and inductively analyzed. Survey results were analyzed in SPSS using descriptive statistics and correlation analyses.

Results: Healthcare workers perceived women patients as ‘more demanding’ and ‘less accommodating’ compared to men. Thus, 64% of healthcare workers perceived female patients as overusing health services; 44%-believed women have higher expectations than male patients; 61%-thought they expected excessive empathy; and 58%-noticed women veering off-topic during consultations. Also, respondents who supported the belief that male patients better understand doctors’ recommendations were more likely to also support the statement that female patients, compared to male patients, more often have higher expectations from doctors ($rs = 0.4$, $p < 0.001$). With age prevalence of gender stereotypes increased among healthcare workers; there were no significant differences by sex of healthcare workers, healthcare facility type, position, or geographical location.

Conclusions: It is crucial to develop and implement gender-sensitive approaches in Ukrainian health facilities, rooted in comprehensive training and continuous professional development targeting prevalent gender stereotypes.

Key messages:

- Gender stereotypes are prevalent among healthcare workers in Ukraine.
- Gender-sensitive approaches and comprehensive training should target prevalent gender stereotypes.

Institutionalising guideline development in a new universal healthcare system: a study in Cyprus

Ourania Kolokotroni

O Kolokotroni[1], H McGuire[2], M Kyriakou[3], P Kouis[4], A Sioftanos[5], A Yiallourou[4], H Achilleos[6], P Yiallouros[4], G Nikolopoulos[4]

[6]Makarios Hospital, State Health Services Organisation, Nicosia, Cyprus
Contact: o.kolokotroni@cut.ac.cy

Issue: Guideline development is a lengthy and diligent process that involves the assessment and interpretation of evidence by a committee. Whilst the implementation of high quality healthcare guidelines ensures consistency and quality in healthcare delivery, many countries worldwide, including Cyprus, lack the capacity and resources to develop de novo guidelines.

Description of the problem: Guidelines developed by internationally recognised organisations, such as NICE, are a valuable resource for countries like Cyprus. The collaboration between NICE and the newly established healthcare system in Cyprus introduced a process for guideline institutionalisation, taking advantage of existing human resources and building guideline development capability in Cyprus.

Results: This process involved recruiting local professionals to form a guideline secretariat. The secretariat, supported by NICE, is responsible for overseeing the guideline development process including technical expert committee (TEC) recruitment and stakeholder consultation. The TEC contextualise an existing NICE guidelines to reflect local considerations. NICE provides quality assurance to ensure changes are contextual in nature and consistent with the underpinning evidence. Despite initial challenges, getting stakeholder buy-in and engaging healthcare professionals in the TEC, one contextualised guideline has been produced and two others are at the final stage.

Lessons: Guideline contextualisation is an efficient and sustainable way of building guideline development capability to institutionalize guidelines in settings with limited capacity.

Key messages:

- De-novo guideline development is time consuming and demanding and many countries require an alternative process for producing locally relevant guidelines, capitalising on existing resources.
- Support by an established organisation ensures quality, is less resource intensive, and builds capability for the sustainability of the process.

Abstract citation ID: ckae144.956
In at the Deep End: Innovative approaches to engaging underserved communities in Northern England

Jayne Jeffries

J Jeffries[1], A Wearn[1], S Hassan[2], K Fryer[3], C Mitchell[4], S Sowden[1]
[1]Population Health Science Institute, Newcastle University, Newcastle Upon Tyne, UK
[2]Chopwell Primary Health Care Centre, NHS, Newcastle Upon Tyne, UK
[3]Population Health, University of Sheffield, Sheffield, UK
[4]Faculty of Medicine, Keele University, Keele, UK
Contact: jayne.jeffries@newcastle.ac.uk

Background: People living in socio-economically deprived communities have greater health needs, but worse access and outcomes from care. A growing international movement of Deep End (DE) general practice networks established to promote health equity, address challenges posed by the inverse care law and advocate for increased research involvement. Researchers, community members and practitioners in the North of England are exploring ways of engaging with underserved communities and addressing low levels of inclusion in research.

Methods: DE research i) co-designing the North East and North Cumbria (NENC) DE network with practitioners to prioritise service investment, research activities and initiatives for local communities; ii) Deep End Research Alliance Yorkshire and Humber (DERA-YH) and Participatory Action Research to increase research capacity and reflect upon the evolution of a novel primary care Community Research Link Worker role (CRLWs).

Results: Prioritisation activities in the NENC DE network, uncovered the volume and complexity of clinical and social need, leading to the co-design and evaluation of initiatives to improve mental health care, increase childhood immunisations, tailor deprescribing, support training, and increase patient inclusion in research. In the DERA-YH, the CRLW model increased participation in research from ethnic minority communities regarding prostate cancer, lung health, dementia, and contraceptive services. Community leaders stated that sharing resources and power in the research process builds trust and interest in research in their communities.

Conclusions: DE networks in Northern England have driven innovative approaches to engage underserved communities in research, fostering empowering and enduring relationships to address health and care inequalities. Co-design methodologies and CRLWs integration into research teams had a transformative impact on the accessibility of research for communities and for the researchers' positionality.

Key messages:

- Deep End networks are advancing approaches to meaningful engagement and partnership working with underserved communities, to address health, care and research participation inequalities.
- We recommend co-design by default and CRLW models to build capacity and embed reflective practice, mutual respect, and power sharing across the research team.

Abstract citation ID: ckae144.957
Social prescribers' referral processes and decision-making about healthy eating and physical activity

Leone Craig

O Petre[1], J Allan[3], L Craig[1], F Douglas[2], J Kyle[1], A Stephen[1], F Thies[1]
[1]University of Aberdeen, Aberdeen, UK
[2]Robert Gordon University, Aberdeen, UK
[3]University of Stirling, Stirling, UK
Contact: l.craig@abdn.ac.uk

Background: Social Prescribing (SP) connects primary care patients with non-medical sources of support within the community. There are various SP models, with different referral routes. Many involve patients being referred to a link practitioner, who considers their needs and then "prescribes" or links them to appropriate local support services or resources, typically provided by the third sector. The present study aimed to explore the SP process and the decision-making of link practitioners, particularly around food and physical activity practices.

Methods: Sixteen semi-structured interviews were conducted with link practitioners working across Aberdeen City. A pragmatic Thematic Framework analysis was undertaken.

Findings: Participating link practitioners described their approach with clients as building rapport and trust while maintaining boundaries and managing expectations, and their community role as resource mapping and networking. Three broad categories of factors were considered during referral: 1) practicality (e.g., location, transport, cost, mobility, availability), 2) clients' engagement (e.g., interest, motivation, readiness for change), and 3) link practitioners' past experiences with services. Challenges identified included navigating waiting lists and service limitations, clients' engagement and expectations, under-resourced services, navigating waiting lists with caseloads and the emotional burden of seeing people in very difficult situations. All link practitioners considered diet and exercise to fit within the remit of social prescribing but emphasised that clients should lead this discussion. Dietary support via social prescribing typically revolved around poverty rather than health.

Discussion: The study provides insight into the practical reality of making social prescribing decisions and has the potential to inform training and evaluation processes and support the development of health-focused social prescribing lifestyle interventions.

Key messages:

- Social prescribing – a personalised approach, with clients supported to identify and achieve their health and wellbeing goals based on their strengths and resources available in the local community.
- Social Prescribing - a promising platform for offering healthy eating interventions tailored to individual needs.

Abstract citation ID: ckae144.958
Changes in anxiety among youth with and without disabilities before, during and after the pandemic

Sinna Lehtola

SMH Lehtola[1], ME Holm[1], O Kiviruusu[1], P Sainio[1], A Lundqvist[1]
[1]THL, Helsinki, Finland
Contact: sinna.lehtola@thl.fi

Background: Disabled youth are a vulnerable group that have faced challenges during the pandemic. Research about mental health and its changes of disabled youth during and after the pandemic is limited. Thus, this study examined changes in anxiety symptoms among youth with disabilities compared to those without disabilities before, during, and after the pandemic.

Methods: We analyzed population-based cross-sectional data from the Finnish School Health Promotion study (SHP) of youths with an age range of 12-29 years obtained in before (2019; n = 155,166), during (2021; n = 160,796), and after (2023; n = 151,224) the pandemic. Disabled youth were identified based on the Child Functioning Module (CFM). Anxiety symptoms were measured using the Generalized Anxiety Disorder-7 (GAD-7). Logistic regression models were applied to investigate population-level changes in anxiety.

Results: Over the years, the prevalence of anxiety symptoms was higher among youth with disabilities (10.2%, CI95% 10.1-10.4) compared to youth without disabilities (40.1%, 39.9-40.4), females having more symptoms than males. Prevalence of anxiety increased significantly during the pandemic (Before: 31.7% 95%CI 31.2-32.3 & During: 41.8%, 41.4-42.3) and continued to increase slightly after (44.4%, 43.9-44.9) among disabled youth. The same trend was seen in non-disabled youth (Before: 7.5%, 7.4-7.7, During: 11.4%, 11.2-11.6 & After: 12.0%, 11.8-12.2).

Conclusions: The prevalence of anxiety among disabled youth increased during the pandemic and has continued to increase even afterward, highlighting the inequality among youth with disabilities. The results indicate that it is important for educators and stakeholders to target measures and resources to support the mental health of youth with disabilities during and after a crisis, improving their equality in schools and society.

Key messages:

- Youth with disabilities experienced anxiety symptoms four times more often than non-disabled youth, and this difference has remained quite stable during the pandemic and afterwards.

- Decision-makers should be aware of this weaker mental health condition of youth with disabilities while planning preventive actions and interventions.

Abstract citation ID: ckae144.959
Unmet health needs during COVID-19 pandemic in Serbia

Milena Jakovljevic

M Jakovljevic[1], *B Matejic*[2], *A Cirkovic*[2], *S Mladenovic Jankovic*[1]
[1]Institute of Public Health Belgrade, Belgrade, Serbia
[2]Faculty of Medicine University of Belgrade, Belgrade, Serbia
Contact: jakovljevicmilena6@gmail.com

Background: The COVID-19 pandemic made health care access more difficult. This study provides insight into significant individual factors associated with unmet needs in 2021 in Serbia.
Methods: The study is a secondary analysis of SILC data, conducted on a sample of 13,855 respondents aged 16 + (source: Statistical Office of the Republic of Serbia). The outcome variable is self-reported unmet need for physician service in last 12 months (yes/no). Multivariate logistic regression is used to identify factors significantly related to unmet needs. Demographic, socioeconomic factors and health needs, which have been found to be significant for outcome in univariate logistic regression, are entered in final analysis.
Results: It was shown that age, marital, employment status, income and health needs were significant factors for unmet needs. Compared to 16-24 age group, aged 65+ were more likely to report unmet needs, OR = 3.5(CI = 2.1-5.6); for 45-64 years old OR = 3.4 (CI = 2.1-5.3); for 25-44 OR = 2.0(CI = 1.3-3.1). Separated/divorced had higher odds for unmet needs than married ones, OR = 1.4 (CI = 1.2-1.8); as well as unemployed, OR = 1.4(CI = 1.2-1.6), and retired, OR = 1.2(CI = 1.0-1.5), than employed. Those from the 1st quintile, based on equalized disposable household income, were more likely to report unmet need compared to the 5th quintile, OR = 1.8(CI = 1.5-2.1). A gradient across all quintiles was proven (for 2nd quintile OR = 1.6(CI = 1.3-1.9), for 3rd OR = 1.4(CI = 1.1-1.7), for 4th OR = 1.3(CI = 1.1-1.5)). Compared to participants with very good/good health, those who perceive own health as very poor/poor had 3 times higher odds (CI = 2.5-3.5) to report unmet need; for those with average health OR = 1.7(CI = 1.5-1.9). Suffering from chronic illness increases odds 2.2 times (CI = 1.9-2.5).
Conclusions: The highest probability for unmet needs was established across most vulnerable groups, which is significant for preparing for future public health crises and preventing increase in health inequalities during them.
Key messages:
- During the pandemic,there was a higher probability of unmet health needs among the most vulnerable groups.
- Strategies need to be put in place to prevent health inequalities deepening in a future crisis.

Abstract citation ID: ckae144.960
Dis-continuity in Continuity-of-Care: a pathway for more equal access to mental health care services?

Viola Burau

V Burau[1], *S Buch Mejsner*[1], *M Fehsenfeld*[1]
[1]Public Health, Aarhus University, Aarhus C, Denmark
Contact: viola@ph.au.dk

Background: Access to healthcare is core to achieving universal health coverage. Reaching and obtaining appropriate health care services requires engagement by health care organizations and users. For people with mental illness, access emerges as a continuous process, reflecting oscillating health conditions. This challenges aspirations of continuity of care (COC), but we know little about the experiences of users.
Methods: We carried out observations of interactions between professionals and users (n = 18) and semi-structured interviews with users, professionals, and managers (n = 33) in the specialised mental health services in Central Denmark Region and FACT-inspired teams in three municipalities. We also conducted 3 focus groups with regional and municipal professionals from these teams. Data was analysed through a qualitative thematic analysis.
Results: From the perspective of users, COC builds on the acknowledgment of their entire life situation. For users, this is about making connections between their past, present and future lives. Past experience affect their present abilities to follow treatment and influence future hopes and expectations. The acknowledgment of these connections often translates into spaces of discontinuity in continuity, where users need occasional breaks from treatment but worry about being excluded from treatment. Crucially, the organization of the FACT-inspired teams allows for flexibility in the intensity of visits and treatment. The norms of professionals also support users' perspectives on COC, as the norms focus on building trust in the relations between users and professionals.
Conclusions: One important step to achieve more equal access is to integrate the social world of users. This requires organizational and professional approaches that allow for user needs for dis-continuity in COC.
Key messages:
- For mental health service users, continuity-of-care includes breaks from treatment (discontinuity).
- More equal health access requires adapting continuity-of-care to needs as perceived by users.

Abstract citation ID: ckae144.961
Intersectional inequalities in child social-emotional health: a case for proportionate universalism

Anneli Ivarsson

A Rosenberg[1], *A Ivarsson*[1], *AM Pulkki-Brännström*[1], *M Lindkvist*[1], *SA Silfverdal*[2], *M Vaezghasemi*[1]
[1]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
[2]Department of Clinical Science, Pediatrics, Umeå University, Umeå, Sweden
Contact: anneli.ivarsson@umu.se

Background: Social-emotional difficulties in early childhood are associated with a range of outcomes across the life course and are related to socioeconomic factors. The aim of this study was to examine intersectional inequalities in social-emotional problems in preschool children relating to their parents' income, education and country of birth in addition to investigating the public health implications.
Methods: This population-based study with a repeated cross-sectional design in the Västerbotten County of Sweden used the Ages and Stages Questionnaires: Social-Emotional (ASQ:SE) for children aged 3 in child health care services over the years of 2014-2018 and socio-economic information from national population registers. The effective sample of 8,823 individuals was analyzed using additive binomial regression in combination with an analysis of individual heterogeneity and discriminatory accuracy (AIHDA) approach to estimate risk differences for social-emotional problems across 27 intersectional groups and discriminatory accuracy.
Results: Average risk differences generally increased in the groups where multiple dimensions of social inequality intersected, with risk differences as high as 18% (95% CI 8 to 28%) and 25% (95% CI 14 to 37%) compared to the most advantaged category. The discriminatory accuracy of all three included regression models was estimated as moderate, but improved in a slight but statistically significant way with the addition of social inequalities.

Conclusions: This study increases our understanding of intersectional and social inequalities in social-emotional problems in preschool children. It supports the need for universal public health policies in addition to policies targeting more vulnerable groups when addressing this issue, consistent with the concept of proportionate universalism. An intersectional research perspective including discriminatory accuracy could increase our knowledge of health inequities and improve public health effectiveness.

Key messages:

- Intersecting dimensions of social inequalities are associated with an increased risk of social-emotional problems in children aged 3.
- Universal public health policies are needed in addition to policies targeting vulnerable population groups with regards to social-emotional problems in young children.

5.S. Poster walk: Public mental health

Work- & family-related stress & the risk of hazardous alcohol use: role of sex and social support

Ridwanul Amin

R Amin[1]*, JS Goppers*[1]*, J Möller*[2]*, K Engström*[2]*, A Sidorchuk*[3,4]*, E Mittendorfer-Rutz*[1]*, K Gémes*[1]

[1]Division of Insurance Medicine, Department CNS, Karolinska Institutet, Stockholm, Sweden
[2]Department of Global Public Health, Karolinska Institutet, Stockholm, Sweden
[3]Centre for Psychiatry Research, Department CNS, Karolinska Institutet, Stockholm, Sweden
[4]Stockholm Health Care Services, Region Stockholm, Stockholm, Sweden
Contact: ridwanul.amin@ki.se

Background: There is a lack of longitudinal studies investigating the effect of individual stress factors on alcohol use behaviour, and how sex and social support may mitigate the effect of these stressors. We aimed to determine the association of work- and family-related stressors with developing hazardous alcohol use over time among habitual drinkers, and to examine the role of sex and social support in these associations.

Methods: A sample of 4,046 individuals, working and living in Stockholm, age 25-55 years, habitual drinkers, who answered the PART study (Swedish acronym for Mental Health, Work and Social Relations) questionnaire regarding work- and family-related stress (exposures) in 1998-2000 (wave1) and 2001-2003 (wave2) were followed until 2010 (wave3) regarding hazardous alcohol use (outcome) measured using Alcohol-Use-Disorder-Identification-Test (AUDIT) score ($>=8$ in men, $>=7$ in women). Weights for selective attrition were calculated, and crude and multivariate (adjusting for sociodemographic, health- and previous stress-related factors) logistic regression models, yielding Odds Ratios (OR) with 95% Confidence Intervals (CI), were used to estimate the exposure-outcome associations. Analyses were stratified for sex and social support in general and at work.

Results: Job strain (a combination of high demand and low control) was not statistically significantly associated with hazardous alcohol use (OR, CI: 1.3, 0.9-1.9). Among those reporting any family-related stress, a significantly higher risk was observed (OR, CI: 1.5, 1.1-2.1), particularly among women (OR, CI: 1.7, 1.02-2.7) and those with low social support (OR, CI: 2.1, 1.2-3.6). These associations became non-significant after adjusting for previous family-related stress.

Conclusions: Public health measures aiming to prevent transitions from habitual to hazardous alcohol use should give special attention to individuals with family-related stress, especially among women and those with low social support.

Key messages:

- While job stress was not significantly associated, those experiencing family-related stress had a higher risk of hazardous alcohol use, especially among women and those without social support.
- Individuals experiencing family-related stress, particularly women and those lacking social support, require special attention in public health prevention strategies for risky alcohol consumption.

Abstract citation ID: ckae144.963
Depressiveness in German higher education students – a systematic review and meta-analysis

Eileen Heumann

E Heumann[1]*, AV Palacio Siebe*[1]*, C Stock*[1]*, K Heinrichs*[1]

[1]Institute of Health and Nursing Science, Charité - Universitätsmedizin Berlin, Berlin, Germany
Contact: eileen.heumann@charite.de

Introduction: Evidence shows that German higher education students are vulnerable to depressive symptoms. However, there is no recent review compiling these findings. Thus, our study aims at describing the extent to which higher education students in Germany are affected by depressive symptoms.

Methods: We searched three databases for suitable publications using three core concepts ('depressive symptoms', 'students', and 'Germany'). The inclusion criteria were: (a) the population studied consisted of students from higher education institutions, (b) data was assessed at higher education institutions in Germany, (c) information on depressive symptoms were pro-vided as outcome of instruments assessing depressive symptoms, (d) articles were published in peer-reviewed journals, in (e) English or German and (f) between 2002 and 2023. Random effects models were used to calculate both general and subgroup-specific pooled prevalence rates. Subgroups were formed based on the included literature (e.g. gender, before or during the COVID-19 pandemic, study phase and programme).

Results: The literature search resulted in 992 articles. After the removal of duplicates and the two-stage screening process, prevalence data was extracted from 60 articles. The overall pooled prevalence rate was 21.1% (95% CI: 17.6% - 24.6%). Medical students (13.2%; 95% CI: 9.9% - 16.4%) and first-year students (11.0%; 95% CI: 7.7% - 14.3%) were less likely to be affected than students in general. Women (29.0%; 95% CI: 21.4% - 36.5%) were more prone to depressive symptoms than men (23.1%; 95% CI: 16.5% - 29.6%). In samples collected during the COVID-19 pandemic, the pooled prevalence rates were higher than in pre-pandemic times (30.6%; 95% CI: 22.1% - 39.1% vs. 18.0%; 95% CI: 14.7% - 21.2%).

Conclusions: This analysis emphasizes the pressing need to address the mental health of higher education students both at the policy level and within universities.

Key messages:

- German higher education students show alarming levels of depressive symptoms, demanding immediate action.

- During the pandemic mental health was even poorer than before, highlighting the need for tailored interventions and support in challenging times.

Gender and Education Differences in Mental Health in Belgium: a Bayesian Age-Period-Cohort Analysis

Pierre Smith

P Smith[1,2], R De Pauw[1,3], B Spruyt[4], F Van Droogenbroeck[4,5], L Van Den Borre[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Institute of Health & Society, Université Catholique de Louvain, Brussels, Belgium
[3]Department of Rehabilitation Sciences, Ghent University, Ghent, Belgium
[4]BISPRO, Vrije Universiteit Brussel, Brussels, Belgium
[5]Data Analytics Lab, Vrije Universiteit Brussel, Brussels, Belgium
Contact: pierre.smith@sciensano.be

Background: Mental illnesses (MI) constitute a growing public health problem, with reports of a higher prevalence among middle-aged adults (age effect), during specific periods such as economic crisis (period effect) and in recent birth cohorts (cohort effect). However, few studies have assessed whether these age-period-cohort (APC) effects were related to general population trends or if they are driven by changes in the mental health status of more vulnerable groups. Therefore, this study aimed to assess gender and educational differences underlying observed APC effects in the prevalence of MI in the Belgian adult population.
Methods: This study used data from six cross-sectional waves of the Belgian Health Interview Survey (1997-2018, ∼ 10,000 respondents per wave). Mental health was assessed using the 12-item General Health Questionnaire. Bayesian hierarchical APC models were applied on the prevalence of MI, taking into account gender and educational differences, as well as some potential confounding factors.
Results: Overall, this study confirmed the higher prevalence of MI in middle-aged adult, in 2013, and in more recent birth cohorts (1980-2000). Accounting for the interaction between gender and education, we found that the MI educational gradient was more pronounced for women than men. Finally, we found that APC trends were different between gender. The odds of having MI tended to be stable across age groups for women, while men showed an increased odds between 50-60 years and a decrease between 60-65 years. Regarding period and cohort effects, the increase odds in 2013 was mainly present in men, while the increase in recent birth cohorts was mainly present in women.
Conclusions: This study emphasizes that the age-period-cohort effects on mental health are different depending on gender and education, thus enriching our understanding on the underlying mechanisms to better guide future public (mental) health policies.
Key messages:
- This study shows the importance of studying not only the overall trends in mental illness, but also the underlying differences in its distribution.
- Insights into gender and educational differences in Age-Period-Cohort effects on mental health is crucial for the development of timely and efficient public health interventions.

Abstract citation ID: ckae144.965
Long-term mental health impairments in survivors of critical illness

Marion Egger

M Egger[1,2], M Finsterhölzl[1], F Wippenbeck[1], F Müller[1], V Huge[3,1], K Jahn[1,4], J Bergmann[1,4]
[1]Neurology, Research Group, Schoen Clinic Bad Aibling, Bad Aibling, Germany
[2]Institute for Medical Information Processing, Faculty of Medicine, LMU Munich, Pettenkofer School of Public Health, Munich, Germany
[3]Critical Care Medicine and Anesthesiology, Schoen Clinic Bad Aibling, Bad Aibling, Germany
[4]German Center Vertigo and Balance Disorders, LMU, University Hospital, Munich, Germany
Contact: megger@schoen-klinik.de

Background: Survivors of critical illness frequently suffer from long-term disabilities, including physical, cognitive, and mental impairments (post-intensive care syndrome). However, long-term studies are scarce and healthcare services for critical illness survivors are limited, not only in Germany. Therefore, we followed-up on anxiety, depression, and post-traumatic stress disorder (PTSD) during post-intensive care unit (ICU) rehabilitation and up to 1 year after critical illness onset.
Methods: Patients at Schoen Clinic Bad Aibling in Germany were eligible for this prospective cohort study after receiving ≥ 5 days of mechanical ventilation. The Hospital Anxiety and Depression Scale (HADS; subcategory score ≥ 8) was conducted after ICU discharge (V1), at discharge from inpatient rehabilitation (V2) and 1 year after critical illness onset (V3). The Impact of Event Scale-6 (score ≥ 1.75) was conducted to assess PTSD at V3. Multiple logistic regressions were performed.
Results: We included 250 patients (62±14 years, 34% female, median stay on ICU 55 days, median duration of rehabilitation 65 days). 10% died before V3. Anxiety decreased during rehabilitation (effect size $r = 0.35$, $p < .001$), but increased again until V3 ($r = 0.42$, $p < .001$). At V3, 54% suffered from anxiety. Depression also decreased during rehabilitation ($r = 0.46$, $p < .001$), and increased again until V3 ($r = 0.39$, $p < .001$). At V3, 44% showed depressive symptoms and 38% suffered from PTSD. COVID-19 diagnosis was associated with increased anxiety ($p < .001$), depression ($p = .068$), and PTSD at V3 ($p = .028$), compared to non-COVID-19 patients. Furthermore, longer duration of mechanical ventilation was associated with increased anxiety ($p = .041$) and depression ($p = .019$) at V3.
Conclusions: Mental health impairments frequently occur in critical illness survivors, and they seem to worsen after rehabilitation. As these impairments can significantly impact daily functioning and quality of life, tailored healthcare services are urgently needed.
Key messages:
- Anxiety, depression, and PTSD are frequent in critical illness survivors, even 1 year after critical disease onset. This calls for tailored healthcare services.
- Patients with COVID-19 and longer mechanical ventilation suffer from more severe mental health impairments.

Exploring anxiety and depression trends: insights from the BELHEALTH cohort 2022-2024 in Belgium

Camille Duveau

C Duveau[1,2], L Hermans[1], H Bruggeman[1], G Nélis[1], R Charafeddine[1], M Dispas[1], S Demarest[1], L Gisle[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Institute of Health and Society, Université Catholique de Louvain, Brussels, Belgium
Contact: camille.duveau@sciensano.be

Background: The swift impact of the COVID-19 pandemic and ensuing restrictions on the mental health of the Belgian population prompted the need for a sustainable system to monitor its evolution. Repeated COVID-19 surveys were conducted between 2020 and 2022 to address this issue, followed by the launch of the BELHEALTH cohort project. Our study aims to analyze the trajectory of anxiety and depression at the post-pandemic period, using data from five waves of the BELHEALTH longitudinal surveys from October 2022 to March 2024. High-risk groups and the potential of social support and resilience to mitigate anxiety and depression were explored.

Methods: The BELHEALTH follow-up cohort of around 7,300 Belgian residents uses online surveys to assess anxiety (with the GAD-7), and depression (with the PHQ-9). The analyses were performed using linear mixed models on the 3,676 individuals who participated in all five waves.

Results: Preliminary results indicated that more people were affected by anxiety in October 2022 (16%) compared to June 2023 (14%), while depression rates were lower in October 2022 (13%) compared to February 2023 (14%) and March 2024 (15%). However, the trajectory of mental health varied across demographic subgroups, with worse outcomes observed among unemployed and younger individuals, as well as those living alone, in the Walloon Region (South of Belgium). Overall, people with a low level of resilience or a low level of social support exhibited higher odds of experiencing depression.

Conclusions: Reducing these social inequities in mental health necessitates the development of structural prevention measures and interventions at the regional level. These measures should target factors such as unemployment, which is particularly prevalent among younger individuals and those living in Wallonia. Additionally, fostering protective factors such as social support and resilience is crucial for mitigating mental health inequalities over time.

Key messages:

- Monitoring mental health and its determinants remains crucial to identify and address social inequities, tailor interventions, and support vulnerable populations.
- Unemployed, younger people, and those residing in the Walloon region are at particular risk.

Abstract citation ID: ckae144.967
Improving the rights of people with mental disorders in the Republic of Croatia

Danijela Štimac Grbić

D Štimac Grbić[1], *L Štimac*[2], *S Štrkalj Ivezić*[3]
[1]Croatian Institute of Public Health, Croatian Public Health Association, Zagreb, Croatia
[2]University of Novi Sad, Novi Sad, Serbia
[3]Psychiatric Department, Clinical Hospital Vrapče, Zagreb, Croatia
Contact: danijela.stim@gmail.com

The mental health care system in the Republic of Croatia, despite the ongoing reform, is still based on hospital treatment. Hospitalizations due to mental disorders are in first place according to the length of stay. According to the annual report of the Ombudsman in the Republic of Croatia, 2% of hospitalizations due to mental disorders are involuntary hospitalization. Coercive measures and deprivation of business capacity are also often used. In order to reduce the number of coercive measures, involuntary hospitalizations and deprivation of professional capacity, it is necessary to increase mental health literacy and knowledge about human rights and the rights of persons with mental disorders, both among mental health experts and among patients and their families, as well as the general public. In order to increase knowledge and skills related to the rights of people with mental disorders, the Croatian Institute of Public Health, has been conducting WHO Quality Rights workshops in Croatian counties since 2019. The two-day workshops include all stakeholders: local politicians and decision-makers, associations of people with mental disorders and their families, employees in the mental health care system with the involvement of the media. So far, the training has been conducted in five major Croatian counties. The Quality Rights e-training platform has been translated into Croatian and the link to access the training is available online. In order to ensure the sustainability of the program and expand knowledge and skills, obtaining a certificate of completed Quality Right training became a requirement for passing the specialist exam in public health and in psychiatry. In five years of implementation of the program, the number of coercive measures in psychiatric hospitals decreased by 58%. Respect for human rights is a prerequisite for improving the mental health care system and the mental health. of both patients and the entire population.

Key messages:

- Respect for human rights is necessary for the mental health of the population.
- Knowledge and skills about the rights of patients with mental disorders reduce the rate of coercive measures.

Abstract citation ID: ckae144.968
Buildings as reflectors of societal values: what features of psychiatric wards reveal about stigma

Evangelia Chrysikou

E Chrysikou[1,2]
[1]The Bartlett School of Sustainable Construction, University College London, London, UK
[2]University of Crete, Crete, Greece
Contact: e.chrysikou@ucl.ac.uk

Built Environment (BE) features bearing domestic attributes align with the concept of psychosocial re-integration. To understand the level of de-institutionalisation in relation to mental health infrastructure, a series of 29 case studies occurred in four countries from 2000 onwards. We collected data from Europe, the UK, New Zealand and more recently in the US: England ($n = 15$), France ($n = 5$), New Zealand ($n = 4$) and the US ($n = 5$). This included five acute wards in England and five in France in 2000-2004, two further acute wards in England in 2015-2017, four facilities in New Zealand in 2017-2020 (catering also for the Māori population), six further wards (older adult rehab, older adult dementia, acute, rehab, PICU, older adults) and two forensic wards in England and five wards in the US in three different hospitals (one mental health and four mental health wards in general hospital: two adult and two adolescent) in 2023-2024. An architectural checklist was developed to evaluate the traits of the exterior and interior and measure the degree of institutionalisation vs homelikeness for mental health buildings. Cross-country comparison revealed recent case studies to be closer to the institutional end with increased anti-ligature features. Most NZ and the US samples were the most institutional ones. The checklist revealed that acuity was potentially not a determinant of institutional versus domestic buildings. Data shown that very few features were universally present, questioning what is the absolute minimum in relation to the illness rather than the policies. The US sample provides further food for thought, especially in relation to the location of psychiatric wards inside general hospitals and the reasons that lead to this. Finally, by looking at the BE for mental health, we uncover issues regarding the service provision and institutional prejudices connected to stigma. This questions the adequacy of de-institutionalisation policies in certain contexts.

Key messages:

- The study of the architecture of healthcare facilities can depict aspects related to the health service provision and raise questions about the effectiveness of rehabilitation strategies.
- The architecture of psychiatric wards questions the success of some de-institutionalisation decision-making in a cross-country comparison.

Abstract citation ID: ckae144.969
Mental health problems identified in early school age and later mental health problems and disorders

Sofie Pant

SW Pant[1], LM Pommerencke[1], SE Jørgensen[1], AM Skovgaard[1], TR Pedersen[1], KR Madsen[1]
[1]Child and Adolescent Health, National Institute of Public Health, Copenhagen, Denmark
Contact: pant@sdu.dk

Background: Poor mental health in childhood and adolescence youth is an important public health challenge. We aimed to examine the prospective association between mental health problems among primary school children and later diagnosed mental disorders and mental health problems in youth.

Methods: A prospective cohort study of children participating in school health nurse examination during first years of primary school (approx. 6 years) in 17 municipalities in the capital region of Copenhagen, Denmark, with follow-up until their 16th birthday. Baseline data included information from national population registers and school health nurse records. Outcome variables: mental disorders diagnosed at hospital from approx. age 6 until 16 years (N = 6,930) and school health nurse records of mental health problems at approx. age 16 (N = 11,250).

Results: Problematic relations to peers in early primary school was associated with later neurodevelopmental disorders, including intellectual disability, autism-spectrum disorder and disorders of hyperactivity and inattention (AOR=4.14, 95% CI 2.15-7.97), and poor home related well-being in youth (AOR=1.67, 95% CI 1.02-2.74). Poor school well-being in early primary school was associated with poor school well-being ten years later (AOR=1.67, 95% CI 1.19-2.34) as well as problematic relations to peers (AOR=1.83, 95% CI 1.08-3.10). Further poor general well-being in early primary school was associated with problematic relations to peers in youth (AOR=2.21, 95% CI 1.17-4.18).

Conclusions: School health nurses identify a group of children in the early years of primary school with mental health problems and an increased risk of later mental health problems and disorders, and therefore they play an important role in the early identification of children at risk.

Key messages:
- Children with problematic relations to peers have up to a fourfold increased risk of later mental disorders.
- The school health nurses play an important role in the early identification of children at risk of later mental health problems.

Abstract citation ID: ckae144.970
Depression and its risk factors in a conflict-affected population: findings from a nationwide survey

Lusine Musheghyan

L Musheghyan[1], Z Sargsyan[1], A Agopian[1], D Abrahamian[2], A Dorian[2]
[1]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
[2]Fielding School of Public Health, University of California, Los Angeles, USA
Contact: lmusheghyan@aua.am

Introduction: The impact of armed conflict and war on mental health is well documented, with limited data on populations living in unrecognized states. In this study, we examined the prevalence and risk factors of symptoms of depression among the Nagorno-Karabakh population during a ceasefire period, prior to a blockade, full-scale military attack, and their forced displacement.

Methods: A total of 1023 women, aged 18-49 years, from all regions of Nagorno-Karabakh, participated in a population-based household survey in 2022, which included the Center for Epidemiologic Studies-Depression (CES-D) 16-item scale to assess their depression symptoms. Simple and multivariable linear regression analyses explored the socio-demographic factors associated with CES-D score.

Results: The mean CES-D score was 8.90 (SD = 8.93), and 13.1% of the respondents had a score >18 (presence of depressive symptoms). The adjusted linear regression showed that CES-D score was higher among divorced (2.66, SE = 1.15, p-value=0.021) or widowed (3.09, SE = 1.57, p-value=0.049) vs. married, and among those having war-related deaths in the household in the previous 2 years (8.60, SE = 1.65, p-value<0.001) vs. not having. Conversely, a vocational/university level (-2.33, SE = 0.70, p-value=0.001) or post-graduate education (-3.81, SE = 1.72, p-value=0.027) vs less than secondary/secondary level, and 3-5 members in the household (-2.71, SE = 1.16, p-value=0.020) vs.1-2 members were significantly associated with lower CES-D score.

Conclusions: Our findings suggest that depression symptoms are highly prevalent among women in conflict-affected areas, with specific socio-demographic factors increasing the risk of depression symptoms. These results highlight the importance of providing mental health support and interventions for women in conflict-affected areas, particularly for those who experienced loss in the family due to war, are divorced or widowed, live in small households, and have lower education.

Key messages:
- Depression symptoms are highly prevalent among women of reproductive age in areas affected by armed conflict and war.
- Mental health intervention is recommended for women in conflict-affected areas who experienced loss due to war, are divorced or widowed, live in small households and/or have lower education.

Abstract citation ID: ckae144.971
Mental health promotion research in co-creation: Lessons from a multisite study in six countries

Cláudia De Freitas

C De Freitas[1,2,3], R Teixeira[1,3], L Sanna[4], WA Tol[5,6]
[1]EPIUnit - Institute of Public Health of University of Porto, Porto, Portugal

[4]Mental Health Europe, Brussels, Belgium
[5]Department of Public Health, University of Copenhagen, Copenhagen, Denmark
[6]Department of Mental Health, Bloomberg School of Public Health, Baltimore, USA
Contact: claudia_defreitas@yahoo.com

Background: Mounting public health threats associated with climate change, epidemiological and economic crises, digitalisation, rising migration, and population aging have uncovered at-risk groups' increased vulnerability to mental ill health. Developing mental health promotion interventions tailored to their specific needs and expectations is essential to protect their wellbeing. However, researchers may find it challenging to identify and implement needed adaptations without engaging with end-users, and other stakeholders, to co-create tailor-made interventions. This study aimed to explore co-creators' views about opportunities and constraints in participatory mental health promotion research.

Methods: Between September 2023 and July 2024, a qualitative study drawing on participant observation of bimonthly meetings and semi-structured interviews with six co-creation facilitators was conducted in the scope of Horizon Europe's project ADVANCE. The multi-methods research approach to co-creation entailed desk reviews and online Delphi surveys co-developed with locally-established Society Advisory Groups, and scenario-based workshops held with stakeholders in the six partner countries: Denmark, Germany, Italy, Lithuania, Netherlands, Switzerland. Thematic analysis of the data was carried out.

Results: Research teams' epistemic stances impact research planning, resource allocation, partnership nourishing and the unravelling of co-option risks during participatory research implementation. Research co-creation adds pressure onto research teams' agenda, skillset and performance, but it also encourages power sharing, mutual learning and greater alignment of research design and implementation with end-users' priorities and aspirations.

Conclusions: Research co-creation is a partnership-based and resource-intensive endeavour that can provide a valuable pathway to improve the relevance, acceptability and sustainability of public mental health promotion research.

Key messages:

- Research co-creation demands planning, adequate resource allocation, flexibility and continuous investment to sustain academy-society partnerships.
- Engaging stakeholders in knowledge co-creation can increase the relevance, acceptability and sustainability of public mental health promotion research.

The course and management of mental illness are both influenced by social contextual factors. Standardised questionnaires are required to monitor inpatients' social environment and to design interventions. This study aims to describe the social environment of inpatients with depression using standardised instruments, and to analyse the instrument's applicability. This cross-sectional study included depressed adult inpatients admitted to a German psychiatric hospital. We used three standardised questionnaires to evaluate social risk factors: the Lubben Social Network Scale (LSNS), the WHO Disability Assessment Schedule (WHODAS) and the Social Cohesion and Trust Scale (SCTS). The appropriateness of the questionnaires was assessed with a context-specific quality appraisal. Our study included 196 patients with depression having a mean age of 38.8 (SD = 13.7) years of whom 50% were female. A total of 164 (85%) of patients reported a family history of mental health problems, and 31 (38.8%) had experienced discrimination. Analyses of the LSNS and WHODAS showed that the prevalence of social isolation and disability was significantly higher among inpatients compared to the general population. The WHODAS scores were highest in patients aged 18-30, while social isolation was elevated but stable among different age groups (range 18.7- 19.4%). Both, the WHODAS and LSNS showed good clinical applicability, comparability, and test properties. A lack of validation in a young population of the LSNS was considered a weakness. The SCTS showed imperfections in its applicability and comparability. Depressed inpatients have a limited social network compared to the general population. We emphasise the importance of assessing the applicability of questionnaires representing social environment as the basis for developing interventions. We recommend systematic monitoring of social characteristics to identify potential targets of intervention and thereby facilitate the management of depression.

Key messages:

- Hospitalised patients with depression have a decreased social functioning and a smaller social network compared to the general population.
- Standardised social environment questionnaires should be consented and used to plan and enrich depression management.

Abstract citation ID: ckae144.973
Association between mental and physical health with poly-substance use among adults in 33 U.S. states

Michael Phillips

M Phillips[1], M Thompson[1], J Massey[1], K Phillips[2]
[1]Office of Public Health Studies, University of Hawaii, Honolulu, USA
[2]Center for Integrated Health Care Research, Kaiser Permanente, Honolulu, USA
Contact: mphil@hawaii.edu

Leveraging national data from 33 states in the U.S. for adults 18 and over (N = 347,060), from the 2020-2022 Behavioral Risk Factor Surveillance System (BRFSS), we investigated the association between current self-reported physical and mental health outcomes and substance use, focusing on alcohol, nicotine, cannabis, and all combinations of poly-substance use. Specifically, we conducted multiple weighted linear regression analyses using self-reported outcomes for poor mental and physical health in the last 30 days to examine seven mutually exclusive combinations: alcohol (A) only, nicotine (N) only, cannabis (C) only, A+N, A+C, N+C, and A+N+C. We adjusted for race, sex, age group, education level, and marital status in our analyses. For poor mental health, mean number of days ranged from 3.49 (SD = 7.07) for A-only to 10.39 (SD = 11.54) for N+C and for poor physical health, means ranged from 2.38 (SD = 6.24) to 7.17 (10.61) for N+C. All adjusted β coefficients were significant for poor mental health days, notably with the three highest being 4.36 (95%CI: 3.72-5.00) for C-only, 5.68 (95%CI: 5.06-6.30) for N+C, and 5.27 (95%CI: 4.76-5.79) for A+N+C. For poor physical health, all adjusted β coefficients were significant except for A+N, with the two highest being 2.88 (95%CI: 2.31-3.45) for C-only, 3.16 (95%CI: 2.62-3.69) for N+C, and 1.83 (95%CI: 1.54-2.11) for N-only. Recent poly-substance use containing nicotine and cannabis was both associated with 5+ days of poorer mental health and 3+ days of poorer physical health. Overall, our findings hold implications for informing future policy discourse, shaping public health campaigns, and designing educational initiatives aimed at the link between mental health and substance use. Understanding the dynamics of poly-substance use involving the three most commonly utilized substances globally among adults is critical for crafting targeted interventions.

Key messages:

- Recent poly-substance use (alcohol, nicotine, and cannabis) is related to poorer mental and physical health in the past 30-days.
- Recent nicotine and cannabis co-use is associated with 5+ days of self-reported poorer mental health and 3+ days of physical health.

Abstract citation ID: ckae144.974
Family: cornerstone for young people to be victims of violence in the university stage

Josue Eli Villegas Dominguez

J Villegas-Dominguez[1], A Estrada Cancino[1], RA Hernandez Hernandez[1], AE Caldare Ojeda[1], JC Viñaz Dozal[1], F Ruiz Garcia[1], YR Sosa Gonzalez[1]
[1]Facultad de Medicina, Campus Veracruz, Universidad del Valle de Mexico, Veracruz, Mexico
Contact: josue_eli@hotmail.com

Introduction: Violence is a pervasive issue that wreaks havoc within communities, with the family serving as a cornerstone for the development of individuals, thereby influencing their behavior within society.

Objectives: To determine the association between a history of family violence and being a victim of violence among university students.

Methodology: This is a cross-sectional, prospective study that included university students of both sexes. Family function was measured using the Family APGAR test, while the dependent variable was experiencing any type of violence during the university stage.

Results: A total of 1148 participants were included, with an average age of 20.47 (±3.3) years, 63.9% were women, 94.9% were cisgender, and 77.3% were heterosexual; 45.3% of participants identified with family dysfunction, 45.3% had witnessed a violent act in their family, and 46% of participants experienced violence at university. When evaluating factors associated with experiencing violence, a positive association (OR/CI95%) was identified for attending a private school (1.4/1.1-1.9), alcohol consumption (2.4/1.7-3.5), having family disfunction (1.5/1.2-1.9) living in a family with violence (2.3/1.8-2.9), knowing friends who experienced partner violence (2.1/1.6-2.7) or family violence (1.9/1.4-2.5). Conversely, a negative association was found for being heterosexual (0.6/0.4-0.8), never witnessing sexual (0.3-0.2-2.5), physical (0.5/0.4-0.65), or psychological (0.3/0.2-0.4) violence in the family, nor experiencing violence during childhood (0.4/0.3-0.5), middle school (0.4/0.3-0.5), or high school (0.4/0.3-0.5) ($p < 0.001$), likewise, not exercising physical, psychological, sexual, digital or other types of violence during college presents $OR = 0$ ($p < 0.001$) in each of these items.

Conclusions: The social environment, alcohol consumption, a history of witnessing violence in family and friends, as well as the perpetration of violence are associated with receiving violence.

Key messages:

- Evidence indicates the importance of the family for the development of its members, since, just by witnessing behaviors, they favor the development of social roles.
- The first contact physician must return to his essence, focusing on the care of the patient in a comprehensive manner, including the environment in which he develops.

[3]Academy for Aging Research, Haus der Barmherzigkeit, Vienna, Austria
[4]Department of Internal Medicine, Medical University of Graz, Graz, Austria
Contact: erwin.stolz@medunigraz.at

Background: Many older adults experience disability in activities of daily living during the last years of life, but survey-based analyses suffer from non-representative samples due to selective participation and attrition. Here, we use individual-level register data on the receipt of the Austrian long-term care allowance (ALTCA) as a proxy for late-life disability.

Methods: In this retrospective mortality follow-back study, we analyse receipt of ALTCA, a cash benefit based on physician assessed disability during the last 10 years of life, among all decedents aged 65 years and over from 2020 in Austria ($n = 76{,}781$). The impact of sex, age of death, and cause of death on the duration and probability of receipt of ALTCA was assessed with regression models.

Results: 10 years before death 10% of older men and 25% of older women received ALTCA, which increased to 27% and 51% at 5 years, 56% and 77% at 1 year, and finally to 70% and 87% at 1 month before death. On average, ALTCA was received for 3.2 years in men and 4.5 years in women. The probability to receive ALTCA and its duration increased sharply with age at death and varied by underlying causes of death: those who died from cancer, myocardial infarction, and external causes of death were less likely to receive ALTCA and experienced shorter durations of it, while those who died from dementia, Parkinson's disease, chronic heart disease, or chronic obstructive lung disease were more likely to receive ALTCA and longer so.

Conclusions: Most older adults received ALTCA for multiple years before death, and this increased strongly with age at death and varied across causes of death. Our register-based estimates of late-life disability were twice as high as survey-based estimates, which points to an underestimation in previous studies. Policy-makers should be aware that costs of long-term care will likely increase as life expectancy rises and deaths from dementia and organ failure increase in ageing European societies.

Key messages:

- A large majority of older adults in Austria experience late-life disability. On average, older men were disabled for 3.2 and older women for 4.5 years.
- Probability and duration of late-life disability increased steeply with age at death and was higher for those who died from dementia, Parkinson's disease, or chronic heart or lung disease.

Abstract citation ID: ckae144.976
A longitudinal study of the impacts of area-level social cohesion on multimorbidity in Scotland

Chunyu Zheng

C Zheng[1], E Abubakar[2], C Dibben[1], A Marshall[2], J Pearce[1]
[1]School of GeoSciences, University of Edinburgh, Edinburgh, UK
[2]School of Social and Political Sciences, University of Edinburgh, Edinburgh, UK
Contact: C.Zheng@ed.ac.uk

Background: Multimorbidity is a growing global public health challenge, commonly referring to the co-occurrence of 2+ conditions but with varying measurements. Prior evidence has linked social cohesion with single health conditions; however, its impact on multimorbidity remains unclear. This study aims to examine the association between area-level social cohesion and multimorbidity and to explore whether this association will vary across multimorbidity measurements and levels of urban-rural classification.

Methods: Using a dataset that links the Scottish Longitudinal Study (5.3% of the Scottish population) with hospitalisation records (2001-2019) and an index that reflects area-level social cohesion (2012), focused on the cohorts of adults aged 40+, we used 3-level logistic regression to account for the clustered data structure of diagnosed chronic conditions over time within individuals within neighbourhoods.

Results: Areas with the highest social cohesion were observed to have the lowest risks of multimorbidity ($p < 0.001$), even after adjusting for area-level income deprivation. Varying by multimorbidity measurements, an inverted U-shaped pattern was observed between reduced area-level social cohesion and increased risks of having 2+ co-occurring chronic conditions; while a linear pattern was found for mental-physical multimorbidity. Moderated by levels of urban-rural classification, as compared to rural residents, urban residents were more sensitive to the impact of social cohesion on the co-occurrence of 2+ conditions; however, for mental-physical multimorbidity, no interaction effects between area-level social cohesion and urban-rural classification were found.

Conclusions: Although varying patterns were seen for different multimorbidity measurements, people living in areas with the highest area-level social cohesion were less likely to be multimorbid. This study offers new insights for developing effective place-based public health interventions.

Key messages:

- This is the first longitudinal study that analysed the association between area-level social cohesion and multimorbidity using a nationally representative dataset based on secondary care data.
- Area-level social cohesion affects multimorbidity, but its impact may vary by multimorbidity measurements and by urban-rural classification.

Introduction of wastewater surveillance of SARS-CoV-2 in Ukraine

Roman Rodyna

R Rodyna[1], D Ponomarenko[2], B Shcherbak-Verlan[1], L Venczel[3], L Shields[3], A Bogdanov[1], K Gamazina[1], G Dravniece[1]
[1]Ukraine Country Program, PATH, Kyiv, Ukraine
[2]Center for Public Health of the Ministry of Health of Ukraine, Kyiv, Ukraine
[3]PATH, Seattle, USA
Contact: rrodyna@path.org

Since the Russian invasion, Ukraine has faced humanitarian crises and challenges in diseases surveillance. The primary healthcare (PHC) system struggled with growing numbers of internally displaced and wounded people. In October 2022, the PATH-led, USAID-funded Support TB Control Efforts in Ukraine (STBCEU) project, supported implementation of wastewater surveillance (WWS) for SARS-CoV-2 in four oblasts on request of the Ministry of Health (MoH), expanding to 18 oblasts by October 2023. Samples were collected from 64 sites twice per week and tested for SARS-CoV-2 and influenza A/B using BioExtract® Premium Mag test kits in regional laboratories. From October 2022 to April 2024, 4,784 samples were collected at municipal aqueducts, with SARS-CoV-2 delta and omicron variants detected across all regions. WWS sample results were compared with routine surveillance to assess trends in concentrations and reported cases among population. Gradual decrease in SARS-CoV-2 concentration to zero by May 29, 2023, coincided with a decrease in morbidity. In the last week of August 2023, the concentration of the SARS-CoV-2 in wastewater began its gradual increase with the beginning of new cases registration among the population within 2 weeks, by mid-September. From October 2023, SARS-CoV-2 dominated in 96.6% of positive WWS testing results; in other specimens, influenza and respiratory viruses have been identified. The implementation of WWS in Ukraine highlighted its effectiveness as a public health tool in settings where traditional surveillance methods are disrupted, providing timely data on the viral pathogens for outbreaks prediction and responses, underscoring its role in preventive health measures. The MOH of Ukraine recommended extending the method nationwide for routine surveillance of SARS-CoV-2 and other pathogens, enhancing Ukraine's capacity to manage public health threats and strengthen the resilience of its health system against future crises.

Key messages:

- WWS in Ukraine underscores its effectiveness as a public health tool, providing timely data on viral pathogens for outbreak prediction and response in disrupted settings.
- Notable decline in SARS-CoV-2 concentration in wastewater correlates with reduced morbidity, highlighting WWS's predictive value.

Food additive preservatives and antioxidants and risk of type 2 diabetes - NutriNet-Santé cohort

Anaïs Hasenböhler

A Hasenböhler[1], G Javaux[1], M Payen de la Garanderie[1], F Szabo de Edelenyi[1], C Agaësse[1], A De Sa[1], M Deschasaux-Tanguy[1], L Fezeu[1], B Srour[1], M Touvier[1]
[1]EREN, Université Sorbonne Paris Nord, INSERM, INRAE, CNAM, CRESS, Bobigny, France
Contact: anais.hasenbohler@eren.smbh.univ-paris13.fr

Background: Experimental studies suggested potential detrimental effects of some food additive preservatives and antioxidants (PA) on metabolic health, but epidemiological data is lacking. This study aimed to investigate for the first time the associations between exposures to a wide range of PA and type 2 diabetes (T2D) risk in a large population-based cohort.

Methods: Participants ($n = 108{,}723$, 79.2% women, mean age=42.5y, $SD = 14.6$) from the French NutriNet-Santé prospective cohort (2009-2023) completed repeated 24h-dietary records including specific brands of industrial products. PA exposure was assessed using composition databases and laboratory assays. We characterised associations between time-dependent exposures to PA and risk of T2D using multivariable Cox models adjusted for known confounders.

Results: 1131 T2D cases were identified during follow-up. Exposures to the following PA were associated with a higher risk of T2D: potassium sorbate E202 (HR per a 25 mg/d increment=1.12, 1.08-1.17, $p < 0.001$), sodium nitrite E250 (HR 0.25 mg/d = 1.06, 1.00-1.12, $p = 0.04$), calcium propionate E282 (HR 25 mg/d =1.07, 1.02-1.12, $p = 0.008$), lecithins E322 (HR 100 mg/d =1.02, 1.01-1.04, $p = 0.008$), citric acid E330 (HR 500 mg/d=1.08, 1.04-1.12, $p < 0.001$), and phosphoric acid E338 (HR 50 mg/d=1.11, 1.05-1.18, $p < 0.001$).

Conclusions: This large prospective cohort revealed positive associations between T2D risk and exposures to several PA widely used in industrial foods.

Key messages:

- This large prospective cohort revealed positive associations between T2D risk and exposures to several PA widely used in industrial foods.
- If these results are confirmed, regulations governing PA's use by the food industry could be re-evaluated for better short- and long-term consumer protection.

Abstract citation ID: ckae144.979
Childhood-to-adulthood body size trajectory and cancer risk: a prospective cohort study

Marko Mandic

M Mandic[1,2]*, F Safizadeh*[1,2]*, B Schöttker*[1]*, M Hoffmeister*[1]*, H Brenner*[1]
[1]Clinical Epidemiology and Aging Research, German Cancer Research Center, Heidelberg, Germany
[2]Medical Faculty, Heidelberg University, Heidelberg, Germany
Contact: markic2209@gmail.com

Background: While excess weight in adulthood and childhood has been associated with increased cancer risk, the link between childhood-to-adulthood body size trajectories and cancer risk requires further investigation.

Methods: We used data from the UK Biobank, a prospective population-based cohort study. The main exposure was childhood-to-adulthood body size trajectory, constructed from self-reported body at age 10 (categories: thinner, average, and plumper than average) and measured body mass index (BMI) at recruitment (normal weight, overweight, and obese). Primary outcome was obesity-related cancer (13 different cancer types).

Results: During a median follow-up of 11.7 years, 21,289 participants developed obesity-related cancers. Having a larger body size at age 10 was strongly associated with being overweight or obese in adulthood. Compared to participants with average childhood to normal adulthood body size trajectory, all trajectories ending in overweight or obesity in adulthood were strongly associated with an increased risk of obesity-related cancers. The strength of the association was mostly determined by adulthood BMI, and similar patterns were observed for colorectal, endometrial, kidney, pancreatic and esophageal cancer. However, a larger body size in childhood was associated with a lower risk of postmenopausal breast cancer.

Conclusions: Although a larger body size in childhood predisposes to overweight and obesity in adulthood, it does not necessarily predispose to an increased obesity-related cancer risk if measures to maintain a healthy weight are taken in adulthood.

Key messages:

- While larger body size in childhood predisposes individuals to overweight and obesity in adulthood, maintaining a healthy weight in adulthood may help mitigate the risk of obesity-related cancers.
- Our findings highlight the importance of preventing and reducing overweight and obesity in adulthood for primary cancer prevention.

[4]Stockholm Gerontology Research Center, Stockholm, Sweden
[5]Swedish Institute for Social Research, Stockholm University, Stockholm, Sweden
Contact: susanna.gentili@ki.se

Background: Older adults frequently experience multiple hospitalizations, owing to their complex health and social needs. This study aims to comprehensively characterize the risk factors associated with avoidable and unavoidable hospitalization among older adults. Specific emphasis is placed on avoidable/unavoidable hospitalization originating from chronic or acute causes.

Methods: Data on 3,166 individuals aged $\geq$60 years were obtained from the Swedish National Study on Aging and Care in Kungsholmen (SNAC-K), linked to the Swedish National Patient Register. Multistate models were used to investigate the risk profiles of participants experiencing their first and recurrent hospitalizations over 15 years. The Swedish National Board of Health and Welfare criteria were used to define avoidable/unavoidable hospitalizations.

Results: Women had a lower hazard of avoidable hospitalizations for chronic conditions as well as unavoidable hospitalizations (HR range 0.46-0.84). However, receiving informal care was associated with 88% increased hazard of avoidable hospitalizations due to chronic causes (95%CI 1.18-2.99), while receiving formal care was associated with 44% increasing hazard of avoidable hospitalization due to acute causes (95%CI1.04-1.98). Factors such as slow walking speed, multimorbidity, and polypharmacy were associated with a high risk of avoidable hospitalizations due to both acute (HR range1.27-3.03) and chronic (HR range1.63-2.54) causes.

Conclusions: Both clinical and functional factors have emerged as key predictors of avoidable hospitalization, underscoring the importance of comprehensive risk assessment and proactive healthcare management strategies to reduce the burden of hospital utilization in older adults.

Key messages:

- Targeted interventions are essential to improve healthcare outcomes among older adults at risk of avoidable hospitalizations due to chronic and acute conditions.
- The study identified predictors such as slow walking speed, multimorbidity, and polypharmacy, underscoring the need for comprehensive risk assessment to prevent avoidable hospitalization.

Abstract citation ID: ckae144.981
The effect of Covid deaths on premature mortality trends in Northern Dimension partnership countries

Pekka Jousilahti

P Jousilahti[1]*, K Harald*[1]*, M Vienonen*[1]*, T Laatikainen*[1,2]
[1]Public Health and Welfare, THL, Helsinki, Finland
[2]Faculty of Medicine, University of Eastern Finland, Kuopio, Finland
Contact: pekka.jousilahti@thl.fi

Background: Potential Years Life Lost (PYLL) is an established method to measure, follow trends and compare disease burden within and between countries. Northern Dimension Partnership in Health and Social wellbeing (NDPHS) network was established in 2003 and includes the following countries: Estonia, Finland, Germany, Iceland, Latvia, Lithuania, Norway, Poland, Russia, and Sweden. Due to the Russian invasion to Ukraine, Russia is now excluded from the collaboration.

Methods: Premature mortality is defined as a death before the age of 70 years. PYLL-rates per 100,000 population are presented in six cause of deaths categories: total mortality, external causes, vascular diseases, cancers, alcohol-related deaths and suicides. Furthermore, 2021 data included deaths due to the Covid infection. Data were obtained from Eurostat and analyses are standardized to EU standard population.

Results: PYLL-rates declined from 2003 to 2017 in all countries and in most causes of death sub-groups. The total (all causes, all countries) PYLL-rate declined between 2003 and 2017 from 7072 to 5154 in men and from 3263 to 2532 in women. However, from 2017 to 2021 the total PYLL-rate increased to 5469 in men and 2623 in women. The increase was explained by Covid mortality. When Covid deaths were excluded, a minor decrease was observed also between 2017 and 2021. In 2021, total PYLL-rates vary largely between countries: from 2804 to 12,393 in men and from 1781 to 4460 in women. Differences between countries in Covid-related and other cause-specific PYLL-rates were also large. In all countries and causes of death sub-groups PYLL-rates were markedly higher in men compared to women.

Conclusions: The number of years lost due to premature preventable mortality have declined markedly in all NDPHS countries in the last two decades. Between 2017 and 2021, some increase was observed due to the Covid-related deaths. Differences between countries in premature mortality are still large.

Key messages:

- The number of years lost due to premature preventable mortality have declined markedly in all NDPHS countries since 2003 but still, in 2021, differences between countries were large.
- Covid-related deaths caused an increase in premature mortality between 2017 and 2021.

[5]Aging Research Center, Karolinska Institutet, Stockholm, Sweden
[6]Research Network on Chronicity, Primary Care and Prevention and Health, Madrid, Spain
[7]CIBERNED, Madrid, Spain
Contact: amaya.bernal@isciii.es

Introduction: Informal care is crucial in Spain's care system, with a rising number of caregivers aged 75 or older, yet studies on its health effects are lacking. This study aims to determine the differential impact of age and care-related variables on the health of older caregivers.

Materials and methods: This is a cross-sectional, national study with a sample of 3,870 informal caregivers from the Spanish 2020 Disability, Personal Autonomy and Dependency Survey. We performed a logistic regression where self-reported deterioration in caregiver health due to caregiving was the dependent variable and age (<75 vs. ≥ 75) was the independent variable. Caregivers' sex, educational level (primary and lower or secondary and higher), income ($<1,150$ euros per month vs. $\geq 1,150$), severe functional limitation of caregivers and care-receptors (yes or no), duration of care (< 8 years vs. ≥ 8 years), and daily hours of care were used as covariates.

Results: One in 6 caregivers was 75 or older (16,1%). Caregivers' mean age was 58.4, and care-receptors' 66.6 years. Women represented 63.0% of caregivers, and 42.8% of care-receptors. Up to 4.6% of caregivers had a severe limitation, and 43.7% of caregivers reported deterioration of their health due to caregiving. A greater perception of deterioration in caregiver health due to caregiving was associated with being 75 years or older ($\beta = 0.34$, $p = 0.009$). Covariates associated with caregivers' health deterioration were being a woman ($\beta = 0.77$, $p < 0.001$), presence of severe limitation of care receptors ($\beta = 0.58$, $p < 0.001$), and increased daily hours of care ($\beta = 0.01$, $p = 0.013$). Caregivers' severe limitation, level of education, income and years of care did not show a significant association with perception of health deterioration.

Discussion: Caregivers older than 75 years in Spain experience a key deterioration in their health associated with caregiving. This vulnerable population must be prioritized in health and social policies.

Key messages:

- One out of 6 caregivers in Spain is aged 75 years or older. Caregiving impacts greatly in their health status.
- Older caregivers is a vulnerable population that must be a priority for health and social services.

Abstract citation ID: ckae144.983
Night shift work increases the risk of irritable bowel syndrome, which is mediated by inflammation

Yuxin Yao

Y Yao[1], *J Ma*[1]
[1]Department of Occupational and Environmental Health, Huazhong University of Science and Technology, Tongji Medical College, Wuhan, China
Contact: yao131434@sina.com

Background: The impact of long-term night shift work on the incidence of irritable bowel syndrome (IBS) is still largely unknown, and the underlying mechanism remains unclear. We aimed to investigate the association of night shift work with IBS risk and further explore whether low-grade inflammation mediated this relationship.

Methods: This cohort study included 239,760 participants who were in paid employment or self-employed from the UK Biobank. In-depth lifetime employment information was used to calculate duration and frequency of night shifts. Low-grade inflammation index (INFLA-score) was calculated from five circulating inflammatory biomarkers. Cox proportional hazard models were used to estimate the relationships between long-term night shift work and IBS risk, and mediation analyses were also performed.

Results: An increasing trend of IBS incidence was observed from day workers to regular night shift workers. Compared to day workers, rarely/some night shift workers (HR 1.097, 95% CI 1.007-1.195) and usual/permanent night shift workers (HR 1.213, 95% CI 1.046-1.407) had higher risk of IBS. Workers with longer duration ($\geq$3 years) (HR 1.241, 95% CI 1.073-1.436) and higher frequency of night shifts ($>$7 shifts/month) (HR 1.248, 95% CI 1.045-1.491) also showed higher IBS risks. INFLA-score significantly mediated the association of long-term night shift exposure with increased IBS risk (mediation proportion 3.6%, $P < 0.05$).

Conclusions: Long-term exposure to night shift work is associated with a higher risk of IBS, the potential underlying mechanism may be the heightened low-grade inflammation.

Key messages:

- Current night shift exposure, longer night shift duration and higher night shift frequency were significantly associated with higher risk of IBS.
- Our findings indicate that night shift work may increase the IBS risk by triggering a cascade of low-grade inflammatory processes.

Abstract citation ID: ckae144.984
Mortality related to different circulatory diseases: a multiple causes of death analysis, 2008-2022

Ugo Fedeli

U Fedeli[1], *V Casotto*[2]
[1]Epidemiological Department, Azienda Zero, Veneto Region, Padua, Italy
[2]Department of Woman's and Child's Health, University of Padova, Padua, Italy
Contact: ugo.fedeli@azero.veneto.it

Background: Mortality from circulatory diseases significantly increased in 2020 compared to pre-pandemic years in many countries. However, data were mostly limited to the underlying cause of death and to the first phases of the pandemic. Analyses of any mention of a disease in death certificates (multiple causes of death approach, MCOD) are more robust to changes in coding rules/practices and to the role of COVID-19 as a competing cause of death.

Methods: Mortality records were extracted from 2008 to 2022 among residents of the Veneto Region (Northeastern Italy, 4.9

million population). Based on MCOD, age-standardized mortality rates (2013 European standard) were computed for ischemic heart diseases (IHD), cerebrovascular diseases (CVD), atrial fibrillation (AF), and hypertensive diseases (HD). The annual percent change (APC) was estimated through the pre-pandemic period (2008-2019), and change in rates during pandemic years were computed compared to 2019.

Results: Before the pandemic, rates were steeply declining for IHD (APC -5.1%; 95%CI -5.5, -4.6) and CVD (-4.0%; -4.4, -3.5); mortality related to HD reduced at a slower pace (-1.9%; -2.3, -1.4), whereas AF-related mortality was increasing (+1.0%; 0.1, 1.8). During the first year of the pandemic, the growth in mortality compared to 2019 was +26% for HD, +18% for AF, +13% for CVD and +12% for IHD. In 2021-2022, rates for CVD and IHD returned to pre-pandemic levels; rates for HD reduced with respect to 2020 but remained above the baseline; AF-related mortality was still increasing.

Conclusions: The pandemic differentially impacted mortality associated to different circulatory diseases, depending on pre-existing long-term trends (increasing for AF) and on susceptibility to severe COVID-19 disease (higher for HD). Continuous surveillance based on MCOD is warranted to properly assess changes in mortality associated to specific circulatory diseases after the end of the pandemic.

Key messages:

- Multiple causes of death analyses are warranted to assess how the pandemic affected pre-existing long term trends in cause-specific mortality.
- Mortality related to different circulatory diseases increased in 2020, but pre-pandemic trends, the extent of the increase in 2020, and further changes observed in 2021-2022 largely diverged.

Abstract citation ID: ckae144.985

The effects of hypothetical psychological interventions on alcohol use in European young adults

Stefanie Do

S Do[1,2], C Börnhorst[1], V Didelez[1,2], W Ahrens[1], A Hebestreit[1], I IDEFICS/I. Family consortia[1]
[1]Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany
[2]University of Bremen, Bremen, Germany
Contact: dostef@leibniz-bips.de

Background: Low psychosocial well-being (PWB) and high emotion-driven impulsiveness (EDI) are associated with alcohol. Yet, it is unclear whether a hypothetical intervention targeting one or the other in adolescence might be more effective in reducing alcohol consumption (AC) in young adulthood. Therefore, we aimed to compare the separate causal effects of PWB and EDI in adolescence on AC in young adulthood.

Methods: We included 505 European young adults from the IDEFICS/I.Family cohort (mean age: 20.2 years; age range: 18.2-23.5 years) who did not drink alcohol at study entry. AC was operationalized as the amount of weekly consumed alcoholic beverages (mean: 4.2 drinks per week; range: 0.3-70 drinks per week). EDI was assessed using the negative urgency subscale from the UPPS-P Impulsive Behaviour Scale. PWB was assessed using the KINDLR Health-Related Quality of Life Questionnaire. Following the principles of target trial emulation, we estimated, separately, the average causal effects of PWB and EDI on AC accounting for relevant confounders and applying a semi-parametric doubly robust method (targeted maximum likelihood estimation). We stratified the results by sex and parental education.

Results: If all adolescents, hypothetically, had high levels of PWB, compared to low levels, we estimated a decrease in the average amount of alcoholic beverages in young adulthood by 0.1 drinks per week [95%-confidence interval: -2.3; 2.1]. Furthermore, if all adolescents had low levels of EDI, compared to high levels, we estimated an increase in alcoholic beverages in young adulthood by 1.5 drinks per week [0.1; 2.9]. Different effects for sex and parental education groups were found.

Conclusions: Hypothetical interventions targeting PWB in adolescents were not found to have effects on reducing AC in young adulthood. Interventions targeting EDI, however, would lead to an increase in AC. This may be due to unmeasured confounding and the missing distinction between drinking motives.

Key messages:

- We demonstrate that causal inference methods, compared to traditional ones, improve the robustness of estimated effect measures and address important sources of bias in European cohort data.
- To inform public health interventions on reducing alcohol consumption, future research should investigate different drinking motives, e.g. alleviating negative emotions or enhancing positive emotions.

Abstract citation ID: ckae144.986

Association between all-cause mortality and diabetic avoidable hospitalization among older patients

Woo-Ri Lee

W-R Lee[1], S-Y Chun[1], N Son[2], Y Son[3], K-B Yoo[4]
[1]Department of Research and Analysis, National Health Insurance Services Ilsan Hospital, Goyang-si, South Korea
[2]Division of Cancer Control & Policy, National Cancer Center, Goyang-si, South Korea
[3]ESON Medical Management Institute, ESON Hospital, Ulsan, South Korea
[4]Division of Health Administration, Yonsei University, Wonju-si, South Korea
Contact: wind0747@gmail.com

Background: In South Korea, the prognosis of avoidable hospitalization in diabetes has not been evaluated, even though the incidence rate is considerably high compared to the Organization for Economic Co-operation and Development average. This study investigated the association between diabetic avoidable hospitalization after the diagnosis of type 2 diabetes mellitus and short- and long-term all-cause mortality.

Methods: Participants were type 2 diabetes mellitus patients aged 60 years and older and gathered through the National Health Insurance Services Senior cohort data from 2008 to 2019. The outcome measures included five-year and overall period all-cause mortality. The main independent variable was the first-year experience of diabetic avoidable hospitalization after type 2 diabetes mellitus diagnosis. Regression analysis was performed using the Cox proportional hazard model. To enhance the robustness of the study results, a sensitivity analysis and inverse probability of treatment weighting method were conducted.

Results: Among 31 222 participants, 2343 (7.5%) died within 5 years of type 2 diabetes mellitus diagnosis and 5314 (17.0%) died in the overall study period after type 2 diabetes mellitus diagnosis. Participants who experienced diabetic avoidable hospitalization one year after being diagnosed with type 2 diabetes mellitus had a higher risk of all-cause mortality compared to those who did not (Five-year: hazard ratio 1.84, 95% confidence interval 1.54-2.21; Overall period: hazard ratio 1.81, 95% confidence interval 1.60-2.06).

Conclusions: Enhancing accessibility and quality of primary care to prevent avoidable hospitalization in older patients with type 2 diabetes mellitus is necessary.

Key messages:

- Older patients with T2DM who experienced avoidable hospitalization exhibited higher all-cause mortality rates in both the short and long terms.

- Enhancing the accessibility and quality of primary care to prevent avoidable hospitalization in older patients with type 2 diabetes mellitus is necessary.

[4]Department of Physiotherapy, University of Debrecen, Debrecen, Hungary
[5]Department of Preventive Medicine and Public Health, Semmelweis University, Budapest, Hungary
Contact: pikopeter@gmail.com

Background: Polymorphisms in the cholesteryl ester transfer protein (CETP) gene are known to be strongly associated with increased cardiovascular risk, primarily through their effects on the lipid profile, and consequently on atherosclerotic risk. The acute heart rate response (AHRR) to physical activity is closely related to individual cardiovascular fitness. This study aimed to investigate the effect of CETP gene polymorphisms on AHRR.
Methods: Our analysis examines the association of five single nucleotide polymorphisms (SNPs; rs1532624, rs5882, rs708272, rs7499892 and rs9989419) and their haplotypes (H) known to be associated with cardiovascular risk in the CETP gene with AHRR in 607 individuals from the Hungarian population. Individual AHRR in the present study was assessed using the YMCA 3-minute step test and was measured as the difference between resting and post-exercise heart rate, i.e. delta heart rate (ΔHR). To exclude the direct confounding effect of the CETP gene on the lipid profile, adjustments for TG and HDL-C levels were applied in the statistical analyses.
Results: Among the five SNPs examined, two showed a significant association with lower ΔHR (rs1532624-Cdom: B = -8.15, $p < 0.001$; rs708272-Gdom: B = -8.09, $p < 0.001$) and reduced the risk of adverse AHRR (rs1532624-A: OR = 2.26, $p < 0.001$; rs708272-A: OR = 2.17, $p < 0.001$). Among the ten haplotypes, two showed significant association with lower ΔHR (H3 - CAGCA: B = -6.79, $p = 0.003$; H9 - CGGCG: B = -14.79, $p = 0.014$) and lower risk of adverse AHRR (H3 - CAGCA: OR = 0.58, $p = 0.038$; H9 - CGGCG: OR = 0.05, $p = 0.008$) compared to the reference haplotype (H1 - AGACG).
Conclusions: Our study is the first to report a significant association between polymorphisms and their haplotypes in the CETP gene and AHRR. It also confirms that the effect of the CETP gene on cardiovascular risk is expressed through the acute heart rate response to physical activity, in addition to its effect on the lipid profile.
Key messages:
- Certain polymorphisms and haplotypes in the CETP gene show a significant association with AHRR.
- The CETP gene polymorphisms exert their effect on cardiovascular risk not only by altering the lipid profile, but also by modifying the heart rate response to physical activity.

Association of Altitude with Mortality among Patients with Hypertension - A Cohort Study

Lin Duo

J Lu[1], L Pang[1], Y Xia[1,2], Z Guo[1], W Yang[1], L Duo[1], Q Zhu[3], T Wang[1]
[1]Fuwai Yunnan Hospital, Chinese Academy of Medical Sciences, Kunming, China
[2]Kunming Medical University, Kunming, China
[3]Yunnan Provincial Center for Disease Control and Prevention, Kunming, China
Contact: duolin@hotmail.com

Background: Available evidence falls short in assessing the risk of all-cause mortality and cardiovascular disease (CVD) mortality among individuals with hypertension residing at various altitudes. This study's objective was to investigate the correlation between residential altitude and the rates of all-cause mortality and CVD mortality among hypertensive patients.
Methods: This prospective cohort study encompassed 67,275 hypertensive individuals aged 35 years and above in the year 2018. Participants were categorized into four distinct groups based on their residence altitude: those living below 500 meters, between 500 and 1499 meters, 1500 to 2500 meters, and above 2500 meters. The study spanned a mean follow-up duration of 4.78 years. The associations between residential altitude and the risks of all-cause and CVD mortality were analyzed using Cox proportional hazards regression models.
Results: Among the 67,275 hypertensive patients included in the study (mean age of 63.9 years, with 45.3% being male), 8,768 deaths were recorded, of which 5,666 were attributed to CVD. Following multivariate adjustment, when compared to the group residing at altitudes below 500 meters, the groups living at altitudes of 500-1499 meters, 1500-2500 meters, and above 2500 meters exhibited significantly elevated risks of all-cause mortality [hazard ratio, HR = 1.45 (95% CI: 1.36-1.54), 1.35 (95% CI: 1.36), and 1.41 (95% CI: 1.28-1.54), respectively] and CVD mortality [HR = 1.47 (95% CI: 1.35-1.58), 1.42 (95% CI: 1.33-1.52), and 1.46 (95% CI: 1.31-1.62), respectively]. For each 500-meter increment in altitude, the risk of all-cause and CVD mortality increased by 10% and 11%, respectively. Subgroup analyses and sensitivity assessments consistently supported this association.
Conclusions: This study's findings indicate a substantial connection between long-term residential high-altitude exposure and increased risks of all-cause mortality and CVD mortality among individuals with hypertension.
Key messages:
- Increased altitude of residence increases the risk of subsequent all-cause and CVD mortality in hypertensive patients.
- This study highlights that relevant guidelines and healthcare providers should consider altitude as an important factor in reducing the burden of hypertension and CVD.

Introduction: This study was created to test the hypothesis that Covid19 pandemic may have influenced the increase in chronic respiratory diseases, particularly asthma, COPD, and mixed forms. This aspect does not seem to have been investigated previously in the literature.

Methods: The study population consisted of all residents in the province of Grosseto in the two study years (2019 and 2022) aged over 17 and under 90 (n. 368,326). For each of them, the presence of chronic lung disease (OUTCOME), Covid 19 positivity (between 2019 and 2022), age, sex, and Charlson index were reported in the database. To test the effect of the study variables on the identified outcomes (asthma, COPD, and mixed forms), a single-variable statistical analysis was conducted, followed by multiple logistic regression in which, in addition to the main variable, sex, age, and Charlson index were included to adjust the results, using STATA Vers. 17.0 Be-Basic Edition

Results: Multivariate statistical analyses showed that those who had COVID between 2019 and 2022 had a 75% higher risk of taking asthma therapy than those who did not (OR 1.75, $p < 0.\ 001$); all other variables were also significantly correlated with the outcome: fewer people were taking asthma therapy in the year 2022 than in 2019 (OR 0.89, $p < 0.001$); men had a lower risk (OR 0.79, $p < 0.001$); and those who had a higher CI had a higher risk (3.43, $p < 0.001$). In the study sample, 2.69% took asthma medication in the study years.

Conclusions: The Covid19 pandemic has had a significant impact on chronic respiratory diseases, especially asthma; patients with higher age and more comorbidities are more likely to develop asthma; males have a lower risk than females, and these data do not seem to have been analyzed in the scientific literature.

Key messages:

- The Covid19 pandemic has had a significant impact on chronic respiratory diseases.
- Patients with higher age and more comorbidities are more likely to develop asthma.

Abstract citation ID: ckae144.990
Diabetes among people with intellectual disabilities vs the general population: a register study

Emilie Stroh

E Stroh[1], M Sandberg[2], J Kristensson[2], A Axmon[1]
[1]EPI@LUND, Lund University, Lund, Sweden
[2]Department of Health Sciences, Lund University, Lund, Sweden
Contact: emilie.stroh@med.lu.se

People with intellectual disabilities have an increased risk of diabetes mellitus (DM). They tend to develop it at earlier ages than the general population, resulting in even higher risks in younger people. However, few studies have separated Type 1 and Type 2 DM. The aim of this study was to assess prevalence of different types of DM in different age groups in relation to the general population. We categorized all people in Skåne, Sweden, as ID (service and support for people with ID and/or autism, or a diagnosis of ID or Down syndrome; $n = 14\ 716$) or general population (gPop; excluding family members of people in ID; $n = 1\ 226\ 955$). Data regarding diagnoses of Type 1 (E10 in ICD-10) and Type 2 (E11) DM were collected for 2014-2021. Age at inclusion (i.e., 2014) was considered as children (0-12 years), adolescents (13-18), young adults (19-24), adults (25-44), lower middle-age (45-54), upper middle-age (55-64), older people (65+). The overall prevalence of Type 1 DM was 2.3% in ID and 1.6% in gPop (relative risk [RR] 2.14, 95% confidence interval 1.93-2.38). In ID, the prevalence was below 2% in the youngest age groups, and then increased with age until upper middle-age, where it reached 6.0%. The risk of Type 1 DM among people with ID compared to gPop was relatively stable, with the RR ranging between 1.16 (older people) to 2.83 (adults). For Type 2 DM, the overall prevalence was 7.2% in ID and 7.8% in gPop (RR 2.00, 1.89-2.13). There was a consistent age-related increase in prevalence in ID, from 0.3% among children to 27.4% among older people. The opposite pattern was found for the risk compared to gPop, with the higher risks (RR 3.63-6.98) in the younger age groups and lower risks (RR 1.27-4.41) in the older age groups. Both types of DM were more prevalent among people with intellectual disabilities than in the general population. However, the patterns of prevalence and risk compared to the general population differed for the two types.

Key messages:

- People with intellectual disabilities have increased risk of both Type 1 and Type 2 diabetes mellitus.
- Type 1 and Type 2 diabetes mellitus displays different age patterns among people with intellectual disabilities.

Towards more effective health monitoring: a comparison of different data sources

Lilli Huhtala-Hedman

L Huhtala-Hedman[1], T Palosaari[1], J Reinikainen[1], A Lundqvist[1], T Jääskeläinen[1]
[1]Population Health Unit, THL, Helsinki, Finland
Contact: lilli.huhtala-hedman@thl.fi

Background: Monitoring the prevalences of chronic diseases and their risk factors at the population level is important to support effective prevention measures, health service planning and health policy-making. The utilization of register information is cost-effective in population health monitoring, but the validity of information is important to assess. The aim of this study was to compare the information on most common chronic diseases and risk factors collected from a population-based Healthy Finland survey and national health registers.

Methods: The study population comprised of 4785 individuals aged 20 years or over from the nationally representative Healthy Finland Health Examination Survey conducted in 2023. Information on the most common chronic diseases were derived from both survey data (including measured and self-reported data) and the national registers. The prevalence in survey data were compared with prevalence in register data for those individuals who participated in the survey. Register data was examined for the previous five years and was obtained from the Care Register for Health Care and medical registers, depending on availability of data. Weighted prevalences were calculated taking into account the sampling design and non-response.

Results: For all examined risk factors and diseases, the prevalence was higher in survey data than in register data. The difference was the greatest for elevated blood pressure: the prevalence in survey data was 48.6% (95% CI 46.5, 50.7) versus 17.3% (15.6, 19.0) in register data. The prevalence of diabetes was 11.5% (10.4, 12.5) in survey and 6.9% (5.9, 7.9) in register data. For sleep apnea, the prevalence in survey data was 8.4% (7.4, 9.3) and 4.4% (3.7, 5.1) in register data.

Conclusions: Register-based information provides more reliable prevalences on diseases needing urgent treatment. Survey data brings out also previously unidentified diseases cases that do not show in registers.

Key messages:

- Register data is cost-effective in health monitoring, but surveys are needed for monitoring risk factors.
- Utilizing diverse data sources enhances getting reliable information to support decision-making.

Abstract citation ID: ckae144.992
Family function, psychological distress and burden in informal caregivers of people with dementia

Marta Nemcikova

M Nemcikova[1], Z Katreniakova[1], V Timkova[1], I Nagyova[1]
[1]Department of Social and Behavioural Medicine, PJ Safarik University in Kosice, Kosice, Slovakia
Contact: marta.nemcikova@upjs.sk

Background: Dementia presents a public health priority due to its high global prevalence, mortality, economic cost, and caregiver burden (CB). Dementia care can be stressful and may negatively influence the health of informal caregivers. This cross-sectional study aimed to identify psychological and social factors associated with subjective CB in informal home care providers of people with dementia (PwD), controlling for sociodemographic, clinical, and care-related variables.

Methods: We included 115 informal caregivers of PwD from community settings (mean age: 54.0±12.4 years; 81.7% women). Participants fulfilled the Zarit Burden Interview (ZBI-12), the Patient Health Questionnaire (PHQ-9), the Generalized Anxiety Disorder Scale (GAD-7), the Family APGAR, and the short IQCODE used to assess dementia severity. Multiple linear analyses were used to analyse the data.

Results: The mean caregiving duration was 4.8±4.8 years, and 55.7% of informal caregivers extend care for >40 hours/week. We found that a total of 52.5 % of informal caregivers experienced a high CB (ZBI-12 cut-off score: 17). Univariate analyses showed an association between depression ($\beta = 0.36$; $p < 0.001$), anxiety ($\beta = 0.52$; $p < 0.001$), family dysfunction ($\beta = 0.36$; $p < 0.001$), and CB. Regression analyses showed that CB was the most strongly associated with anxiety ($\beta = 0.51$; $p < 0.001$). This association weakened (0.47; $p < 0.01$) when family function was added to the final model ($\beta = -0.22$; $p < 0.05$). The final model explained 23.5% of the variance in CB. No associations between the caregiver's age, sex, caregiving duration, the extent of care per day, use of community care, dementia severity, and depression were identified.

Conclusions: Long-term care for people living with dementia can be very demanding. Thus, the implementation of tailored interventions to enhance family function and diminish psychological distress can mitigate level of caregiver burden. [Grant support: APVV-22-0587].

Key messages:

- Dementia caregiving is a global public health priority.
- The caregiver's burden and distress can be alleviated by the interventions focusing on family dysfunction.

Abstract citation ID: ckae144.993
Serum homocysteine levels and mortality: a cohort study

Sujeong Shin

S Shin[1], M Kim[1]
[1]Family Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea
Contact: sj.kbsmc@gmail.com

Background: Homocysteine, an intermediate metabolite derived from dietary methionine, plays a pivotal role in deoxyribonucleic acid expression and contribute to its antioxidant capabilities. Elevated homocysteine levels can increase the risk of cardiovascular disease (CVD), cancer, and neurological disorder; however, low levels of homocysteine are generally not considered harmful. This study evaluates the association between all levels of homocysteine-both low and high-and the risk of all-cause and cause-specific mortality in Korean adult men.

Methods: A study involving 221,356 Korean adult men categorized them into quintiles based on their homocysteine levels. The main outcomes examined were mortality from all causes, cardiovascular disease (CVD), cancer, and dementia. Hazard ratios (HRs) were determined using Cox proportional hazards models, and the dose-response relationship between homocysteine levels and mortality risk was further analyzed using a restricted cubic splines model.

Results: Compared to the reference category (Q2, 8.8-9.9 μmol/L), there was a significant increase in all-cause mortality associated with both low and high homocysteine levels after adjusting for multiple variables (Pinteraction=0.002). Furthermore, spline regression revealed a U-shaped relationship between homocysteine levels and both all-cause and CVD mortality, with an inflection point at 9.1 μmol/L. This U-shaped association was not observed in the subgroup that received vitamin supplements.

Conclusions: Among young and middle-aged Korean adult men, both low and high homocysteine levels were found to increase the risk of all-cause and CVD mortality, demonstrating a U-shaped relationship. However, this association lost statistical significance with vitamin supplementation. These findings underscore the importance of monitoring both low and high homocysteine levels as potential mortality risk factors in men and suggest a possible protective role of vitamins.

Key messages:

- Both low and high levels of homocysteine in young and middle-aged Korean men are associated with increased risks of all-cause and cardiovascular mortality, demonstrating a U-shaped relationship.
- Vitamin supplementation appears to nullify this association, suggesting a potential protective effect against mortality.

Abstract citation ID: ckae144.994
Cadmium exposure and hypertension: a systematic review and a dose-response meta-analysis

Vincenzo Giuliano

V Giuliano[1], P Verzelloni[1], M Vinceti[1,2], T Filippini[1,3]
[1]Department of Biomedical, Metabolic and Neural Sciences, Università degli Studi di Modena e Reggio Emilia, Modena, Italy
[2]Department of Epidemiology, Boston University, Boston, USA
[3]School of Public Health, University of California, Berkeley, USA
Contact: vincenzogiuli@hotmail.it

Background: Since the shape of the relation between Cd exposure and risk of HTN has not been previously investigated, we aimed to perform a systematic review with dose-response meta-analysis in epidemiological studies.

Methods: After registration of the review in PROSPERO database (ID: CRD42022382030), we searched for eligible articles in online databases using Mesh-terms/keywords related to Cd, HTN, and BP. Eligible criteria were: adult population, assessment of exposure through Cd concentrations in blood or urine, risk estimates for HTN, observational design. Whenever possible, we computed summary odds ratio (OR) with 95% confidence interval (CI) and performed a dose-response meta-analysis on overall studies and subgroups.

Results: We eventually included 8 articles for both the qualitative and quantitative analysis published between 2006-2023 almost of cross-sectional design, 7 and 4 assessing blood and urine Cd concentrations, respectively. Comparing the highest versus lowest exposure, we found increased risk of HTN for both blood (OR = 1.12, 95% CI 0.92-1.36) and urine assessment (OR = 1.09, 95% CI 0.94-

1.28). Dose-response meta-analysis showed an almost linear increased risk for blood Cd concentrations until 1.5 μg/L above with it plateaued. In contrast when using urine concentrations for exposure assessment, risk started to increase above 0.5 μg/g creatinine.

Conclusions: Our results confirm the recent findings of non-linear relation between Cd exposure and risk of both CVD and diabetes and the subsequent need to lower Cd exposure on a public health perspective.

Key messages:
- Cadmium exposure showed positive association with risk of hypertension.
- Public health efforts should be implemented to lowed cadmium exposure to decrease CVD risk.

Abstract citation ID: ckae144.995
Patient referral pathways to leisure providers: impacts on physical activity and falls risk

Charlotte Cuddihy

C Cuddihy[1,2], *H Jopling*[1]
[1]Public Health, West Suffolk Hospital, Bury Saint Edmunds, UK
[2]Public Health, NHS Lothian, Edinburgh, UK
Contact: charlotte.cuddihy2@nhs.scot

Background: Physical activity aids prevention and management of noncommunicable diseases. Yet many UK adults, particularly those with long-term health conditions, do not meet recommended activity levels. In 2021, West Suffolk Foundation Trust commissioned local leisure provider Abbeycroft to offer 24 week tailored physical activity programs as part of respiratory and frailty patient pathways.

Objectives: Evaluation of activity and outcome data for all 1670 individuals referred between January - December 2023 to determine future commissioning decisions.

Results: 256 participants had completed a 24 week pathway by the time of analysis. Compared to baseline, they demonstrated statistically significant ($p < 0.05$) self-reported improvements on the Short Warwick Edinburgh Mental Well-being Scale (median 25 to 27) amongst 68.9% of participants; and on the self-reported International Physical Activity Questionnaire 62.1% reduced time spent sitting (average 436 to 300 minutes/ week), 75% increased metabolically active minutes (average 955 to 2632 minutes/week) and the proportion of participants with a low (inactive) score decreased by 61%. Of 40 frailty patients, 87.5% lowered their self-reported Short Falls Efficacy Scale Score (14.6 to 10.4) and observed Timed Get up and Go (13.55 to 9.53 seconds), indicative of moving from a higher risk to lower falls risk ($p < 0.05$). 24 week retention exceeded 80% for all ages except 16-20 years. 17.8% of participants were >75 years.

Lessons: Both pathways have been recommissioned and new tailored pathways for Parkinson's disease, COPD and cancer are planned. This partnership working is a sustainable, integrated way to embed prevention in the community but needs time to build relationships and streamline data sharing.

Key messages:
- Hospital and community referral pathways to leisure providers significantly improve patient well-being, physical activity and falls risk.
- These pathways are affordable, adaptable across conditions and show high retention.

Abstract citation ID: ckae144.996
Joint effect of tobacco and meat on cardiovascular disease and treatment adherence in Indian Women

Jannatul Ferdous

J Ferdous[1], *OH Jin-Kyoung*[1]
[1]Cancer Control and Policy, National Cancer Center Graduate School of Cancer Science and Policy, Ilsandong-gu, South Korea
Contact: jfmousumi.rz02@gmail.com

Background: Cardiovascular disease (CVD) is a leading cause of death for both men and women in India. But it is often overlooked in women. Tobacco and meat consumption are common risk factors for CVD. While individual studies have explored the link between tobacco or meat consumption and CVD, their joint effect remained understudied.

Methods: The study analyzed data from the National Family Health Survey 2019-21, of 711431 women aged 15 to 49 in India. Univariate and multivariate logistic regression were used to assess the risk of individual and joint effects of tobacco and meat consumptions on self-reported CVD prevalence. Age, BMI, education, wealth index, residency, region, religion, and alcohol were used as covariates. Additionally, interactions model was assessed. Lastly, treatment adherence for CVD was studied, considering treatment behavior, insurance, and healthcare access barriers.

Results: Cardiovascular disease prevalence was 0.72%. The risk of CVD was higher among the smokers [aOR: 2.26(1.83-2.73)] than smokeless tobacco [aOR: 1.34(1.21-1.49)] consumers. In contrast daily meat consumers showed higher risk [aOR: 1.23(1.03-1.47)] than meat non-consumers. Women who were consumers of both tobacco and meat had risk of [aOR: 1.15 (1.02 - 1.30)] CVD compared to who did not consume both tobacco and meat. Interaction was not detected between tobacco and meat consumption. CVD treatment adherence was higher among the women who possess an insurance [OR: 1.11(1.04-1.19)]. The risk of treatment non-adherence was higher among women who were aged below 40 with no education and from the poorest section of the society. Barriers for accessing health care facilities were solo attendance, provider availability, and drug access.

Conclusions: Tobacco and meat both need to be addressed to control CVD among women. Empowering women and bringing them under government insurance with an improve health care system are crucial.

Key messages:
- The joint effect of tobacco and meat consumption increased the risk of cardiovascular diseases among women. However, there was no interaction effects observed between tobacco and meat consumption.
- Healthcare facilities needs to be improved and awareness among young adults are extremely crucial for better CVD treatment management among women in India.

Abstract citation ID: ckae144.997
Patterns of overeating in middle-aged Chinese from Hong Kong

Jean Kim

J Kim[1], *K Sze*[1], *P Poon*[1], *F Qi*[2], *A Wong*[1]
[1]The JC School of Public Health & Primary Care, The Chinese University of Hong Kong, Shatin, Hong Kong
[2]The George Institute, School of Public Health, Imperial College, London, UK
Contact: jhkim@cuhk.edu.hk

Background: Obesity is one of the most important risk factors for non-communicable diseases worldwide. Overweightness may be attributable to a wide spectrum of overeating behaviours. However, the various types of overeating behaviors are under-studied in Asia, particularly in non-adolescent age groups. This study aims to estimate the prevalence and factors associated with various overeating patterns among middle-aged Chinese adults.

Methods: A random telephone survey was conducted in 2023 on Hong Kong Chinese adults between 35 and 59 years or age ($n = 785$). An instrument composed of modified Positive-Negative Emotional Eating (EE) Scale, Night Eating Questionnaire-Chinese (NEQ), Binge Eating Disorder Screener (BED-7), Depression Anxiety and Stress Scales (DASS-21), demographic factors, BMI and number of reported gastrointestinal (GI) conditions was used. Multiple regression analyses were conducted to test the association of demographic factors, BMI, GI conditions as well as dysphoric mood with overeating behaviors.

Results: Hong Kong Chinese middle-aged adults reported the following past-month prevalence of overeating behaviors: positive EE (26.1%), general overeating (12.4%), negative EE (9.2%), binge eating (6.0%) and night eating behavior (1.8%). Nightshift work, mental stress, being single and younger age were common risk factors for the various overeating patterns among middle-aged men. Anxiety, high/low educational levels and younger age were common risk factors among middle-aged women. Obesity was associated with binge eating and positive EE in men (OR: 1.7-4.0) and associated with negative EE and general overeating (OR:2.3-2.7) in women.

Conclusions: This study noted that binge eating, night eating, positive/negative EE, and GOB were distinct eating patterns requiring different clinical approaches. The significant association between various overeating behaviors with BMI, indicates that these individuals should be prioritized to receive healthy eating interventions.

Key messages:

- Adult overeating is not a singular behavior but represents an array of different eating patterns with different risk factors.
- Like their Western counterparts, overeating behaviors in Chinese adults are often linked to dysphoric mood, therefore treatment of obesity may require psychological counseling.

Abstract citation ID: ckae144.998

Frailty and related factors among community-dwelling older adults in Türkiye

Si̇bel Sert

S Sert[1], OH Aydilek[1], E Kavlu[1], O Er[1], S Metintas[1], MF Onsuz[1]

[1]Public Health Department, Eskisehir Osmangazi University, Eskisehir, Türkiye

Contact: sibel4397@gmail.com

Background: Frailty in elderly can lead to complex challenges in the follow-up and management of health services. Ensuring comprehensive primary care services and social support can avert, reverse, or mitigate frailty in old age. We aimed to evaluate frailty and its associated factors in individuals aged $\geq$65 years.

Methods: We conducted a cross-sectional study in patients applying to primary care centres in 2024, in a city where 10% of the population is elderly. The centres were divided into clusters based on the socioeconomic status of the regions they serve, and nine were randomly selected by weight. A total of 1154 elderly who consecutively presented were included. A questionnaire including sociodemographic characteristics, Edmonton Frailty Scale, Loneliness Scale for the Elderly (LSE), Charlson Comorbidity Index (CCI), International Falls Effectiveness Scale (FES-I) was applied to the elderly.

Results: The mean age was 71.3±5.3 years, and 50.8% were male. In the study, 20.1% were frail, and 19.6% were apparently vulnerable. It was found that those aged 70-79 and $\geq$80 years, women, deceased/separated from their spouses, those with low education, those whose occupation was housewife, those earning below minimum wage, those who lived alone, non-exercisers, those taking $>$8 medications/day, and those who had $\geq$2 falls/last year were more frail. In multivariate logistic regression analysis, illiteracy (Odds ratio-OR:15.2, 95%CI:1.7-135.5), taking $>$8 medications/day (OR:4.1, 1.7-9.9), falling $\geq$2 times/last year (OR:3.4, 1.8-6.4) and $\geq$4 points on the CCI (OR:1.9, 1.0-3.4) were found to be predictors of frailty. Each score on the FES-I and LSE increased the risk of frailty by 1.08 (1.05-1.11) and 1.13 (1.08-1.17) times, respectively.

Conclusions: One in five people was found to be frail. Low education level, $>$8 medications/day, $\geq$2 falls in the last year, severity of comorbidity, fear of falling, and high levels of loneliness were found to be predictive factors for frailty.

Key messages:

- Encouraging a healthy lifestyle to prevent comorbid diseases and early interventions to avoid falls can reduce frailty.
- Providing social activities in primary care and promoting the elderly to participate in these activities can help prevent loneliness, which is a risk factor of frailty.

Abstract citation ID: ckae144.999

Gene Expression Changes in CAD Patients Due to Smoking Using Matched Samples

Mohammed Merzah

M Merzah[1], S Póliska[2], L Balogh[3], J Sándor[1,4], I Szász[1,4], S Natae[1], S Fiatal[1]

[1]Department of Public Health and Epidemiology, University of Debrecen, Debrecen, Hungary

[2]Department of Biochemistry and Molecular Biology, University of Debrecen, Debrecen, Hungary

[3]Cardiology and Cardiac Surgery Clinic, University of Debrecen, Debrecen, Hungary

[4]ELKH-DE Public Health Research Group, University of Debrecen, Debrecen, Hungary

Contact: Merzah.karbala@gmail.com

Background: Smoking is a well-known risk factor for coronary artery disease (CAD). However, the effects of smoking on gene expression in the blood of CAD patients in Hungary have not been extensively studied.

Aim: To identify differentially expressed genes associated with smoking in CAD patients.

Methods: Eleven matched samples, based on age and gender, were selected for analysis in this study. All patients were non-obese, non-alcoholic, non-diabetic, and non-hypertensive and had moderate to severe stenosis of one or more coronary arteries, confirmed by coronary angiography. Whole blood samples were collected using PAXgene tubes. Next-generation sequencing was employed using the NextSeq 500 system to generate high-throughput sequencing data for transcriptome profiling. The differentially expressed genes were analyzed using the R programming language.

Results: The median age of patients was 67 years (range: 54-75). RNA sequencing was performed on two groups: smokers and non-smokers. After quality control and filtering, gene expression data were obtained for all samples. Using DESeq2, we identified 279 differentially expressed genes with a p-value $\leq$ 0.05 and a log2 fold change $\geq$1. Of these genes, 160 were upregulated in the smokers, and 119 were downregulated compared to non-smokers. Gene ontology analysis revealed that the upregulated genes were enriched for pathways related to immune responses and activities (FDR$<$ 0.03). Specifically, upregulated genes were involved in keratinocyte differentiation, cornification, and epidermis development. The downregulated genes were enriched for cell-cardiac muscle cell adhesion (FDR= 0.004) and epithelium development (FDR= 0.001) pathways.

Conclusions: This research illuminates smoking's biological effects, aiding personalized medicine for predicting and treating smoking-related diseases.

Key messages:

- Smoking alters gene expression in CAD patients' blood, identifying 279 differentially expressed genes, revealing smoking's biological effects.
- The study underscores gene expression profiles' role in personalized medicine, predicting smoking-related disease risks and tailoring CAD patient treatments.

Abstract citation ID: ckae144.1000
Intersecting Pathways: Understanding Dementia, Hearing Loss, and Health Disparities

Donata Stonkute

D Stonkute[1]
[1]Max Planck Institute for Demographic Research, Rostock, Germany
Contact: stonkute@demogr.mpg.de

Background: Dementia is a major public health concern, affecting care dependency and disability in older ages. In Europe, around 14.1 million people live with dementia, a number that is expected to increase to 15.9 million by 2040. Hearing loss (HL), followed by education, has been proposed as the most important modifiable risk factor for dementia. This study aims to investigate how sex, educational attainment and HL intersect to influence dementia-free life expectancy (DemFLE) in older adults.

Methods: Using population register data covering all Finnish residents aged 50 years or older from 2010 to 2019, we apply discrete-time multistate Markov models. Transition probabilities between states, such as HL and dementia, are estimated with multinomial logit models stratified by sex and education. Multistate life tables are used to compute sex- and education-specific DemFLE.

Results: We identified 316,361 individuals with a diagnosis of dementia and 317,115 individuals with a diagnosis of HL, representing 1,449,873 and 2,738,970 person-years respectively. 14% of individuals with HL were eventually diagnosed with dementia, compared to only 8% of individuals without HL. We hypothesise that DemFLE will vary significantly by sex and education, with additional modulation by the presence of HL. Specifically, we expect that the presence of HL will further reduce DemFLE, and that the magnitude of this reduction will be relatively greater among those with lower educational attainment.

Conclusions: This study contributes to the emerging literature on the impact of hearing loss on dementia. While both dementia and hearing loss are irreversible health conditions, hearing loss can be managed by hearing aids. If we find evidence that hearing loss is associated with different levels of risk of dementia by educational attainment, it would suggest avenues for effective interventions and public health policies to ensure more equal ageing processes in the population.

Key messages:

- Hearing loss may intersect with education and sex in the risk of dementia, providing evidence for the importance of addressing hearing health inequalities in dementia prevention efforts.
- Understanding the interactions between hearing loss, education and sex can inform policies to promote healthy ageing and reduce the burden of dementia on individuals and health systems.

Contact: sarganas-margolisg@rki.de

Background: Polypharmacy, the use of 5 or more medications simultaneously, favors the risk of adverse drug events, drug interactions, potentially inappropriate medication (PIM), hospitalizations, falls, frailty, and mortality. This analysis presents the prevalence of polypharmacy and associated factors in people aged 66+ years living in Germany.

Methods: Data from the nationally representative Study on Health of Older People in Germany (Gesundheit 65+) conducted between 2021-2023 by the Robert Koch Institute, was analyzed. All medicines used, prescribed and over-the-counter, in the 7 days before the interview were documented and classified into anatomical therapeutic chemical codes. Weighted prevalences and associated factors for polypharmacy are presented.

Results: 96% of the sample ($N = 1{,}474$) took at least 1 medication in the 7 days before the interview. Of these, 39% took up to 4 medications, 39% 5-9 and 22% 10+. The overall prevalence of polypharmacy was 61% (95%CI 58-65%) and was significantly higher in women (64%) than in men (59%). Polypharmacy increased with age, from 52% in the age group 66-74 (53% in men, 51% in women), 66% in the age group 75-84 (63% in men, 69% in women) to 81% in the age group 85 + (72% in men, 86% in women). People with low educational level had a polypharmacy prevalence of 63% (58% in men, 66% in women) compared to 56% (55% in men, 58% in women) in those with high educational level. Severe difficulties in organizing daily medication intake were reported in 1% of people taking up to 4 medicines, in 4% of people taking between 5-9 medicines and in 16% of people taking 10+. The prevalence of PIM increased with the number of medicines used: 13% in 1-4 medicines, 31% in 5-9 medicines, and 53% in 10+ medicines.

Conclusions: Polypharmacy was more frequent in women, older age groups and in people with low educational level. It was associated with increased difficulty in organizing medication intake and with PIM use.

Key messages:

- Polypharmacy is very common, affecting more women, older age groups, people with a low educational level and is associated with PIM use.
- Strategies to promote appropriate medication use are needed.

Abstract citation ID: ckae144.1002
Prevalence and Correlates of Cannabis Use among Cancer Survivors

Sangeeta Gupta

S Gupta[1]
[1]Public and Allied Health Sciences, Delaware State University, Dover, USA
Contact: sangeetaguptaa@yahoo.com

Background: Delaware has legalized marijuana use for both medical and recreational use. This study identified factors associated with cannabis use among adults with chronic relative to individuals without a history of cancer in the First State.

Methods: Combined data (2020, 2021 and 2022) from the Behavioral Risk Factor Surveillance System (BRFSS) were analyzed for Delaware. Multivariable logistic regression examined individual-level demographic, socio-economic, clinical, and behavioral predictors associated with marijuana use stratified by history of cancer.

Results: Cannabis use was lower among cancer survivors compared to individuals with no history of cancer (6.76% vs. 13.43%). However, a higher proportion of cancer survivors reported use for medical purposes (75.13% vs. 64.28%). Marijuana use prevalence decreased with age among cancer survivors. After adjusting for sex, age, educational attainment, self-reported race/ethnicity, mental health status and physical health status, current smoking (odds ratio [OR], 4.24 vs. 2.74) and binge drinking (OR, 2.45 vs. 1.75) were associated with cannabis use in both groups.

Conclusions: Adults with cancer were more likely to use marijuana. Marijuana use prevalence decreased with age. Public perceptions of marijuana is becoming more acceptable. Risk of medical conditions such as cancer increase with age. As such, older adults might also become consumers of marijuana. Clinicians should screen for marijuana use among patients and initiate open discussions with patients about the benefits and risks associated with marijuana.

Key messages:

- Need for ongoing cannabis research to better understand and inform its use for medical purposes.
- Development of high-quality standardized education materials and clinical practice guidelines for marijuana use.

[5]BRISPO, Vrije Universiteit Brussel, Brussels, Belgium
[6]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Brussels, Belgium
Contact: lisa.cavillot@sciensano.be

Background: The COVID-19 pandemic led to significant excess mortality in 2020 in Belgium. By using microlevel cause-specific mortality data for the total Belgian adult population in 2020, three outcomes were considered in this study aiming at predicting sociodemographic (SD) and socioeconomic (SE) patterns of 1) COVID-19 specific death compared to survival; 2) all other causes of death (OCOD) compared to survival; 3) COVID-19 specific deaths compared to all OCOD.

Methods: Multivariable logistic regression models were fitted for the three outcomes. In addition, we computed conditional inference tree (CIT) algorithms, complementing regression models, to identify and rank the strongest SD and SE predictors of the three outcomes.

Results: Older people, males, people living in collectivities, first-generation migrants, and deprived SE groups experienced higher odds of dying from COVID-19 compared to survival; living in collectivities was identified by the CIT as the strongest predictor followed by age and sex. Education emerged as one of the strongest predictors for people not living in collectivities. Overall, similar patterns were observed for all OCOD except for first- and second-generation migrants having lower odds of all OCOD compared to survival; age group was identified by the CIT as the strongest predictor. Older people, males, people living in collectivities, first- and second-generation migrants, and people with lower levels of education had higher odds of COVID-19 death compared to all OCOD; living in collectivities was identified by the CIT as the strongest predictor followed by age, sex, and migration status. Education and income emerged as the strongest predictors among people not living in collectivities.

Conclusions: This study identified important SD and SE disparities in COVID-19 mortality underlying the importance of implementing preventive measures, particularly within the most vulnerable populations, in infectious disease pandemic preparedness.

Key messages:

- Living in collectivities appeared to be the strongest predictor of COVID-19 death across all age groups, highlighting the importance of preventive measures in reducing the transmission of the virus.
- Poor education plays a crucial role in predicting COVID-19 death among people not living in collectivities, highlighting the importance of targeting preventive measures towards low educated groups.

Abstract citation ID: ckae144.1004

COVID-19 vaccine effectiveness and hybrid immunity in the respiratory season of 2022-23 in Hungary

Beatrix Oroszi

B Oroszi[1,2], JK Horváth[1,2], G Túri[1,2], K Krisztalovics[1,2], K Kristóf[3]

[1]Center for Epidemiology and Surveillance, Semmelweis University, Budapest, Hungary
[2]National Laboratory for Health Security, Semmelweis University, Budapest, Hungary
[3]Institute of Laboratory Medicine, Semmelweis University, Budapest, Hungary
Contact: orobea@gmail.com

Background: There has been an increase in COVID-19 vaccine hesitancy among the general population, accompanied by a decline in confidence that vaccines provide adequate protection. We estimated the effectiveness of the COVID-19 vaccines (CVE) and hybrid immunity against medically attended COVID-19 during the 2022-2023 respiratory season in Hungary.

Methods: We conducted a test-negative design study involving 68 GPs. Patients aged $\geq$18 years presenting with acute respiratory infection were swabbed. Cases and controls were patients testing positive and negative for SARS-CoV-2 by RT-PCR, respectively. Exposure was defined as having received at least one COVID-19 booster dose, taking into account the time since the last vaccination. CVE was estimated using logistic regression, adjusted for symptom onset date, age, chronic condition and sex.

Results: We included 247 cases and 1073 controls in the analysis. 196 samples were sequenced, and Omicron BA.5, BQ.1 and XBB.1 were the most frequent sub-variants. The CVE was 52.9% (95% CI: 15.2-73.9%), and 72.3% (95% CI: 32.0-88.7%) in the 18-59, and 60+-year-old population who received the final dose within the past year, respectively. Self-reported COVID-19 in the previous 60-365 days did not confer protection against reinfection, however, when combined with booster vaccination, it reduced the risk of COVID-19 by 63.0% (95% CI: −28.0-89.3%) and 87.6% (95% CI: 26.4-97.9%) among the 18-59 and 60+ age groups, respectively.

Conclusions: Booster vaccination within one year after the last dose confers significant protection against symptomatic infection, particularly among the elderly. Those who have previously been

infected with SARS-CoV-2 may also benefit from booster vaccinations.

Key messages:

- COVID-19 booster campaigns must be intensified, focusing mainly on the elderly.
- Providing clear guidance on the timing and target groups of vaccination and emphasising the benefits of vaccination can help to achieve higher coverage.

Abstract citation ID: ckae144.1005
Sex differences at different ages in 30-day survival of COVID-19 hospitalized patients in Israel

Avi Magid

A Magid[1,2], *Y Niv*[3], *MS Green*[4]
[1]School of Public Health, Ben-Gurion University of the Negev, Be'er Sheva, Israel
[2]Management, Rambam Health Care Campus, Haifa, Israel
[3]Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel
[4]School of Public Health, University of Haifa, Haifa, Israel
Contact: magid.avi@gmail.com

Background: Sex differences in mortality from COVID-19 have been described. It is not clear to what extent sex is an independent risk factor for mortality or is confounded by co-morbidities and whether it varies by age. It is also not clear whether it is constant over time since diagnosis. We studied sex differences in 30-day mortality rates in patients hospitalized with COVID-19, after controlling for co-morbidities.

Methods: Data on patients hospitalized with COVID-19 were extracted from the majority of general hospitals in Israel during 2020 to 2022. The outcome variables were death during 30 days from onset of hospitalization. Sex differences in survival rates were assessed using Cox proportional hazards models controlling for age, heart disease, cancer, respiratory disease, diabetes and hypertension.

Results: Mortality rates in women were significantly lower than in men in all age groups. There was an approximate 5-6 year lag in the mortality rates between men and women.

Conclusions: Sex was an independent predictor of 30 day mortality from COVID-19 with women experiencing better survival. This advantage was not explained by differences in co-morbidities or the magnitude of the differences in survival by age. The sex differences in the 30-day mortality of hospitalized patients are compatible with the male dominance in the incidence rates of many infectious diseases. Poorer survival of men hospitalized for COVID-19 is likely to be part of the disease mechanism and should be explored further.

Key messages:

- Poorer survival of male COVID-19 patients seems to be part of the disease mechanism and should be explored further.
- Sex differences in disease should be included in personalized management of disease.

Abstract citation ID: ckae144.1006
Feta safe than sorry - gastroenteritis outbreak associated with contaminated cheese

Fiona McGuire

F McGuire[1], *M Ward*[1], *E Smyth*[1], *E Murphy*[1]
[1]Public Health, Health Service Executive, Tullamore, Ireland
Contact: fiona.mcguire@hse.ie

A gastroenteritis outbreak among attendees at a catered HSE event was notified. No faecal samples were obtained - all cases had recovered. An outbreak control team was convened. A retrospective cohort study hypothesised that "people who attended the HSE event and subsequently became unwell did so as a result of consuming food at the event". Epidemiological, environmental, and microbiological investigations commenced. An outbreak-specific food questionnaire was distributed. The food business was inspected, obtaining food samples. Survey responses were analysed.The attack rate was 25%. Associations were identified between illness and specific foods. Multivariable regression highlighted: feta salad ($OR = 36.22$ [95% CI 2.24-585.52] $p = 0.01$), and turkey ($OR = 12.57$ [95% CI 1.12-140.58] $p = 0.04$). Most (93%) turkey consumers had consumed feta salad. Microbiology of unopened feta cheese, sourced by the caterer from a supermarket, was positive for E coli at 1.7 x 105. The Food Safety Authority of Ireland corroborated separate illness complaints from a family consuming the product. The supermarket voluntarily withdrew the product internationally.This outbreak prompted a cross-sectoral food safety investigation. Despite no pathogen detection in a faecal samples, epidemiological evidence led to the withdrawal of contaminated feta by the supermarket, removing over 1000 units from the market, emphasising the importance of epidemiology in protecting public health.

Key messages:

- Epidemiological investigation resulted in mass contaminated cheese withdrawal internationally.
- Cross-sectoral work is important to safeguard public health.

Abstract citation ID: ckae144.1007
Paediatric iGAS Morbidity and Mortality in Ireland 2022-2023 episodic upsurge

Orla Cotter

O Cotter[1], *D Foley*[2], *F Cloak*[3], *U Fallon*[3], *CÓ Maoldomhnaigh*[2], *P Mc Keown*[3]
[1]Department of Public Health Dublin/Midlands, Health Service Executive, Dublin, Ireland
[2]Children's Health Ireland, Crumlin Hospital, Dublin, Ireland
[3]National Health Protection Service, Health Service Executive, Dublin, Ireland
Contact: orlacotter103@gmail.com

There was an unseasonal upsurge in invasive Group A Streptococcal (iGAS) activity in Ireland during the 2022/2023 winter period. In particular, there was an increase in the proportion of paediatric infections and a rise in the age specific death rate for those under the age of 18, from 0.10 to 1.43 per 100,000. This review aimed to describe the demographic and clinical factors associated with paediatric iGAS infection during this upsurge. All iGAS cases under the age of 16 years, notified to Public Health between 1st October and 30th June 2023, were included. A review of hospital records for each case was conducted using a standardised electronic data collection proforma. Descriptive, univariate and multivariate analysis was conducted using SPSS statistical package. There was a total of 183 cases of iGAS notified during this upsurge in Ireland. A hospital chart review was conducted for 169 of these cases, giving a response rate of 92.3%. The median age was 4 years (range 0-15,) with 44.4% (75) having a previous healthcare attendance during their illness. Varicella coinfection occurred in 27.8% (47) of cases. There was respiratory viral coinfection in 40.8% (69) of cases, and this was significantly associated with an increased risk of death RR 6.49 (95% CI 4.45 - 29.08) $p < 0.05$. A respiratory site of infection was also significantly associated with an increased risk of death RR 10.13 (95% CI 2.23 - 45.95) $p < 0.001$. However, both factors did not remain significant once adjusted for age, sex, ethnicity and deprivation index. This national review demonstrated the significant burden of paediatric iGAS morbidity and mortality during this upsurge. A significant proportion of cases, 37.9% (64) were associated with vaccine preventable illness, with respiratory viral infections and a respiratory site of infection both being significantly associated with an increased risk of death.

Key messages:

- A significant proportion of iGAS cases were associated with a vaccine preventable illness.
- A respiratory site of iGAS infection was significantly associated with an increased risk of death in paediatric cases.

Abstract citation ID: ckae144.1008
Intersectional inequality through economic difficulties and lifestyle on body mass index in Sweden

Antonio Moreno-Llamas

A Moreno-Llamas[1], *M San Sebastián*[2], *P Gustafsson*[2]
[1]Department of Sociology and Social Work, University of the Basque Country, Leioa, Spain
[2]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
Contact: antonio.moreno@ehu.eus

Background: A high body mass index (BMI) is listed among the top five risk factors for the Swedish population. Socially disadvantaged groups, including women, low-educated, and immigrants, are even at higher risk of a high BMI who may also face economic constraints, physical inactivity, and poor-quality diets. However, complex intersectional transmission of inequalities to BMI remains unexplored. Therefore, we aimed to examine intersectional inequalities in BMI mediated by economic strain and lifestyle in the Swedish population.

Methods: By using the Health on Equal Terms cross-sectional surveys in 2016, 2018, 2020, and 2021 in the Swedish population (n = 44,177 inhabitants aged 24 and over), we performed an intersectional mediation analysis to estimate how inequalities across intersectional strata, by gender (women or men), education (primary, secondary or university), and migration status (Swedish native or migrant), may be sequentially transmitted through economic strain (yes or not in the last 12 months) and unhealthy lifestyle (physical inactivity or inadequate fruit/vegetables consumption) to BMI (continuous).

Results: Compared with high-educated native men, socially disadvantaged strata experienced more economic strain, which in turn led to poorer health-related lifestyles and ultimately to a higher BMI. Some strata such as high-educated women, despite having a lower BMI, still experienced more pronounced transmissions of inequality on BMI through economic difficulties.

Conclusions: Not only inequalities in BMI, but also the material and behavioral pathways underpinning the inequalities, act by intersectional patterns. Public health interventions should ensure adequate economic resources to access healthy food and physical activity across all social strata groups.

Key messages:

- Intersectional inequalities in BMI were driven by economic strain and lifestyle.
- Economic strain and poorer lifestyles were not only more prevalent in lower stratus but also more detrimental.

Abstract citation ID: ckae144.1009
Using HIS administrative data for initial assessment of comorbid patients' status (Covid-19 case)

Natalya Usheva

I Mircheva[1], *N Usheva*[1], *M Mirchev*[1], *S Kiselkova*[2]
[1]MU - Varna, Faculty of Public Health, Varna, Bulgaria
[2]UMHAT St. Marina -Varna, Department of Medical Activity Reporting and Coding, Varna, Bulgaria
Contact: nataly_usheva@hotmail.com

Background: Despite numerous published articles, most of the studies on COVID-19 focused on influence of clinical characteristics and treatments on severity. Yet, the epidemiological viewpoint was rarely discussed. Based on our experience with comorbid hospitalized COVID-19 patients, we aim to show that HIS administrative data can be used to identify individuals that are more prone to worse outcome thus improving patient management not only during pandemics.

Methods: A retrospective single-center study was conducted using archived anonymized HIS administrative data for all 8319 COVID-19 patients in the university hospital 'Saint Marina'-Varna, Bulgaria, in the period 14/06/2020-31/12/2021. Up to 7 comorbidities per patient were registered in HIS with ICD-10 codes, used for our analyses. Non-parametric tests and logistic regression were used at α=.05, 95%CI.

Results: Comorbid patients were 5741(69%), 50.3% $\geq$69y, 52% male; 1602(27.9%) died, 64% $\geq$69y, 54.4% male. Deceased were older ($p< .01$) and had more comorbidities ($p< .01$). Multimorbid patients (OR = 4.43; 3.80-5.17), male (OR = 4.72; 3.83-5.82) and older ones (OR = 1.91; 1.57-2.34) had higher odds of dying. The odds of dying increased with the number of comorbidities from OR=.635; .559-.721 for 1 to OR = 4.23; 3.28-5.46 for 7. From 4967 comorbid diseases (451 ICD-10 codes), only those from code groups A, J, N, E, I, Z were suitable for analysis. Patients with A41.9 (OR = 213.69; 52.88-863.43), J80 (OR = 52.88; 32.58-85.56), N17 (OR = 18.63; 10.24-33.87), E11.7 (OR = 4.72; 3.09-7.19), I13.2 (OR = 4.67; 3.151-6.93), Z95 (OR = 3.81; 2.74-5.31), I63 (OR = 3.56; 2.25-5.61), E66 (OR = 3.12; 2.10-4.64) died more often.

Conclusions: Our findings match the results based on EMR data: death with COVID-19 was associated with comorbidities (sepsis, acute RDS and kidney, heart and renal failure, diabetes, cerebral infarction, obesity, implants and grafts), age, gender, i.e. HIS administrative data can be used for quick assessment of comorbid patients' status.

Key messages:

- HIS administrative data can be used for quick assessment of multimorbidity and following personalized treatment is highly recommended to decrease hospital mortality not only in times of pandemic.
- Older Bulgarians have many comorbidities from ICD code groups A, J, N, E, I, Z, and are more prone to death, especially in times of pandemic. Public health measures are needed to prevent comorbidity.

Abstract citation ID: ckae144.1010
A Groundbreaking Prevalence Survey Conducted in Mauritania for Enhanced Sickle Cell Control

Stephanie Cohen

S Cohen[1], *P Baguet*[1], *E Bernit*[1], *B Soudier*[1], *L Petiteau*[1], *E Mahmoud*[2]
[1]NGO, Santé Sud, Marseille, France
[2]DPH, Ministry of Health, Nouakchott, Mauritania
Contact: stephanie.cohen@santesud.org

Issue/Problem: Sickle cell disease is a major concern in sub-Saharan Africa, with a prevalence of 0.5 to 2% among children and a mortality rate exceeding 50% in untreated cases. However, the lack of reliable data hampers effective public health policies and resource allocation. To address this, Mauritania's Ministry of Health, with technical support from NGO Santé Sud, conducted its first prevalence survey in 2023-24. The findings will support advocacy for a national strategy on the disease and offer valuable insights for neighboring countries with similar challenges.

Description of the problem: The prevalence survey comprised 3 field missions over 7 weeks, conducted across 24 primary healthcare facilities during immunization days, in Nouakchott, Dakhlet-Nouadibou, Trarza, Ghorgol, Brakna, Guidimakha and Assaba regions: 1,642 infants (0-9 months) underwent screening for sickle cell disease, with parents' consent, and 30 paramedics and laboratory technicians were trained to administer point-of-care tests.

Results: The survey found that 9.7% of tested children were carriers of hemoglobinopathies, with 0.6% diagnosed with sickle cell disease. Lab technicians and nurses have improved knowledge about the disease and are better equipped for point-of-care testing. This initiative is expected to enhance sickle cell disease control by providing crucial data for advocacy and may lead to a nationwide newborn screening program, in line with WHO recommendations.

Lessons: This initiative highlighted the efficiency of screening infants for sickle cell disease, emphasizing the need for effective organization involving stakeholders from central to local levels. Screening during immunization days proved highly efficient in testing numerous children. Success depends on adequate human resources, technical skills, and dedicated health personnel. Additionally, having a team member to inform and counsel families, especially when test results are positive, proved crucial.

Key messages:

- A prevalence survey on sickle cell disease to generate robust data for advocacy efforts in Mauritania.
- Conducting a prevalence survey on sickle cell disease in Mauritania for a better control of the disease.

Abstract citation ID: ckae144.1011

Reactive surveillance of deaths involving a fall among the elderly in France, 2015 to March 2023

Marion J Torres

MJ Torres[1], *A Fouillet*[2], *A Ung*[1], *Z Hebbache*[3], *D Martin*[3], *E Coudin*[3], *L Guldner*[1], *N Beltzer*[1]
[1]Department of Non-Communicable Diseases and Injuries, Santé Publique France, Saint-Maurice, France
[2]Department of Data Science, Santé Publique France, Saint-Maurice, France
[3]CépiDc, National Institute of Health and Medical Research, Kremlin-Bicêtre, France
Contact: Marion.Torres@santepubliquefrance.fr

In 2022, France launched an elderly anti-fall plan with a goal to reduce fatal falls by 20% within 5 years. In a reactive monitoring approach ensuring comparability over the period, our study aims to develop an algorithm to identify deaths involving a fall using free-text medical causes in death certificates. This will enable proactive surveillance and evaluate plan effectiveness upon completion. We devised an algorithm based on textual search of fall-related expressions in death certificates. Performance metrics were assessed by contrasting algorithm-identified deaths with those flagged by ICD-10 fall-related codes. We compared also temporal dynamics between the algorithms from 2015 to 2021. Analysis was performed by age group, gender and place of death. Additionally, our algorithm enabled estimation of fall-related death trends from 2015 to 2023. The free-text algorithm exhibited robust performance, with a sensitivity and PPV of 95% when compared to deaths coded with an ICD-10 fall-related underlying or associated cause. Temporal trends between both were highly correlated (correlation coefficient=0.99). Instead of the usual 10000 deaths for fall, we revealed about 13000 deaths linked to falls considering both primary and associated causes. Among these, approximately three-quarters were coded as the underlying cause of death in ICD-10 coding. Regarding trends, the results are preliminary and suggested an increase in mortality rates related to falls detected by the algorithm between 2015 and 2022. Our approach distinguishes falls from other competing causes that often relegate them to secondary status in the chain of morbid events leading to death. With free-text medical causes accessible within 3 to 4 months, monitoring deaths involving falls can be done at a detailed geographic level and in a more reactive way. Looking ahead, we must also consider incorporating the impact of epidemics and/or heat waves to accurately evaluate the effectiveness of the anti-fall plan.

Key messages:

- Algorithm using free-text of death certificates identify deaths involving falls.
- Our innovative approach isolates falls from other competing causes, elevating their significance in death processes.

Abstract citation ID: ckae144.1012

Infertility in the Capital Region of Denmark: Prevalence and population characteristics

Marie Holm Eliasen

MH Eliasen[1], *M Grønkjær*[1], *L Schmidt*[2], *P Elsborg*[1], *CG Toxværd*[1], *D Vassard*[2,3]
[1]Center for Clinical Research and Prevention, Copenhagen University Hospital – Bispebjerg and Frederiksberg, Frederiksberg, Denmark
[2]Department of Public Health, University of Copenhagen, Copenhagen, Denmark
[3]Department of Gynaecology, Fertility, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark
Contact: marie.holm.eliasen@regionh.dk

Background: Infertility is a disease defined by failure to achieve a pregnancy within 12 months of trying. Infertility has-until now-not been monitored in Denmark for three decades. The aim of this study was to assess the prevalence of infertility in persons aged 25-44 years in the Capital Region of Denmark, and to describe characteristics of persons with infertility.

Methods: Life-long experience of infertility was assessed in the Danish Capital Region Health Survey 2021, including 56,245 participants from the general population aged $\geq$16 years (response rate 54.9%). In this study, only persons aged 25-44 years who had tried to have children (thus knowing their fertility) were included, resulting in 8,203 participants. Characteristics of persons with infertility were assessed using national registries (socio-demographics) and questionnaire data (health status). Descriptive analyses and multivariate logistic regression models weighted for survey design and non-response were performed.

Results: Among persons aged 25-44 years, who had tried to have children, 20% had experienced infertility. Among those, 44% did not achieve the children they wanted. Infertility was most common among women (22%) and persons aged 35-44 years (21%). No associations were observed between infertility and ethnicity, education, and employment status. Persons with infertility were more likely to have poor physical health, have higher level of stress symptoms and have obesity compared with persons in same age group, who had tried to have children but not experienced infertility.

Conclusions: Infertility is very common in the general population and is associated with unmet fertility desires as well as poor physical health and high stress level. These findings highlight the importance of focusing on and prioritizing treatment and prevention of infertility and emphasize the need for further research in and continued monitoring of infertility.

Key messages:

- Infertility is very common in the general population and associated with unmet fertility desires and poor health highlighting the importance of prioritizing treatment and prevention of infertility.
- Continuous monitoring of infertility in the general population is essential as well as further research into risk factors and consequences of infertility.

[5]Nursing, Ribera Salud, Valencia, Spain
[6]MOI, Ribera Salud, Valencia, Spain
Contact: jadelgado@vinaloposalud.com

Background: Surgical site infection (SSI) is a major health problem associated with high morbidity and mortality, the consequences of which can be very serious for the patient and costly for the organisation. Surveillance systems provide insight into the incidence of SSI, the analysis of which enables improvement plans to be established to reduce it. Traditionally, surveillance systems have been based on manual medical record review for evidence of the presence of surgical infection.

Objectives: To create and validate a global SSI diagnostic algorithm and to optimise the SSI workload of Preventive Medicine services.

Methods: The study population included patients undergoing surgical procedures of rectal surgery, colon surgery, knee replacement surgery, hip replacement surgery, coronary bypass and valve surgery, at the Hospital Universitario Vinalopó in Elche ($n = 1240$). Data mining was used to collect clinical, microbiological and postoperative follow-up values from the electronic medical record. Machine Learning techniques were used to train ($n = 1054$) and validate the model ($n = 186$). Time spent on SSI surveillance of the preventive medicine service was measured.

Results: Model performance after validation was: sensitivity of 0.83 specificity of 0.87, accuracy of 0.87, an F1 score of 0.45, and an area under the curve of 0.87. The time spent by preventive medicine staff in identifying patients with surgical site infection decreased from 168 person-hours per procedure per quarter to 34 person-hours, a 77% reduction in the workload allocated to this task.

Conclusions: This project not only improves surveillance efficiency, but also optimises the workload in Preventive Medicine services very significantly.

Key messages:

- This project improves the efficiency of surgical site infection surveillance and significantly optimises the workload in preventive medicine departments.
- It makes it possible to extend surveillance to new surgical procedures and to work more intensively on preventive measures.

Background: Cognitive impairment (CI) has been widely reported as a frequent non-fatal cancer outcome. 15% to 25% of breast cancer (BCa) patients may have CI; however long-term variations of cognitive performance during and after the cessation of the treatments remains unclear. The present study aims to describe the evolution of cognitive performance in BCa survivors that are still in follow-up at breast cancer clinic, 10 years after diagnosis.

Methods: 506 women with BCa admitted to the Portuguese Institute of Oncology, Porto, in 2012, were evaluated with the Montreal Cognitive Assessment (MoCA) before any treatment, after one, three, five, and ten years. Patients with a MoCA score $\leq$1.5 standard deviation below the mean of age- and education-specific norms were considered to have probable cognitive impairment (PCI). The 10-year follow up started in October 2022, and is still in progress (as of March, 118 were evaluated). All women that are still being followed at IPO-Porto for consultations and treatments were evaluated with MoCA assessment.

Results: PCI prevalence at the 10 years was 43.0% (95%Confidence Interval: 34.1%-52.7%). Several pathways for cognitive performance were identified throughout the 10-year follow-up: 58 women (49.2%) never had PCI at baseline assessment or during follow-up; 19 women (16.1%) had PCI at baseline, from whom 5 (4.2%) had PCI in all evaluations, 2 (1.7%) did not have PCI in any follow up evaluation, 2 (1.7%) had PCI during follow up, but not at 10 years and 3 (2.5%) had PCI again only at the 10-year follow-up; 5 women (4.2%) did not have PCI at baseline but had PCI at least once during follow-up but not at 10 years, and 24.6% had PCI for the first time at 10 years.

Conclusions: The results show a high prevalence of PCI 10 years after diagnosis with a significant part being new cases. These results highlight the need for including regular assessments of cognitive performance as a part of the clinical follow-up of BCa survivors.

Key messages:

- There is a high prevalence of cognitive deficits in breast cancer suvivors 10 years after diagnosis.
- Including cognitive evaluations of breast cancer survivors during clinical follow up are recommended.

Abstract citation ID: ckae144.1015
Assessing primary healthcare quality through avoidable hospitalizations: a systematic review

Arianna Anniballo

F Pierri[1], *D Mercuri*[1], *G Di Lorenzo*[1], *V Soccodato*[1], *A Anniballo*[1], *C Forcella*[1], *E Renzi*[1], *P Villari*[1], *V Baccolini*[1], *G Migliara*[2]
[1]Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Life Sciences, Health, and Health Professions, Link Campus University, Rome, Italy
Contact: arianna.anniballo@uniroma1.it

Background: Avoidable hospitalization (AH) for ambulatory care sensitive conditions (ACSC) has been widely used as a measure of the performance of primary health care. However, the lack of a standardized definition of these conditions and the absence of conclusive evidence regarding their efficacy across diverse healthcare settings remain significant challenges. This review aims to systematically identify and synthesize the utilization of AH for ACSCs as a metric for evaluating the quality of primary healthcare (PHC) and factors influencing such quality.

Methods: We conducted a systematic search for peer-reviewed studies on 3 electronic databases. Studies that used AH for ACSCs to investigate the quality of PHC were included. The following characteristics were extracted: study design, ACSCs definition, AH rates, intervention if applicable, PHC and or patients' characteristics associated to AH rates, such as accessibility, continuity of care, demographics, socio-economic status, and comorbidities.

Results: 73 relevant articles were identified, published between 1994 and 2023 and mostly in USA. Preliminary findings based on 56 articles indicate that the majority (48.2%) employed the list of ACSCs from the AHRQ (i.e. the prevention quality indicators) (48.2%). Meanwhile, 12 studies (17.9%) used lists developed or modified by the authors, and another 7 (12.5%) adopted lists previously utilized in other research. Studies conducted in Brazil, Canada and USA employed lists issued by relevant national institutions.

Conclusions: Although preliminary, these findings highlight two main trends. Firstly, in countries where health authorities have established a standardized set of ACSCs, a notable uniformity is observed. Conversely, in the absence of such standards, variability in defining these conditions is likely to increase. This variation could hinder the comparability across different Primary Health Care (PHC) service organizations and affect the analysis of care quality.

Key messages:

- Most studies used established indicators for the measuring of primary healthcare quality.
- Diverse ACSC definitions across countries impair the generalizability of healthcare quality analysis.

Abstract citation ID: ckae144.1016

Sodium and potassium intake in adults: the Italian Health Examination Survey 2023 – CUORE Project

Chiara Donfrancesco

C Donfrancesco[1], C Lo Noce[1], B Marcozzi[1], A Di Lonardo[1], S Vannucchi[1], M Morello[2], S Di Carlo[2], D Galeone[3], P Bellisario[3], L Palmieri[1]
[1]ISS, Rome, Italy
[2]Tor Vergata University Hospital, Rome, Italy
[3]Italian Ministry of Health, Rome, Italy
Contact: chiara.donfrancesco@iss.it

Background: The WHO recommends a 30% relative reduction in mean population intake of salt/sodium within 2025 (baseline 2010) and an adequate potassium intake. To these ends, the Italian Ministry of Health (MoH) has strengthened prevention/health promotion. To update the assessment of the habitual salt and potassium intake in the Italian general adult population, national health examination surveys (HESs), funded by the MoH-CCM, are conducted within the CUORE Project.

Methods: In 2023 a new HES started including salt and potassium intake assessment by the use of 24h urine collection. Up to now, data from random samples of residents in 7 Regions (of 20 regions) distributed in North, Centre and South of Italy and aged 35-74 years are available (686 men, 702 women). Urinary excretion is assayed by a central lab. Persons with urinary volume < 500 ml and/or a urinary creatinine content referred to body weight outside the range of population mean ± 2 standard deviations are excluded.

Results: Out of 657 men and 671 women, mean level of salt per day was 9,2 g (95% CI: 9,0-9.5 g) and 7,1 g (6,9-7,3 g) respectively, and mean level of potassium per day was 2,9 g (2,8-3,0 g) and 2,4 g (2,3-2,5 g) respectively. A salt intake level lower than the WHO recommended target of 5g/day was detected in 9,5 % (5,2 -13,9 %) of men and 23,7 % (17,5 -29,9 %) of women and a potassium intake level higher than the WHO recommended target of 3510 mg/day was detected in 22,4 % (16,3 -28,6 %) of men and 9,7 % (5,4 -14,0 %) of women.

Conclusions: These preliminary data showed that in Italian adults the average salt intake is still higher and the average potassium intake is still lower than recommended. Compared to 2008, the habitual salt intake decreased of about 12% in 2018 and remained stable in 2023; the habitual potassium intake remained stable in 2008, 2018 and 2023.These results justify and encourage the ongoing preventive initiatives of MoH, facilitating the meeting of WHO targets.

Key messages:

- In Italian adults the average salt intake is still higher than recommended and the habitual salt intake decreased compared to 15 years ago.
- In Italian adults the average potassium intake is still lower than recommended and remained stable compared to 15 years ago.

Abstract citation ID: ckae144.1017

Are early emotional and behavioral problems related to subsequent asthma in preschool children?

Helena Fabian

H Fabian[1], N Durbeej[1], J Dahlén[1], A Dahlberg[1]
[1]Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden
Contact: helena.fabian@pubcare.uu.se

Background: The most common mental health problems in preschool children are emotional and behavioral problems, and one of the most common chronic inflammatory diseases in children is asthma. Most research on the relationship between emotional and behavioral problems and asthma includes school-aged children. The current study aimed to explore the association between emotional and behavioral problems during preschool years and the risk of asthma in a Swedish context.

Methods: The study was a longitudinal cohort study, with 6954 children aged 3-5 years for which data on emotional and behavioral problems through the Strengths and Difficulties Questionnaire were collected in Uppsala Region, Sweden, between 2013 and 2017. The cohort was followed with data from the National Patient Register from 2013 to 2022. Asthma was defined as having at least three diagnoses (ICD-10 codes: J45-J46) during follow-up. Unadjusted and adjusted cox regression models were used to analyze data.

Results: A total of 269 children (3.9%) had diagnosed asthma during follow-up. Preliminary results show that children with emotional symptoms, rated separately by mothers (HR: 1.62, 95% CI: 1.20-2.20), fathers (HR: 1.49, 95% CI: 1.10-2.03), and preschool teachers (HR: 1.53, 95% CI: 1.08-2.16) had increased risk of being diagnosed with asthma according to unadjusted cox-regression models. In addition, children with total emotional and behavioural problems, rated by fathers (HR: 1.51 95% CI: 1.10-2.07) were also at higher risk of being diagnosed with asthma. These associations remained significant when adjusting for background and sociodemographic factors.

Conclusions: Our findings point to the significance of a clinical awareness of the relation between emotional and behavioral problems and asthma in young children. Our findings highlight the importance of also considering somatic problems, including asthma, in children with early signs of emotional and behavioral problems.

Key messages:

- Emotional and behavioral problems in preschool children is related to being diagnosed with asthma.
- Somatic problems, as asthma, needs to be considered in children with emotional and behavioral problems.

7.S. Poster walk: Public health innovation and transformation

Abstract citation ID: ckae144.1018
Systematic review of clinical effectiveness and safety of abdominal aortic aneurysm screening in men

Elaine Foley

E Foley[1]*, K Jordan*[1]*, A Lopez*[1]*, M Carrigan*[1]*, A Maher*[1]*, M O'Neill*[1]*, M Ryan*[1,2]*, S Spillane*[1]
[1]Health Technology Assessment, Health Information and Quality Authority, Dublin, Ireland
[2]Department of Pharmacology & Therapeutics, Trinity Centre for Health Sciences, Trinity College Dublin, Dublin, Ireland
Contact: efoley@hiqa.ie

Background: Abdominal aortic aneurysm (AAA) is characterised by a bulging in the aortic wall. AAA is typically asymptomatic until aneurysm rupture, which is associated with a very high mortality rate (approximately 80%). In the context of an ageing population and increasing life expectancy, innovative approaches to early detection and intervention are needed. The aim of this review was to assess the clinical effectiveness and safety of one-time ultrasound screening for AAA in men.

Methods: Systematic searches were conducted in electronic databases and grey literature sources. The primary outcomes of interest were AAA-related mortality, AAA rupture, all-cause mortality, rate of surgical repair and safety. The following study designs were included: systematic reviews, randomised controlled trials (RCTs), comparative observational studies and population-based non-comparative observational studies.

Results: Results from a systematic review by the US Preventive Services Task Force analysed 4 population-based RCTs, showing that one-time population-based screening for AAA in men (≥ 65 years) led to significant reductions in AAA-related mortality (OR = 0.65, 95% CI: 0.57 to 0.74), AAA rupture (OR = 0.61, 95% CI: 0.54 to 0.69) and emergency surgeries (OR = 0.53, 95% CI: 95% CI: 0.44 to 0.64) at 13-15 years follow-up, relative to no screening. Separate to this systematic review an additional 24 studies reported on clinical effectiveness, safety and psychosocial harms of AAA screening. Limited evidence from these studies suggest screening was associated with a reduction in AAA-related mortality and rupture but also transient psychological distress in some cases.

Conclusions: One-time ultrasound screening in men $\geq$65 years appears to offer benefits in terms of reducing AAA ruptures and AAA-related mortality, though the balance of benefits and harms requires careful consideration. In an ageing population, AAA screening could be transformative, by reducing mortality and rupture risks.

Key messages:

- One-time ultrasound screening for AAA in older men ($\geq$ 65 years) can reduce AAA-related mortality and rupture.
- In the context of an ageing population in Europe, AAA screening could be transformative, but benefits must be weighed against potential risks.

Abstract citation ID: ckae144.1019
Public health innovation labs framework development: a design study of GGD West-Brabant Netherlands

Skander Essafi

S Essafi[1,2]*, E van Eck*[2]*, K Tabeau*[1]
[1]Erasmus School Health Policy Management, Erasmus University Rotterdam, Rotterdam, Netherlands
[2]Innovation Lab, GGD West-Brabant, Breda, Netherlands
Contact: skander.es@gmail.com

Introduction: Innovation Labs are spaces that encourage the creation, development and testing of novel ideas within organizations. While there are known frameworks for the organization of such labs in the private sector, current literature does not reflect a framework for developing a public health Innovation Lab (PHI-Lab) specifically.The aim of this study was to develop an evidence-based framework for a PHI-Lab together with the Dutch Municipal Health Service(GGD).

Methods: Our design thinking study consisted of 4 phases: Discovering, Defining, Creating and Evaluating.An initial framework was developed based on the public and public health sectors in the literature.To create and evaluate the framework,a document analysis of the GGD was performed,and co-creation and testing sessions were organized with 11 internal and 11 external stakeholders of the GGD.

Results: The final PHI-Lab framework is composed of: rationale, enablers and barriers, environment, approach, outcomes and values. Findings emphasized practical reasons for investing in a PHI-Lab, such as the shortage of health professionals.Stakeholders highlighted that proactive leadership and innovation culture are crucial enablers for the setup of the PHI-Lab.The right space and human resources (environment) and methods including design thinking and cross-collaboration (approach) were highlighted as important strategies for overcoming innovation challenges.Despite barriers such as bureaucracy and resource limitations, tailoring solutions to organizational objectives is key to the PHI-Lab's success and sustainability, with added values of inclusiveness, adaptability and fun.

Conclusions: This study highlighted some practical additions to the initial framework that are specific to the public health setting, although mostly an adaptation from the public sector.Findings emphasize that there isn't a one-size-fits-all solution to develop a PHI-Lab.This framework has the intention of benefiting other public health organizations.

Key messages:

- The framework has the intention of benefiting other public health organizations within established networks and partnerships.
- Proactive leadership and innovation culture are crucial enablers for the organizational setup of the innovation lab.

Abstract citation ID: ckae144.1020
Driving innovation in primary healthcare though co-creation with stakeholders in Switzerland

Anna Romanova

A Romanova[1,2]*, M Oetterli*[3]*, F Landis*[3]*, A Balthasar*[1,2,3]*, P Käppeli*[1,3]*, N Messerli*[1,2]*, S Mantwill*[1,2]
[1]Faculty of Health Sciences and Medicine, University of Lucerne, Lucerne, Switzerland
[2]Swiss Learning Health System, University of Lucerne, Lucerne, Switzerland
[3]Interface Politikstudien Forschung Beratung, Lucerne, Switzerland
Contact: anna.romanova@unilu.ch

Issue/problem: Primary healthcare systems worldwide face challenges such as socio-demographic shifts, increasing chronic diseases, rising costs, and workforce shortages, demanding innovative solutions for the future of primary care.

Description of the problem: Addressing the complex challenges of creating a resilient primary healthcare model involves considering interdependent factors such as health policies, funding, workforce training, technology, and evolving diseases, alongside diverse stakeholder interests. To tackle this, the 'Health2040: Co-creation of a

Future Outpatient Primary Healthcare Model in Switzerland' project was launched in 2023 to develop a forward-looking model by integrating insights from various stakeholders.

Results: The project involved 40 stakeholders, including patients, researchers, healthcare professionals, policy-makers, and insurers, in two full-day workshops aimed at co-creating a vision and actionable framework for Switzerland's future primary care. The first workshop focused on developing and visualizing potential models, while the second targeted the transition to these new models and the creation of an implementation plan. These sessions were underpinned by a comprehensive literature review on emerging primary care models, providing a scientific foundation for the discussions.

Lessons: Successful co-creation requires significant preparatory efforts and innovative creativity techniques, such as Future Newspapers, brainstorming, games, and user personas. Engaging stakeholders throughout various stages of the project helped to enhance relevance. Feedback from a steering group on the workshop's concept, methodologies, and evidence synthesis was instrumental. Healthcare practitioners also contributed their insights on patient personas, ensuring the models developed were pertinent to actual healthcare practices. Stakeholder engagement process was essential for fostering innovative ideas and ensuring stakeholder buy-in for the developed solutions.

Key messages:

- Co-creation with stakeholders is a promising way to develop innovative solutions for health systems.
- Integrating stakeholder input is crucial at all the project stages, from preparation to evaluation.

Abstract citation ID: ckae144.1021
Commuting violence: Social, mental and academic consequences. Is this concept necessary to adopt?

Miranda Hernández Rico

M Hernández Rico[1], JE Villegas Dominguez[1], MP Ramos Tenorio[1], FY Vicente Molina[1], JC Viñas Dozal[1], F Ruiz Garcia[1]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
Contact: mi.hdez.r16@gmail.com

Introduction: Violence has emerged as a pressing public health issue due to its global impact, prompting the need to coin the term 'commuting violence' (CV). This term refers to any form of aggression experienced by students traveling from the University to other locations such as their homes or vice versa, considering that this situation could have health and academic consequences for students.

Objectives: To determine the consequences associated with CV in university students.

Methods: A cross-sectional and prospective study was conducted, including students from a Medical School in Veracruz, Mexico, from August to December 2023. Invitations to participate were extended to students of medicine, chiropractic, and radiology technology.

Results: A total of 279 participants with a mean age of 20 (±3.0) years were included. 89.6% of students perceive insecurity on their journey to the university, primarily due to the presence of suspicious individuals (93.9%); 70.6% of participants reported knowing a peer who has experienced CV, leading them to avoid certain streets (92.5%) to avoid it. Insecurity felt on the journey home from school showed a significant association (OR/CI95%) for anxiety due to JV of (7.2/3.2-16), stress due to CV of (11.1/4.74-25.9), and paranoia due to CV of (4.48/2.02-9.92). A total of 140 (50.2%) students reported experiencing CV, with the most frequent manifestations being sexual harassment (79.3%) and verbal harassment (57.8%), as well as two (1.4%) attempted rapes. Experiencing CV was positively associated with students avoiding class schedules before 8:00 a.m. (3.6/1.69-7.63) and after 6:00 p.m. (4.6/1.7-11.94), as well as absenteeism (7.37/2.51-21.67) and thoughts of dropping out (12.9/2.75-60.36) ($p < 0.05$).

Conclusions: PV is a relevant situation that exists within the well-being of students, impacting them both in anticipation and when faced with it. The concept of CV should be considered for use in future research.

Key messages:

- We propose the concept of Commuting violence as an element to be taken into account since it has been demonstrated that this situation interferes with the academic activity of the students.
- Commuting violence occurs during academic activities, so universities should propose actions to make students feel safe on their daily journey to the university.

Abstract citation ID: ckae144.1022
'Positive disruption': catalysing system-wide work on health inequalities through embedded research

Andrew Passey

A Passey[1], J Woodall[1]
[1]School of Health, Leeds Beckett University, Leeds, UK
Contact: a.c.passey@leedsbeckett.ac.uk

Background: This presentation explores embedded research as an innovative model for bridging system-level knowledge to action gaps in public health. Embedded researchers (ERers) are university-employed researchers co-located in public health organisations, who work to boost capacity in these organisations to tackle inequalities by better use of evidence in decision-making, evaluation and service improvement

Methods: Drawing on the initial phase of the role and wider literature, we qualitatively reflect on strengths and limits of a system-level ERer model. Most ERer evidence draws on a one-to-one organisational model. This presentation explores a different model of an ERer embedded in and working across a public health system (health services, municipality, third sector) in a large city in north England

Results: Our focus is on catalytic features of the ERer role (1) positionality: being embedded at system-level gives fuller understanding of inter-organisational connections and of the implications of emergent system changes; (2) convening: bringing together partners improves mutual awareness and builds interest in collectively pursuing research aligned to identified population health needs and public health priorities in the city; (3) co-production to build capacity: working with a new cross-organisational partnership to collectively address issues constraining opportunities to pursue system-level research; working with the municipality to explore the production/use of research to inform decisions on approaches towards health inequalities. This includes work on links between public health and other functions focused on social determinants of health

Conclusions: This presentation outlines distinctive consequences of system-level embedded research in a city-wide public health system. It critically appraises the transferability of this model of knowledge production and mobilisation at the intersection of system and cross-organisational action on health inequalities.

Key messages:

- System-level embedded research is an innovative model for helping to bridge system-level knowledge to action gaps in public health.
- The model has catalytic benefits and transferability potential, although this needs to be considered in relation to the specific context for proposed system-level embedded research.

Abstract citation ID: ckae144.1023
The NHS London Legacy and Health Equity Partnership: Evaluation of an equity lens framework

Leonora Weil

A Zuriaga-Alvaro[1], J Inskip[1], E Johnson[1], L Kamau[1], J Wilson[1], LG Weil[1,2]
[1]NHS Legacy and Health Equity Partnership, National Health Service, London Region, London, UK
[2]United Kingdom Health Security Agency, London Region, London, UK
Contact: leonora.weil@ukhsa.gov.uk

Background: Disparities in COVID-19 vaccination uptake emphasised stark inequalities linked to ethnicity and deprivation, highlighting lack of trust and access barriers. London health leaders committed to create a community-centred legacy through the development of the NHS Legacy and Health Equity Partnership (LHEP); A novel 2-year programme aiming to close the equity gap in vaccinations, screening and access to health, focused on underserved communities, delivered in collaboration with London partners and communities. LHEP focused on 12 unique programmes with a key role of system leadership. Outputs included 15 reports, 6 conference presentations, 7 academic publications, 6 community workshops and 5 toolkits including development of an overarching LHEP framework aiming for long-term legacy.

Methods: An evaluation was designed to assess the benefits and limitations of the programme and framework through 16 semi-structured interviews and 5 focus groups delivered with key stakeholders. Ethical approval was obtained from the UKHSA Research Ethics Group. Data was coded inductively and drawn into themes.

Results: LHEP was said to add value through a) a dedicated team championing health equity and visible focus of leadership within the equity space b) fostering community engagement enabling dialogue between health systems and communities c) advocating co-production, building trust, focusing on communities in vulnerable circumstances d) programme innovation and agility d) drawing from COVID-19 lessons and disseminating learning. Interviewees stressed a legacy beyond vaccinations, establishing London as a blueprint for others.

Conclusions: Lessons were drawn into the ‘LHEP Approach for Health Equity’, a concise framework to guide partners to embed health equity, gathering 4 key tenets to ensure ‘no community is left behind’; data, evidence and learning; commitment from leaders and strong partnerships, allow for innovation and consider sustainability and communities at the centre.

Key messages:

- Legacy and Health Equity Partnership is a 2-year multistakeholder programme aiming to tackle inequalities for the diverse communities of London that built evidence and led system change.
- Evaluation stressed the impact of establishing London as a blueprint to follow and a framework to guide and support partners striving for health equity.

Abstract citation ID: ckae144.1024
Equity assessment in innovative cancer genomic interventions: the Can.Heal project

Ana Molina-Barceló

A Molina-Barceló[1], P Romeo-Cervera[1], M Pinto-Carbó[1], M Vanaclocha-Espí[1], T de Pablo-Pardo[1], R Alessandrello[2], E Van Valckenborgh[3], M van den Bulcke[3]
[1]Cancer and Public Health, Foundation for the Promotion of Health and Biomedical Research, Valencia, Spain
[2]Value Based Procurement, Agency for Health Quality and Assessment of Catalonia, Barcelona, Spain
[3]Department of Epidemiology and Public Health, Cancer Centre, Brussels, Belgium
Contact: ana.molina@fisabio.es

Background: The Can.Heal project (https://canheal.eu/) aims to build a cancer and public health genomic platform. The aim of this study is to assess the extent of integration of the equity perspective in the Can.Heal project.

Methods: An Equity Guide was developed in the context of the Can.Heal project including guidance and support to implement equity-focused actions in cancer genomics. The Guide consists of a comprehensive set of 18 equity actions organized into three domains: 1) capacity-building, 2) cancer genomic research, 3) cancer genomic services. An equity self-assessment tool was developed to assess the degree of incorporation of the equity perspective in the innovative interventions included in the project, for both the definition and the execution phase. A descriptive analysis was performed.

Results: Taking into account the 3 domains, the most progress in incorporating equity perspective, in both the definition and execution phase, is observed in the “capacity building” domain (75% and 30%), followed by the “cancer genomic services” domain (43% and 11%), and the “cancer genomic research’ domain (33% and 10%). Equity actions mostly followed in both phases are: “multidisciplinary approach” (80% and 40%), “networking” (70% and 20%), and “ethics, law, and citizen engagement” (80% and 40%). The least performed actions are: “equity evidence assessment” (0% and 0%), “equity in return of genomic results” (29% and 0%), “patients’ experience’ (13% and 0%) and “diverse samples in research studies and clinical trials” (25% and 25%).

Conclusions: Equity perspective is more considered in the definition phase. More efforts should be done in the execution of equity actions in the Can.Heal project.

Key messages:

- Including a multidisciplinary approach, networking and considering ethics, law, and citizen engagement are the most followed equity actions in Can.Heal project.
- There is a need to integrate equity perspective in Can.Heal project, especially in cancer genomic research.

Abstract citation ID: ckae144.1025
Data governance challenges on smart home involving multiple research sites

Kang Wang

K Wang[1], S Cao[2], P Morita[1]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada
[2]Systems Design Engineering, University of Waterloo, Waterloo, Canada
Contact: k386wang@uwaterloo.ca

Background: The development of Ambient Assisted Living (AAL) technology has great potential for ubiquitous health monitoring through collaboration between multiple research sites, but its use poses significant challenges to data governance. This study aims to investigate data governance challenges arising when smart home data flows across different research sites.

Methods: A four-analytic-dimension method was used to identify potential data-related issues that may occur when heterogeneous smart home data moves around multiple research sites. These dimensions include data domain, stakeholders, value, and governance goal.

Results: Data domain has difficulty in categorizing new data types generated by analytical models without a specified agreement, and determining the regulations for varying levels of anonymization and privacy protection is unclear in the AAL research field. Stakeholders in the AAL project may hold have different norms and practices for data use. Although some common values may be shared, such as improving the quality of homecare, conflicts may still arise and need to be regulated by data governance. Shifting AAL data between stakeholders may reduce its value, as different stakeholders may have varying interests. For instance, removing identifiable information from data to preserve privacy may reduce its value for researchers exploring individuals' activity patterns. Governance goals are objectives for maintaining and facilitating data. While some governance goals can be widely acknowledged and shared, such as ensuring data security and privacy, conflicts may still exist over others, such as data access.

Conclusions: The big data generated by smart home technology highlights the need to develop proper data governance models to regulate data. This study's implications include a better understanding of potential data-related challenges when data flows around multiple research sites, helping policymakers set up suitable data governance models.

Key messages:

- AAL tech for health monitoring poses data governance challenges due to varying stakeholder norms and values.
- Proper data governance models need to be developed for AAL data as it remains challenges in data domain, stakeholders, value, and governance goal.

Abstract citation ID: ckae144.1026
The role of communication in the successful implementation of the Slovenian NCCP

Katarina Plantosar

K Plantosar[1], A Duratovic Konjevic[1], S Tomsic[2], J Zgajnar[3], B Zakotnik[4], K Torkar[2]
[1]Communication Department, Institute of Oncology Ljubljana, Ljubljana, Slovenia
[2]Epidemiology and Cancer Registry, Institute of Oncology Ljubljana, Ljubljana, Slovenia
[3]Division of Surgery, Institute of Oncology Ljubljana, Ljubljana, Slovenia
[4]Division of Medical Oncology, Institute of Oncology Ljubljana, Ljubljana, Slovenia
Contact: kplantosar@onko-i.si

Issue: Cancer remains a significant global public health challenge, necessitating comprehensive strategies for effective control and management. Slovenian National Cancer Control Programme (NCCP) addresses this challenge by prioritizing proactive communication with various stakeholders engaged in cancer care planning, delivery and advocacy. The communication strategy within this programme plays a pivotal role in its successful implementation.

Description of the problem: Active engagement and collaboration among stakeholders is crucial for achieving the programme's objectives. NCCP seeks to address this challenge through various communication activities by fostering dialogue, sharing best practices, and facilitating networking opportunities among oncology professionals throughout Slovenia. Additionally, it seeks to strengthen partnerships with sectors beyond health and prioritizes engagement with cancer patient advocacy groups.

Results: The programme has devised a long-term communication strategy, guiding annual communication plans to engage stakeholders and foster support for its objectives. Notable communication activities in the period 2022-2024 include: organizing annual meetings for different oncology stakeholders including cancer patient associations, hosting impactful professional events, conducting visits to regional cancer hospitals, distributing e-newsletters and managing a NCCP website. Initial outcomes indicate strengthened communication and collaboration among professionals and institutions in the field of oncology nationwide. Engagement with patient advocacy groups has facilitated discussions on topics important to patients.

Lessons: Effective communication with diverse stakeholders is crucial for comprehensive cancer control. Collaborating across sectors enhances the impact of cancer control initiatives. Enhanced networking fosters innovation and synergy among oncology professionals, positioning Slovenia for greater success in cancer control.

Key messages:

- Slovenia's NCCP prioritizes proactive communication, fostering collaboration among stakeholders. Annual events, newsletter, and partnerships strengthen awareness and drive comprehensive cancer control.
- Long-term communication strategy of Slovenia's NCCP drives stakeholder engagement, and supports strategic objectives. This proactive approach strengthens comprehensive cancer control efforts.

Background: Molecular Tumor Boards (MTBs) are pivotal in the current management of oncological patients, integrating molecular diagnostics with clinical expertise to tailor precise treatments. Within the framework of EU-funded 'Building EU Cancer and Public Health Genomics platform' (Can.Heal) project that aims at streamlining genomics implementation in public health, we are developing a policy brief to promote MTBs' adoption across the EU.

Methods: A two-step approach was employed to delineate strategies for MTB implementation. Firstly, we conducted a systematic review and meta-analyses (if feasible) up to November 2023, on studies assessing the MTBs' clinical impact. Secondly, based on the results of the review, we conducted an expert consultation to identify key areas to improve MTBs implementation and impact.

Results: 48 studies were included, whose results were heterogeneous in terms of organizational aspects and number of experts involved (mean n: 6, range: 2-19). Average implementation rate of the recommendations issued by the MTB was 43.1% (3.2%-92%), with a turnaround time from testing to recommendation of 36 days (15-58). By pooling data from 12 studies ($n = 1623$), a favorable overall survival [HR = 0.63 (95% CI 0.53-0.76), I2 42.0%] was reported for patients managed in hospitals with MTBs versus not. Similar estimates were reported when the outcome was progression free survival [HR = 0.63 (95% CI 0.54-0.72), I2 = 0.0%], based on 8 studies ($n = 1106$). The subsequent expert consultation identified 5 key areas for MTB implementation: genetic data sharing, standards for results' interpretation, equitable access to MTB, optimization of the testing process, and funding and reimbursement.

Conclusions: The policy brief underscores the significant clinical benefits of MTB-recommended therapy, improving patients' outcomes. Nevertheless, addressing resource allocation and infrastructure development is essential to optimize MTB utilization and enhance patient outcomes.

Key messages:

- Our results highlight that MTBs-recommended therapy translates into tangible clinical benefits.

- More fundings and resources are needed to optimize and fully implement MTBs in clinical practice.

Abstract citation ID: ckae144.1028

Collection and use of patient-reported experience measures: approach to improve health care

Irisa Zile-Velika

I Zile-Velika[1], *V Mavcutko*[1], *E Cudina*[1], *I Liepina*[1], *I Gavare*[1]
[1]Department of Research and Health Statistics, Centre for Disease Prevention and Control, Riga, Latvia
Contact: irisazile@inbox.lv

Background: Patient experience is one of the fundamental determinants of healthcare quality. There is progress in the collection of PREM in national level for hospitalized patients since 2020 in Latvia.
Aim: Analyze (2020.-2022.) in-patients Top-box rates about communication, share-decision making, patient safety and Net Promoter Score (NPS).
Methods: Project starting point was 2019. Agreement with EC, Sant'Anna School, Ministry of Health and Centre for Disease Prevention and Control of Latvia. Since 2020, the collection of PREM has been taking place regularly in hospitals (around 40% from all hospitals) and on average 20% response rate of those who agreed to participate in the survey. PREM questionnaire according to HCAHPS (Consumer Assessment of Healthcare Providers and Systems) standards, including Picker Institute patient experience questions. In line with OECD (Organization for Economic Co-operation and Development) recommendations, patient safety issues are also included. Top-box rates (most positive response) and percentiles (25th - 75th) were calculated.
Results: Totally 17019 adult (18 years and more) patient responses were analyzed with response rate 20.3% (n = 83983). 74.6% (67.5-78.2) during hospital stay doctors always explain things in a way you could understand and sufficiently involved in the decision-making process of treatment - 75.0% (70.1-81.4). During hospital stay 4.1% (n = 601) experienced patient safety incidents which were patient-reported. The most common groups were wrong patients, medication errors, incl. adverse drug reactions and falls. Hospitals achieved a NPS of 61 for 3 year period (2020.-2022.).
Conclusions: Collecting information about the patient experience may be the starting point for engaging patients and moving to more patient-centered health care. The results of these in-patient PREM data can be used to identify areas of improvement and make changes to better meet the needs and expectations of their patients.
Key messages:

- It is a good practice for the implementation of new health care quality data - patient experience reported measures at the national level.
- Feedback about the patient experience on regular basis provides insight into patient needs, preferences and values, which can help to improve the quality and safety of care.

[5]MRC Epidemiology Unit, University of Cambridge, London, UK
[6]Center for Genomics and Systems Biology, New York University, New York, USA
Contact: ma4643@nyu.edu

Background: The UAE Healthy Future Study (UAEHFS) is one of the first large prospective cohort studies in the Gulf region which examines causes and risk factors for chronic diseases among adult UAE nationals. Missing values are often unavoidable in empirical research and can in many cases, lead to bias. The aim of this study is to estimate the percentage of depression in the UAEHFS pilot data using the eight-item Patient Health Questionnaire (PHQ-8) variables, using different statistical methods.
Methods: Five common statistical machine learning methods of handling missing values were included in this analysis. These are mode imputation, k-nearest neighbor (KNN) imputation, classification, and regression trees (CART), random forest (RF) imputations, and random sample from observed values (Sample). 100 multiple imputations were used.
Results: 487 (94.2 %) eligible participants were included in the analysis. 231 (44.7%) were included in the complete case analysis. The median age was 30 years (Interquartile-Range: 23 - 38). More males (67.8%) than females included in the analysis. The estimated percentage of depression was 8.4%, 8.9%, 9.9%, 12.5%, 15.4% and 17.9% by the mode, complete case, sample, RF, CART, and KNN respectively. In additional analyses, the estimated proportions of depression were 11.5% by the Complete Case, 11.9% by KNN, 13.2% by K-means clustering, and 13.2% by Random Forest.
Conclusions: The estimated percentage of depression in the UAEHFS pilot data varies between the applied methods of handling missing values. This shows that the problem of missing values in the variables is not negligible. Further research is needed using multiple imputations in the main UAEHFS dataset after completing recruitment.
Key messages:

- For the depression missing values, we recommend using multiple imputations not to generate data but to prevent the exclusion of observed data.
- To have a better estimate of the percentage of depression, is recommended to use different machine learning methods.

Abstract citation ID: ckae144.1030

Improving data quality by implementing an electronic medical record seems to depend on the context

Florian Wurster

F Wurster[1], *T Hansen*[1], *J Jaschke*[2], *J Köberlein-Neu*[2], *MR Okumu*[1], *H Pfaff*[1], *C Rusniok*[1], *U Karbach*[1]
[1]IMVR - Quality Development and Evaluation, University of Cologne, Faculty of Human Sciences & Faculty of Medicine, Cologne, Germany
[2]Health Economics and Health Services Research, University of Wuppertal, Wuppertal, Germany
Contact: florian.wurster@uni-koeln.de

Background: The European healthcare system is reliant on its digital transformation to deal with challenges like rising expenditures or workforce shortage. The digital transformation is inevitably accompanied by the implementation of electronic medical records (EMR) and the ongoing adaptation of existing ones. Systematic reviews indicate that this process can have an impact on medical records data quality (DQ) [1]. At micro level, DQ is essential to ensure high quality of care. At macro level, sufficient DQ is a prerequisite for big data analyzability. In this field, completeness is a commonly analyzed dimension of DQ and empirical results indicate that completeness can improve but also deteriorate as a result of the described implementation or adoption of EMRs [2]. The aim of this work was to investigate the implementation of EMRs in comparable settings and to observe and discuss possible differences in the change in DQ.

Methods: Data was collected on three surgical clinics of a German academic teaching hospital before and after the implementation of an EMR. Paper-based and electronic medical records were compared. Analysis focused on ten items that were commonly documented in both record types (e.g. pain). T-tests and χ^2-tests were used to compare average completeness per record type and percentage of completeness per item.

Results: A total of $N = 659$ records was analyzed. Overall, results show a significant improvement in completeness from an average of 6.0/10 items in the paper-based record type to 7.2/10 in the EMR ($p<.05$). At clinic level, improvement rates vary from 0.9 to 1.4. At the level of the specific items, significant deteriorations are visible in certain clinics.

Conclusions: Results suggest that DQs variability is context-dependent (e.g. on the clinic's turnover rate or its patient's length of stay). Due to the unavoidable digital transformation, a detailed context and needs analysis involving all stakeholders should be carried out before any changes are made.

Key messages:

- The application of advanced analytics such as big data or AI training is reliant on the availability of high-quality datasets.
- Electronic medical records have been demonstrated to enhance data quality, but it remains uncertain how and why improvements appear to be context-dependent.

The COVID-19 pandemic, along with seasonal influenza, highlights the need for innovative public health strategies. Co-administering COVID-19 and influenza vaccines offers advantages for healthcare workers (HCWs), streamlining vaccination efforts and enhancing public health resilience. Recent evidence supports the safety and efficacy of this approach, endorsed by health authorities worldwide. However, its acceptance remains a concern. This study explores HCWs' acceptance of vaccine co-administration in three campaigns post the introduction of the anti-SARS-CoV-2 vaccine. During three consecutive flu seasons from October 2021 to January 2024, a cross-sectional study was conducted in a large Italian teaching hospital. Data for 2021/2022, 2022/2023 and 2023/2024 were compared, focusing on healthcare workers present in all datasets. McNemar's test examined changes in acceptance of co-administration. In addition, a conditional logistic regression model was designed to assess the determinants of co-administration through the vaccination campaigns in the three years. During these vaccination campaigns 7457 HCWs were observed (62.78% women, median age 43). Co-administration surged, particularly in 2022/2023, showing a 280.71% increase, consistent across all professional categories ($p < 0.001$). Controlling for gender and professional category, acceptance of coadministration showed a significant association respectively with "open days" twice a month (OR 2.9 CI [2.7; 3.6]) and a hospital vaccination clinic two days a week on weekdays (OR 4.5 CI [4.1; 5.4]) compared to conducting vaccinations at a clinic open everyday during the campaign period; no association was highlighted with age. This study investigates a facet of an increasingly significant topic, demonstrating that co-administering vaccines for SARS-CoV-2 and influenza is emerging as an effective strategy in annual vaccination campaigns, thanks to its safety and the streamlining of logistical and organizational processes.

Key messages:

- The co-administration of vaccines offers a promising strategy to enhance vaccination rates among healthcare workers.
- By identifying factors influencing acceptance, it aims to inform targeted interventions for maximizing vaccine uptake and public health resilience.

Impact of infectious diseases associated with passenger ships on ports: a systematic review

Johannes Neumann

J Neumann[1], J Zimmermann[1], M Frese[1], S Kleine-Kampmann[2], M Dirksen-Fischer[2], V Harth[1], J Heidrich[1]

[1]University Medical Center Hamburg-Eppendorf, Institute for Occupational and Maritime Medicine, Hamburg, Germany

[2]Hamburg Port Health Center, Institute for Hygiene and Environment, Hamburg, Germany

Contact: joh.neumann@uke.de

Background: In an enclosed ship environment, close contact between passengers and crew members is inevitable. As a result, passenger ships can be a suitable environment for the transmission of infections between people. In this context, it is essential to establish effective prevention and control measures to protect the health of passengers and crew members while ensuring that shipping minimizes its contribution to the global spread of disease. The aim of this review is to provide knowledge on the impact of infectious diseases on board large passenger ships on the port, the port community and other land-based operations to better understand the effectiveness of the prevention, mitigation and management (PMM) measures implemented, in particular ship-to-shore communication.

Methods: A systematic literature review was conducted according to the PRISMA guidelines, searching three databases and including additional articles from hand searches up to November 2023. Peer-reviewed studies of infectious disease outbreaks on large passenger ships that described ship-shore interaction, port preparedness, impact on the port community, and impact on other modes of transportation were included.

Results: A total of 555 publications were initially identified. Finally, 22 articles were included. Most studies reported on COVID-19 outbreaks on cruise ships; other communicable diseases reported were influenza, gastroenteritis and varicella. The articles highlighted the importance of comprehensive management plans and proactive risk assessment during infectious disease outbreaks.

Conclusions: Effective stakeholder collaboration, ship-to-shore communication, and coordination of medical transport, isolation, and quarantine measures are essential components of infectious disease PMM in maritime passenger shipping and ship-to-shore operations. The findings suggest that further research is needed to improve the evidence and knowledge about this important issue.

Key messages:

- Proactive risk assessment, comprehensive management plans and effective collaboration are critical to preventing, mitigating and managing infectious diseases on passenger ships.
- Overall, very little evidence of effective practices and capacities related to the interaction of passenger ships with land-based operations, stakeholders and port communities.

Evaluating the psychological antecedents of vaccination in applicants to primary health care centers

Cansu Özbaş

C Özbaş[1], M Tokatlı Doğan[1], FN Baran Aksakal[1]
[1]Public Health, Gazi University, Ankara, Türkiye
Contact: cansuultav@gazi.edu.tr

Background: Vaccine acceptance can be enhanced by understanding the psychological antecedents of vaccination. The 5C model identifies relevant factors: confidence, complacency, constraints, calculation, and collective responsibility. This study aims to evaluate these factors among primary health care center applicants in Ankara.

Methods: A total of 1712 individuals aged 18 and over, who visited primary health care centers, participated in the study. The face-to-face survey included questions about sociodemographic characteristics, Vaccination Psychological Antecedents Scale, individuals' attitudes and behaviors towards vaccination, and internet usage. Factors with a significance level of $p < 0.20$ from previous analyses were assessed using multivariate logistic regression analysis. The factors influencing the decision to get vaccinated without hesitation when necessary were investigated.

Results: The likelihood of getting vaccinated without hesitation in necessary situations is higher among those with higher income than expenditure(OR:1,517, 95%CI=1,094-2,104), those without chronic diseases in their family(OR:1,411, 95%CI=1,109-1,795), and those who do not actively use social media(OR:1,380, 95%CI=1,051-1,813). Additionally, an increase in the confidence score(OR:1,276, 95%CI=1,239-1,315) and the collective responsibility score (OR:1,096, 95%CI=1,058-1,134), was associated with an increased likelihood, while an increase in the calculation dimension(OR:0,928, 95%CI=0,895-0,962) was associated with a decreased likelihood.

Conclusions: Income status, presence of chronic illness in the family, active social media usage, confidence, collective responsibility, and calculation are factors influencing vaccine acceptance without hesitation. Communication strategies based on trust and collective responsibility should be developed to improve vaccine acceptance. The risk factors causing vaccine hesitancy among social media users should be investigated, and measures should be taken.

Key messages:

- Develop trust-based, collective responsibility-focused communication to boost vaccine acceptance.
- Investigate and address social media-driven vaccine hesitancy.

Abstract citation ID: ckae144.1034
Human-swine interface: is the hepatitis E virus a real risk for humans?

Sara Arnaboldi

S Arnaboldi[1], F Righi[1], A Scarazzato[1], E Pavoni[1], V Filipello[1], D Lelli[2], T Trogu[2], A Lavazza[2], L Romanò[3], B Bertasi[1]
[1]Food Safety, Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Brescia, Italy
[2]Animal Health and Welfare, Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Brescia, Italy
[3]Biomedical Sciences for Health, University of Milan, Milan, Italy
Contact: sara.arnaboldi@izsler.it

Background: Hepatitis E virus (HEV) is the agent of hepatitis E, an emerging public-health infection with an increasing incidence in Europe. Due to the apparent lack of species barriers, HEV is considered a zoonotic agent, with swine as the main reservoir. This study investigated HEV prevalence in humans and domestic pigs in Northern Italy, a highly anthropic area with the highest pig farm density, to gain insights into the risk of HEV transmission from swine to humans.

Methods: A total of 508 blood samples were collected from blood donors (341 males and 167 females; from 18 to 66 years old) and from 1619 pigs in 40 different farms. Serological analyses were performed with ELISA to detect anti-HEV antibodies. In addition, 120 faecal pool samples collected from the pig farms with the highest seroprevalence and 69 salami produced in the same area were analysed to detect viral genome by Real-time PCR.

Results: In humans, HEV seroprevalence was 4.9% (CI95% 0.03-0.07); positive donors were mainly males, with seroprevalence increasing up to 12% (CI95% 0.09-0.15) in the 46-55 age group. Seroprevalence in swine was 53.00% (CI95% 0.50-0.55), with HEV detected in only 1% (CI95% 0.001-0.045) faeces. All food samples tested negative.

Conclusions: Even if the seroprevalence in pigs highlighted that HEV was actively circulating in the farms, the low seroprevalence in humans, the scarce HEV detection in swine faeces, and the absence in food products suggested that HEV transmission via faecal-oral or foodborne routes is unlikely, probably due to the implementation of severe biosecurity measures and high standards of hygiene in swine farms, and the continuous assessment of the critical points in the pig supply chain (from farm to fork). The serological surveillance of humans and the monitoring of farmed animals are needed to support the competent authorities in timely managing public health issues, improving human health and veterinary safety from a One Health perspective.

Key messages:

- In the human-swine interface is important to monitor HEV presence.
- The One Health approach is essential to control zoonotic diseases.

Abstract citation ID: ckae144.1035
Aedes aegypti surveillance under the International Health Regulations - experience at Madeira Island

Mariana Fialho

M Fialho[1], B Peixoto[2], J Moreno[3], M Carrapatoso[1], J Moreira[2], M Melim[4]
[1]Public Health Unit, Local Health Unit Médio Ave, Santo Tirso, Portugal
[2]Public Health Unit, Local Health Unit Gaia e Espinho, Gaia, Portugal
[3]Public Health Unit, Autonomous Region of Madeira's Health Service, Madeira, Portugal
[4]Regional Health Authority, Autonomous Region of Madeira, Madeira, Portugal
Contact: mariana.fialho@gmail.com

Problem: Aedes aegypti was first identified on Madeira Island in 2005, persisting since then. This mosquito transmits various haemorrhagic diseases and caused a Dengue outbreak in 2012-2013. The island has two seaports and one airport that may serve as points of entry or dissemination of these diseases, potentially leading to a new outbreak or international disease spread. We aimed to assess Ae. aegypti presence at the island's seaports and airport during 2023.

Description: Data was collected from 52 entomological panels produced by the Regional Health Department throughout 2023. This data is publicly available on the Institute of Health Administration's website. Ovitraps capture eggs, larvae, and pupae of Ae. aegypti, and BGtraps capture adult mosquitos. Positivity refers to the proportion of times an ovitrap recorded eggs in the entomological cycle.

Results: In 2023, there were 204 active ovitraps at the island (17 at the airport, 9 at Funchal's seaport 8 at Caniçal's seaport) and 24 BGtraps (2 at the airport, 2 at Funchal's port and 1 at Caniçal's port). Weekly reports revealed a median of 2243 (0-14448) eggs and 14 (0-234) mosquitos in all traps. Positivity was higher in the second semester. On average, ovitraps' positivity at the airport (avg 6.4%; 0-59%) and at Caniçal's port (avg 2.8%; 0-47%) were lower than the positivity of the island (avg 14.8%). Funchal's port had a higher positivity than the island (avg 15.9%; 0-67%). Per-ovitrap, the average weekly positivity rate rose by 15%, 10% and 5% at Caniçal's port, airport and Funchal's port, respectively, compared to 2012-2022.

Lessons: Ae. aegypti's eggs prevalence increased in 2023. The high positivity of eggs suggests an increased likelihood of mosquitos nearby. The detection of immature forms triggers actions to prospect the surrounding area for identification and elimination of breeding grounds, as well as the placement of salt in water accumulation areas. This is particularly important at high-traffic areas such as seaports and airports.

Key messages:

- The increase in Ae. aegypti egg positivity in 2023 on Madeira Island suggests a higher risk of disease transmission.
- It is essential to prioritize vector control measures at seaports and the airport in Madeira Island.

Abstract citation ID: ckae144.1036
The Contrasting Risk Communication Strategies of European Leaders during the COVID-19 Crisis

Saoirse Moriarty

S Moriarty[1]
[1]University of Birmingham, Birmingham, UK
Contact: smoriarty@randeurope.org

COVID-19 brought the role of leaders under intense scrutiny; their communication and framing of the crisis was crucial during the initial period of uncertainty. UK prime minister Boris Johnson and German chancellor Angela Merkel, managed and communicated the first wave of the crisis (March-June 2020) very differently. The clear contrast between pandemic response in two countries, with similar population sizes, wealth, and exposure to COVID-19, provides a lens through which to reflect on the different risk communication strategies utilized by both leaders. Following a grounded theory approach, the communication strategies of both leaders were examined. Transcripts from 31 press conferences from the initial announcement of COVID-19 to the end of the first wave were examined, and key themes identified. The analysis was framed using the CDC's Crisis and Emergency Risk Communication lifecycle model, allowing for a structured comparison across different phases of the crisis. The findings were examined through the broader socio-political context of their communication. Similar themes were present in both leaders' speeches, this included a focus on national identity; national strategy; health situation and social solidarity. However, they did so in markedly different ways. Merkel's consistent, evidence-based communication strategy was more closely aligned with risk communication best practice compared to Johnson's initial populist approach, which ultimately required a significant mid-crisis adjustment. Their different approaches also reflect their personas as political figures.

Key messages:

- The consistent, science-based communication strategies exemplified by Merkel closely followed risk communication best practice and is likely enhanced public compliance and trust during the crisis.
- These finding demonstrate the importance of incorporating a political lens to understand leaders approaches to risk communication and in public health research more broadly.

Abstract citation ID: ckae144.1037
From hesitancy to decision: shifts from intentions to uptake of Influenza and COVID-19 vaccines

Sara Moura

S Moura[1], *J Guerreiro*[2], *S Romano*[2], *E Paulino*[3], *A Rodrigues*[2,4,5]
[1]Public Health Unit, Entre Douro e Vouga Health Unit, Feira, Portugal

[4]Life and Health Sciences Research Institute, School of Medicine, University of Minho, Braga, Portugal
[5]ICVS/3B's-PT Government Associate Laboratory, Braga, Portugal
Contact: sarapintomoura@gmail.com

Background: Vaccine hesitancy is context-related and risks coverage. In a context of growing hesitancy, this study aims to characterize and identify factors underlying shifts in Influenza and COVID-19 vaccines intention and uptake.

Methods: Questionnaires were administered to a random sample of the 60+ years old Portuguese population ($n = 1400$), before (Q1) and at the end of the campaign (Q2). Sociodemographic, clinical data and intention to Influenza/COVID-19 vaccine uptake, using a Likert-scale (0-2: refusal; 3-7: hesitancy; 8-10: acceptance), were assessed on Q1. On Q2, self-reported vaccination status and motives. A logistic regression was performed to identify underlying factors.

Results: COVID-19 vaccine: 26.2% of those reporting acceptance went for non-uptake (214/818), stating low susceptibility/severity and fear of side effects. Factors associated were not having chronic disease (OR 2.07, $p<.05$) and age 60-64 (OR 4.16, $p<.05$). 25.5% of those who refuse went for vaccine uptake (27/106), stating self-initiative. Age 65 + (OR 43.82, $p<.05$) was associated with the shift; 56.4% of the hesitant individuals went for non-uptake (154/273). Higher education associates with non-uptake (OR 0.53, $p<.05$). Influenza vaccine: 11.5% of reported acceptance went for non-uptake (100/873), stating low susceptibility/severity. Associated factors were age 60-64 (OR 5.85, $p<.05$), not having chronic diseases (OR 2.64, $p<.05$) and living alone (OR 2.34, $p<.05$). 23.4% of those refusing decided for vaccine uptake (29/124), stating self-initiative/risk awareness. Associated factor was age 60-64 (OR 6.41, $p<.05$). 69.5% of hesitancy went for uptake (139/200). Chronic disease associates with non-uptake (OR 0.26, $p<.05$).

Conclusions: Intention is a good predictor but not decisive for uptake. This research provides better understanding of shifts in intention versus vaccine uptake, as well as factors and motives for hesitancy, allowing more robust interventions ahead of a vaccination campaign.

Key messages:

- For the Influenza vaccine, 13% of individuals reporting acceptance or refusal changed their mind. From the group reporting hesitancy, 70% decided for vaccine uptake.

- For the COVID-19 vaccine, 26% of individuals reporting acceptance or refusal changed their mind. From the group reporting hesitancy, 56% decided for non-vaccine uptake.

Seroprevalence and associated factors of toxoplasmosis in female children and adolescents in Germany

Laura Giese

L Giese[1], *F Seeber*[2], *A Aebischer*[2], *R Kuhnert*[3], *M Schlaud*[3], *K Stark*[1], *H Wilking*[1]
[1]Infectious Disease Epidemiology, Robert Koch Institute, Berlin, Germany
[2]Infectious Diseases, Robert Koch Institute, Berlin, Germany
[3]Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: giesel@rki.de

Background: Toxoplasmosis is a parasitic disease that causes a high burden of disease worldwide. Infections occur mainly through the consumption of undercooked meat or the ingestion of contaminated cat feces from the environment. In Germany, seroprevalence in adults is exceptionally high by international comparison (50%), which could be due to the frequent consumption of raw pork products. Comparable analyses for children and adolescents are missing but are needed to estimate the public health problem and to suggest countermeasures.

Methods: As part of the second wave of the representative German Health Interview and Examination Survey for Children and Adolescents (2014-2017), serum of 1,453 girls aged 3 to 17 years was tested for the presence of T. gondii IgG antibodies using enzyme linked fluorescence assay (ELFA). We calculated overall and stratified seroprevalence and used multivariable logistic regression models based on Directed Acyclic Graphs to identify associated factors. Adjusted odds ratios (aOR) with 95% confidence intervals (CI) are being reported.

Results: Overall, 94 out of 1,453 girls tested positive for T. gondii resulting in a seroprevalence of 6.3% (95% CI: 4.7-8.0). With each year of life, the chance of being seropositive increased significantly by 1.2 (95% CI 1.1-1.3). A low social status (aOr 2.7; 95% CI 1.3-5.9) and living in rural (aOR 2.6; 95% CI 1.1-5.7) or urban (aOR 2.2; 95% CI 1.1-4.4) areas were found to be associated with seropositivity. No regional distribution patterns or differences between vegetarians and non-vegetarians were seen.

Conclusions: Six out of 100 girls become infected with T. gondii during the first 18 years of life. Independent risk factors identified in our study have also been associated with seropositivity in other countries. Meat consumption appears to have a reduced impact on the risk of infection in children and adolescents compared to adults, calling for different prevention strategies in this population.

Key messages:
- Toxoplasmosis causes a high infection pressure for girls and young women in Germany.
- Transmission pathways might differ between age groups with more environmentally associated infections in children and adolescents.

Abstract citation ID: ckae144.1039
Risk factors for COVID-19 among healthcare workers: a hospital-based cohort study in Portugal

Background: Healthcare workers (HCWs) have an increased risk of transmitting SARS-CoV-2 infection to frail patients and are also at higher risk of exposure. Hence, it is essential to understand the risk factors for infection of HCWs to limit adverse events occurring in healthcare facilities. This study aimed to identify risk factors for symptomatic COVID-19 infection among HCWs in the hospital context.

Methods: We used data from a hospital-based cohort study followed between December 2020 and January 2022 in three central Portuguese hospitals. Following the study protocol, RT-PCR testing was performed whenever an HCW reported any symptom compatible with COVID-19. Characteristics of infected (at least one positive RT-PCR with symptoms) versus non-infected HCW were compared using the Chi-square test.

Results: A total of 3034 HCWs were followed during 13 months and 533 had a positive test for SARS-CoV-2. A higher percentage ($>$ 40 %) of infections were in individuals without a primary vaccination scheme. Other than age, no differences were found regarding individual characteristics: infected HCWs had a higher percentage of individuals aged 18 to 50 years old compared to the non-infected HCWs (74.7 % versus 66.2 %, $p < 0.001$). Regarding work functions, no differences were found for self-report of working in direct contact with COVID-19 patients. Additionally, the percentage of HCWs who declared to perform tracheal intubation procedures was similar in infected versus non-infected HCWs (6.2 % versus 8.9 %, $p = 0.080$).

Conclusions: Infected HCWs were younger than the non-infected. HCWs working in direct contact with patients or performing tracheal intubations didn't exhibits increased rates of infection suggesting the success of preventive measures and other standard procedures in limiting infection transmission in healthcare facilities.

Key messages:
- HCWs working in direct contact with COVID-19 patients or performing tracheal intubations were not the most infected personnel.
- Preventive measures and other standard procedures were successful in limiting COVID-19 infection transmission in healthcare facilities.

Abstract citation ID: ckae144.1040
Home-based nursing care for clients carrying multidrug-resistant organisms: a focus group study

Tessa Langeveld

TJC Langeveld[1,2], *M Haverkate*[1], *F de Haan*[1], *R Eilers*[3], *A Timen*[2,4]
[1]Centre for Infectious Disease Control, RIVM, Bilthoven, Netherlands
[2]Athena Institute, Vrije Universiteit, Amsterdam, Netherlands
[3]Hanze University of Applied Sciences, Groningen, Netherlands
[4]Primary and Community Care, Radboud University Medical Centre, Nijmegen, Netherlands
Contact: tessa.langeveld@rivm.nl

Background: The growing population of vulnerable clients receiving home-based nursing care, combined with the worldwide increase in the prevalence of multidrug-resistant organisms (MDROs), poses a new burden on nursing staff. This study aimed to gain insight into the experiences, attitudes, perceptions, dilemmas in daily practice and needs of nursing staff providing home-based nursing care for clients carrying MDROs.

Methods: Seven focus group discussions with home-based nursing staff (N = 34) were performed in the Netherlands between April and July 2022, using a semi-structured, open-ended topic list based on the I-change model and seven domains synthesized by Flottorp et al. Data were analysed using thematic analysis.

Results: Home-based nursing staff often considered infection prevention and control recommendations inconsistent, unclear or inapplicable in daily practice. Although participants acknowledged the importance of these precaution measures, their proportionality was sometimes questioned. Participants indicated to be influenced by perceptions, knowledge and behaviour of their colleagues and clients. In addition, they frequently experienced untimely, incomplete or inconspicuous information transfers about clients carrying MDROs. Concerns were expressed that clients were often insufficiently informed, debating the roles and responsibilities of involved healthcare professionals in providing and exchanging information. Finally, participants elaborated on the effect of the covid-19 pandemic and expressed the need for organisational support in providing education and sufficient resources regarding MDROs.

Conclusions: Insights of this study have aided in aligning upcoming MDRO guidelines for home-based nursing care in the Netherlands. Organisational support in expanding knowledge and providing sufficient resources is essential and clarity about roles and responsibilities of involved healthcare professionals regarding information transfer and informing patients is needed.

Key messages:

- Expanding knowledge, sufficient resources and adequate information transfer about MDRO carriage are essential to ultimately prevent transmission and spread of MDROs.
- The specific context of home-based nursing care for clients carrying MDROs should be acknowledged in MDRO guidelines.

Abstract citation ID: ckae144.1041

A mixed method approach to evaluate a vaccine hesitancy assessment among parents in Dutch language

Daphne Bussink-Voorend

D Bussink-Voorend[1], JLA Hautvast[1], T Wiersma[1], R Akkermans[1], MEJL Hulscher[2]
[1]Primary and Community Care, Radboud University Medical Center, Nijmegen, Netherlands
[2]IQ Healthcare, Radboud University Medical Center, Nijmegen, Netherlands
Contact: daphne.bussink-voorend@radboudumc.nl

Vaccine hesitancy (VH), as a driver for falling vaccine uptake rates, is a significant public health challenge. It is important to monitor this phenomenon and compare results in a unambiguous manner. However, in Dutch and possibly other languages, there is no unequivocal translation for VH. Therefore, we aimed to develop and cross culturally validate a method to assess VH in a simple and self-reported manner, using five differently worded alternatives reflecting 'doubt', 'reluctance', 'uncertainty', 'concerned' and 'indecision'. We designed a mixed method study with a quantitative and qualitative evaluation. In the quantitative evaluation, parents were asked to rate experienced vaccine hesitancy in their decision about vaccinations on a 10-item Likert scale, using the five differently worded alternatives. We analyzed internal consistency with Cronbach's alpha and correlation with the short parental attitudes about childhood vaccination (PACV-5) scale. A total of 532 parents participated in the survey. We found that the five worded alternatives measured the same construct, indicated by a Cronbach's alpha of 0.95. The wording resembling 'doubt' had the highest correlation with the PACV score (coefficient -0.525, $p < 0.001$). We subsequently conducted cognitive interviews with 12 parents with lower education levels to evaluate their interpretation of the five wording alternatives and the comprehensibility of the question itself. The wordings resembling 'doubt' and 'uncertainty' were viewed as most clear and reflecting VH, although some participants had a negative association with 'uncertainty'. Overall, the question was well understood and minor suggestions were provided to improve comprehensibility. Based on the integrated results of both studies, we conclude that using the word resembling 'doubt' in Dutch language is the best instrument to assess VH. We encourage uniform translation of vaccine hesitancy in other languages to enable comparison of results across countries.

Key messages:

- Uniform translation of the term vaccine hesitancy in other language is important to enable comparison of results across countries.
- In Dutch language, the word resembling 'doubt' is the best instrument to assess vaccine hesitancy.

Treatment of kidney disease: an analytical decision model at a Swiss university hospital

Olga Endrich

O Endrich[1,2,3], K Triep[3], M Messerli[2], C Nakas[4], M Fiedler[1,5]
[1]University Institute of Clinical Chemistry, Inselspital University Hospital, Bern, Switzerland
[2]Insel Data Science Center, Inselspital University Hospital, Bern, Switzerland
[3]Health Information Management, Insel Gruppe, Bern, Switzerland
[4]Laboratory of Biometry, University of Thessaly, Thessaly, Greece
[5]Medical Directorate, Insel Gruppe, Bern, Switzerland
Contact: olga.endrich@insel.ch

Background: An observational hospital-based cohort study, where the kidney disease staging is identified as a digital marker, and the association between the standardised staging of Kidney Disease (KD) and the outcomes is assessed along the treatment process.

Methods: The clinical and administrative data for all patients are stored in the Clinical Data Warehouse. A specific digital marker for an exact KD staging is applied. Three retrospective patient cohorts for exact and imprecise staging and missing diagnosis are defined and compared regarding the in-hospital mortality, all-cause mortality and disease progression.

Results: In total, 83146 hospitalisations of 40421 patients with KD, treated in 2014-2023 (2016-2023 will be updated) were identified; the number of the first hospitalisations with exact staging was 847

(2%), unprecise 29934 (72%) and missing diagnosis (26%). The demographic and baseline factors distribution between groups was tested with no association (chi-squared test statistic). The median survival time with a 95% CI was 7.94 (7.66, 8.81) years for the exact and 7.47 (7.42, 7.53) for the imprecise staging group. A log-rank and loglikelihood tests indicated a significant difference in survival between the groups, $p < 0.0001$. The Cox regression model shows a statistically significant difference in Hazard Ratio; KD staging, age, Elixhauser van Walraven index, treatment, nephrotoxic medication, contrast agent application, and AKI were identified as the significant covariates, C-statistic 0.730, Likelihood ratio test, Wald test, log-rank score on 42 df, $p < 2e\text{-}16$. ANOVA analysis confirmed a significant difference in cost distribution between the groups. An economic decision model proposal integrates the findings, combining a profile-level Markov cohort with a Discreet Time-To-Event Simulation DICE.

Conclusions: The study demonstrates a better outcome regarding all-cause mortality, in-hospital mortality, and costs if a standardised KD staging was applied.

Key messages:

- Intuition (clinical judgement) and standardised kidney disease staging perform differently regarding clinical outcomes and costs.
- The study demonstrates a better outcome regarding all-cause mortality, in-hospital mortality, and costs if a standardised KD staging was applied.

Introduction: As the second leading cause of death in the EU, cancer is expected to see a 55% rise in new cases globally over the next two decades. The European Code Against Cancer (ECAC) and the EU's Beating Cancer Plan (EBCP) provide resources for understanding and preventing cancer. The BUMPER project aims to develop a cancer prevention App to make the ECAC more accessible to the public.

Objectives: Understand the factors influencing the use of a cancer prevention app among users with different digital health literacy levels and to evaluate the app's usability.

Methods: Mixed-methods approach was used to gather user feedback. FGDs explored user perspectives on app usage, while a cross-sectional survey assessed usability through task completion on an initial app wireframe. The pilot was conducted across seven EU countries in late 2023.

Results: 77 participants participated in the pilots and FGDs across seven EU countries. The average task completion time was approximately 79 seconds. Participants rated their confidence to complete the tasks at 3.96 and difficulty at 2.28 on a scale of 1 to 5. The average task pass rate was 92.11%. Qualitative findings highlighted the need for evidence-based content, user-friendly design, language accessibility, offline functionality, and data security. Participants also stressed the importance of clear instructions, regular updates, and robust tracking features. Despite some challenges, the app was generally well-received, with users appreciating its educational potential and tracking capabilities.

Conclusions: The BUMPER project's pilot study demonstrated the cancer prevention App being developed as a potential tool for cancer education and awareness. Despite navigational and language challenges, the app was favorably received by a diverse user base, underscoring the need for ongoing improvements in user guidance, comprehension, and functionality to enhance accessibility.

Key messages:

- BUMPER project's cancer prevention app shows promise in pilot study, enhancing cancer education and awareness.
- Despite challenges, the app was well-received, highlighting the need for ongoing improvements to enhance accessibility.

[4]Local Health Authority ASL LE, Lecce, Italy
[5]Health Management, Local Health Authority ASL Naples 2 North, Naples, Italy
Contact: mariaelisabettamormile@gmail.com

Background: The Covid-19 pandemic has highlighted structural and functional weakness of local health services. Italy carried out its reorganization with DM 77/2022, financed by Mission 6 PNRR of the CE. The model adopted aims to move from a reactive to proactive medicine, to be implemented close to the places where citizens live. The priority objective is to know data on the progress of chronic pathologies and non self-sufficiency using advanced digitalization tools.

Methods: 14 types of administrative data from 2022 to 2023, concerning 180000 (ISTAT data) people in the Lecce Social Health District (DSS Lecce), were analyzed with AI (Chat GPT).

Results: Thanks to algorithms, 6 categories of clinical complexity were identified. The analysis showed that the population assisted is 198696, for temporary presences, with the most represented age group being 50-55 years. Births decreased by 36% in 10 years (from 1681 to 1076), with 2197 deaths in 2023. 42,38% of the population (average age 38,58 years) did not use healthcare resources, while 57,62% (average age 54,19 years) required them. 48646 patients have cardiovascular disease, but only 10% with heart failure were actively monitored. 25047 have metabolic disease, 11195 are diabetics, 5929 have chronic respiratory diseases, 8167 chronic neurological diseases and 907 are cancer patients. Increasing age leads to polymorbidity and show signs of social, economic and health fragility.

Conclusions: the strategic objective of the Lecce DSS was management of chronicity according to specific care pathways, PDTA. Create healthcare teams capable of being case managers depending on the level of complexity (family doctors, nurses, etc). With the 2024 data there will be 3 consecutive years of analysis which will allow the development of predictive systems to identify population clusters at risk of increasing complexity and in need of proactive medical interventions, use of telemedicine with the support of a Territorial Operations Center.

Key messages:

- AI-driven stratification supports personalized health plans to improve healthcare delivery, patient outcomes, and optimize resource allocation.
- A new model of Population Health Management supported by Artificial Intelligence.

Next-generation public health surveillance: extreme heat event prediction and monitoring system

Irfhana Zakir Hussain

I Zakir Hussain[1], A Oetomo[1], J Kaur[1], PP Morita[1]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada
Contact: irfhana.zakirhussain@uwaterloo.ca

Background: Extreme Heat Events (EHEs) are a growing threat to public health. The increase in the frequency of occurrence of once rarer EHEs and the rise in their average temperatures are dangerously drastic for public health outcomes. Despite this, existing public health surveillance (PHS) systems fail to leverage IoT and AI technologies to facilitate real-time, continuous monitoring of EHE indicators and its associated health risks. This study closes this gap by proposing a comprehensive PHS system that can, in real-time monitor and predict EHE indicators to provide timely alerts to public health authorities.

Methods: The EHE PHS system collects EHE detection metrics, including indoor temperature and humidity levels, from IoT sensors and thermostats to map them across Canada, primarily focusing on low-income communities. The system also integrates historical climate data (surface temperature, humidity, wind speed and direction, and air quality indicators) from Environment Canada. The system uses the data to train initial prediction models including CNN, LSTM and GNN. The validated model will be integrated into the system, enabling real-time EHE prediction. The output will be displayed in user-friendly visualizations on the EHE PHS system's dashboard capabilities.

Results: The system allows for the analysis of real-time data through dashboards and provides alerts when certain indicators (e.g. excessive or prolonged heat) detrimental to public health outcomes are detected. The alerts enable valuable lead time for public health authorities to implement proactive measures, such as issuing heat advisories and deploying resources to vulnerable areas.

Conclusions: The EHE PHS system will serve as a blueprint for global public health researchers, utilizing IoT and AI technologies for proactive crisis prevention. This knowledge will inform the development of heat-resilient policies and set a precedent for global public health crisis prevention.

Key messages:

- The proposed EHE PHS system uses AI and IoT technologies, to enhance EHE prediction, risk identification, and real-time monitoring for effective public health interventions.
- By integrating advanced predictive models and environmental data, the system facilitates early detection of EHE risk, which can significantly mitigate the health impact on vulnerable populations.

Abstract citation ID: ckae144.1046
Safety in Teletriage by Nurses and Physicians in the US and Israel - a Tale of 2 Systems

Motti Haimi

M Haimi[1,2,3], SQ Wheeler[4]
[1]Health Administration, Yezreel Valey Academic College, Emek Yezreel, Israel
[2]Technion, School of Medicine, Haifa, Israel
[3]Meuhedet Health Services, North District, Haifa, Israel
[4]Teletriage.com, California, USA
Contact: morx@netvision.net.il

Background: The safety of telemedicine in general and telephone triage (teletriage), in particular, have been a focus of concern since the 1970s. Inadequate telehealth systems may compromise patient safety.

Objectives: Our aim was to explore ways that developed teletriage systems produce safe outcomes by examining key system components and questioning long-held assumptions.

Methods: We examined safety by performing a narrative review of the literature using key terms concerning patient safety in teletriage. In addition, we conducted system analysis of 2 typical formal systems, physician led and nurse led, in Israel and the United States, respectively, and evaluated those systems' respective approaches to safety. Additionally, we conducted in-depth interviews with representative physicians and 1 nurse using a qualitative approach.

Results: The review of literature indicated that research on various aspects of telehealth and teletriage safety is still sparse and of variable quality, producing conflicting and inconsistent results. The interviews with health care professionals demonstrated several challenges encountered during teletriage, mainly making diagnosis from a distance, treating unfamiliar patients, a stressful atmosphere, working alone, and technological difficulties. However, they reported using several measures that help them make accurate diagnoses and reasonable decisions, thus keeping patient safety, such as using their expertise and intuition, using structured protocols, and considering non-medical factors and patient preferences (Shared Decision-Making).

Conclusions: Remote encounters about acute, worrisome symptoms are time sensitive, requiring decision-making under conditions of uncertainty and urgency. Patient safety and safe professional practice are extremely important in the field of teletriage, which has a high potential for error. There is a need identifying safe systems to guide developers and clinicians about needed improvements.

Key messages:

- Patient safety and safe professional practice are extremely important in the field of teletriage.
- We need to guide developers and clinicians about needed improvements in teletriage systems.

Abstract citation ID: ckae144.1047
AAL for independent aging: Practical guidelines for smart living environment development

Gaya Bin Noon

G Bin Noon[1], S Abhari[1], G Morgan[1], F Manning[2], J Teague[2], PP Morita[1,3,4]
[1]School of Public Health Sciences, University of Waterloo, Waterloo, Canada
[2]Standards Research, CSA Group, Toronto, Canada
[3]Techna Institute, University Health Network, Toronto, Canada
[4]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada
Contact: gbinnoon@uwaterloo.ca

Background: Active Assisted Living (AAL) refers to the use of IoT devices to support quality of life, independence, and healthier living for care recipients. AAL-enabled smart homes have particular potential to help older adults reach their health and independent living goals, but there is a dearth of guidance on practical implementation. Additionally, different technology companies have each developed their own practices, leading to confusion and inconsistency. The objective of this work is to explore requirements for use of AAL in smart living environments for older adults, providing suggestions for best practice for AAL use considering their unique circumstances.

Methods: A review of academic and grey literature was performed to identify existing best practices and gaps for development of AAL-enabled environments. A technology review was also performed on 156 unique devices to understand the AAL tech ecosystem.

Results: Little guidance exists regarding designing smart living environments for older adults, though it exists for the two elements separately. The distinguishing elements are how AAL may connect the older adult to their care network, how the home may accommodate changing health needs, and older adults' unique vulnerability. Furthermore, a large issue is a lack of interoperability and communication, which must be addressed in order to make AAL systems as low-effort and aligned with older adults' preferences as possible.

Conclusions: As both tech and older adults' needs evolve, key requirements of AAL-enabled smart living environments are robust data sharing pathways, planning for modifiability, and protecting the privacy of residents. The findings of this work will be used to identify opportunities for AAL standards development.

Key messages:

- AAL-enabled smart homes must be able to accommodate an older adults' shifting care needs and preferences over time.
- It is necessary to establish how AAL smart home data may be shared with and used by care partners and providers.

Abstract citation ID: ckae144.1048
Trustworthiness of EHRs: Key Factors from a User-Centered Study in Germany

Niklas von Kalckreuth

N von Kalckreuth[1], *M Kopka*[1], *C Schmid*[1], *C Kratzer*[1], *A Reptuschenko*[1], *M Feufel*[1]
[1]Department of Psychology and Ergonomics, Technical University Berlin, Berlin, Germany
Contact: niklas.vkalckreuth@tu-berlin.de

Background: The integration of digital technologies, particularly Electronic Health Records (EHRs), promises substantial improvements in patient care and cost reductions. However, the success of EHRs depends heavily on patient trust and usage, which are influenced by their control over data visibility, storage, and sharing. Identifying the factors that enhance the perceived trustworthiness of EHRs is essential for increasing their reliability and acceptance in healthcare settings.

Methods: Participants ($N = 30$) first interacted with an interactive EHR prototype, then evaluated its trustworthiness and suggested improvements during semi-structured interviews. These interviews were transcribed and analyzed using thematic analysis to identify key themes affecting perceptions of the EHR's trustworthiness.

Results: Through thematic analysis, we developed a categorical system encompassing five principal themes: provider reputation, information quality, system characteristics, user control, and user feedback. The analysis revealed that deficiencies in design and usability indirectly affect perceptions of privacy and data security.

Conclusions: Our study underscores the critical role of contextual factors-including provider reputation, strategic IT partnerships, and user feedback-in cultivating trust in Electronic Health Record (EHR) systems. Addressing privacy concerns and bolstering user trust necessitates not only a professional approach to design and usability but also clear communication about adherence to rigorous data privacy and security standards. In Germany's tightly regulated environment, clearly communicating EHR security standards is crucial. Enhancing trust also involves robust customer support, user control over their data, and leveraging social proof like high download rates or positive reviews. These approaches could significantly improve EHR acceptance and trust in digital health across the country.

Key messages:

- The perceived trustworthiness of EHRs is essential for increasing their reliability and acceptance in healthcare settings.
- Effective communication and design are critical for building trust in digital health technologies. Trust in EHRs grows with transparent data policies and empowering user controls.

Abstract citation ID: ckae144.1049
Characteristics predisposing to the utilization of Internet websites offering e-prescriptions

Mariusz Duplaga

M Wojcieszko[1], *P Smoła*[1], *M Duplaga*[2]
[1]Doctoral School of Medical and Health Science, Jagiellonian University Medical College, Cracow, Poland
[2]Department of Health Promotion and e-Health, Jagiellonian University Medical College, Cracow, Poland
Contact: mariusz.duplaga@uj.edu.pl

Background: The introduction of e-prescriptions in the Polish healthcare system was accompanied by the emergence of websites offering easy access to medication without adequate medical assessment. This study aimed to analyze the characteristics of Polish users of such services.

Methods: The analysis presented here is based on the online survey conducted in June 2023 among 1661 adult Internet users. The multivariable logistic regression model (MLRM) was developed for the variable reflecting the use of e-prescribing web services (EPWS). Sociodemographic variables, self-assessed health status, the presence of chronic disease (CHR) and disabilities (DIS), the frequency of Internet (IU) and social media use (SMU), and finally, digital health literacy (DHL) were included in MLRM as independent variables.

Results: The percentage of respondents who used EPWS was equal to 18.2% ($n = 303$). MLRM revealed that age, vocational and income status, CHR, SMU, and DHL were significant predictors of EPWS use. Older respondents were less likely than younger ones to use EPWS (odds ratio (OR), 95% confidentiality interval (95%CI): 0.97, 0.97-0.99. Persons suffering from the chronic disease, when compared to those without such disease, used EPWS less frequently (OR, 95CI: 0.59, 0.43-0.80) and unemployed when compared to employees (OR, 95%CI: 0.53, 0.32-0.88). A higher likelihood of using EPWS was observed among respondents with the highest income in comparison to those from the group with the lowest income (OR, 95%CI: 1.52, 1.02-2.52) and among more frequent social media users (OR, 95%CI: 3.88, 1.90-7.93). Finally, the increase of DHL score by 1 unit was associated with the increase of the likelihood of EPWS use by 9% (OR, 95%CI: 1.09, 1.05-1.12).

Conclusions: A significant number of adult Internet users utilize EPWS in Poland. Lower age, unemployment, and chronic diseases are negative predictors of EPWS use. More intense SMU and unexpectedly higher DHL predispose to the use of such services.

Key messages:

- Even persons with high e health literacy are inclined to use web portals offering e-prescriptions.
- The high prevalence of the utilization of e-prescribing websites requires awareness campaigns warning about related potential risks.

Abstract citation ID: ckae144.1050
How advanced is your digital public health system? A qualitative analysis of suitable indicators

Laura Maaß

L Maaß[1,2], *M Badino*[2,3,4], *I Iyamu*[5,6], *F Holl*[2,7]
[1]SOCIUM Research Center on Inequality and Social Policy, University of Bremen, Bremen, Germany
[2]Leibniz ScienceCampus Digital Public Health Bremen, Bremen, Germany
[3]School of Public Health, National University of Córdoba, Córdoba, Argentina
[4]School of Medicine, University of Alcalá, Alcalá de Henares, Spain
[5]School of Population and Public Health, University of British Columbia, Vancouver, Canada
[6]BC Centre for Disease Control, Vancouver, Canada
[7]DigiHealth Institute, Neu-Ulm University of Applied Sciences, Neu-Ulm, Germany
Contact: laura.maass@uni-bremen.de

Background: Revealing the full potential of digital public health (DiPH) systems necessitates a wide-ranging tool to assess their maturity. Essential domains that need to be considered include the literacy and interest in DiPH tool application by society and the workforce and the legal and ICT maturity of DiPH systems. No review has investigated indicators on these national DiPH system maturity (DiPHSM) domains yet. Our narrative review and qualitative analysis aimed to map the landscape of indicators related to DiPHSM measurement and rank them based on their importance for such assessments.

Methods: As original indicators were not published in scientific databases but as grey literature, we used DuckDuckGo to apply a pre-defined search strategy for 11 countries from all continents classified as having reached level 4 of 5 in the Global Digital Health Monitor. Of the 1484 identified references, 137 were included which named 15806 indicators. Consensus on importance was defined as at least 3 or 4 authors rating an indicator as important.

Results: We recognized 180 indicators on different constructs with importance for DiPHSM analysis, including the availability and use of Smartphones, computers, the Internet or the DiPH intervention, the existence of skilled workforce, infrastructure (investment), and interoperability between interventions, the secondary use of health data, a DiPH strategy and controlling agency, or the application of big data and artificial intelligence for health data collection, analysis, and sharing.

Conclusions: Our study holds the potential to develop more comprehensive tools for DiPHSM assessments. Further examination is required to analyze the suitability and applicability of all identified indicators for diverse healthcare settings. By working towards a uniform evaluation of DiPHSM, we foster informed decision-making among healthcare planners and practitioners, improve resource distribution, and continue to drive innovation in healthcare delivery.

Key messages:

- Maturity assessment tools need to consider the complexity of DiPH systems. Thereby, DiPH system evaluations need to be accompanied by analyses of the legal, ICT, and literacy perspective maturities.
- New methods are needed to systematically assess and use multidisciplinary grey literature for research.

Abstract citation ID: ckae144.1051
Patient and practice characteristics related to patient's consent for health data exchange

Jelle Keuper

JJ Keuper[1,2], K Hek[1], LHD van Tuyl[1], RS Batenburg[1,3], RA Verheij[1,2]
[1]NIVEL, Utrecht, Netherlands
[2]School of Social and Behavioral Sciences, Tilburg University, Tilburg, Netherlands
[3]Faculty of Social Sciences, Radboud University, Nijmegen, Netherlands
Contact: j.keuper@nivel.nl

Background: Sharing patient health data electronically between healthcare providers can prevent medical errors and improve patient safety. In the Netherlands, exchange of health information is facilitated on a national level and is only allowed with patient consent. Consequently, it is important to know which factors are related to this patient consent.

Methods: Routine electronic health records data from up to 10% of Dutch general practices (sourced from the Nivel Primary Care Database) were utilized, covering the period from 2016 to 2020. We examined whether patient consent for health data exchange varied depending on patient and practice characteristics, which are expected to have a relationship with granting consent for health data exchange. Therefore, multilevel analysis was performed.

Results: The percentage of patients granting consent ranged between 40%-50% in the period 2016 to 2019, while this was 97% in 2020, due to the governmental corona opt-in regulation. Significant disparities were observed across several of the included patient and practice characteristics in relation to patient consent for all the years examined. In most years, patient consent provision varied by gender, age, socioeconomic position, location, and healthcare use. Practice characteristics showed notable differences in patient consent across information systems, patient volumes, and practice types over all years examined.

Conclusions: We observed significant variations in patient consent for health data exchange, both among the included patient (need) and practice characteristics. These differences may stem from unequal exposure to opportunities to grant consent, differences in risk of inadequate communication between healthcare providers, levels of health literacy, and practice resources. These factors should be taken into account by policymakers when further implementing and upscaling the national health data exchange system.

Key messages:

- Variations in patient consent for health data exchange were observed among different patient groups and general practices.
- Variations in patient consent for health data exchange may stem from unequal exposure to opportunities to grant consent, levels of health literacy, and practice resources, among other factors.

Integrating an AI-powered symptom assessment application (SAA) in a hospital network in Portugal

Nisha Kini

N Kini[1], F Cotte[1], MP Pereira[2], A Pimenta[1], M Schmude[1], J Nevell[1], FD Lourenço[2], A Besarab[2], MS Monteiro[2], PS Flores[2]
[1]Clinical Studies, Ada Health Gmbh, Berlin, Germany
[2]CUF Digital, CUF Hospital, Lisbon, Portugal
Contact: nisha.kini@ada.com

Introduction: Patients often struggle to understand medical information and healthcare worker shortage strains health systems. Integrating SAAs that guide patients and provide diagnostic decision support (DDS) to doctors can help. This study evaluates the impact of the SAA 'Ada', a class IIa medical device, after its integration into the patient portal of a Portuguese hospital network, CUF, on clinical workflow and patient health.

Methods: This on-going post-market quality improvement study, started in Nov 2023 and has enrolled 664 participants. Participating doctors complete a baseline survey. Consenting patients conduct symptom assessments and answer survey questions within the app. The patient's symptom report is shared with their physician, who then completes a post-consultation survey.

Results: After using Ada, 86% of patients could enter all their symptoms, 79% felt more prepared for their consultation, and 39% felt less health anxiety (N = 664). In the baseline survey, most doctors utilize online resources (96%) in the absence of a symptom checker, followed by discussions with colleagues (65%) for challenging cases (N = 26). In the post-consultation survey, 95% of doctors found Ada's condition suggestions reasonable, with only 10% disagreeing with its triage classification. Doctors reported time saving and increased consultation efficiency (64%), and 59% felt more confidence in their diagnosis. A majority said that Ada provided them with additional information about patients (77%). Ada also improved consultation efficiency (74%), preparation (78%), patient engagement (82%), and health knowledge (77%; N = 22).

Conclusions: By providing personalized health information, Ada prepares patients for their consultation, resulting in improved patient engagement and facilitation of clinical conversation. Incorporating a SAA into routine patient care enhances quality of consultation, reduces consultation time, increases efficiency, and provides DDS to doctors.

Key messages:

- Digital health enhances patient engagement, clinical efficiency, and diagnostic decision support for doctors in healthcare settings.
- Ada's personalized health information empowers patients, improves consultations, and reduces health-related anxiety.

Abstract citation ID: ckae144.1053

Using artificial intelligence to support and streamline rapid systematic evidence reviews

Maureen Dobbins

M Dobbins[1,3], *R Traynor*[1], *E Clark*[1], *S Neil-Sztramko*[1,2]
[1]NCCMT, McMaster University, Hamilton, Canada
[2]Health Research Methods, Evidence & Impact, McMaster University, Hamilton, Canada
[3]School of Nursing, McMaster University, Hamilton, Canada
Contact: dobbinsm@mcmaster.ca

Issue: The Rapid Evidence Service, initiated by the National Collaborating Centre for Methods and Tools (NCCMT) during COVID-19, supports public health decision making by conducting rapid reviews on priority topics.

Description of issue: Integral to rapid reviews is an expedited timeline but the quantity of available literature for most public health review questions takes significant time to screen manually. NCCMT integrated 4 artificial intelligence (AI) features into the screening process. DAISY Rank applies predictions learned from manual screening patterns to re-order remaining studies, with most relevant appearing first. AI Screening automatically screens remaining studies based on prediction scores. Check for Screening Errors and Re-Rank Report use previous screening patterns to identify studies that were potentially falsely excluded and predict the total number of included studies, respectively. These features were tested by comparing results provided by AI with those produced manually for select test sets.

Results: NCCMT used AI to support and expedite screening, assess screening progress, and/or minimize risk of inappropriately excluding studies for 35 rapid reviews on 20 topics. Using DAISY Rank enabled one screener to review over 4000 references in 9 hours, compared to a different review, where the same amount of screening took 28 hours without DAISY Rank. AI Screening correctly excluded up to 80% of irrelevant search results across reviews. Check for Screening Errors identified 37 potential includes manually excluded in one review; these were reviewed and 3 were included. Re-Rank Report allowed NCCMT to re-allocate staff to subsequent steps in the review process when most included studies were identified.

Lessons: Integrating AI features into screening led to less time required, better anticipated timelines, more accurate staff allocation and reduced errors. More rigorous study of AI best practices is needed to continue to improve rapid review method efficiencies.

Key messages:

- Rapid reviews can be an important source of evidence for decision makers if they can be completed quickly but maintain rigor and accuracy.
- AI holds promise as a way to improve screening efficiency.

[2]Department of Environmental Sciences, Informatics and Statistics, Ca' Foscari University of Venice, Venice, Italy
[3]LILA Onlus, Milan, Italy
Contact: v.casigliani7@gmail.com

Background: Media play a pivotal role in disseminating accurate information, particularly regarding U=U (Undetectable = Untransmittable), to increase awareness and reduce stigma. This study analyses HIV Italian communication on Facebook and Instagram, with a focus on U=U evidence.

Methods: A mixed-method analysis examined posts on HIV, with linked articles, from Italian news sources from 01/2009 to 04/2023. News sources were categorised as "reliable" or "unreliable" using independent third-party classification. Topic analysis identified the main topics in the posts, while an inductive content analysis was conducted on linked articles regarding U=U. The language and the accuracy in explaining U=U was evaluated through a checklist.

Results: A total of 10,539 Facebook and 749 Instagram posts were analysed, with 716(7%) and 18(2%) from unreliable sources respectively. Reliable and unreliable content surged around World AIDS Day(WAD) on both platforms. On Facebook, the frequency of unreliable content increased over time, whereas on Instagram it was rare and recent. On Facebook, topics varied between reliable and unreliable sources. The 3 most frequent topics from reliable sources were WAD, voluntary HIV spread, and public figures with HIV; those from unreliable sources were Death and Migrant People; Luc Montagnier and COVID-19 Conspiracies; Public Figures with HIV. On Instagram, the first 3 topics were the Italian National Institute of Health and Prevention, WAD, and public figures with HIV. A total of 68 articles nominating U=U were found and analysed, revealing 4 main areas: U=U definition, Prevention, Impact on people living with HIV, and Stigma. The accuracy in explaining U=U was generally low, with 6 articles(8.8%) providing only a definition.

Conclusions: HIV communication in Italy is limited and centered around WAD, with persisting bias. The dissemination of the U=U evidence is lacking. Urgent action is needed to shift the narrative and emphasize this evidence

Key messages:

- HIV communication in Italy is limited and concentrated around World AIDS day.
- The U=U evidence is poorly disseminated, often providing only a definition and medical explanation.

Abstract citation ID: ckae144.1055

Validation of the Multidimensional Scale of Perceived Social Support among LGBT population in Serbia

Željka Stamenković

Z Stamenkovic[1,2], *J Todorovic*[1,2], *N Brkljac*[3]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]School of Public Health and Health Management, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

[3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: zeljka.stamenkovic@med.bg.ac.rs

Background: Social support represents the belief that one is valued, cared for, and loved by others in a social network and a lack of it may lead to adverse outcomes such as a relapse into depression or emotional distress in physically ill patients. The Multidimensional Scale of Perceived Social Support (MSPSS) is an instrument aimed to measure an individual's perception of how much he or she receives outside social support. This study aimed to examine the validity and reliability of the Serbian version of MSPSS in a sample of LGBT population in Serbia.

Methods: The cross-sectional study included 504 respondents, members of the LGBT population living in Serbia. The instrument used was the MSPSS as a self-report measure, containing twelve items rated on a 7-point Likert scale. MSPSS consists of three subscales: Family, Friends, and Significant Others. Exploratory (EFA) and confirmatory factor analyses (CFA) were performed with two independent random samples.

Results: The average score on the scale of social support was 5.58± 0.84 (scale of social support by family 4.62±1.41, scale of social support by friends 5.93± 1.99, and scale of social support by the significant others 6.20±0.96, respectively). The Cronbach's alpha for the entire social support scale was $\alpha = 0.772$. The three-factor structure of the MSPSS was proved with EFA and CFA. The factor loadings varied between 0.630-0.817. The three factors explained a total of 52.68% of the variance (factor 1- 28.62%, factor 2. 13.16%, factor 3- 10,90%). The three-factor model was adopted during the CFA when the three-factor model CFI (comparative fit index) was 0.969.

Conclusions: The MSPSS has shown good reliability, internal validity and construct validity and can be used as a convenient measure of social support among the LGBT population. Both EFA and CFA yield a three-factor structure consistent with the theory underlying the measure's development.

Key messages:

- The results of the study suggest that the Multidimensional Scale of Perceived Social Support has acceptable psychometric properties for use with the LGBT population.
- This study supports the use of the MSPSS for assessing community-based collaboration using the three-factor model among the LGBT population.

Abstract citation ID: ckae144.1056
Development of Digital Health Gender and Sexual Health Literacy scale

Elisabetta Corvo

W De Caro[2], P Di Biagio[4,2], M Di Carlo[3,2], E Corvo[1]
[1]Graduate College, Canterbury Christ Church University, Canterbury, UK
[2]Research Group, CNAI, Rome, Italy
[3]Department of Biomedicine & Health, University of Rome Tor Vergata, Rome, Italy
[4]Health Professionals Department, ASL Roma 1, Rome, Italy
Contact: sii@cnai.pro

Introduction: Health literacy, as the ability to obtain, process and understand health information, including gender and sexuality awareness, appears to be underdeveloped in terms of measurement tools and thematic materials. The literature indicates the existence of serious deficits in gender and sexual health literacy at all levels, with implications for relationships with citizens and patients.

Methods: Delphi study agreement was conducted and a pool of potential scale items was generated, reflecting a range of skills and abilities within each domain. Items were carefully worded to ensure clarity, cultural sensitivity and relevance to different gender identities and sexual orientations. Expert review and cognitive pre-testing were employed to refine item wording, assess content validity, and ensure that the 10-item scale was comprehensible and relevant to the target population.

Results: The theoretical development of the 10-item Digital Health Gender and Sexual Health Literacy Scale was successfully completed. The scale items were designed to provide a comprehensive measure of an individual's ability to navigate the digital landscape for gender and sexual health information.

Conclusions: The theoretical validation of the Digital Health Gender and Sexual Health Literacy Scale (DiGeSHeL) provides the community with a promising tool to assess individuals' confidence and ability to use digital technologies for sexual health information and resources. However, further research is needed to validate the scale and test its reliability with a diverse group of participants. Once validated, this scale could be a valuable tool for sexual health promotion programmes to identify gaps and evaluate the impact of digital literacy interventions.

Key messages:

- Gender and sexual literacy are crucial for health.
- Health literacy as six vital sign.

Abstract citation ID: ckae144.1057
Family-based sexual health intervention for adolescents; A systematic review and meta-analysis

Priya Paudyal

D Mataraarachchi[1,2], T Shepherd[1,2], G Ariyadasa[1,2], R Bajpai[2], N Corp[2], P Paudyal[1,2]
[1]Institute for Global Health and Wellbeing, Keele University, Staffordshire, UK
[2]School of Medicine, Keele University, Staffordshire, UK
Contact: p.paudyal@keele.ac.uk

Background: Family-based interventions are important in promoting adolescent sexual health outcomes. However, the effectiveness of these interventions in promoting adolescent sexual and reproductive health (ASRH) in Lower and middle-income countries (LMIC) has not been empirically evaluated. This review aimed to summarise the effectiveness of family-based sexual and reproductive health interventions in promoting ASRH in LMIC.

Methods: We conducted a systematic search for studies published in English from 2000 to October 2023 using MEDLINE, PsyINFO, CINAHL, Web of Science, and EMBASE databases. Studies were included if they involved adolescents aged 10-19 years, included family members in a key intervention component, evaluated the effectiveness of the interventions using an experimental or quasi-experimental design, assessed ASRH outcomes reported by adolescents and were conducted in LMIC setting. Standardized mean difference (SMD) and 95% confidence intervals were computed and meta-analyses were conducted using random effect models.

Results: Ten articles involving 2,246 participants were included in the review. The studies were nostly conducted in Africa. Across studies, there was no significant impact of family-based interventions in improving adolescent sexual health knowledge (SMD=0.5, 95%CI: -1.98 to 2.98), attitudes (SMD= -0.05, 95%CI: -1.92 to 1.82), practices (SMD=0.53, 95%CI: -0.69 to 1.75), or sexual communication with their family (SMD= 0.14, 95%CI: -0.42 to 0.7). Although individual studies reported a mixed effect of family-based interventions in improving sexual health outcomes, the pooled results from the meta-analysis showed no significant impact of family-based interventions.

Conclusions: Our review did not find any significant impact of family-based interventions in improving ASRH in LMIC. We recommend interventions using innovative approaches and novel strategies to align with the socio-cultural and economic background of the study setting.

Key messages:

- This study found no significant impact of family-based interventions in improving ASRH in LMIC.
- Additional studies, particularly from Asia, using culturally relevant interventions is required in this area.

Mental health of Finnish cis- and transgender youth before, during and after the COVID-19 pandemic

Olli Kiviruusu

O Kiviruusu[1], L Sares-Jäske[1], S Therman[1], J Lehtonen[1,2], J Suvisaari[1]
[1]Equality Unit, Finnish Institution for Health and Welfare, Helsinki, Finland
[2]Gender Studies, University of Helsinki, Helsinki, Finland
Contact: olli.kiviruusu@thl.fi

Background: Transgender youth report more mental health problems than their cisgender peers, but little is known about their mental health during and after the COVID-19 pandemic. We studied symptoms of anxiety and depression among cis- and transgender youth before, during, and after the pandemic using large nationwide samples.

Methods: Data from the Finnish School Health Promotion survey from years 2019, 2021 and 2023 (461,249 students in total; mean age 15.7, SD 1.3) were used. Self-reports covered official gender, gender identity, symptoms of anxiety (Generalized Anxiety Disorder Scale-7 $\geq$10) and depression (Patient Health Questionnaire-2 $\geq$3). Categories of cisgender boy (officially boy; gender identity boy; $N = 214{,}423$), transfeminine youth (officially boy; gender identity girl, both, neither, or it varies; $N = 5{,}069$), cisgender girl (officially girl; gender identity girl; $N = 224{,}753$), and transmasculine youth (officially girl; gender identity boy, both, neither, or it varies; $N = 14{,}508$) were formed.

Results: In all timepoints, proportion of those with anxiety or depression was higher among transfeminine youth compared with cisgender boys and among transmasculine youth compared with cisgender girls. In all groups anxiety and depression increased significantly from 2019 to 2021 (ORs 1.4-1.8, $p < 0.0001$), with no significant differences in these changes between cis- and transgender groups. From 2021 to 2023, anxiety (OR 0.91, $p = 0.015$) and depression (OR 0.77, $p < 0.0001$) decreased among transmasculine youth but increased among cisgender girls (ORs 1.11 [$p < 0.0001$] and 1.07 [$p < 0.0001$], interactions $p < 0.0001$). Among transfeminine youth, generalized anxiety symptoms decreased from 2021 to 2023, whereas they remained at the level observed in 2021 among cisgender boys (interaction $p = 0.0025$).

Conclusions: In Spring 2023, we found still increasing mental health problems among cisgender girls, while among transgender youth the post-pandemic developments were more positive.

Key messages:

- Post-pandemic, we found further increases in mental health symptoms in cisgender youth, while among transgender youth the development seemed more promising.
- Transgender youth experience more anxiety and depression than their cisgender peers, thus gender diversity deserves still more attention in educational, social, and health care services.

Abstract citation ID: ckae144.1059
Implementation Measures to Break the Gender Gap - a Scoping Review

Judith Mollenhauer

J Mollenhauer[1], S Sgraja[2], VE Amelung[2], M Kloepfer[3], U Seeland[4], C Kurscheid[1]
[1]figus - Research Institute for Health and System Research, Cologne, Germany
[2]Hannover Medical School, Hanover, Germany
[3]Institute for Gender Health, Berlin, Germany
[4]Otto von Guericke University, Magdeburg, Germany
Contact: j.mollenhauer@figus.koeln

Background: For myocardial infarction, in-hospital lethality is still significantly higher in women than in men in Germany. Medical guidelines and nursing expert standards include recommendations for gender-sensitive care (GSC+), but it is unknown how these are implemented in health care practice. Research question: Which measures facilitate the implementation of GSC+?

Methods: Systematic literature research was conducted on Pubmed, web of science and CINAHL with adequate keywords connected with Boolean connectors.

Results: The initial literature search yielded a pool of 23,508 items. After removing irrelevant articles and duplicates 119 articles were included in the present scoping review. Among fifteen generated dimensions, which are summarized to six main dimensions (education, research & science, politics, LGBTQ+ care & education, institutions of care and career advancement), the included articles are related. Education is the dimension with the most identified articles. Key messages of main dimensions are that GSC+ • must be anchored in compulsory subjects of curricula; • must be considered in research. Researchers need to be aware and should follow a structured framework for generating sex-specific guidelines; • can get gain access to politics through purposeful lobby work; • in terms of LGBTQ+ care should be learnt from health care providers to LGBTQ+ people through case studies; • should be implemented strategical through change agents in institutions of care; • can be enhanced through aware women in leading positions, to implement GSC+ successfully.

Conclusions: The implementation of GSC+ has a positive impact on patient care and could reduce undesirable events or outcomes. To reach the implementation target the politics must set frame conditions and universities, science and health care providers have to integrate them. Moreover, the generation of evidence is important to promote GSC+ so that health care professionals have a defined work assignment for GSC+.

Key messages:

- The research results provide a comprehensive overview of the existing literature on implementation measures of gender-sensitive care.
- Healthcare providers are sensitized to gender-sensitive care so that patient care can be further improved.

Abstract citation ID: ckae144.1060
What do we know about femicide in Italy? Data and insights from a repeated cross-sectional study

Giorgia Gabrielli

G Gabrielli[1], F Porru[2], W Ricciardi[1], MR Gualano[3]
[1]Department of Life Sciences and Public Health, Catholic University of the Sacred Heart, Rome, Italy
[2]Department of Public Health, Erasmus University Medical Center, Rotterdam, Netherlands
[3]UniCamillus-Saint Camillus International University of Health Sciences, Rome, Italy
Contact: giorgia.gabrielli95@gmail.com

Background: Gender-based violence represents a huge public health issue, affecting mental, physical health and productivity. It is a significant obstacle to achieving gender equality and the empowerment of all women. While the overall homicide rate is decreasing in Italy, femicide, the intentional killing of women due to gender-related motivations, remains stable over time. This is the first study in Italy to evaluate potential risk factors of femicide, exploring the sociodemographic characteristics of victims and perpetrators of femicides, as well as the geographic distribution across Italy, with insights into differences between the size of municipalities and between geographic areas.

Methods: A repeated cross-sectional study was conducted to investigate femicides in Italy from 2020 to 2023 using data sources from Non Una Di Meno, an Italian NGO, and the Italian National Institute of Statistics.

Results: Our preliminary findings show that the majority (83%) of homicides of women were femicides. On a final sample of 403 femicides, in most cases (94,3%) the victims were more likely to be hit by their current or former partner or by a family member. In 97% of cases perpetrator was a man. In more than 50% of cases, both the victims and the perpetrators were under 55 years old (respectively, 51,8% and 57,9%). Femicide rates was 0.33 per 100,000 women. There appear to be no significant differences between the rates of femicide as the size of the municipality and the geographic macro-area vary, highlighting the extensive spread of the phenomenon throughout the territory.

Conclusions: Our findings show that femicide is a systematic and widespread phenomenon that occurs mostly within the home and needs interventions at the European level to prevent systemic violence against women. Moreover, this study provides methodological considerations to define femicide, suggests improvements to data collection methods and offer insights for future research in this field.

Key messages:

- It is important to gather robust data on gender-based homicide, as it represents a public health issue.
- Femicide is a pervasive and systematic phenomenon that predominantly occurs within the home and requires intervention at the European level.

Abstract citation ID: ckae144.1061

Association between dietary supplements and frailty by sex: a cross-sectional study in South Korea

Hyunjoo Kim

HJ Kim[1], *HS Suh*[2], *E Lee*[1]
[1]College of Pharmacy, Research Institute, Seoul National University, Seoul, Korea, South
[2]College of Pharmacy, Kyung Hee University, Seoul, Korea, South
Contact: yupkisys89@snu.ac.kr

Background: Evidence regarding the benefits of dietary supplements against frailty is lacking. Therefore, we aimed to examine the association between the use of dietary supplements and frailty. The analyses were stratified by sex to consider the sexual dimorphism in frailty.

Methods: This study used national, cross-sectional survey data from South Korea, namely the Korea National Health and Nutrition Examination Survey (KNHANES, 2018-2020). Adults aged 50 years were included. Data for up to four supplements were collected for each participant. A 46-item frailty index was constructed to assess frailty. All percentages (%) were weighted to represent the national population. The association between the use of dietary supplements and frailty was investigated using a linear regression analysis with socioeconomic/lifestyle factors and the amount of nutrient intake from diet included as covariates.

Results: Of the included 27,384 older adults, 57.28% were women. The proportion of supplement users was significantly higher in women (64.31% vs. 77.71%, $p < 0.001$). Any supplement use was negatively associated with frailty (B = -0.015, $p < 0.001$), and the association was more significant in women (Any supplement use * women: B = -0.012, $p = 0.002$). From the multivariable regression analysis stratified by sex, the use of red ginseng (men: B = -0.019, women: B = -0.015) and calcium (B = -0.027, women: B = -0.012) were negatively associated with frailty in both sexes while the statistical significance for vitamin C was found only in men (B = -0.020) (all $p < 0.05$).

Conclusions: Our findings demonstrated a significant negative association between the use of dietary supplements and frailty. The associations varied by type of supplements and by sex. The findings should be validated using prospective data.

Key messages:

- Red ginseng and calcium supplements were negatively associated with frailty in both sexes.
- We assessed frailty using frailty index which highlights the potential role of dietary supplements beyond the context of physical or musculoskeletal function.

[6]Obstetrics & Gynecology, Soroka University Medical Center, Beer-Sheva, Israel
[7]Medical Manager Southern District, Maccabi HealthCare Services, Southern District, Israel
Contact: chenz@yvc.ac.il

Background: Endometriosis is a chronic gynecological disease that affects about 10% of women of reproductive age. Its symptoms vary in severity and manifestation. Diagnosis is often delayed by an average of 10 years, which may significantly affect women's lives. This study explores how endometriosis morbidity affects women's relationships, intimacy, and employment over their lifetime.

Methods: An online survey was conducted in February 2024 among Jewish Israeli women aged 18 to 50. Out of the 573 women, 270 were diagnosed with endometriosis. The survey collected information on the women's diagnostic status, pain severity, social support, negative interactions, life-course impact, and distance from the doctor's clinic.

Results: Women with endometriosis experience a negative impact on their life course compared to women without the disease, particularly in relationships and intimacy (39.41 vs. 18.44, $p<.001$) and employment (19.39 vs. 19.11, $p<.001$). A multivariate regression model was used to predict the effect of endometriosis on the women's life course and revealed that a negative impact on relationships and intimacy ($R2=.385$, $n = 505$) might be predicted by longer travel distance to the doctor's clinic, higher reported pain level, less reported social support level, and higher reported negative interactions. Furthermore, a negative effect on employment ($R2 = .270$, $n = 513$) was predicted by a longer distance to the clinic, a higher reported pain level, less reported social support level, and higher reported negative interactions.

Conclusions: Enencing supportive environments and increasing accessibility to health services is vital to improving the negative impact of endometriosis on women's lives.

Key messages:

- Endometriosis treatment requires a multi-faceted approach, including supportive frameworks, reducing negative interactions, and addressing gaps in health service accessibility.
- Awareness must be raised among employers regarding endometriosis, creating a supportive environment and making necessary adjustments for employees to openly communicate their needs and struggles.

Abstract citation ID: ckae144.1063
Capacity mapping of comprehensive sexuality education in Gabon: A qualitative analysis

Ruth-Janet Koumba Maguena

RJ Koumba Maguena[1]*, EB Ngoungou*[2]*, S Van den Broucke*[1]
[1]Université Catholique de Louvain, Louvain-la-Neuve, Belgium
[2]Université des Sciences de la Santé, Libreville, Gabon
Contact: ruth-janet.koumba@uclouvain.be

Background: Access to comprehensive sexuality education (CSE) is crucial for adolescent health and well-being. Following UNESCO's recommendations, Gabon revised its sex education policy in 2017 to better address adolescents' sexual health needs. This study aims to map the capacities of the public health and education sector to implement Gabon's CSE policy.

Methods: Semi-structured interviews were held with 15 professionals from ministries, NGOs, and development partners. Thematic analysis guided by Aluttis et al's public health capacity model allowed to assess the existing capacities and gaps in leadership, organizational structures, partnerships, resources, and knowledge development for CSE.

Results: The implementation of CSE in Gabon is hindered by socio-cultural and political factors, including the taboo on adolescent sexuality influencing perceptions of CSE content, natalist policies, and socio-economic disparities. Governmental involvement in CSE is limited to key ministries. Organizational structures for CSE lack cohesion due to changes in governance regimes and a lack of support for civil society organizations. Human resources are unevenly distributed, and financial constraints impede government initiatives, causing a strong reliance on external funding. An important role in supporting CSE is played by development partners and partnerships between stakeholders. While knowledge development for CSE is underway, monitoring and evaluation procedures are insufficient, and evidence mobilization by key professionals is insufficient.

Conclusions: Enhancing stakeholder collaboration, addressing structural constraints, and mobilizing human and financial resources are critical for effective CSE implementation in Gabon. Addressing these barriers requires coordinated efforts among stakeholders and addressing systemic challenges. This study provides insights for policymakers and practitioners to strengthen CSE programs and promote adolescent sexual health in Gabon.

Key messages:
- CSE implementation is hindered by taboos on adolescent sexuality, natalist policies, and socio-economic gaps.
- Evaluation and evidence mobilization deficits limit effectiveness.

9.S. Poster walk: Health literacy

Abstract citation ID: ckae144.1064
The role of health literacy in adherence to the Mediterranean diet

Rafaela Rosário

A Duarte[1]*, J Martins*[1]*, S Martins*[2]*, C Augusto*[1]*, MJ Silva*[1]*, F Magalhaes*[1]*,*
C Lopes[1]*, R Rosario*[1]
[1]School of Nursing, University of Minho, Braga, Portugal
[2]ProChild CoLAB Against Poverty and Social Exclusion – Association, Guimarães, Portugal
Contact: rrosario@ese.uminho.pt

Background: Health literacy has emerged as a crucial concept in public health. It is considered a modifiable determinant influencing health-related decision. One such decision is the adoption of specific dietary patterns. The Mediterranean diet has garnered recognition as one of the healthiest diets. This study aims to explore the association between health literacy levels among adults in socially vulnerable contexts and their adherence to the Mediterranean diet.

Methods: This study is part of a cluster-randomized trial conducted in primary schools from socially vulnerable contexts. A total of 469 parents of school-aged children agreed to participate. Health literacy was assessed using the Health Literacy Survey Questionnaire. Adherence to the Mediterranean diet was evaluated using the MEDAS questionnaire. Anthropometric and sociodemographic variables were self-reported via questionnaire. Parental BMI was calculated using weight/heightˆ2. Education level was categorized into two groups (less than higher education and higher education), while professional status was classified based on the occupational categories of collar color. Generalized linear models were utilized for the analysis.

Results: Individuals with higher levels of health literacy present a greater odd to adhere to the Mediterranean diet (B = 0.022, 95% CI 0.010-0.035), even after adjusting for potential confounders (B = 0.019, 95% CI 0.006-0.032).

Conclusions: Health literacy emerges as a crucial factor influencing individuals' dietary choices, as evidenced by its association with higher adherence to the Mediterranean diet. These findings underscore the importance of implementing policies and initiatives aimed at promoting health literacy, particularly among individuals from socially vulnerable contexts. Enhancing public health interventions to bolster health literacy should be prioritized to foster better dietary decision-making.

Key messages:
- Health literacy plays an important role in the adoption of Mediterranean diet among adults from socially vulnerable contexts.
- Implementing policies to aim the promotion of health literacy, particularly among individuals from socially vulnerable contexts are necessary.

Today's society exposes children to vast amounts of health-related information, presenting significant challenges in navigating this content. European health literacy (HL) research underscores the primary school's role in educating children's HL. Several HL interventions have been developed for a school setting and few have used co-design with adolescents. However less is known about co-designing HL activities with children. Therefore, this study aims to identify barriers and facilitators for co-designing HL activities with 9 to 12-year-old children in school settings. We use 4 phases of design-based research for the process of co-designing learning activities with multiple teams of 6-8 children in school settings. First, children Reflect on HL and empathize and define skills they want to design activities for. They Design activities through ideation and prototyping. We use a variety of creative methods for the sessions and analyses, such as body mapping and affinity mapping. The evaluation of the effectiveness regarding HL and learning outcomes will be performed in Test and Evaluate phases. Our preliminary results show that children need short and clear assignments for the sessions to reach the goals. Children are enthusiastic to participate and like the methods used in the session, although the concept of HL is sometimes difficult to comprehend. It is challenging for children to come up with creative and appropriate elements for activities without correct health information. We are awaiting results from Test and Evaluate phase on the effect on HL levels and learning outcomes. Children are able to co-design HL activities together with HL and health promotion researchers. By giving children a voice and hands-on experience in the design process, we are able to create activities that are suitable for the target population. This co-design process will be evaluated and adapted to an intervention for the "healthy school" program in the Netherlands.

Key messages:

- By co-designing HL activities children actively learn about health literacy.
- Children are important and capable co-designers for HL activities when working together with HL researchers.

Contact: santosh.sharma@ul.ie

Patient and public involvement (PPI) in health research is increasing, in recognition for its potential to enhance the quality and relevance of research. To date, there has been no comprehensive review of the literature on the design of infographics with patients and the public in health research. This scoping review aims to explore the extent and nature of PPI in the design of infographics, a commonly used tool for communicating complex health information to diverse audiences. The review used Arksey and O'Malley's methodological framework by Levac et al. Comprehensive searches were carried out in the following databases: Scopus, PubMed Central, Web of Science, EMBASE, CINAHL Complete, PsychINFO, and Cochrane Library. Identified citations were exported to Endnote and imported into Rayyan software for title and abstract screening. Preliminary results report a total of 738 citations imported, out of which 364 duplicates were removed and 374 citations underwent title and abstract screening. Of these, 80 citations were relevant for full-text review. Two independent reviewers evaluated full texts, resolving discrepancies through discussion or by a third reviewer. 62 studies were included in the review. Relevant data was extracted, and numeric and narrative analyses were performed to synthesize findings across included studies. The review found growing interest in PPI for health infographic design, using diverse approaches to engage patients and the public at various design stages. A wide variety of health topics were represented including disease specific topics, pain and weight gain. Common themes identified included the importance of accessibility, clarity, and cultural sensitivity in infographic development, as well as challenges related to generalisability, social desirability bias and ensuring meaningful involvement. This review offers insights and suggests further research and practice in leveraging PPI to optimize the design and impact of health infographics.

Key messages:

- Growing Interest and Importance of Patient and Public Involvement (PPI) in Health Research Design.
- Challenges and Opportunities in Infographic Design for Health Communication.

Abstract citation ID: ckae144.1067
Development of a risk-stratified shared decision-making tool for colorectal cancer screening

Deborah Jael Herrera

Contact: djherrera5947@gmail.com

European guidelines stress the importance of informed decision-making in colorectal cancer (CRC) screening. However, tailored tools that facilitate decision-making for underserved people and general practitioners (GPs) in Flanders are lacking. This study aimed to develop a tailored shared decision-making (SDM) tool for CRC screening, specifically a video decision aid, using a co-creative process. The development involved two rounds of focus group discussions with underserved people and five local quality group meetings with GPs in various parts of Flanders, Belgium. Qualitative data were analyzed using a Modified-Grounded Theory Analytical (M-GTA) approach to identify key themes. Findings revealed four core themes. The first theme, 'Recognizing the Barriers to Screening', identifies challenges such as a lack of time, staff, and tools for GPs, as well as language and literacy barriers for underserved people. The second theme, 'Learning from Existing Tools', highlights successful elements like visuals and simple language and limitations such as low accessibility and poor navigation. The third theme, 'Determining the Content and Design,' reveals that GPs seek user-friendly tools for at-home viewing, while underserved people value personalized and clear information about CRC risk factors and screening costs. The final theme, 'Identifying Strategies for Integration,' stresses the importance of a structured, collaborative care approach for the successful integration of the tool. The proposed modifications for the SDM tool include enhancing its accessibility with multiple language options, using simple and relatable visuals, and providing personalized risk discussions for underserved people and GPs. Nonetheless, further testing is needed to confirm the effectiveness of the SDM tool in supporting preventive talks and informed decision-making in CRC screening among these target groups.

Key messages:

- A structured, collaborative care approach is needed for successful SDM tool integration during preventive talks with underserved people.
- Further testing is needed to confirm the tool's effectiveness in supporting informed decision-making in CRC screening for underserved people.

Abstract citation ID: ckae144.1068
Scoping Review of Health Literacy Interventions among Migrant Communities in Europe

Maria João Marques

A Seyfulayeva[1], *S Dias*[1,2], *R Peruhype*[1], *MJ Marques*[1,2]
[1]NOVA National School of Public Health, Public Health Research Centre, Lisbon, Portugal
[2]Comprehensive Health Research Center, REAL, NOVA University Lisbon, Lisbon, Portugal
Contact: maria.joao.mrqs@gmail.com

Background: The increase in migration trends in Europe has brought attention to the significant health disparities between migrant and native populations, which are largely rooted in social determinants of health such as economic difficulties, language barriers, and limited access to services. Tailored health literacy (HL) interventions can serve as an intermediate factor between social determinants of health and health outcome, thereby holding great potential for addressing these disparities. Despite a growing body of research on migrant health, there remains a gap in our understanding of effective HL interventions for this population.

Methods: A scoping review was conducted following the Joanna Briggs Institute (JBI) updated guidelines and the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) checklist. Electronic searches were carried out across five databases (PubMed, SCOPUS, Web of Science, PsychINFO, and CINHAL) and supplemented by a manual search. We included European studies on migrant HL interventions, conducted between 2011 and 2023, and published in English or Portuguese language.

Results: Out of 1018 records, 7 studies met eligibility criteria. Predominantly situated in Northern and Western Europe (85.5%), interventions primarily targeted female migrants (71.4%) through in-person courses (42.9%). Identified intervention strengths included culturally adapted content, migrant engagement, and access to written materials. Gaps included mental health interventions and community outreach.

Conclusions: This scoping review provides a comprehensive overview of HL interventions targeting migrant populations, highlighting their characteristics, strengths, and gaps. These findings serve as a foundational step towards developing guidelines for effective HL interventions within migrant communities.

Key messages:
- Most European health literacy interventions for migrants target women and are conducted in North or West Europe.
- Cultural adaptation and community engagement are key strengths of migrant health literacy interventions, yet gaps remain in mental health support and community outreach efforts.

Abstract citation ID: ckae144.1069
Visualizing science - the rise of graphical abstracts in public health journals

Duarte Vital Brito

D Vital Brito[1]
[1]Public Health Unit, Western Lisbon Local Health Unit, Lisbon, Portugal
Contact: duartebrito6@gmail.com

Background: As graphical abstracts (GA) gain popularity in scientific journals, they enhance visibility and engagement by summarizing research articles visually, while reaching both scientists and lay audiences more effectively. This study assesses the integration of GA in public health journals, focusing their role in enhancing scientific dissemination.

Methods: We conducted a descriptive quantitative analysis of 163 top-tier journals in Public Health, Environmental, and Occupational Health, using SCImago rankings. The analysis focused on factors such as mentions of GA and video abstracts (VA) in guidelines, mandatory use of GA, accessibility to GA, and adherence to GA's best practices, which include graphical support, titles, and basic explanations.

Results: Of the journals analysed, 43 (26.4%) mention GA in their guidelines; only three (1.8%) require their mandatory use. Eight journals (4.9%) offer GA as part of paid promotional services, while 16 (9.8%) provide easy access to GA in their articles, and just six adhere to basic best practices. VA is mentioned in 25 journals (15.3%), with only nine (5.5%) featuring both GA and VA. Dedicated website sections for GA or VA are found in six journals (3.7%). Elsevier B.V. and Wiley-Blackwell are leaders in promoting GA usage, with 19 and nine mentions in guidelines, respectively.

Conclusions: The adoption of GA in public health journals is increasing, yet full adherence to best practices is not widespread. This trend points to a more visually engaging form of scientific communication, potentially influencing publication standards and research dissemination. The study underscores the need for further training in GA production and promotion among researchers and editors. Additionally, the emergence of GA as a paid promotional tool indicates a novel approach to broadening research outreach, with relevant implications for the standardization of scientific communication across Europe.

Key messages:
- Only 26.4% of public health journals mention graphical abstracts, highlighting the need for wider adoption to enhance research visibility.
- Graphical abstracts boost engagement, but adherence to best practices remains low, underlining the need for better training in visual communication.

Abstract citation ID: ckae144.1070
Digital health literacy and associated socio-demographic characteristics in the French population

Axelle Quiviger

A Quiviger[1], *C Allaire*[2], *E du Roscoät*[2], *J Mancini*[3]
[1]DATA, Santé Publique France, Saint-Maurice, France
[2]DPPS, Santé Publique France, Saint-Maurice, France
[3]SESSTIM Research Unit, Aix-Marseille University, Marseille, France
Contact: axelle.quiviger@santepubliquefrance.fr

Background: With the development of digital devices in the health field, digital health literacy has become an important issue in promoting and protecting people's health. Digital health literacy was measured in a representative sample of the French adult population in order to assess its level and to identify the socio-demographic characteristics of individuals with the lowest literacy levels. Comparisons with works carried out in other European countries as well as implications for the implementation of digital interventions will be discussed.

Methods: Digital health literacy was assed using the HLS19-DIGI-HI Instrument. This 8-item scale measuring the skills related to dealing with digital health information was introduced in the 2023 Health Barometer survey, conducted by the French national public health agency. The survey included French-speaking individuals living in France, aged 18-85, selected through randomly generated phone numbers. 3007 persons were interviewed using a computer assisted telephone interview. A continuous score and categories were calculated to determine the level of Digital Health Literacy. Their associations with sociodemographic characteristics were studied using univariate and multivariate analysis.

Results: 1902 persons declared they used internet to search information or advice on health on internet in the last 12 months and completed the Digital health literacy questionnaire. 61 % of these individuals have a low level of digital health literacy (29 % "inadequate" and 32% "problematic"). Multiple sociodemographic characteristics were associated with lower levels of literacy in univariate and multivariate analysis.

Conclusions: These results are useful to better understand and assess the digital health literacy of the population according to their socio-demographic characteristics. They will provide a knowledge base to implement web-based interventions for promoting targeted digital health interventions, according to targeted audiences.

Key messages:

- This study in large random sample of the French population showed frequent difficulties to deal with online health information.
- Multiple sociodemographic characteristics were associated with digital health literacy and can help to support implementation of targeted digital health interventions.

Abstract citation ID: ckae144.1071
Adolescent mental health literacy and help-seeking behaviours. Cross-Sectional survey in Barcelona

Eulàlia Hernández Encuentra

M Boixadós Anglès[1], E Hernández Encuentra[1], R Casañas Sánchez[2], J Martín Fernández[2], F Lalueza Bosch[3], L Merino Rubio[1]
[1]Faculty of Psychology and Education, Open University of Catalonia, Barcelona, Spain
[2]Research, Les Corts Mental Hygiene Center Association, Barcelona, Spain
[3]Faculty of Information and Communication, Open University of Catalonia, Barcelona, Spain
Contact: ehernandez@uoc.edu

Background: Adolescents' mental health information and help-seeking is critical for preventing the development of mental disorders. This study aims to examine the relationship between mental health literacy and information and help-seeking behaviours, as well as the effects of age and gender.

Methods: A cross-sectional online survey on a representative sample of 2,240 secondary school students in Barcelona from 11 randomly selected schools. Participants are evenly distributed by age (25% each course) and gender.

Results: Most adolescents show good recognition of mental disorders and knowledge of mental health (M = 6.39/10; SD = 1.97 and M = 7.75/10; SD = 1.21 respectively). They report having good literacy (M = 3.25/5; SD = 0.71) to search and manage online health information (eHealth literacy), and around half of them affirm having enough knowledge about mental health for them. Search engines (35.7%) and talking to family/friends (31.8%) are preferred for mental health information-seeking, but 19.8% chose not to engage in active information-seeking behaviour. When having mental health concerns, they prefer seeking help ("I would not ask for help" M = 2.4/7; SD = 1.93), and turning to family (M = 4.7/7; SD = 2.4) and friends (M = 4/7; SD = 2.1), instead of health professionals (M = 2.5/7; SD = 3.5). Chi-square test reveals that: lower recognition of mental disorders is associated with not help-seeking; lower mental health knowledge is associated with beliefs that information for mental health promotion, prevention, and care is unnecessary; and higher eHealth literacy is related to information searching in social media, but not to active searching. The ANOVA test reveals a significant gender-age interaction in certain variables, particularly in the recognition of mental disorders, which is higher in girls and increases with age.

Conclusions: Higher eHealth literacy is related to information-seeking on social media, but not to active search. Girls have a higher level of recognition of mental disorders.

Key messages:

- Adolescents need a support network to seek mental health help, as they often avoid seeking professional help.
- Mental health promotion activities would benefit from further exploration of gender differences.

Abstract citation ID: ckae144.1072
Stakeholders' perspectives on informed decision-making for migrant women in CC prevention programs

Tharsini Veeravagu

T Veeravagu[1,2], N Hamdiui[2], ML Stein[1], N Al-Rubaie[1], J van Wijk[1], MPA Bouman[3], R Crutzen[4], A Timen[2]
[1]Centre for Infectious Disease Control, RIVM, Bilthoven, Netherlands
[2]Department of Primary and Community Care, Radboud University, Nijmegen, Netherlands
[3]Centrum Media en Gezondheid, Gouda, Netherlands
[4]Care and Public Health Research Institute, Maastricht University, Maastricht, Netherlands
Contact: tharsini.veeravagu@rivm.nl

Background: This study gathered the perspectives of stakeholders regarding participation in cervical cancer (CC) screening and human papilloma virus (HPV) vaccination among migrant women in the Netherlands. Considering their perspectives by developing interventions that are tailored to migrant women's information needs regarding CC screening and HPV vaccination will support informed decision-making.

Methods: In total five focus group discussions were held with community leaders, healthcare professionals and communication experts separately. The focus group discussions were transcribed verbatim in Dutch, and analyzed thematically according to the Grounded Theory.

Results: The analysis resulted in six themes. The first theme describes the existing views and misconceptions regarding CC (screening) and HPV vaccination in the target population according to the stakeholders. The second theme is about the current approach of informing about these health programs, and its belonging barriers. Theme three dives into the differences within the target population, such as generations and level of language. Theme four describes the conditions to which interventions should adhere. In theme five and six suggestions for interventions were introduced, focused on the target population and their (social) network respectively.

Conclusions: The results of this study showed that stakeholders are willing to play a role to support informed decision-making regarding CC (screening) and HPV vaccination among migrant women, but they need more training to support. Community leaders express a need for training to gather more medical knowledge of CC and its prevention programs. Healthcare professionals expressed a need for more insight into the practical, cultural, religious and emotional aspects that play a role within this target population. Communication experts emphasize the need for customized information materials and a more district-oriented approach.

Key messages:

- Stakeholders operating at different levels are willing to play a role in increasing informed decision-making regarding CC screening and HPV vaccination.
- Migrant women's (social) network need more training and support to be able to provide tailored information regarding CC screening and HPV vaccination.

Abstract citation ID: ckae144.1073
Public and professional attitudes to the digitisation of health and social care in Ireland

Daráine Murphy

D Murphy[1], *I Novak*[1], *D Hyland*[1], *E Burke*[1], *M Higgins*[1], *K O'Carroll*[1], *L Weir*[1], *R Flynn*[1]
[1]Health Information and Quality Authority, Dublin, Ireland
Contact: damurphy@hiqa.ie

Background: The European Commission has set targets for all EU citizens to have access to electronic medical records by 2030. In Ireland the Sláintecare health reform programme has set goals around the use of digital technologies in health and social care. The Health Information and Quality Authority (an independent authority established to drive high-quality and safe care for people using health and social care services in Ireland) in partnership with the Health Service Executive (public healthcare provider) and the Department of Health (Ministry) conducted a National Engagement on Digital Health and Social Care. The aim of this engagement was to understand the opinion, attitudes and comfort levels of the public and professionals working in health and social care around digitisation of health and social care.

Methods: The National Engagement on Digital Health and Social Care used a mixed-method approach to data collection. There were two surveys, a national telephone survey with a representative sample of the public (n = 2009) and an online survey with professionals working in health and social care (n = 1020). There were separate focus groups with professionals and with the public, including representatives of minority groups.

Results: Preliminary results indicate that the public and professionals have positive attitudes to digital health and social care. Of the public surveyed 73% said that they are likely to access their online health record. Professionals feel that when the public have access to information via an online health record they will be better informed about their health (88%). Both the professionals and public feel that it is important to ensure patient choice around the format and delivery of care.

Conclusions: The research provides valuable insights and gives the public and professionals a platform to voice their opinions and have a meaningful impact on how digital health and social care is developed and implemented in Ireland.

Key messages:
- This research provides unique insights and a deeper understanding into the attitudes of Irish public and professionals working in health and social care towards digital health.
- Research findings will inform national policy, legislation and recommendations on the use of digital health tools in Ireland.

Abstract citation ID: ckae144.1074
Mixed-methods systematic review of shared decision-making tools for cancer screening

Deborah Jael Herrera

DJ Herrera[1], *W van de Veerdonk*[1,2], *NM Berhe*[1,3], *S Talboom*[4], *M van Loo*[2], *A Ruiz-Alejos*[1], *A Ferrari*[1,5], *G Van Hal*[1]

Contact: djherrera5947@gmail.com

Shared decision-making (SDM) tools hold promise for guiding informed choices in cancer screening. However, their effectiveness among underserved people, as well as the specific characteristics of these tools preferred by this group and clinicians, remains unclear. This review aimed to synthesize evidence on the effectiveness of SDM tools for cancer screening and explored the preferences of underserved people and clinicians regarding the specific characteristics of the SDM tools. A mixed-method convergent segregated approach was employed, which involved an independent synthesis of quantitative and qualitative data. Articles were systematically selected and screened, resulting in the inclusion and critical appraisal of 55 studies. Results from the meta-analyses showed that SDM tools for cancer screening are effective in reducing decisional conflict for both the general population and the underserved, and in increasing cancer screening knowledge and intention for underserved people only. Subgroup analyses showed minimal heterogeneity for decisional conflict outcomes, measured over a six-month period. Insights from the qualitative findings revealed that underserved people highly preferred SDM tools with relevant information about cancer risk, culturally tailored content, and high accessibility, both during clinical encounters and beyond. Meanwhile, clinicians highly preferred tools that can be easily integrated into medical systems, and can effectively guide SDM, while considering their patients' values and the limited time for consultation. There is strong evidence on the effectiveness of SDM tools in facilitating informed choice in cancer screening, especially among underserved people. However, evidence on long-term outcomes remains insufficient. Additionally, considering the difference in preferences of key stakeholders in terms of tool characteristics, fostering collaboration with them during the creation of an SDM tool for cancer screening is essential.

Key messages:
- Shared decision-making tools are effective in increasing screening knowledge and intention among underserved people.
- Considering the difference in preferences of key stakeholders in terms of tool characteristics, fostering collaboration with them during the creation of an SDM tool for cancer screening is essential.

Abstract citation ID: ckae144.1075
Is genomic testing properly evaluated? A systematic review of health technology assessment reports

Giuseppe Migliara

G Migliara[1], *A Sciurti*[2], *V Baccolini*[2], *I Mussetto*[2], *AE Kaminska*[2], *A Pistollato*[2], *A Anniballo*[2], *I Leone*[2], *C Marzuillo*[2], *P Villari*[2]
[1]Life Sciences, Health, and Health Professions, Link Campus University, Rome, Italy
[2]Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
Contact: gmigliara@gmail.com

Background: The last decade has witnessed a steady embrace of Personalized Medicine. However, the evaluation of genetic/genomic tests is not straightforward. The purpose of this systematic review is to identify health technology assessment (HTA) reports assessing genetic and genomic tests, to summarize the methodologies used, the maturity level of the evidence included in it and the highlighted gaps in research.

Methods: PubMed, Scopus, and Web of Science were searched. Additionally, a desk research was performed on the main HTA reports repositories. HTA reports expressly created to assess genetic/genomic technologies including at least three core evaluation components (analytic validity, clinical validity, clinical utility, economic evaluation, organizational aspects, ethical, legal, and social implications) were included. This study was supported by the EC and MUR under PNRR - M4C2-I1.3 Project PE_00000019 'HEAL ITALIA'.

Results: Overall, 27331 unique records were retrieved, 55 of which were included in the systematic review. The reports were mainly from Australia (29%), Canada (27%) and UK (25%), regarded

pharmacogenomics (36%) and oncology (35%), and analysed test use for treatment choice (29%) and diagnosis (13%). The most reported evaluation components were economic evaluation (87%), clinical utility (76%), and clinical validity (67%). Personal utility (7%), ethical (15%), legal (11%) and social (24%) implications and the patient's perspective (27%) were poorly represented. Analytical validity, safety, and organizational aspects were included in about half of the reports.

Discussion: Although these are only preliminary results, the substantial lack of a shared standard in the evaluation of genetic/genomic applications appears clear, given the heterogeneity of the dimensions addressed between reports, as well as the need to strengthen the evaluation of the neglected dimensions, often of primary importance in the definition of the value and risks of personalized medicine.

Key messages:

- The findings highlight the lack of a standard in evaluating genetic/genomic applications.
- A common methodology should be developed to comprehensively evaluate genetic/genomic applications.

Background: Emerging Infectious Diseases (EIDs) pose a significant threat to global human health; they can lead to epidemics and pandemics with severe repercussions on human life, economic performance, and societal well-being. Despite the recognized negative impact of the EIDs, current research lacks a comprehensive global framework to assess the significance and interaction of various environmental and anthropogenic factors driving emergence of these diseases.

Methods: In this study, we examine both environmental and anthropogenic factors and their relation to the emergence of EIDs, focusing on historical trends from 1975 to 2020. We focus on 10 diseases with pandemic and epidemic potential. Spatial data on outbreaks in humans and animals from 1975 to 2020 were retrieved from the GIDEON database. Using Bayesian statistical models, we pinpoint regions at increased risk, and we focus on a new indicator based on the human-forest proximity.

Conclusions: Our results show that human-forest proximity together with biodiversity loss, and high population density increase the likelihood of diseases being transmitted from animals to humans, influencing where outbreaks occur among human populations. Lastly, we introduce a country vulnerability index that combines our risk assessment with the IHRC3 indicator from the WHO, which gauges a country's capability to handle zoonotic diseases. These combined indices help us to assess each country's ability to respond to an outbreak. The study also addresses data limitations and proposes directions for future research, emphasizing the importance of our findings in shaping public health policies and decision-making.

Key messages:

- Anthropogenic drivers shape the distribution of outbreaks in human populations.
- Human-forest proximity exacerbates the likelihood of Emerging Infectious Disease.

Abstract citation ID: ckae144.1077
Level of tobacco dependence and beliefs towards heated tobacco products

Barbara Gradowicz-Prajsnar

B Gradowicz-Prajsnar[1], M Kozela[1], J Sytnik-Czetwertyński[2], M Polak[1]
[1]Department of Epidemiology and Population Studies, Jagiellonian University Medical College, Cracow, Poland
[2]Centre of Postgraduate Medical Education, Centre of Postgraduate Medical Education, Warsaw, Poland
Contact: barbara.gradowicz@uj.edu.pl

Nicotine dependence affects not only behaviors related directly to smoking, quit attempts or looking for alternative products but also beliefs about smoking. We sought to assess whether the level of tobacco dependence is associated with beliefs and feelings towards heated tobacco products (HTP) and to assess the relationship between tobacco dependence and the motivators to quit HTP use. Random population sample of Polish citizens aged 18+ years, former smokers, current HTP users was recruited. Tobacco dependence was assessed using 5 question; participants were classified into two groups of tobacco dependence (low or high) using a two-stage cluster analysis. An extensive questionnaire on beliefs on HTP use was administered. The $\chi 2$ test and logistic regression were used. There were 2,500 participants (62.6% women) of median age=36 years (Q1=29, Q3=45). The median number of years of smoking was 10 (Q1=5, Q3=15) and median number of years of HTP use was 2 (Q1=1, Q3=3). High tobacco dependence was found in 958 (38,3%) participants. Compared to low dependence, high tobacco dependence was related with feeling of strong need for HTP use (69.7% vs. 47.6%, $p < 0{,}001$). High level of tobacco dependence was positively related to perceived social pressure against smoking (72.9% vs. 44.9%, $p < 0{,}001$), but it did not differentiate perceived social pressure against HTP use. Compared to low tobacco dependence, participants with high tobacco dependence more often indicated fear of illness OR = 1,73 95%CI=1,46-2,07, own resolution OR = 1,32 95%CI =1,12-1,55 and price OR = 1,34 95%CI=1,13-1,59 as possible motivators to quit HTP use. Level of tobacco dependence in former smokers shaped beliefs and feelings towards HTP use. High tobacco dependence contributed to strong need to use HTP and also increased perception of social pressure against smoking, but not against using HTP. It also increased the importance of fear of illness, price and one's own resolution as motivators to quit HTP use.

Key messages:

- High level of tobacco dependence in former smokers results in stronger perceived social pressure against smoking but not against HTP use.
- High tobacco dependence in former smokers is related with stronger need to use HTP.

[2]Department of Botany, Trinity College Dublin, Dublin, Ireland
Contact: lukecura@tcd.ie

Background: It is estimated that by 2050, ten million people will die each year from antimicrobial resistant infections. AMR is driven by the improper use of antimicrobials, particularly in agriculture. 73% of the antimicrobials sold globally are used in food-producing animals.

Problem: EU regulations 2019/6 and 2019/4 on veterinary medications and medicated feed require behavior change by farmers to reduce their antimicrobial use. While this is welcomed by public health professionals, the response of the farming community is more complicated, as these regulations exist within the complex context of the global food system and current political unrest between farmers and the EU. Given the influential role of agricultural media for farmers' decision making, it is critical to understand how AMR and associated public health and EU policies are being communicated to farmers and how the views of specific stakeholders including farmer representative organizations, veterinary bodies and government regulators are being represented. To examine this problem, a case study content analysis of three major agricultural newspapers in Ireland is undertaken.

Results: Preliminary results suggest that AMR and AMU have been covered in the agricultural media with specific coverage on these EU policies. This includes negative coverage, with key terms such as "threatens", "risk", or "warns", as well as potentially positive views (e.g. "hope"). Preliminary results also suggest that the agricultural media might be a useful source to identify the farming community's concerns and reactions to EU policy, for example calls by farmer representative bodies for the national government to intervene.

Lessons: Public health professionals must recognize the important role of farmers in addressing AMR. Evaluating how EU policies on AMR are represented in the agricultural media can help to better understand how this public health issue and its solutions are being communicated to these important stakeholders.

Key messages:
- Public health professionals must recognize the importance of animal health and the role of farmers in addressing the AMR problem.
- It is critical to evaluate how EU policies on AMR and associated One Health issues are communicated to non-public health professionals.

Abstract citation ID: ckae144.1079
Evaluating mental health care initiatives after Ghana's mental health act: a systematic analysis

Maria Fabiana Rizzieri

M Rizzieri[1], *A Hannawa*[1]
[1]Faculty of Communication, Culture and Society, Università della Svizzera italiana, Lugano, Switzerland
Contact: rizzieri.fabiana@gmail.com

Mental health disorders affect 970 million people worldwide. Particularly in Africa, mental health is a growing concern, as it faces poverty and limited healthcare services. The Ghana Mental Health Act (GMHA 2012) marked a significant milestone in the development of a legislative framework supporting the provision of mental healthcare. However, evidence of progress since then is scarce. This systematic review examines the mental health initiatives that have been implemented since GMHA. Bronfenbrenner's Socio-Ecological and Vygotsky's Sociocultural Theory are used as frameworks to organize the interventions by ecological layers and cultural practices. All peer-reviewed articles published since the GMHA were retrieved from PubMed, Cochrane and Science Direct, using "mental health interventions," "-collaborations," "-health programs" and "Ghana" as keywords. The search yielded 3839 articles. Next, publications that were not conducted in Ghana or did not focus on mental health were excluded yielding a final sample of 69 articles for the review. Consistent with the GMHA's guidelines interventions were conducted in communities (n = 56; 81%) rather than hospitals (n = 13; 19%). Most of them focused on institutional ecological levels (i.e., schools, health centers, traditional healing conventions; n = 29; 42%), followed by interpersonal (n = 14; 20%) and community-level (n = 14; 20%) approaches. Half (n = 33; 48%) entailed some form of cultural responsiveness, such as adapting educational tools to cultural contexts or accounting for spiritual beliefs. Only 23% (n = 16) of the interventions targeted children or adolescents. The findings of this review suggest three implications for future mental health research. First, stigma reduction and mental health literacy need to become a stronger focus. Second, research on children and adolescents needs to be increased. Third, interventions led by European partners must be tailored carefully to the Ghanaian beliefs system.

Key messages:
- Assessing the community-based approach of mental health interventions following the Mental Health Act's legalization in Ghana.
- European partners need to understand the context and the local culture before planning to research or implement intervention materials. Adaptation is key in the effectiveness of the intervention.

Global malaria vaccine research and community perception in Africa: a systematic review

Muhammad Chutiyami

M Chutiyami[1], *UM Bello*[2], *D Salihu*[3]
[1]School of Nursing and Midwifery, University of Technology Sydney, Sydney, Australia
[2]Department of Physiotherapy and Paramedicine, Glasgow Caledonian University, Glasgow, UK
[3]College of Nursing, Al Jouf University, Sakaka, Saudi Arabia
Contact: muhammad.chutiyami@uts.edu.au

Background: Malaria vaccine is one of the critical areas in tropical health research, considering the success recorded in other vaccine-preventable diseases. This review provides an overview of global malaria vaccine research and systematically reviews community perception of the vaccine in Africa.

Methods: A validated search was conducted to identify scientific literature on malaria vaccines in the Scopus database from 2005. Bibliometric indicators explored include publication/citation indices over time and the overall research themes using VOSviewer. A further in-depth search was undertaken in five databases to identify studies on community perception of malaria vaccine in Africa. Studies were screened, quality appraised, and narratively synthesized.

Results: 6457 malaria-vaccine-related documents were found in 160 journals/sources from 189 countries/territories. There were 214,323 total citations, with 33.2 average citations per document and 167 documents' h-index. The United States, United Kingdom and Australia combined produced more than 60% of the publication output. Six themes emerged from the global malaria vaccine research: Merozoite surface protein, characterization, trials, infant/children, traveler, and research/review. Twenty studies (n = 20) met the inclusion criteria for the systematic review. Overall perceptions of malaria vaccines varied in African communities (26.2-88.2%), in addition to higher willingness to accept the vaccines (32.3%-96.0%), poor knowledge/awareness (11%-60%) and misconceptions (19.2%-20.9%). Other issues identified include vaccine availability and logistics.

Conclusions: Malaria vaccine research and citations have increased considerably, mainly targeting vaccine development and safety/efficacy in Africa. African communities' perceptions of the vaccine varied, with most of the population willing to accept the vaccine.

Key messages:

- An increase in number of malaria vaccine research targeting vaccine development, and safety and efficacy in Africa.
- Varried malaria vaccine perception in Africa, including willingness to accept the vaccine, awareness, misconceptions, availability and logistics.

[2]Regional Direction of Primary Health, Ministry of Health, Monastir, Tunisia
[3]LTIM - LR12ES06, University of Monastir, Monastir, Tunisia
Contact: cyrine.bennasrallah@gmail.com

Background: Advocating for a One-Health approach is crucial for ensuring effective rabies surveillance in Africa, including Tunisia. Collecting information is essential to evaluate the prevalence of dog bites and rabies in Tunisia. To address this, we conducted an analysis of reported incidents in the central region of Tunisia from 2019 to 2022. This analysis aimed to generate valuable insights that can inform strategies for rabies elimination in Tunisia, highlighting the importance of the One-Health approach.

Methods: We carried out a descriptive study using surveillance data from Monastir governorate in Central Tunisia. All humans exposed to animals, residents in Monastir Governorate and declared to the regional directorate of primary health care from January 1, 2019 to December 31, 2022 were included in our study. Data were entered, cleaned, and analyzed using Excel.

Results: During the studied period, 7789 cases of human exposures to animals were reported with an annual average of 1969 ± 207 exposures per year. The annual incidence rate of exposure to animal bites was 324 per 100,000 population. The sex-ratio was 2.07 and almost one third of exposed humans were aged less than 15 years-old. The most listed offending animals were dogs (65.2%), followed by cats (24.4%). The number of exposures by unvaccinated dogs increased significantly during our study period. Post-exposure prophylaxis (PEP) was applied among 99% ($n = 7772$) of declared exposures. Among them, 2.5% ($n = 202$) did not complete the PEP recommended protocol. During our study period, rabies was confirmed in 39 animals. Two fatal human rabies cases were declared respectively in 2021 and 2022.

Conclusions: Rabies remains a worrying health problem in Tunisia with a high percentage reported among youth and males. Targeting children and adolescents by education and information campaigns about preventive measures and mass dog vaccination are the key to ending this scourge.

Key messages:

- It is crucial to reinforce preventive strategies, such as mass dog vaccination programs.
- Public awareness about rabies prevention should be enforced in order to decrease Human rabies risks.

Contact: gingrass@myumanitoba.ca

Background: End-stage renal disease (ESRD) patients have muted memory B cell formation and reduced humoral responses to COVID-19 vaccination; however, early innate immune responses have yet to be characterized. Sex-stratification is also limited in COVID-19 vaccination research.

Methods: We collected blood before (BD1) and 1-4 days post-dose 1 (PD1) of BNT162b2 vaccination for RNA-sequencing in ESRD patients ($n = 35$ BD1; 18 PD1) and healthy controls (HC) ($n = 31$ BD1; 30 PD1). Additionally, 20 plasma cytokines were quantified in ESRD patients ($n = 39$ BD1, 35 PD1) and HC (34 BD1, 15 PD1).

Results: Transcriptional profiling of vaccine responses identified 125 significantly differentially expressed genes (DEG) ($padj<0.04$) in ESRD patients and 107 DEGs ($padj<0.05$) in HC. 71 DEGs were shared, 54 unique to ESRD, and 36 unique to HC. DEG, pathway analyses, and cytokine responses in the combined dataset showed ESRD patients were more inflamed than HC at baseline, with an elevated inflammatory cytokine profile compared to HC. These results were driven by female ESRD patients where IL-2, IL-10, and IP-10 were more significant in females ($p < 0.001$) compared to males ($p < 0.01$). While IL-6, IFN-γ, IL-13, eotaxin, were exclusively associated in females ($p < 0.05$). Healthy females also had a stronger immunological response to vaccination compared to healthy males.

Conclusions: Despite baseline inflammation, ESRD patients were able to mount similar early immune responses to vaccination as HC, with females in both populations more reactogenic than males. Sex-stratification is recommended for ongoing immunological research to better understand unique responses to COVID-19 vaccination.

Key messages:

- End-stage renal disease patients have similar early innate immune responses to COVID-19 vaccination as healthy controls.
- Sex-stratification is important to identify unique immunological responses that may be leveraged for sex-specific vaccination strategies.

Background: Limited longitudinal data exist on chronic kidney disease (CKD) in African populations undergoing epidemiological transitions. We investigated incidence, long-term predictors, and progression of CKD among Ghanaians residing in rural- and urban-Ghana, and Ghanaian migrants in the Netherlands (Amsterdam).

Methods: We analysed data from 2183 participants in the transcontinental population-based prospective RODAM-cohort, followed for approximately seven years. CKD incidence and its progression to end-stage renal disease (ESRD) were defined using KDIGO criteria. CKD incidence was calculated using age-and sex-standardization for those without CKD at baseline. Long-term predictors of CKD incidence were identified using one-step robust Poisson regression. CKD progression to ESRD from baseline was also assessed using robust Poisson regressions.

Results: Overall age-and-sex standardized CKD incidence was 11.0% (95%CI; 9.3%-12.3%). Rural and urban-Ghanaians had higher CKD incidence (12.5%;8.5%-15.5%; 12.3%;8.2%-15.8%; respectively) than Amsterdam-Ghanaians (7.6%; 5.4%-10.6%). Residence in Amsterdam was associated with lower CKD incidence compared to rural Ghana after adjustments (Incidence Rate Ratio=0.34; 0.13-0.89), but not with urban-Ghana (IRR=1.07; 0.69-1.67). CKD incidence predictors were advanced age, female sex, alcohol consumption, uric acid levels, and hypertension. CKD progression to ESRD was 2.5% (1.4%-3.6%) in rural- Ghana, 2.3% (1.3%-3.2%) in urban-Ghana and 0.0% in Amsterdam.

Conclusions: One-tenth of Ghanaians developed CKD over seven-years, with higher incidence in Ghana compared to Europe. Age, female sex, alcohol use, uric acid levels, and hypertension were predictive factors. CKD progression to ESRD was minimal. High CKD incidence among Ghanaians, especially among non-migrants, calls for in-depth assessment of contributing factors and targeted interventions.

Key messages:

- We observed higher CKD Rates in Rural/Urban Ghana vs. Amsterdam:Indicating geographic Disparities.
- CKD Predictors: Age, Sex, Alcohol, Uric Acid, Hypertension (Minimal ESRD Progression). Interventions target: Non-Migrant Ghanaians.

Environmentally sustainable health and social care – A proposal for goals and steering for Finland

Pia Wulff

P Wulff[1], L Alanko[5], S Iivonen[2], A Nissinen[4], L Setälä[3], P Meriläinen[2], H Savolainen[4], K Alhola[4], E Suomalainen[4], J Pulkki[1]

[3]The Wellbeing Services County of Southwest Finland, Turku, Finland
[4]Finnish Environment Institute, Helsinki, Finland
[5]Demos Helsinki, Helsinki, Finland
Contact: pia.wulff@tuni.fi

Issue: Health and social services cause significant environmental impacts. In Finland, national steering towards environmentally sustainable health and social care has been lacking.

Description of the problem: A multidisciplinary research project (EKO SOTE 2022-2023) was designed to investigate aims and steering mechanisms for environmentally sustainable social and health care in Finland. The project aimed to propose national steering and monitoring mechanisms for stronger environmental sustainability within the sector. Data for the proposal was collected from literature, review of national legislation, interviews, surveys, and co-development events. The project also aimed to calculate the carbon footprint of Finnish health and social care with the EEIO model ENVIMAT.

Results: It was estimated that health and social care contributed to 6.5% of Finland's national carbon footprint in 2019, of which the share of health care was 4.2%. The new goal 'Social and health care is carbon neutral and minimizes the environmental burden by 2035' was proposed to be incorporated in the national strategic steering. Wellbeing service counties (WSC) as public care providers were suggested to be included as responsible actors in the Finnish Climate Act. National networks and targeted project funding for WSCs were found important. Three sets of indicators were designed for monitoring environmental sustainability: minimum indicators for all WSCs for national monitoring, voluntary indicators for regional monitoring, and indicators for advanced regions to pioneer best practices.

Lessons: According to the informants, national steering for environmentally sustainable health and social care is urgently needed. The national goal should be ambitious, wide-ranging, and feasible, and cover environmental aspects broadly. The steering requires multiple mechanisms: normative, strategic, informational, and economic. WSCs should be empowered to develop suitable means to achieve the national goal.

Key messages:

- The project provided an ambitious, feasible, and comprehensive national goal and steering model for reducing the environmental impact of health and social care in Finland.
- Collaborative efforts and joint steering model could advance environmental sustainability in health and social care.

Contact: hajzer.zsuzsa@etk.unideb.hu

Background: Our team has demonstrated in a number of pre-clinical studies that special bees fed with syrups containing natural plant extracts contain a number of active substances that have beneficial effects on the human body. We have previously reported that bees fed with green walnut have beneficial effects on sugar metabolism, lowering serum glucose levels and reducing insulin resistance.

Methods: We conducted a prospective double-blind functional food study with 45 healthy volunteers using a strict inclusion and exclusion criteria with ethical approval. Participants ate 30 gramms of honey layered under 150 ml of yoghurt twice a day for 3 weeks. Fifteen participants consumed honey from bees fed with green

walnut extract, while 15 participants consumed honey from bees fed with sea buckthorn extract, and 15 participants in the control group consumed acacia honey. Sleep quality was assessed with the SQS questionnaire, and quality of life with the SF-36, EORTC Q-C30 and EQ-5D tests on days 0 and 22 of the study.

Results: Consumption of both specific honey resulted improvements in the life quality parameters and in the sleep quality. 'Buckthorn honey' showed significant differences after the 3rd week: physical function improved (25.3±0.5 vs 27.4±2.8; p = 0.04), anxiety-depression decreased (1.4±3.6 vs 1±0.3; p = 0.03), complex physical status (84.1 ±9.7 vs 88.7±6.9; p = 0. 04), while 'green walnut honey' improved EQ-5D complex quality of life (84.1±9.7 vs 88.9±6.9; p = 0.01), overall quality of life functioning (90.6±14.9 vs 99.2±4.2; p = 0.03), EORTC Q-C30 total score (467.1±30.6 vs 487.4±21.4; p = 0.03).No such positive effects were confirmed in the control group.

Conclusions: Honey from bees fed with sea buckthorn extract has many beneficial physiological effects on the human body, improving physical well-being and reducing anxiety and depression. Honey from bees fed with green walnut extract improves the complex quality of life.

Key messages:

- Improving the quality of life with nutrition is an increasingly important research field, playing a key role in our life.
- Our research has shown that honey from bees fed with green walnut and sea buckthorn extract improves several parameters in the quality of life.

[2]Department of Emergency Medicine, Taipei Medical University Hospital, Taipei, Taiwan
[3]Department of Emergency Medicine, Taipei Medical University, Taipei, Taiwan
Contact: er.chao@tmu.edu.tw

Background: Prior studies have offered valuable insights into risk factors associated with bicycle crashes at intersections. Nevertheless, limited research focuses on investigating three types of bicycle crashes that commonly occur on road segments: overtaking, rear-end, and door crashes.

Methods: In the present research, risk factors for these three types of crashes on road segments were examined by analyzing British STATS19 reports of crashes from 1991 to 2020. We calculated adjusted odds ratios (AORs) with 95% confidence intervals (CIs) for multiple risk factors using multivariate logistic regression models. The analysis included 127,637 bicycle crashes, categorized into 18,350 overtaking, 44,962 rear-end, 6,363 door, and 57,962 other crashes.

Results: Speed limits of $\geq$ 40 miles per hour (mph) (AOR = 2.238, 95% CI = 2.159-2.320), heavy goods vehicles (HGVs) as crash partners (AOR = 2.867, 95% CI 2.473-3.323), and elderly crash partners (AOR = 2.013, 95% CI = 1.937-2.092) were significant risk factors for overtaking crashes. Notable risk factors for rear-end crashes included midnight hours (AOR = 1.269, 95% CI = 1.190-1.354) and unlit darkness (AOR = 1.486, 95% CI = 1.404-1.573). Speed limits 20-30 mph (AOR = 16.185, 95% CI = 13.514-19.382), as well as taxis and private rental automobiles (AOR = 2.695, 95% CI = 2.310-3.145), were factors associated with door crashes. Further intriguing findings from our joint-effect analysis included higher probabilities for overtaking crashes in rural regions when older drivers and HGVs were crash partners (AOR = 2.93, 95% CI = 2.79-3.08 and AOR = 2.62, 95% CI = 2.46-2.78).

Conclusions: The mentioned risk factors have remained mostly consistent since our previous study was conducted in 2011. However, current research elucidated that certain factors have become more significant under specific circumstances. For instance, in rural areas, cyclists were more likely to be involved in overtaking crashes with heavy goods vehicles as crash partners.

Key messages:

- Bicycle crash; Road segment; Door crash; Overtaking crash; Rear-end crash

[6]School of Population Health, RCSI University of Medicine and Health Science, Dublin, Ireland
Contact: ms1920@ic.ac.uk

Background: Policies to reduce free sugar intake in the population often suggest alternative low or no sugar products that may contain low-calorie sweeteners (LCS). However, the health effects of LCS are controversial and little is known about whether free sugar and energy intake differ between people with varying levels of LCS product consumption. This study examines the associations between LCS product consumption and free sugar and energy intake in UK adults from 2008 to 2019.

Methods: Repeat cross-sectional data from the UK's National Diet and Nutrition Survey (2008/09 to 2018/19) involve 8304 adults aged $\geq$18 years (mean 48.7, SD 18.3) with 58.4% being women. Consumption of LCS products (grams/day) were obtained from 4-day diet diaries and participants were categorized into four groups (No-LCS, Low-LCS, Mid-LCS, High-LCS) based on LCS consumption tertiles in 2008/09. Linear regression analysed associations with LCS group, year, their interaction, and adjusted for sociodemographic factors.

Results: All four groups consumed free sugar (relative to total energy intake) above recommended levels (5% kcal/day) throughout the study period. In 2008/09, the mean free sugar intake for the No-LCS group was 58.1 grams/day, and the mean total energy intake was 1855.7 kcal/day, which were not significantly different from the High-LCS group. Over time, free sugar intake declined by -1.0 g/year (95%CI: -1.4, -0.6) whereas total energy intake declined by -6.0 kcal/year (95%CI: -11.4, -2.1) in the No-LCS group. The High-LCS group showed similar declines leading to no significant difference in mean free sugar and total energy intake between the No-LCS and High-LCS groups in 2018/19.

Conclusions: In this representative study of UK adults, similar levels of free sugars and total energy intake were observed among those with no LCS and those with the highest LCS product consumption from 2008 to 2019. Absence of LCS product consumption in diets were not associated with higher free sugar intake.

Key messages:

- The high level of LCS product consumption was not associated with lower free sugar intake among UK adults. These finding challenges policies promoting LCS to reduce UK adults' free sugar intake.
- The finding that UK adults consistently consumed free sugar above recommended levels highlights the ongoing need for policy interventions.

[4]Faculty of Medicine, University of Porto, Porto, Portugal
[5]Centre for Mathematics, University of Porto, Porto, Portugal
Contact: susana.m.santos@ispup.up.pt

Background: Studying the risk factors for obesity development and timely identification of individuals at increased risk are key for obesity prevention. We aimed to assess the associations of multiple prenatal, infancy and childhood exposures with overweight/obesity at 13 years (y) and develop static and dynamic multiple-exposure prediction models.

Methods: In 4232 mother-child pairs from the Generation XXI birth cohort, we assessed, during pregnancy/infancy and childhood, 55 sociodemographic factors, anthropometric measures, lifestyle behaviors, and clinical exposures related to the mother and the child and categorized body mass index z-scores as normal weight and overweight/obesity at 13y. Static models for pregnancy/infancy, 4, 7 and 10y, and a dynamic model were fitted using Elastic Net and logistic regression and were compared in terms of predictive performance.

Results: Mothers with lower educational level and household income, no partner, overweight/obesity before and after pregnancy, excessive gestational weight gain, pregnancy complications and who were smokers during pregnancy had children with a higher risk of overweight/obesity at 13y. Children with higher BMI during infancy, overweight/obesity during childhood, an early introduction of solid foods (before 4 months), a higher consumption of soft drinks at 4y and females had a higher risk of overweight/obesity at 13y. We observed the lowest predictive performance for the pregnancy/infancy model (prediction error of 36%) and the highest predictive performance for the 10y and dynamic models (prediction errors of 17%).

Conclusions: We identified the most important predictors of overweight/obesity in adolescence, most of them modifiable, and able to be targeted in prevention strategies. Predicting overweight/obesity risk in adolescence might be suboptimal if only considering pregnancy/infancy data and improves as closer to the age of the outcome, with no additional benefit in using a complex dynamic model.

Key messages:

- Prevention of overweight/obesity should start during prenatal life.
- Children at higher risk of overweight/obesity may be identified years earlier using prediction models in clinical practice.

Contact: eyedry@snu.ac.kr

Background: While the impact of light pollution on human health is gaining recognition, its role in transmitting the effects of maternal exposure to the fetus remains unclear. This study is to investigate the association between exposure to artificial light at night (ALAN) during pregnancy and risk of congenital glaucoma.

Methods: All birth cohorts spanning from 2008 to 2011 in urban areas of South Korea, comprising over 90% of the total population, were identified in the Korean National Health Insurance database. Average levels of ALAN at the residential addresses of mothers during pregnancy were estimated using time-varying satellite data for a composite view of persistent night-time illumination at ∼1 km2 scale.The odd ratios (ORs) and 95% confidence intervals (CIs) of the association between residential ALAN and risk of congenital glaucoma - was computed using logistic regression. These calculations were adjusted for socio-demographic factors and area-level risk factors (night-time traffic noise and particulate matter with an aerodynamic diameter $\leq$ 10 μm).

Results: A total of 745,458 mother-father-child trios (mean [SD] age of the mothers, 32.4 [3.8] years; 387,275 [52.0%] boy) were included in the study. In fully adjusted models, an IQR (21.8 nW/cm2/sr) increase in ALAN level was associated with an OR of 1.12 (95% CI: 1.05, 1.19) for incident congenital glaucoma. The exposure-response curve demonstrated an upward slope with a threshold at approximately 62 nW/cm2/sr.

Conclusions: In this nationwide population-based case-control study, higher levels of residential ALAN during pregnancy were associated with increased risk of congenital glaucoma. Future studies with more detailed information on exposure, individual adaptive behaviors and potential mediators are warranted.

Key messages:

- This study indicates an association between elevated levels of ALAN exposure in pregnant women and a heightened risk of congenital glaucoma in their offspring.
- These results are consistent with a growing body of evidence underscoring the detrimental effects of ALAN on health, reinforcing its potential role as a risk factor for congenital glaucoma.

Abstract citation ID: ckae144.1090
Supply of Alcohol in Early Childhood Leads to Higher Rates of Drinking in Adolescence

Albert Ksinan

A Ksinan[1], G Ksinanova[1], H Pikhart[1,2], M Bobak[1,2]
[1]RECETOX, Masaryk University, Brno, Czechia
[2]Department of Epidemiology & Public Health, University College London, London, UK
Contact: albert.ksinan@recetox.muni.cz

Background: Adolescents often experience their first encounter with alcohol at home, provided by parents who perceive it as a means of safeguarding their children against later alcohol-related issues. However, research shows that parental supply of alcohol is a risk factor for adolescent drinking. Notably, existing studies solely focused on parental supply during adolescence, neglecting the prospective evaluation of parental alcohol provision during early childhood on later alcohol use.

Methods: The data came from the Czech part of the European Longitudinal Study of Pregnancy and Childhood (ELSPAC), a longitudinal birth cohort study ($N = 5,777$). Mothers reported on the frequency of offering alcohol to children when children were 3, 5, 7, and 11 years old. The outcome was adolescent alcohol use at ages 15 and 18, reported by adolescents, mothers, and pediatricians. Control variables included sex, maternal education, family structure, and parental alcohol consumption.

Results: Three classes of children were identified based on parental alcohol supply: abstainers (75.5% of sample), infrequent sippers (16.2%), and frequent sippers (8.3%). Parental drinking increased the risk of both infrequent and frequent sipping. These classes were entered into two structural models (age 15 and age 18 alcohol use modeled as latent factors), alongside covariates. Compared to abstainer class, infrequent and frequent childhood sippers exhibited significantly higher alcohol consumption at age 15 ($\beta = .21$, $p < .001$; $\beta = .25$, $p < .001$, respectively) and age 18 ($\beta = .11$, $p < .05$; $\beta = .24$, $p < .001$, respectively).

Conclusions: This study represents the first prospective investigation quantifying early childhood alcohol exposure and its subsequent association with adolescent alcohol consumption. Findings emphasize the influence of family dynamics on alcohol behaviors, underscoring the necessity for targeted preventive measures, particularly within families with higher parental alcohol consumption.

Key messages:

- Offering alcohol to children at ages 3-11, even infrequently, significantly increases the risk of more frequent drinking at ages 15 and 18, compared to those with no early exposure.
- Parents who drink are more likely to have children who sip alcohol early, leading to higher alcohol consumption in adolescence. Prevention efforts should focus on family habits and early education.

Abstract citation ID: ckae144.1091
Declining trends of overweight and obesity in 4-year-olds during 2007-2022 in Northern Sweden

Johanna Kuisma Löfbom

J Kuisma Löfbom[1], *O Sandström*[1], *A Ivarsson*[2], *W Lohr*[2], *E Lundberg*[1], *SA Silfverdal*[1], *M Vaezghasemi*[2]

[2]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
Contact: johanna.kuisma.lofbom@regionvasterbotten.se

Background: Overweight among preschool children is a huge public health issue. The prevalence of both childhood overweight and obesity increased during the COVID-19-pandemic. Our aim was to study the development of overweight and obesity among 4-year-olds in Västerbotten, Sweden, from 2007 until 2022 with special focus on the COVID-19-pandemic and the year after.

Methods: This is a repeated cross-sectional study that utilized individual data from most 4-year-old children living in Västerbotten County, Sweden in 2007-2022, implying that the children were born 2003-2108. We included encrypted and anonymized individual anthropometrical data from the routine 4-year-old Child Health Care visit. There were 47 004 4-year-old children living in the county and we included data from 42 584 children, 21 966 boys and 20 618 girls at the age of 46-51 months.

Results: Overweight and obesity decreased over the study period. In 2007 the prevalence of overweight was 13.4% for boys and 14.9% for girls and obesity 3.7% for boys and 2.7% for girls. In 2022 the prevalence of overweight had declined to 9.5% for boys and 12.1% for girls and the prevalence of obesity to 1.8% and 2.1%, respectively. During the COVID-19-pandemic the prevalence of overweight and obesity for both boys and girls increased and then rapidly returned to the pre-pandemic level in 2022.

Conclusions: In a setting with free standardized Child Health Care, we present a clear decline in the prevalence of overweight and obesity among Swedish preschool children over time. As in other settings the prevalence of overweight and obesity increased during the COVID-19-pandemic, but we also report a rapid decline in overweight and obesity after the pandemic. It is essential to understand the underlying mechanisms responsible for this favorable trend.

Key messages:

- We present clear decline in the prevalence of overweight and obesity in preschool children over time in a setting with free standardized Child Health Care.
- It is important to understand the possible mechanisms of the favorable trend of decrease of the prevalence of overweight and obesity in children pre- and post-pandemic.

Abstract citation ID: ckae144.1092
Diabetes, hypertension, and hospitalizations during pregnancy: a multivariate analysis

Introduction: The study analyzes the correlation between socio-demographic variables and pathologies encountered by women during pregnancy. The presence of these pathologies is recorded at the time of compiling the CAP (Certificate of Assistance for Birth).

Methods: Data analysis pertains to the Certificate of Assistance for Birth (CAP) concerning residents in the territory of AUSL South-East Tuscany in the years 2021 and 2022. The number of women of childbearing age in Tuscany in 2022 is 150,959, while the number of births analyzed in the study is 9,053. The study conducts multivariate analysis between socio-demographic variables and pathological outcomes.

Results: Controlling for age, citizenship and other factors, the risk of gestational diabetes is significantly higher ($p < 0.05$) among mothers: over 40 years old ($OR = 1.56$), with citizenship in PFPM countries ($OR = 1.60$) and particularly, compared to Italians, among women from Indian subcontinent ($OR = 3.73$) and the Maghreb ($OR = 2.04$), with lower educational levels ($OR = 1.28$) compared to graduates, obese ($OR = 2.43$). The risk of gestational hypertension is significantly higher ($p < 0.05$) among mothers: over 40 years old ($OR = 1.71$), obese ($OR = 2.50$), nulliparous ($OR = 1.60$). The risk of one or more hospitalizations during pregnancy is significantly higher ($p < 0.05$) among mothers: not employed ($OR = 1.31$) and homemakers ($OR = 1.32$) compared to employed, from Indian subcontinent ($OR = 1.82$) and the Maghreb ($OR = 1.75$) compared to Italians, with gestational hypertension ($OR = 2.06$).

Conclusions: Unlike gestational diabetes and hospitalizations during pregnancy, gestational hypertension does not show significant associations with the mother's socio-demographic characteristics. However, gestational diabetes and hospitalizations during pregnancy are correlated with different variables: they are more common among women over 40, foreigners, homemakers, with lower educational levels, obese, and with low family economic status.

Key messages:

- It has been observed that some variables are also risk factors for adult age pathologies, such as diabetes and hypertension.

- The importance of Early Childhood Development and early interventions can improve children's health and well-being.

Abstract citation ID: ckae144.1093
Use of intraoral mobile photography for screening of oral health in children

Lia Mania

L Mania[1,2], K Nanobashvili[1], T Manjavidze[1,3], M Benashvili[4], I Astamadze[2]
[1]School of Health Sciences, University of Georgia, Tbilisi, Georgia
[2]Department of Healthcare, Tbilisi Humanitarian University, Tbilisi, Georgia
[3]Department of Medical Statistics, NCDC, Tbilisi, Georgia
[4]Business Statistic Department, National Statistics Office of Georgia, Tbilisi, Georgia
Contact: lia.mania.phd@ug.edu.ge

Background: The aim of the study is to evaluate the diagnostic accuracy of intraoral mobile photography to assess caries intensity (DMFT/deft), simplified oral hygiene index (S-OHI) and modified gingival index (MGI).

Methods: Children aged 7-12 were included in the study. The clinical doctor evaluated the oral health indicators by visual examination: DMFT, deft, S-OHI, MGI were calculated. Dental students independently captured photos with a mobile phone (iPhone-11) in 8 predetermined projections. Dental images were kept in coded folders for research anonymity. Another professional calculated index based on the photos. Variables were used with binary values (DMFT/deft $= 0/\geq 1$; MGI$=0/\geq 1$; S-OHI$\leq 1.2/>1.2$). Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of dental photography were evaluated and Cohen's Kappa was calculated to measure the level of agreement between two independent observers.

Results: 2864 photographs were evaluated for 358 participants. The sensitivity and specificity of intraoral mobile photography for DMFT index is 95.8 (95% CI: 93.4-98.3) and 89.2 (95% CI: 83-95.5); For deft index: 100.0 (95% CI: 100-100) and 88.6 (95% CI: 79.3-98); For MGI: 89.7 (95% CI: 85.8-93.5) and 91.4 (95% CI: 86.3-96.5); For S-OHI: 77.6 (95% CI: 67.6-87.6) and 93.8 (95% CI: 91-96.6); The PPV value for DMFT, deft, MGI and S-OHI is 96.2; 97.7; 95.6 and 74.3 and the NPV value is 88.3; 100.0; 80.9 and 94.8 respectively. It was achieved substantial and perfect agreement between two independent raters: For DMFT, deft, MGI, S-OHI indices Cohen's Kappa =0.85; 0.93; 0.78; 0.70 correspondingly.

Conclusions: Intraoral mobile photography, if applied within appropriate guidelines is reliable for assessing caries intensity, simplified hygiene index and modified gingival index as well as visual screening and may become a priority for dental public health. The involvement of dental students in studies of similar design is appropriate.

Key messages:

- Intraoral mobile photography can be used for oral health screening in children.
- The involvement of dental program students in screening studies conducted with intraoral mobile photography is appropriate.

Abstract citation ID: ckae144.1094
Unintended pregnancies in the context of intimate partner violence: Findings from the ELSA-Study

Petra J Brzank

PJ Brzank[1], D Jepsen[2], M Engelhard[1], K Winter[1], M Nowak[1]
[1]Institute for Social Medicine, Rehabilitation, University of Applied Sciences Nordhausen, Nordhausen, Germany
[2]Institute of Medical Sociology, University Hospital Halle, Halle, Germany
Contact: petra.brzank@hs-nordhausen.de

Intimate partner violence against women (IPV) is a widespread problem with serious consequences for victims and for society. Women affected by IPV have an empirically proven particular risk of unintended pregnancies. ELSA "Experiences and Living Conditions of Unintended Pregnant Women - Counselling and Care Services" is the first study in Germany to analyse the connections between the situations of women and unintended pregnancies. Using an online questionnaire, women from 1) a random representative sample of residents with a child under 6 years of age and 2) a sample of 662 women from abortion facilities or counselling centres were surveyed in 2021. The data ($n = 5{,}101$) were analysed in order to compare the life situation and needs of victimized versus non-victimized women. 333 women (6.5% of the total sample; 95% CI [6.2, 7.6]) reported IPV. Victimized women had a 5.6 times higher risk for an unintended pregnancy (95% CI [4.2, 7.5]) and 3.2 times higher risk for an abortion (95% CI [2.0, 5.0]). The pregnancy was sig. more frequently the result of forced sex (CV$=$ .210***). Victims with unintended pregnancies had a sig. poorer mental health before ($t(510) = 7.081^{***}$), during ($t(510) = 5.501^{***}$) and after birth ($t(456) = 5.234^{***}$) as well as before ($t(503) = 4.905^{***}$), during ($t(224) = 3.408$) and after ($t(503) = 3.352^{***}$) abortion. They were sig. more likely to report feelings of guilt and shame (CV $=$ .182***), self-blame (CV $=$ .149***) and anxiety (CV $=$ .190***) after the pregnancy was determined and they received sig. more unsolicited information from the medical staff (CV $=$ .254**). The result shows that victimized women are in an increased risk situation in the context of unintended pregnancies. Health care professionals can play a special role in prevention and intervention. Nationwide awareness-raising training, protocols and commitment are required.

Key messages:

- The study confirms international findings on IPV and unintended pregnancies for Germany.
- There is a need for a sensitive approach within the health system to enhance prevention.

Data-driven prediction of early language delay at Youth Health Care Services in the Netherlands

Polina Putrik

P Putrik[1], M Hendriks[2], C van de Kraats[2], R Reijs[1], B Ravesteijn[2]
[1]Kennis & Innovatie, GGD Zuid Limburg, Heerlen, Netherlands
[2]Erasmus School of Economics, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: polina.putrik@ggdzl.nl

Introduction: Language development in early childhood significantly impacts future academic success, social interaction, and emotional well-being. This study aimed to develop and evaluate a prediction model using data on developmental milestones and parents' socio-economic background known at age 2, and translate the results into an interactive digital dashboard and pilot it with Youth Health Care (YHC) professionals and parents.

Methods: A mixed-method study on retrospective cohort of children attending YHC at age 2, followed up until age 4. Data on language development, gender, parental education, and home language environment were obtained from YHC digital dossiers and linked to parental socio-economic status characteristics, and perinatal outcomes and healthcare costs using a secure remote access environment of Statistics Netherlands. Random forest and logistic regression models were computed with language development at age 4 as an outcome, initially using all available data at age 2 as predictors and then with a restricted model using variables readily available in YHC settings. Models performance was assessed using sensitivity, specificity, and AUC value. Results were visualized through an interactive dashboard and pilot-tested in simulated consultations.

Results: Among 9,148 children, 13.2% had language development delay at age 4. The full model had an AUC of 0.78, while the

restricted model (gender, parental education, language environment, and language development), achieved an AUC of 0.77. YHC professionals and parents recognized the value of individualized, data-driven risk assessment for potential language delay to stimulate the discussion of preventive interventions.

Conclusions: A good quality prediction model for language development at age 4 can be derived from just a few background characteristics of the child and parents at age 2. The digital dashboard presents a practical approach of integrating prediction model results into daily YHC practice.

Key messages:

- Language development at age of 4 can be predicted as early as age of 2 using just a few background characteristics of child and parents, which presents a window of opportunity for prevention.
- The digital dashboard presents a practical approach of integrating prediction model results into preventive care practice.

Abstract citation ID: ckae144.1096
Maternal education and antenatal attendance in Georgia: A cohort study

Waseem Saad

W Saad[1], *MM John*[1], *ES Adeboye*[1], *M Haj*[1], *T Manjavidze*[2]
[1]School of Health Sciences, University of Georgia, Tbilisi, Georgia
[2]University of Georgia, Tbilisi, Georgia
Contact: waseem.std@ug.edu.ge

Background: Antenatal care (ANC) and maternal education are important determinants for maternal and newborn health outcomes. Understanding the impact of maternal education on ANC is crucial.

Purpose: To examine the association between maternal education and ANC attendance.

Methods: A retrospective cohort study utilized nationwide electronic medical birth registry data (2020-2022) in Georgia. the study includes pregnant women and their newborns. A randomized sample was selected, and extracted variables included maternal age, parity, body mass index, education, year of delivery, gestational age, infant sex, Apgar score, birth weight, delivery type, and newborn status. Statistical analysis via IBM SPSS v23 involved chi-square, t-tests, and logistic regression.

Results: The sample size contains 4976 mothers after excluding cases with missing data (n = 25). The mean maternal age was 30.5 years (SD = 5.4), with a mean BMI of 28.0(SD = 4.8), and the mean gestational week was 38.4(SD = 2.0), with a mean birth weight of 3263.0 (SD = 568.0) grams. Highly educated women had more than 3 times higher odds (OR = 3.636,95%CI:2.575-5.134) of having at least one ANC visit compared to those with Unknown education. primiparous women had significantly higher odds of having at least one ANC visit compared to Multiparous women, OR = 1.519, (95%CI:1.081-2.135). The chi-square test showed significant difference between ANC visits and the number of liveborn/stillborn ($\chi^2 = 53.026$, $p < .001$). Moreover, there was a significant association between birth weight categories and ANC visits ($\chi^2 = 167.095$, $p < .001$).

Conclusions: Our study emphasizes the role of education in improving access to ANC among women with low education levels. We can increase ANC visits and improve maternal and newborn health outcomes by focusing educational efforts on pregnant women. Additionally, focusing on high-risk populations, and using tailored interventions can further improve ANC attendance along with maternal and neonatal health.

Key messages:

- Boosting ANC access and improving maternal and neonatal health by tailored community programs.
- Conservative communities and underrepresented communities require additional resources to promote tailored healthcare. and extra effort in education about ANC.

Abstract citation ID: ckae144.1097
Reduced physical activity in youth during the COVID-19 pandemic: systematic review and meta-analysis

Helena Ludwig-Walz

H Ludwig-Walz[1], *W Siemens*[2,3], *S Heinisch*[4], *I Dannheim*[5,6], *J Loss*[7], *M Bujard*[1,8]
[1]Federal Institute for Population Research BiB, Wiesbaden, Germany
[2]Institute for Evidence in Medicine, Medical Center - University of Freiburg, Freiburg, Germany
[3]Cochrane Germany, Cochrane Germany Foundation, Freiburg, Germany
[4]University of Education, Karlsruhe, Germany
[5]Regional Innovative Centre of Health and Quality, Fulda University of Applied Sciences, Fulda, Germany

[7]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
[8]Institute of Medical Psychology, University Heidelberg, Heidelberg, Germany
Contact: helena.ludwig-walz@bib.bund.de

Background: Emerging research suggests that physical activity among children and adolescents decreased during the COVID-19 pandemic. As a summarizing analysis of changes in youth's physical activity for Europe is lacking, we performed a systematic review and meta-analysis to close this research gap. Amongst others, we examined the relevance of restriction stringency policies and potentially vulnerable groups.

Methods: In consideration of the PRISMA statement, we searched seven databases and included studies for children and adolescents (≤19 years) of the WHO European Region that compared physical activity during the pandemic with a pre-pandemic baseline using validated measurement instruments. We used the Oxford Stringency Index as an indicator of restriction stringency. Screening for eligibility, data extraction, assessment of the study risk of bias (using ROBINS-E instrument) and certainty grading of evidence (using the GRADE approach), were all done in duplicate. Data were pooled in random effects models (Trial registration: PROSPERO: CRD42023395871).

Results: Of 14,897 non-duplicate records, 26 publications (n = 15,038 pre-pandemic, n = 13,041 during pandemic) met our inclusion criteria. Comparison before vs during the COVID-19 pandemic revealed a significant reduction in total physical activity (standardized mean difference [SMD], -0.57 [95% CI, -0.95; -0.20]) and moderate-to-vigorous physical activity (SMD, -0.43 [95% CI, -0.75; -0.10]), corresponding to a decrease of 12 min/day (a 20% reduction of the WHO recommendation). Subgroup analyses suggested that children aged 8-12 were particularly affected. The analyses outline a possible association between school closures and more reductions in physical activity.

Conclusions: A sharp decline in all forms of physical activity was recorded among European children and adolescents during the COVID-19 pandemic, particularly in middle childhood. Policy-makers, teachers and practitioners must act to reverse this decline.

Key messages:

- Physical activity in European children & adolescents decreased significantly during the COVID-19 pandemic.
- Immediate action by policy-makers and practitioners is imperative to reverse this trend.

[5]Barcelona Institute for Global Health, Barcelona, Spain
[6]CIBERESP, Madrid, Spain
[7]Campus del Mar, Universitat Pompeu Fabra, Barcelona, Spain
Contact: chrysamouatsou@gmail.com

Background: Prenatal exposure to persistent organic pollutants (POPs) has been linked to elevated symptoms related to attention deficit hyperactivity disorder (ADHD) in a few studies, but findings remain inconclusive. We aimed to explore how prenatal exposure to POPs affects the developmental course of ADHD symptoms from early childhood to adolescence in the Rhea cohort in Crete, Greece.
Methods: We determined concentrations of HCB, DDE, and PCBs in first-trimester maternal serum. Child ADHD symptoms were reported by mothers using the ADHD Test at 4 years and the Conners' Parent Rating Scale at 6, 11 and 15 years. Group-Based Trajectory Modeling was used to classify 551 participants into 4 distinct groups: Stable low (60.1%), Stable high (9.6%), Low-increasing (14.6%), and High-decreasing (15.7%) symptoms. Adjusted multinomial regression models were applied to assess the risk of being grouped into an adverse developmental trajectory as compared to the reference group (stable low), in relation to prenatal POP exposure in 465 children. The analyses were performed in sex-specific manner.
Results: Prenatal HCB exposure was associated with elevated risk of being grouped in the stable high ADHD symptoms trajectory only in girls (RRR [95%CI]: 2.0 [1.04, 3.82]). Overall, exposure to DDE and sum of PCBs was linked to decreased risk of membership in an adverse ADHD symptoms trajectory. More specifically, in utero exposure to DDE and sum of PCBs was associated with lower risk of being grouped in the low-increasing trajectory for boys (RRR [95%CI]: 0.7 [0.54, 0.95] and 0.5 [0.32, 0.88], respectively) and in the high-decreasing symptoms group for girls (RRR [95%CI]: 0.6 [0.44, 0.84] and 0.5 [0.30, 0.93], respectively).
Conclusions: The findings suggest that prenatal exposure to HCB is linked to increased risk of stable high ADHD symptoms from preschool age and up to adolescence. The association was pronounced only in girls, a group for which less is understood in relation to ADHD.
Key messages:

- Prenatal exposure to HCB increases the risk of persistently high ADHD symptoms from preschool age to adolescence.
- The impact of prenatal HCB exposure on ADHD symptoms is evident in girls.

Abstract citation ID: ckae144.1099
Psychosomatic complaints at age 15-16 and subsequent depression and anxiety disorders

Joakim Wahlström

J Wahlström[1]*, SB Låftman*[1]*, V Östberg*[1]
[1]Centre for Health Equity Studies, Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
Contact: joakim.wahlstrom@su.se

Background: In recent years, the prevalence of self-reported mental health issues such as psychosomatic complaints has risen among adolescents in several countries, including Sweden. Despite this trend, a gap in the understanding remains regarding the implications of these complaints, including their ability to predict more severe mental health conditions. Depression and anxiety represent common mental health disorders among youth today, significantly affecting daily functioning. In light of this, the current study aims to investigate the association between self-reported psychosomatic complaints at age 15-16 and the likelihood of being diagnosed with depression or anxiety by age 20.
Methods: Data was drawn from Futura01, a cohort study of Swedish adolescents who attended grade 9 in 2017 (n = 5,225). Information on psychiatric diagnoses was obtained from the Swedish National Patient Register. Psychosomatic complaints were captured through self-reported frequencies of headache, stomach ache, and difficulties falling asleep, which were aggregated into an index (ranging from 3-15). Covariates included sex, parental education, parental country of birth, family type, and prior diagnoses of ADHD, depression, and anxiety. Binary logistic regression analyses were performed.
Results: The findings show that higher levels of psychosomatic complaints at age 15-16 were prospectively associated with increased odds of being diagnosed with depression (OR = 1.28, 95% CI 1.22-1.34) as well as anxiety (OR = 1.30, 95% CI 1.25-1.35) by age 20, even after adjusting for prior diagnoses and other covariates.
Conclusions: This study highlights the potential for psychosomatic complaints during adolescence to act as early indicators of future mental health disorders. Recognising the importance of these complaints and implementing public health interventions targeting mental health issues among youth could help improve mental health outcomes in late adolescence and young adulthood.
Key messages:

- Adolescents reporting frequent psychosomatic complaints at age 15-16 were more likely to receive subsequent specialised care due to a depression or anxiety diagnosis in a Swedish sample.
- Interventions directed at youth experiencing frequent psychosomatic complaints may have a beneficial impact on their future mental health outcomes.

Abstract citation ID: ckae144.1100
An intergenerational study of mental health among parents and adolescents

Merete Labriola

M Labriola[1,2]*, T Lund*[3]*, L Lindholdt*[4]
[1]Department of Social Medicine, University of Copenhagen, Copenhagen, Denmark
[2]Center of Health Research, University Hospital Zealand, Nykøbing, Denmark
[3]Holbaek Hospital Research Hub, Holbaek Hospital, Holbaek, Denmark
[4]Department of Public Health, Aarhus University, Aarhus, Denmark
Contact: Merete.Labriola@sund.ku.dk

Background: The aim of this study was to examine the association between parents' mental disorders and adolescents' self-rated health, using both subjective and objective assessment of parents' mental health status.
Methods: This cohort study was based on the Danish Future Occupation of Children and Adolescents cohort. Study population 25,891parents (biological parents or registered guardians) linked to 13,067 adolescents. Survey data were merged with register data on parent mental health, and logistic regression was used to analyse association between the register- and self-report data on parents mental health, and self-rated global health among their offspring.
Results: Adolescents' self-rated health was associated with their parents' mental disorders, showing an unadjusted OR of 1.5 (95% CI 1.4-1.6) when assessing parental mental disorders using ICD-10

diagnoses and an unadjusted OR of 2.0 (95% CI 1.8-2.2) when using the adolescents' self-reported measure on the parental mental disorder. Adjustment for adolescents' sex, adolescents' mental disorders during childhood, parental education, and parental labour market attachment led to a decreased association between parents' mental disorders and adolescents' self-rated health in both analyses with an adjusted OR of 1.2 (95% CI 1.1-1.4) when assessing parents' mental disorders using ICD-10 diagnoses and an adjusted OR of 1.8 (95% CI 1.6-2.0) when using the adolescents' self-reported measure on parental mental disorder.

Conclusions: This study documents a clear pattern in mental disorders across generations and that parental labour market attachment as well as mental disorders in earlier life phases are risk factors for developing mental disorders in adolescence. The results point to the importance of public health interventions aimed at the more vulnerable group of adolescents, where mental health problems are observed over two generations.

Key messages:

- There is a clear pattern in mental disorders across generations.
- Parental labour market attachment are risk factors for developing mental disorders among their offspring.

Alcohol intake and patterns of multi-site musculoskeletal pain in the British Whitehall II study

Ziyi Zhao

Z Zhao[1], *T Lallukka*[1,3], *T Chandola*[2], *A Britton*[1]
[1]Epidemiology and Health Care, University College London, London, UK
[2]Sociology, University of Hong Kong, Hong Kong, China
[3]Public Health, University of Helsinki, Helsinki, Finland
Contact: rmjlzz1@ucl.ac.uk

Background: Patterns of multi-site musculoskeletal (MSK) pain and its relationship with alcohol drinking among white-collar employees and retirees remain unclear compared to blue-collar workers. This study aimed to examine the relationship between alcohol drinking and MSK pain through latent class analysis (LCA) in current and retired white-collar employees.

Methods: We used the data from the 7th phase (2000-2002, n = 6,967, response rate 71.6%) of the British Whitehall II study, chosen for its availability of MSK items and approximately 1:1 ratio of employees to retirees, allowing for an evaluation of the relationship between alcohol drinking and MSK pain by employment status. LCA was used to distinguish patterns of multi-site MSK pain. A multinomial logistic regression model was used to examine the association between alcohol drinking and the identified pain patterns, with analyses conducted separately for employees and retirees.

Results: We identified five latent classes for pain (back/cervical: 7.1%, cervical: 28.9%, upper limb: 29.4%, combined LBP/upper limb/cervical: 13.2%, and LBP alone: 21.5%). Increased alcohol intake might be associated with elevated odds of upper limb pain in current drinkers, but this could not be statistically confirmed (OR: 1.04, 95% CI: 0.99-1.09). Employment status may modify the association with a significant interaction found between alcohol intake and retirement (p-value: 0.043). Every 7-unit increase in alcohol intake is associated with 18% and 12% higher odds of pain in LBP/UBP/cervical and upper limbs, respectively (95% CI: 1.02-1.37; 1.02-1.23).

Conclusions: Increased alcohol intake was associated with pain patterns only among retired white-collar employees but not the current ones. Interventions on alcohol consumption could help confirm if, reducing alcohol intake or avoiding hazardous drinking, for white-collar retirees prevents not only upper limb pain but also more complex pain patterns.

Key messages:

- Musculoskeletal pain in white-collar employees and retirees contributes to the cervical and upper extremities, differing from low back/neck pain studies among general or blue-collar workers.
- The association between alcohol drinking and pain patterns may differ across employment status. Reducing alcohol intake might be advised to retired drinkers for preventing multi-site pain.

Abstract citation ID: ckae144.1102

Novel approach to combining interview and register data – Case: social security and pediatric cancer

Ella Näsi

E Näsi[1,2], *A Teittinen*[2], *M Perkiö*[1], *L Kokkinen*[1]
[1]Social Sciences, Tampere University, Tampere, Finland
[2]Research Unit, Social Insurance Institution of Finland, Helsinki, Finland
Contact: ella.nasi@tuni.fi

A parallel examination of interview data and register data provides a more holistic overall picture of social security needs and use than any one type of data alone. In our study, we aimed to build a comprehensive understanding of the benefit and service needs of parents whose child is diagnosed with cancer. Conducting solely interviews would have provided subjective perceptions of individuals in the midst of a challenging life situation, but the data would have lacked information of the participants' documented use of social security benefits and services. On the other hand, utilizing solely register data, would have provided an objective overview of actual service use. However, register data alone would not have shed light on whether the benefits and services received were sufficient from the recipients' point of view. In our study, parents' interviews and their register data from the Social Insurance Institution of Finland (Kela) offered complementary perspectives on the same life situation. Parents' interviews provided information on support needs, service experiences as well as service deficits. The same families' register data was used with their permission producing exact data on the insurance benefits and services that the family had applied for and received. The interviews were analysed as chronologically progressing narratives while the data received from Kela was depicted on timelines. When conjoined, the interview and register data formed a comprehensive picture of the benefit and service needs and use of families, whose child had cancer. In addition, this kind of triangulation revealed service deficits that were acknowledged by the interviewees and identified also through the register data. We argue, that combining subjective interviews together with institutional register data allow researchers to identify issues in the service system, which require improvements from the recipients' and the system's perspective.

Key messages:

- The use of multiple types of data allows researchers to construct a holistic understanding of individuals' social security needs and use.

- Combining interview and register data allows researchers to identify issues in the service system, which require improvements.

Abstract citation ID: ckae144.1103
Health as predictor of unemployment. A population based study in Belgium

Helena Bruggeman

J Van der Heyden[1], *H Bruggeman*[1], *P Smith*[1,2]
[1]Health Information, Sciensano, Brussels, Belgium
[2]Institure of Health & Society, Université Catholique de Louvain, Brussels,
Contact: helena.bruggeman@sciensano.be

Background: Health and employment are interrelated, but this can be both the result of social causation and health selection. Insights in the association between health and employment should be explored in different settings and countries because contextual factors may differ. In this study we investigate if at the Belgian population level, ill health leads to a higher risk of unemployment.

Methods: We used data from the Belgian health interview survey 2018 linked with administrative data from the compulsory health insurance including information on employment status in 2018 and 2019. The sample for this study consisted of people with a paid job, aged 18-64 year, with no record of having being unemployed in 2018 (n = 3769). Multivariate logistic regression was used to assess if the risk of becoming unemployed in 2019 varied in function of the health status assessed in the 2018 survey.

Results: After adjustment for age, sex, education and social support, the risk of becoming unemployed was significantly higher for people with moderate to very bad self-rated health compared to those in good health (OR 2.76; 95% CI 1.34-5.67). Similarly, unemployment in the year following participation in the survey was significantly higher among people with activity limitations because of health problems (OR 2.32; 95% CI 1.14-4.72). The higher the number of chronic diseases and conditions, the higher the risk of unemployment (OR 1.37; 95% CI 1.13-1.53). Specific predictors of unemployment were a history of serious depression in the past 12 months (OR 4.47; 95% CI 1.85-10.80) and hypertension (OR 2.54; 95% CI 1.08-6.00).

Conclusions: In Belgium, health problems are a risk factor of getting unemployed. Especially people with a history of serious depression in the past year have a higher risk to lose their job. The findings confirm the health selection of unemployment and the need for the labour market to invest in interventions to support people with health problems to keep or find a job.

Key messages:

- As employment is a fundamental right, also for people with health problems, further efforts are needed to create an inclusive labour market, with also job opportunities for more vulnerable people.
- To be able to understand better the link between health and unemployment at population level, longitudinal population data are needed including both dimensions.

Abstract citation ID: ckae144.1104
Health care and social benefits among long-term unemployed

Sanna Kärkkäinen

S Kärkkäinen[1], *J Laaksonen*[1], *M Mesiäislehto*[1]
[1]Public Health and Welfare, THL, Helsinki, Finland
Contact: sanna.karkkainen@thl.fi

Background: There is limited knowledge on the diverse pathways behind long-term unemployment. It is considered that impaired health may lead to exclusion from working life, and that unemployment together with financial difficulties may impair health. In this study, we identify different pathways behind long-term unemployment, and analyse differences in health care and social benefits use based on the diverse pathways. This study contributes to the early identification and supportive efforts for those in risk of labour market marginalisation.

Methods: Those who had been mainly unemployed in years 2020 and 2021 were identified among all working age (18 to 64 years) Finnish citizens. Register data from Statistics Finland, the Social Insurance Institution of Finland and THL were combined for the analysis. Sequence analysis was conducted for individuals with main activity information for each observation years from 2013 until 2021 (n = 72,485, age 26 to 64 in year 2021).

Results: Those unemployed for two years were on average 49 years of age (38% women). Five clusters were identified based on the main activity over the nine observation years: unemployed (54%), students (3%), employed (23%), inactive (10%) and those returned to unemployment (10%). Health care attendance was most frequent among those in cluster inactive. Mental health diagnoses were most common among those in clusters inactive and students. Share of those with musculoskeletal diagnoses doubled from 2013 until 2021 among the previously employed. Yearly percentage of those with sickness absence (>10 days) varied from 5 to 13% based on a cluster and a year. Share of recipients of basic social assistance was relatively stable throughout the years in all clusters being highest among inactive (50 to 60%) and lowest among students (6 to 18%).

Conclusions: Information on labour market background might be useful for preventive efforts and while developing services and social security for those in long-term unemployment.

Key messages:

- There exists diverse backgrounds behind long-term unemployment.
- Labour market background should be considered while developing services for those in long-term unemployment.

Abstract citation ID: ckae144.1105
Sick-leave trajectories among people sickness absent with stress-related diagnoses; cohort studies

Katalin Gemes

K Gemes[1], *E Petterson*[1], *K Farrants*[1], *E Friberg*[1], *K Nilsson*[1], *S Sjölund Andoff*[1], *K Alexanderson*[1]
[1]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
Contact: katalin.gemes@ki.se

Background: Stress-related disorders are common sickness absence (SA) diagnoses in many Western countries. Knowledge of SA and disability pension (DP) patterns among people with such SA is needed. Thus, the aim was to identify future SADP trajectories among people with a new SA spell due to stress-related diagnosis and to examine sociodemographic and health-related factors associated with identified trajectories.

Methods: Using microdata from nationwide registers, we included all people living in Sweden with a new SA spell >14 days due to stress-related diagnoses (ICD-10 code F43) in 2011 (N = 32,417) or 2018 (N = 65,511), respectively. These two cohorts were followed prospectively for 13 months from the SA spell start, to identify trajectory groups of mean SA/DP days/month using group-based trajectory modeling. We used multinomial logistic regression to explore associations between sociodemographic and health-related predictors and trajectory membership.

Results: We identified the following SA/DP trajectories in both cohorts: steep drop (30.6% and 35.9% of all included in 2018 and 2011, respectively); fluctuating (8.7%, 11.2%); fast decrease (25.5%, 24.4%); medium decrease (18.1%, 13.1%); slow decrease (10.8%, 7.3%), and constant high (6.2%, 8.0%). Compared to the steep drop trajectory, individuals in the other trajectories were more likely women, older, and had prior SA/DP or secondary outpatient healthcare visits. Starting the SA spell full-time was the strongest predictor for the slow decrease and constant high trajectory, and previous SA or diagnosis of other mental disorders were predictors of the constant fluctuating and constant high trajectory.

Conclusions: The similarity of the identified trajectories in the two cohorts is a strength. The results reveal the diversity of future SA/DP in this patient group, indicating the importance of identifying patients at risk of long-term SA who might need further interventions early in the process.

Key messages:

- In two population-wide cohorts with a new sickness absence (SA) spell with stress-related diagnoses, six trajectories of SA/disability pension days were identified during the 13-month follow-up.
- Most of those in the cohorts had trajectories that ended with no SA/DP after 13 months, while two trajectories, including 15-19% of individuals, showed high or varying SA/DP days during the follow-up.

The relationship between mental health and employment: a systematic review of cohort studies

Helena Bruggeman

H Bruggeman[1], *J Héroufosse*[2], *J Van der Heyden*[1], *P Smith*[1,3]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Faculty of Public Health, Université Catholique de Louvain, Brussels, Belgium
[3]Institute for Health and Society, Université Catholique de Louvain, Brussels, Belgium
Contact: helena.bruggeman@sciensano.be

Background: Knowledge on the bi-directional association between employment status and mental health is important, as it affects multiple dimensions of our daily lives, both at the individual and societal level. Given that the mental health status and employment situation of individuals are likely to change over time, there is an important need for longitudinal data to better understand causality patterns in this association and the underlying mechanisms.

Methods: A systematic review was carried out based on the PRISMA guidelines in 3 electronic databases: PubMed, Embase, and PsycInfo. Studies eligible for inclusion were cohort studies, involving the general population, and assessing the relationship between employment status and mental health longitudinally.

Results: In total, 3,733 studies were identified and 36 met the inclusion criteria. The eleven studies focusing on the social causation hypothesis highlighted the negative long-term impact of unemployment and unstable employment on mental health. Four studies observed mental health improvements upon re-entering employment, although limited and in more specific contexts. The fourteen studies focusing on the health selection hypothesis found a lower probability for individuals with mental health problems in finding and maintaining employment. Finally, the eleven studies assessing the two hypothesis simultaneously found that mental health problems were both a consequence of and risk factor for poor employment status, although some important moderating factors, such as gender differences, influence the direction and strength of the association.

Conclusions: This review underscores the bi-directional association between the employment status and mental health of individuals, highlighting the need to develop targeted prevention (e.g. mental health support in the workplace) and interventions strategies (e.g. supported employment programs) in both the mental health and labor market systems.

Key messages:

- The bidirectional link between employment and mental health highlights the need for concurrent responses to break the vicious cycle between poor mental health and social exclusion.
- To reduce the clinical and social burden of mental health problems, gender differences must be taken into account in mental health and employment support practices and policies.

Abstract citation ID: ckae144.1107
Longitudinal associations of daily activities and presenteeism among teleworkers in Japan

Yuichiro Otsuka

Y Otsuka[1], *O Itani*[1,2], *Y Kaneita*[1]
[1]Public Health, Nihon University School of Medicine, Tokyo, Japan
[2]Public Health, International University of Health and Welfare, Narita, Japan
Contact: otsuka.yuichiro@nihon-u.ac.jp

Objectives: Many workers had to switch their standard work from the office to home-based telework during the COVID-19 pandemic. Previous studies reported that telework was associated with increased sickness presenteeism. Several studies have examined the association between lifestyle behaviors and presenteeism among workers. However, there are few studies investigating the relationship among teleworkers. Thus, this study examined the association between daily activities and presenteeism in a longitudinal cohort of teleworkers in Japan.

Methods: A prospective cohort study with a two-year observation was conducted. The participants were 831 workers belonged to five companies in Japan. For both surveys, self-administered questionnaire surveys on daily activities and presenteeism were conducted. Presenteeism was assessed using the short-form Japanese version of the World Health Organization Health and Work Performance Questionnaire. The data were analyzed using a generalized estimating equation approach, controlling for potential confounders such as age, gender, working hours, position, and health status.

Results: 742 participants who teleworked in both surveys with no missing answers were analyzed. Among male workers ($n = 427$), chatting ($\beta = 5.30$, 95% CI: 1.52-9.07) and setting daily goals ($\beta = 4.16$, 95% CI: 1.52-9.07) were associated with decreased presenteeism. Among female workers, exercise ($\beta = 4.33$, 95% CI: 0.95-7.71) was associated with decreased presenteeism.

Conclusions: Although gender differences were observed, there is preliminary evidence from longitudinal studies that frequent activities such as chatting, setting daily goals, and exercising may protect against presenteeism among teleworkers. Our findings could be used to educate daily telework activities to prevent sickness presenteeism.

Key messages:

- Daily activities during telework may worsen or improve presenteeism.
- Social isolation may be an important indicator of presenteeism during telework.

Abstract citation ID: ckae144.1108
Subtle Biases Towards a New Colleague Depend on Sexual Orientation and Relationship Status

Nikola Komlenac

N Komlenac[1], *A Aigner*[1], *M Haller*[1], *J Birke*[1], *A Walther*[2]
[1]Medical University of Innsbruck, Innsbruck, Austria
[2]Department of Clinical Psychology and Psychotherapy, University of Zurich, Zurich, Switzerland
Contact: nikola.komlenac@i-med.ac.at

Background: Allonormative beliefs entail the idea that all people desire sexual activity with other people. Single and/or asexual individuals may face social disapproval or discrimination for not being in line with allonormative beliefs. The present study investigated whether individuals offered help or were likely to befriend a new co-worker differently depending on the co-worker's sexual orientation (i.e., heterosexual vs. asexual) and relationship status (i.e., in a relationship vs. single).

Methods: The online study included 1,028 participants (50.0% women and 50.0% men; Mage = 29.2, SD = 8.8) from German-speaking countries. Each participant read one of twelve short descriptions of a working situation in which they got to know a new co-worker. The description of the new colleague's gender, sexual orientation, and relationship status varied. Participants had to indicate how likely they would share information with, befriend, gossip about, or have other-interests in the new colleague. A multivariate analysis of co-variance was calculated.

Results: Female participants had lower intentions to share knowledge with persons who were singles by circumstance than with persons in a relationship and male participants were more likely to befriend a single gay man by choice than a gay man in a relationship.

Conclusions: Bias against single persons or prejudice resulting from heteronormative beliefs might lead to subtle differences in behavior towards a co-worker. Such subtle "micro-practices" can be harmful because micro-practices accumulate over time and situations. Interventions at organizations need to help employees realize their own biases that might be based on prejudices against people with different sexual orientations and relationship statuses.

Key messages:

- Overall women are more pressured by allonormative ideas and might therefore have lower intentions to share knowledge with persons who were singles by circumstance than with persons in a relationship.
- The differing treatment of single gay men by choice and gay men in relationships may not be solely due to adherence to allonormativity, but rather could stem from heterosexist beliefs.

Abstract citation ID: ckae144.1109
Deployment of in-body wearable devices in healthcare and at work: closing the EU regulatory gap

Maria Eva Foldes

S Marassi[1], *ME Foldes*[2]
[1]Leiden University & The Hague University of Applied Sciences, The Hague, Netherlands
[2]Erasmus School of Health Policy and Management, Rotterdam, Netherlands
Contact: evafoldes@yahoo.com

Background: In-body wearable devices can protect workers' health and safety. Moreover, they might provide data that could be capitalized on in the context of the European Health Data Space (EHDS), which aims at fostering a single market for medical devices and high-risk AI systems. Yet, neither EU legislation nor national law regulates the use of in-body wearables at the workplace and the related data protection and safety issues. This regulatory gap impacts on workers' rights.

Methods: The study explores whether the EU regulatory framework used in the healthcare sector for medical devices could fit the in-body wearables' application in employment. The legal and policy analysis takes the perspective of workers' rights and discusses the application of a key GDPR principle: lawfulness. The research discusses the potential transformations in the EU health data protection framework that could close the regulatory gap.

Results: The EU regulatory framework for medical devices (focused on product safety, performance, and quality) is not equipped to address the data protection challenges linked to the use of in-body wearables for occupational health and safety purposes. The GDPR's principle of lawfulness and the related guidance by EU and national data protection authorities lack clarity on employers' possibilities to apply in-body wearables for occupational health purposes. Filling the regulatory gap is conducive to appropriate qualification and risk-based classification of in-body wearables, which affect pre- and post-market requirements and impact on data protection.

Conclusions: a. The EU legislator could use its social policy competence to regulate the use of in-body wearables to protect workers' health while safeguarding their data. b. EU authorities should clarify whether and how the data collected by in-body wearables at the workplace could be shared and (re)used within the EHDS. c. Further input by data protection authorities is needed to close the regulatory gap.

Key messages:

- The EU should regulate the use of in-body wearables to protect workers' health and safety.
- Health data gathered through the application of in-body wearables at the workplace may be an asset for the EHDS.

[12]Population Health Sciences, University of Bristol, Bristol, UK
Contact: amanda.hughes@bristol.ac.uk

Background: Obesity is highly stigmatized, with negative obesity-related stereotypes widespread across society. Internalized weight stigma (IWS) is linked to negative outcomes including poor mental health and disordered eating. Previous evidence examining population groups at higher risk of experiencing IWS comes from small, nonrepresentative samples. Here, we re-assess previously reported associations of IWS with social factors in a large general population birth cohort study for the first time.

Methods: In the Avon Longitudinal Study of Parents and Children (ALSPAC), we explored differences in IWS at age 31 years by sex, ethnicity, socioeconomic factors, and sexual orientation using multivariable regression. Using data collected over a 32-year period, we explore the impact of family, peer, and wider social influences in adolescence, and bullying from mid-childhood to adulthood, whilst minimising risk of recall bias.

Results: In models adjusted for potential confounders and BMI in childhood, adolescence, and adulthood (N = 4060), IWS was higher for females (0.56 S.D. higher, CI:0.50-0.61), sexual minorities (0.17 S.D. higher, CI:0.09-0.24), and less socioeconomically advantaged individuals (0.16 S.D. higher (CI:0.08-0.24) for those whose mothers had minimum or no qualifications, compared to a university degree). The social environment during adolescence and young adulthood was important: IWS was higher for people who at age 13 years felt pressure to lose weight from family (0.13 S.D., CI:0.03-0.23), and the media (S.D. 0.17, CI:0.10-0.25), or had experienced bullying (0.25 S.D., CI:0.17-0.33 for bullying at age 23 years).

Conclusions: Internalized weight stigma differs substantially between demographic groups, and this is not explained by differences in BMI. The family environment during adolescence, bullying, and pressure to lose weight from the media may have long-lasting impacts on adult IWS. These may be fruitful avenues for intervention to reduce IWS and its consequences.

Key messages:

- Females, sexual minorities, and socioeconomically disadvantaged adults are at greater risk of IWS irrespective of BMI.
- To reduce IWS, interventions should improve the family and social environment.

Background: In the German Federal Armed Forces (GFAF) workplace health promotion measures (WHPM) are implemented since 2015 to promote the health of military and civilian employees and thus improve the ability to defend state interests. Here the aim is to evaluate the social and health benefits associated with WHPM in relation to expenditures for WHPM.

Methods: Calculations are based on data from departmental reporting (full survey) on WHPM, the number of participants and days of incapacity for work (DIW). Mean indirect costs for the WHPM participation and DIW were calculated as 249.33 Euro per DIW. To assess the costs for the use of health care services and social and health benefits a longitudinal observational study (T0: 06-09/2022; T1: 06-09/2023) was conducted online and paper based. The survey invitation was addressed to 223.967 employees of the GFAF. Statistical analyses were performed using R software.

Results: In departments offering WHPM the chance of DIW is lower (-19%) compared to departments without WHPM offers and in case of DIW, the duration is shorter (-10%). In T0 23.568 (10.5%) and in T1 14.059 (6%) employees participated. 63.9% (T1: 3.070/4.805) reported positive effects of WHPM on their working ability and general health status (T1: 63.0% (3.013/4.782)). Of those participating in WHPM 81% (T0: 5.442/6.716) would recommend the GFAF as an employer. A number of 4.540 employees participated in both surveys, of which 2.249 participated in WHPM. The average costs per employee participating in WHPM compared to employees not participating are 0,4% higher (T0; T1: 3,5%) and thus almost equal.

Conclusions: Although WHPM need expenditures, the total costs per employee participating and not participating in WHPM are comparable. WHPM participants report better self-rated health status, higher working ability and commitment to the employer than non-participants. The chance of DIW is reduced in departments offering WHPM to its employees.

*shared authorship

Key messages:

- Although WHPM need expenditures, the total costs per employee participating and not participating in WHPM are comparable.
- Employees participating in workplace health promotion measures report higher working ability and commitment to the employer.

Marketing or health promotion? A citizen science study of social media influencers' health content

Sascha Gell

S Gell[1,2], *E Engel*[1,2], *R Heiss*[1], *K Karsay*[2], *J Schmidhofer*[1]
[1]Center for Social & Health Innovation, MCI, The Entrepreneurial School, Innsbruck, Austria
[2]Department of Communication, University of Vienna, Vienna, Austria
Contact: sascha.gell@mci.edu

Background: Social media influencers (SMI) became the dominant source of health information among adolescents, exerting influence through appealing content and para-social relationships. Personalized social media feeds of adolescents paired with latent platform algorithms result in myriads of individual information environments, which remain closed to researchers. Citizen science offers a solution to peek inside this black box and identify: What health content is disseminated by social media influencers and consumed by adolescents?

Methods: The citizen science study adopted a contributive approach, where adolescents collected and categorized SMI profiles and posts from their own feeds with a pre-tested survey tool which was available on Google Tabs. Data collection was conducted on Instagram, TikTok, and YouTube between April and May 2023 and subsequently analyzed by the research team.

Results: The study involved 19 school classes, containing 326 students, aged 12 to 19 years. They documented 255 SMI profiles and 2147 posts, primarily on Instagram and TikTok. Key topics included fitness, beauty ideals, and nutrition, while mental and sexual health received less attention. Although 41.5% of the posts contained advertising, the citizen scientists classified 63.5% as health-promoting. Topics relating to dietary supplements (84.1%), addictive substances (55.6%), nutrition (53.8%) and sport (47.2%) were particularly ad-heavy. Despite mental and sexual health having the lowest advertising rates at 35.4% and 37.7% respectively, this still accounts for over one third of the documented posts.

Conclusions: SMI present a distorted image of health that emphasizes nutrition, fitness and beauty ideals, while topics such as mental and sexual health are neglected. The positive reception of posts containing ads indicates a lack of critical reflection. Policies for advertising practices and balanced health education, including media literacy, are necessary to address these trends.

Key messages:

- Social media influencers propagate a distorted health image, defined by nutrition, fitness, and beauty ideals.

- Adolescents lack the necessary skills to critically reflect on ad littered social media influencer health content.

Abstract citation ID: ckae144.1113
Exploring Electronic Personal Health Record usage in Northern Italy: a cross-sectional study

Anastasia Cataldo

Background: The Electronic Personal Health Record (EPHR) is a patient-centered tool that enables citizens to manage their health information. The EPHR has been implemented worldwide, including in Italy, and holds immense potential, but it has shown a generalized underutilisation. Therefore, this paper aims to identify its fulfillment and the reasons behind its poor use, potentially uncovering the key to unlocking its benefits.

Methods: A survey was distributed on social media and in the waiting rooms of vaccination facilities in a Region of Italy. Multivariable regression models were conducted to detect a connection between the general population's usage of the EPHR and specific independent variables.

Results: Of the 1634 respondents, 710 activated the EPHR, especially women, Italians, highly educated, unemployed, with good health but affected with chronic diseases. Amongst those who activated the EPHR, the multivariate analysis showed that the number of accesses to the platform was significantly associated with lower age (adjusted Odds Ratio (adjOR) 0.96 $p = 0.015$), higher level of education (adjOR 2.17 $p = 0.029$), unemployment (adjOR 5.61 $p = 0.008$) and considering the information on the EPHR complete (adjOR 3.83 $p = 0.001$). As age increases, the perceived ease of access to the EPHR decreases (adjOR=0.98 $p = 0.049$). Having a higher level of education (adjOR=0.41 $p = 0.042$), autonomy in reading health materials (adjOR=0.32 $p = 0.043$), and less self-confidence in filling out medical forms (adjOR=0.61 $p = 0.033$) were linked to a decrease in perceived ease of access.

Conclusions: The study showed that the EPHR is more utilised by specific categories of citizens, especially the young and those with higher education. More efforts should be made to increase access to the EPHR for the whole community by making it more intuitive and user-friendly. The present study provides valuable foundations to foster the implementation of a platform for sharing health data at a European level.

Key messages:

- The Electronic Personal Health Record (EPHR) is underutilised despite its potential; it's mainly accessed by young and highly educated individuals.
- Efforts to increase EPHR usage must focus on improving accessibility and ease of access, as well as enhancing user confidence and autonomy in managing health information.

Issue: RisCoin, a prospective monocentric longitudinal observational study, aimed to identify risk factors for COVID-19 vaccine failure. Secondary aim is to monitor symptoms, SARS-CoV-2 infection, vaccination status of 3816 enrolled healthcare workers (HCW) and 180 patients with inflammatory bowel disease (IBD). Since the LMU University Hospital Munich served both as study sponsor and employer of the HCW, a secured approach was required.

Description of the solution: Participants accessed the study app (CentraXX, KAIROS GmbH, Germany) via pseudonymized Contact-ID with irreversible anonymization after 6 months. Key app features were the serological results report, bidirectional messaging, and weekly survey for self-reported data on vaccinations, infections, and symptoms. Active app use was defined as submitting >1 weekly survey during the study period 10.2021-12.2022.

Results: Over 15 months, our study team maintained 1964 two-way communications with 958 participants via the app. Of 3979 participants with app access, 3622 (91%) were active users, 2606 (65%) submitted 1 to 11 surveys, 1016 (26%) made ≥12 submissions (P75, "frequent users"). Frequent users were more likely to be IBD patients ($p = 0.001$), female ($p < 0.001$), aged 60 or older ($p < 0.001$). Staff in administration and nurses were more likely to be frequent users compared to physicians ($p < 0.001$). Main problems included the initial operational system disparities resulting in app crashes and continuous need for app reactivation. Both led to loss of active participants and required substantial staff resources to onboard and support participants during the study.

Lessons: The study app enabled secure, flexible, bidirectional communication with all participants. Despite technical issues, the majority actively used the app and provided valuable longitudinal data through weekly survey submissions.

Key messages:

- A study-specific app provides a flexible and secure bidirectional anonymous communication for the study team and participants.
- Adherence to app-based communication and data collection for pandemic monitoring was particularly high among patients, nurses and administrative staff.

Abstract citation ID: ckae144.1115
Predicting hospital readmission in multimorbid patients with the use of AI: A systematic review

Yara Zain

Y Zain[1], N Hassan[1], K Marley[1], RD Slight[1,2], DW Bates[3], SP Slight[1]
[1]School of Pharmacy, Newcastle University, Newcastle, UK
[2]Newcastle Upon Tyne Trust Hospitals, Freeman Hospital, Newcastle, UK
[3]Medical School, Harvard University, Boston, USA
Contact: yara.zain@newcastle.ac.uk

Background: Multimorbid patients are at higher risk of hospital readmission due to the complex nature of their conditions. Identifying those who may be at particularly high risk would allow us to intervene early and potentially delay or prevent such readmissions occurring, thus reducing healthcare costs. We conducted a systematic review investigating the use of machine learning models in predicting 30-days unplanned hospital readmission of multimorbid patients.

Methods: This review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Guidelines, and was registered with PROSPERO (CRD42022373937). We searched MEDLINE, Embase, Web of Science and Cumulative Index to Nursing and Allied Health Literature (CINAHL). Included studies developed an AI model for prediction of 30-days hospital readmission for adult patients with two or more health conditions. The CHARM and PROBAST checklists for data extraction and bias assessment were used. The quality of included studies was assessed with the CASP checklist.

Results: Eighteen papers were eligible for inclusion. A total of 669 predictors were reported with an average of 37 used per model. Predictors were classified as modifiable and non-modifiable with the most common modifiable predictors being hospital length of stay, hypertension, anaemia and obesity. Average sensitivity and specificity of the models was reported to be 72% in 13 studies and 79.2 in 11 studies, respectively. Area under the curve (AUC) was reported in 13 studies, five of which were considered to have good discrimination power (AUC>0.8).

Conclusions: Machine learning models are capable of accurately predicting 30-days hospital readmission of multimorbid patients. Identifying modifiable predictors with highest weight allows for better planning and resource allocation to potentially reduce the risk of 30-days readmissions. An important area for future work would be the implementation of these high performance models in practice.

Key messages:

- Hospital readmissions are preventable and identifying those at higher risk allows us to intervene early.
- Machine learning models are capable of predicting 30-days readmission of multimorbid patients.

Abstract citation ID: ckae144.1116
A Multi-Modal Approach for A Healthier Weight and More Active Lifestyle

Bertha Ochieng

B Ochieng[1]
[1]School of Allied Health Sciences, Leicester, UK
Contact: bertha.ochieng@dmu.ac.uk

Background: Obesity and overweight has been increasing globally and in the UK over the last few years, bringing along a wide array of challenges in health and wellbeing. Not only do they take a heavy toll on those affected, but obesity and overweight-related ill-health is costing the UK National Health Service £6.1 with projected costs to run up to £9.7 billion in 2050. This project aimed to apply artificial intelligence to identify the predictive indicators for obesity and co-create an intervention with public health practitioners and stakeholders.

Methods: Using health and wellbeing public health population data from the 2015, 2018 and 2022 from a city in the East Midlands, we applied artificial intelligence that uses machine learning techniques to discover insights, find hidden patterns and discover relationships in the data about engaging in physical activity and a healthy diet. The data on dietary choices and physical activity preferences were further analysed using advanced machine learning techniques.

Results: The outcomes from our machine learning process revealed patterns of physical activity engagement and diet from specific locations, along with a range of demographic variables that influence individuals' patterns of physical ability and dietary practices. These findings, which will be presented in detail, have been integrated into a comprehensive city map. This map not only showcases opportunities for engaging in a healthy lifestyle but also aids in prioritising interventions in areas of greatest need.

Conclusions: The AI technology we employed allowed us to parameterise and generalise our findings with the possibility of scaling up the machine learning approach to other similar datasets. The findings facilitated the development of bespoke training for public health officers working with underserved communities, further demonstrating the impact of applying AI to inform the design of public health interventions.

Key messages:

- Applying Artificial Intelligence to public health data has the potential to inform the development of effective interventions and increase precision.
- Using AI in public health data can generate new insights into population health and well-being and inform public health policy.

Abstract citation ID: ckae144.1117
Dual-tiered insights: cross-examining entities in free text electronic health records

Salem ElHassan

S ElHassan[1,2], *A Sdralias*[2,3], *R Hamilton*[2], *A Shamsizadeh*[1,2]
[1]Faculty of Engineering & Digital Technologies, University of Bradford, Bradford, UK
[2]Research & Development, InFact UK Ltd, Shipley, UK
[3]School of Science & Technology, Hellenic Open University, Patras, Greece
Contact: salem@in-fact.com

Background: Poor determination and processing of actions at the primary care level are found to be associated with unstructured and cluttered electronic health records (EHRs). Physicians recommend that EHRs must highlight entities, such as action items, findings, follow-ups, and reasons for medication changes. There's consensus around the success of large language models (LLMs) in detecting clinical and non-clinical entities in EHRs. However, end-to-end systems make limited efforts to go beyond entity and relationship detection to support clinical decision-making.

Methods: We propose a two-tier system that generates case-based comparative reports for entities highlighted by physicians in EHRs. First, we fine-tuned a custom Bidirectional Encoder Representations from Transformers (BERT) model that detects the required entities within the EHRs. Second, a clustering-based service generates a report comparing the detected entities of a specific EHR with other EHRs sharing the same conditions determined by the healthcare professional.

Results: The system leverages the MIMIC IV deidentified free-text clinical notes dataset. The first-tier successfully classified entities with a macro-score average range of [0.87 - 0.94]. For the second tier, preliminary simulations on a set of test samples were made to cluster the entities. The simulations leverage a custom statistical tests engine offering a suite of entity-type specific tests. The results of these tests are used to generate the case-based detected entities comparative report.

Conclusions: Highlighting clinical and non-clinical entities bridges the communication gap between primary and secondary care. Clustering these entities extends the capability of LLMs in clinical support decision systems by providing healthcare professionals with the ability to run comparative analyses between EHRs. The comparative analysis reports provide a factual comparison between a selected number of detected entities and their thresholds.

Key messages:

- Clustering clinical and non-clinical entities extends the capacity of named entity recognition in clinical decision-making systems.
- Ability to generate a comparative analysis report based on figures extracted from recognised entities in free-text electronic health records.

Abstract citation ID: ckae144.1118
Evolution of online health-related information seeking in France from 2010 to 2023

Axelle Quiviger

A Quiviger[1], *P Ducrot*[2], *JB Richard*[1]
[1]DATA, Santé Publique France, Saint-Maurice, France
[2]DPPS, Santé Publique France, Saint-Maurice, France
Contact: axelle.quiviger@santepubliquefrance.fr

Background: Given the rapid ongoing progression of the internet and increase in health information available online since 2010, it is important to understand how these changes impact online health information-seeking behaviour of the population and the way of managing one's health. This study aims to describe the evolution of the use of internet to seek health-related information as well as the characteristics of online health information seekers.

Methods: We used data from the French nationally representative surveys Health Barometers. It is a cross-sectional repeated survey of random representative samples of the French population conducted by the French national public health agency since 1992 using computer-assisted telephone interviewing. It serves to measure the evolution of key indicators regarding health-related behaviors, attitudes, and opinions in the general population and includes individuals aged 18-75 years old selected through randomly generated phone numbers. In the 2010, 2014, 2017 and 2023 editions, the same question was asked about the internet use as a source of health information. Evolutions over time were assessed using chi-square tests. Associations with sociodemographic characteristics and health status were evaluated using logistic regression models.

Results: Although internet access increased steadily during this period, from 72.8% in 2010 to 95.2% in 2023, the use of the internet as a source of health information rose between 2010 and 2014 (from 37.3% to 67.9%), decreased significantly in 2017 (60.3%) and rose again in 2023 at 65.3 %. The study describes the characteristics of the online health information-seekers trough time.

Conclusions: The past decade was marked by a breakthrough of the use of internet in the general population and the use of internet to seek health information. The analysis of the digital health information-seekers serves the public health authorities in their mission to provide accessible information on public health.

Key messages:

- This study aims to describe the evolution of Online Health-Related Information Seeking in France from 2010 to 2023 and the characteristics of digital health information-seekers.
- The analysis of the digital health information-seekers serves the public health authorities in their mission to provide accessible information on public health.

[2]Digital Society Initiative, University of Zurich, Zürich, Switzerland
[3]IBME, University of Zurich, Zürich, Switzerland
[4]Digital Law Center, University of Geneva, Geneva, Switzerland
Contact: paola.daniore@uzh.ch

Background: The increasing volume of publicly available data offers health researchers opportunities to explore public sentiment through open data research on issues such as vaccination hesitancy and fake news propagation. To ensure ethical conduct and maintain public trust, assessing public perceptions of open data research in healthcare is crucial.

Methods: We conducted 10 focus groups across the German, French, and Italian-speaking regions of Switzerland. We presented participants with real-world examples of open data research in healthcare and guided discussions using a semi-structured format. The topic areas were: (1) using Twitter data to assess public opinion on gene-editing technology, (2) assessment of health policy documents, (3) using Twitter data to predict individual health status and (4) using YouTube data to assess public sentiment on health policies. We assessed our findings using a thematic analysis approach.

Results: Gathering insights from 75 citizens, four major themes emerged: (1) Expectations towards actors and open data research, such as using research findings for societal benefit, and ensuring transparency in data use through informed consent; (2) Supportive measures including communication strategies to raise awareness and inform the public about the use of publicly available data for health research; (3) Concerns about data reuse for purposes beyond the study's objectives, especially for financial gain, and about data validity and privacy, particularly for sensitive health data; and (4) Mitigative measures to minimize harm, such as through the involvement of external oversight committees.

Conclusions: Our findings indicate public support for open data research in healthcare, provided that specific expectations are met. Developing a guiding framework for legitimate open data research in healthcare is a valuable next step, with a focus on enhancing public awareness through communication campaigns and providing oversight measures to foster public trust.

Key messages:

- Open data research in healthcare relies on public data use without explicit consent, which can disconnect the research community from society.
- We found that public support for open data research in healthcare is generally present, however it is also conditional on communication and policy efforts addressing their concerns.

Abstract citation ID: ckae144.1120
Prediction of mental health risk in adolescents via a smartphone app: a feasibility pilot study

Aglaia Freccero

T Bellido Bel[1], *B Kadirvelu*[2], *A Freccero*[1], *M Di Simplicio*[1], *AA Faisal*[2,3], *D Nicholls*[1]
[1]Division of Psychiatry, Department of Brain Sciences, Imperial College London, London, UK
[2]Brain & Behaviour Lab, Imperial College London, London, UK
[3]Chair in Digital Health & Data Science, Universität Bayreuth, Bayreuth, Germany
Contact: aglaia.freccero21@imperial.ac.uk

Background: The prevalence of mental health problems in adolescents is a global public health concern. Machine learning (ML) can analyse multidimensional data collected by phone sensors (passive tracking) and symptom self-reporting (active tracking) to model and predict mental health states. However, research in adolescents is lacking. This study investigated the feasibility of using ML to predict mental health in a non-clinical population of adolescents from active and passive data collected through the Mindcraft mobile app.

Methods: We recruited 103 secondary students (aged 14-18) who first completed the Strengths and Difficulties Questionnaire (SDQ) and then used the Mindcraft app for two weeks. The app integrates sensor data (location, steps, noise, light, battery, app usage) and self-reports. We extracted 85 sensor-based features and 19 from questionnaires to develop a gradient-boosted ensemble ML model. This model identifies students with abnormal SDQ scores and was evaluated using leave-one-out cross-validation.

Results: All students completed the active questionnaires; 67 also provided passive sensor data. 31 had abnormal SDQ scores. Using passive data, the ML model reached a balanced accuracy of 0.64 and an AUC score of 0.57. Incorporating both data types improved accuracy to 0.67 and AUC to 0.70. Feature importance scores showed step count and questionnaire on racing thoughts and hopefulness as most significant.

Conclusions: Our findings affirm the potential of integrating passive and active data collection to monitor mental health in real-world settings. Our ML model demonstrated moderate accuracy in predicting adolescents' mental health risk measured with a behavioural screening questionnaire. This study will guide the development of a ML-driven, personalised mobile intervention for early symptom detection and mental health self-management, which might constitute an innovative and scalable tool for mental health prevention and intervention in adolescents.

Key messages:

- This study shows the feasibility of using active and passive data to predict mental health risk in adolescents.
- This study informs the development of a personalised machine learning-driven mobile intervention.

Abstract citation ID: ckae144.1121
Can a zero-shot learning Large Language Model code complex interview data?

Elias Balt

[4]Psychiatry and Psychosocial Care, Koraal Mental Health Facility, Sittard, Netherlands
[5]Research, Ggz Oost-Brabant, Boekel, Netherlands
Contact: e.balt@113.nl

Background: Psychological autopsy is essential to establish theories, explore trends and identify previously unexplored psychosocial risk factors in suicide research. However, qualitative research has been scrutinized for being prone to interpretation bias, problems with accuracy, challenges to reproducibility, and is very time- and cost intensive. The current study aimed to investigate if a Large Language Model can achieve sufficient agreement with a researcher in the deductive coding of interview data obtained in a psychological autopsy study of suicide, to be integrated with qualitative research procedures.

Methods: Data from 38 interviews was deductively coded by a researcher and a LLAMA 3 based language model. The model performance was evaluated in four increasingly difficult coding tasks, including binary classification and data summarization. Intercoder agreement scores were calculated using Cohen's Kappa.

Results: The preliminary results showed that the LLM achieved substantial agreement with the human coders for the binary classification task (.78). The variability in performance was influenced by code definitions. The results of the quality of LLM interpretation and summarization will also be presented.

Conclusions: State-of-the-art LLM can be easily integrated into the qualitative analyses of psychological autopsy interviews and may improve real time monitoring of suicides. We recommend a human-AI collaborative model, whereby deductive coding by the LLM is complemented by human inductive coding and further interpretation.

Key messages:

- Integrating an LLM with qualitative research procedures is feasible in a collaborative model.
- Integrating an LLM with qualitative research procedures allows near real-time monitoring based on qualitative data, which extends to other public health fields.

Abstract citation ID: ckae144.1122
EvalDepApps: How to evaluate depression management based on evidence and end users

Noemí Robles

[6]Marina Salud, Denia, Spain
Contact: nrobles@uoc.edu

The use of apps is increasing in the field of mental health due to their ease of use and accessibility, although there is not enough evidence on their effectiveness and safety. EvalDepApps aims to develop an evaluation tool for depression management apps. A systematic review with meta-analysis (SRMA) was performed to evaluate the efficacy and safety of apps for depression, and to identify the evaluation criteria used. PRISMA methodology was followed. The MEDLINE, PsycINFO, and Embase databases were consulted. The risk of bias was assessed with the RoB2 scale. An online 2 rounds Delphi was carried out to prioritize the most relevant criteria identified. 44 people (26 professionals, 18 patients) were invited. They were asked to rate the importance of each criterion on a Likert scale (1 - 6). Those that obtained a high consensus were selected; those with a medium were submitted to the 2nd round. Empathization (6) and co-design (6) sessions were held with patients (23) and professionals (33) in Catalonia, the Canary Islands and Andalusia to identify what relevant aspects the tool should have. Twenty-nine studies were included in the SRMA (67% unclear bias), finding a significant effect of mHealth interventions in reducing depressive symptoms compared to non-active control (Hedges $g = -0.62$, 95% CI: -0.87 to -0.37, $I2 = 87\%$). In Round 1 of the Delphi (59% participation) 24 criteria obtained a high consensus, 20 a medium and 7 a low. In Round 2 (52% participation), 4 criteria reached high consensus. The empathy sessions showed that the actions most requested by patients were reduce anxiety, and information about their condition; for professionals, suicide prevention. Regarding co-design, it was proposed that the tool provide ranking of the apps, recommendation systems and a very visual format. The RSMA and Delphi guarantee that the tool will be based on scientific evidence and expert judgment, while empathization and co-design that it will fit with the needs of end users.

Key messages:

- It is relevant to evaluate the quality of health apps, especially those addressed to vulnerable populations such as people with depression.
- It is crucial that the development of evaluation tools for digital health interventions will be developed based on evidence-based but also includes end users.

Abstract citation ID: ckae144.1123
Strategies to advancing digital health equity: perspectives from underserved groups

Sarah Wilson

S Wilson[1]*, C Tolley*[1]*, R Mc Ardle*[2]*, R Slight*[3]*, N Hassan*[1]*, S Slight*[1,3]
[1]School of Pharmacy, Newcastle University, Newcastle Upon Tyne, UK
[2]Translational and Clinical Research Institut, Newcastle University, Newcastle Upon Tyne, UK
[3]Department of Cardiothoracic Surgery, The Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK
Contact: sarah.wilson@newcastle.ac.uk

Digital Health Technologies (DHTs) are revolutionizing healthcare. However, there is a lack of demonstrable health benefits across all populations. To advance digital health equity, we explored the perspectives of underserved groups on strategies to support digital inclusivity. Participants belonged to two or more CLEARS (Culture (ethnicity, language, religion), Limiting conditions (visual or hearing), low Educational attainment, older Age, Residence (rural, deprived or no fixed address), low Socioeconomic status) groups. This framework encompassed sociodemographic factors associated with digital exclusion and recognizes the role of intersectionality.(1) Twenty-nine individuals participated in focus groups ($n = 4$) or interviews ($n = 11$) and shared their perspectives on the barriers to DHTs, innovative ideas to improve inclusivity, and perceived feasibility of implementing changes. An inductive reflective thematic analysis was used to analyze the transcripts, assisted by N-Vivo. Participants experienced fragmented communication with healthcare providers when using DHTs, explaining how they received a no-reply SMS message asking them to confirm an appointment via a link but were unable to access the link. Current solutions to overcoming such barriers included using non-digital routes (e.g., visiting a pharmacy) or calling non-emergency healthcare services. Many participants expressed the need for DHT support services to be implemented to provide educational support and access to devices. However, some participants raised concerns about the financial strain this might place on healthcare systems. Future research should evaluate the feasibility of implementing different DHTs support services across different settings to advance digital health equity.

(1)Wilson et al. (2023). Strategies to develop, design, implement and support digital health equity in key underserved groups: protocol for a systematic review. Alzheimer's & Dementia.

Key messages:

- Strategies to mitigating digital exclusion within healthcare should be designed with underserved groups.
- Future research should evaluate the feasibility of implementing different DHTs support services across different settings to advance digital health equity.

Abstract citation ID: ckae144.1124
Accessibility engineering in the mhealth industry - A multi-case study

Katharina Hasenlust

K Hasenlust[1]*, AV Reinschluessel*[2]*, M Rother*[1]
[1]Digital Media Lab, University of Bremen, Bremen, Germany
[2]HCI Group, University of Konstanz, Konstanz, Germany
Contact: kahasenl@uni-bremen.de

Medical apps, i.e. apps that fall under the EU Medical Device Regulation (MDR), are increasingly becoming a relevant part of healthcare in European countries. This is particularly evident in the numerous partnerships between app vendors and insurers as well as in the launches of national reimbursement programs. However, when it comes to enabling as many patients as possible to benefit from the medical advantages associated with the use of these apps, funding is only one part of the equation. It is up to the app vendors to develop barrier-free user interfaces so that people - regardless of individual characteristics such as cognitive abilities, physical limitations or language skills - can interact successfully with the app. Little is known about how these companies approach the topic of accessibility, what challenges they face and how big the impact of medical device legislation and other regulations on accessibility is. Against this background, we are undertaking a case study in several companies offering apps on the German market that are certified as medical devices and targeted at patients. Through interviews with employees with various roles (e.g. business, engineering, design) we are aiming at reconstructing the development processes of the apps with a focus on accessibility. We plan to expand the results by interviews with experts, e.g., in the area of MDR conformity assessment. 20 interviews in four companies have revealed that accessibility only plays a minor role during development. As a result, the topic is not systematically addressed, but only a few features are implemented. The app's compatibility with screen reader or voice control was not explicitly addressed in any of the companies. There was also no deliberate involvement of people with disabilities in user studies. The preliminary results also indicate that the influence of medical device legislation on the implementation of accessibility is negligible.

Key messages:

- User interface accessibility has a very low priority in the mhealth companies we have examined so far.
- The current regulations are not sufficient in enforcing the basic implementation of accessibility features requiring more guidance and detailed regulations, given our sample of companies.

Abstract citation ID: ckae144.1125
The physician-AI relationship: partnering for precision medicine via clinical decision support

Hadar Samuel

H Samuel[1]*, T Norman*[1]*, S Vaknin*[2]*, M Saban*[3]
[1]Health Policy Research Team, Myers-JDC-Brookdale Institute, Jerusalem, Israel
[2]Gertner Institute for Epidemiology and Health, Sheba Medical Center, Tel HaShomer, Israel
[3]School of Health Sciences, Tel Aviv University, Tel Aviv, Israel
Contact: hadars@jdc.org

Background: Clinical decision support systems (CDSSs) can enhance physician decision-making, but successful adoption depends on positive user attitudes. Understanding Israeli physicians' attitudes toward CDSSs is crucial for overcoming implementation barriers and refining training.

Methods: Semi-structured interviews explored knowledge, experiences, perceived benefits/drawbacks, and potential barriers/facilitators to CDSS use among 25 Israeli physicians across specialties, roles, settings, and experience levels selected via stratified sampling. Individual 45-minute video interviews were conducted in January-July 2023.

Results: Familiarity and CDSS experience varied substantially across medical specialties. While risk calculators, information systems, and expert systems disseminating contemporary research insights are widespread, AI-based system adoption is relatively low outside radiology. Physicians expressed positive attitudes, recognizing CDSSs' potential to enhance clinical work, reduce errors, and alleviate burdens. However, concerns included AI systems' impact on workload, patient relationships, skill erosion, and overreliance. Key implementation barriers involved technological infrastructure, organizational processes, physician perceptions, and system features. Facilitating factors included tailored design, focused training, continuous accuracy/reliability validation, and clear autonomy/liability guidelines.

Conclusions: Addressing key concerns around transparency, trustworthiness and responsible use is crucial for AI-CDSS to fulfill its promise of enhancing quality and outcomes. Insights from Israeli clinicians provide guidance on priorities like transparency of data and algorithms as well as ensuring AI behaves ethically. Collaboration among technology designers, healthcare professionals and stakeholders can help develop systems that physicians trust to improve care while safeguarding patients. Ongoing evaluation is also needed to optimize AI-CDSS over time.

Key messages:

- Understanding physician attitudes is key to overcoming barriers to clinical decision support system adoption and optimizing training protocols.
- Addressing transparency, trustworthiness, and ethical considerations around AI clinical decision support systems is crucial for enhancing quality care.

Contact: niina.metsa-simola@helsinki.fi

Background: Hospitals at home are increasingly offering outpatient parenteral antimicrobial therapy (OPAT) in an attempt to reduce costly inpatient care, but these settings favor broad-spectrum antibiotics that require less frequent dosing than penicillin. Benzyl penicillin could be delivered via continuous infusion pumps (eCIP), but studies on their safety and efficacy in OPAT are scarce, and it remains unclear how much the availability of eCIPs increases penicillin use in real-life settings.

Methods: We examined 462 electronic healthcare records of erysipelas patients treated between January 2018 and January 2022 in a large Finnish OPAT clinic. Average marginal effects from logistic models were estimated to assess how the introduction of eCIPs in December 2020 affected penicillin use, and to compare clinical outcomes between patients with and without eCIPs.

Results: Introduction of eCIPs increased the predicted probability of penicillin treatment by 36.0 percentage points (95% confidence interval 25.5-46.5). During eCIP implementation, patients who received an eCIP had 73.1 (58.0-88.2) percentage points higher probability than patients without an eCIP to receive penicillin treatment. They also had about 20 percentage points higher probability to be cured at the time of discharge and three months after it. Patient and nurse satisfaction regarding eCIPs was very high.

Conclusions: Benzyl penicillin eCIP treatment is effective and safe, and substantially increases the use of penicillin instead of broad-spectrum antibiotics. To reduce the risk of antimicrobial resistance, eCIPs could increasingly be promoted for use in OPAT clinics, and there should be adequate education and support in their implementation.

Key messages:

- Continuous infusion of benzyl penicillin via elastomeric infusors substantially decreases broad-spectrum antibiotic use among erysipelas patients treated at home.
- When erysipelas patients can be treated with outpatient parenteral antibiotic therapy, the use of elastomeric benzyl penicillin infusors is safe and effective and should thus be increasingly promoted.

A global adoption of cryptocurrency and blockchain technology into the healthcare system

Teresa McKelvy

J Johnson[1], B Berkshire[1]

[1]Herbert H. & Grace A. Dow College of Health Professions, Central Michigan University, Mount Pleasant, USA
Contact: mckel1td@cmich.edu

Background/Objectives: Blockchain technology is revolutionizing various industries by enhancing security, transparency, and efficiency. In healthcare, its small-scale application demonstrates the potential to transform healthcare. This study explores how cryptocurrency and blockchain technology enhance healthcare financial stability, secure medical information exchange, increase payment recovery and interoperability.

Methods: Guided by the Diffusion of Innovations (DOI) Theory, this study reviews 34 articles on blockchain and cryptocurrency adoption in healthcare. We performed a thematic analysis focusing on empirical data, theoretical analyses, and existing implementations. Data were categorized by DOI elements: relative advantage, compatibility, complexity, trialability, observability, and social system. The findings were synthesized into a detailed framework for adopting these technologies in healthcare.

Results: Our analysis shows that cryptocurrency offers a secure, decentralized payment platform, eliminating the need for third-party intermediaries. Blockchain adoption enhances payment and patient record protection. Cryptographic methods ensure data integrity, transparency, and security, preventing modifications once recorded. Altering data requires consensus from the network majority, protecting healthcare providers from ransomware attacks.

Conclusions: Evidence suggests that cryptocurrency and blockchain will disrupt healthcare payments, data management, and accommodate interoperability within the next decade. These technologies promise improved security, improved public health research, and increased trust in the healthcare system.

Key messages:

- Our research will be assessing the challenges of integrating digital coins and blockchain technology into the healthcare system.
- Examine the potential benefits and risks of implementing blockchain technology in healthcare settings.

Abstract citation ID: ckae144.1128
Innovative risk score to diagnose depression using data from the UAE Healthy Future Study

Mitha Albalushi

M Al Balushi[1,2], *J Guan*[1], *M AlBlooshi*[1], *S Al Balushi*[1], *A Ahamd*[1]
[1]Public Health Research Center, New York University Abu Dhabi, Abu Dhabi, UAE
[2]Institute of Public Health, CMHS, United Arab Emirates University, Abu Dhabi, UAE
Contact: ma4643@nyu.edu

Introduction: Depression has been recognized as a major mental health disorder. Diagnosing depression remains a challenge due to its complex multifactorial nature. The UAE Healthy Future Study is a long-term cohort study that focuses on understanding the factors that contribute to chronic disease among Emiratis. It involves answering a comprehensive questionnaire, undergoing physical measurements such as Body Mass Index (BMI), and biological samples for analysis. We analyzed the eight-item depression screening instrument Patient Health Questionnaire (PHQ-8) for this project.

Methods: Out of 487 participants included in the PHQ-8, 205 participants (42.1%) were included in the statistical analysis after omitting missing values. A multivariate Least Absolute Selection Shrinkage Operator (LASSO) logistic regression model was performed using gender, age, BMI, waist circumference, hip circumference, body fat percentage, high-density lipoprotein (mg/dL), lowdensity lipoprotein (mg/dL), total cholesterol (mg/dL), diastolic blood pressure, systolic blood pressure, hemoglobin A1C, as predictors. The primary outcome was the binarized total PHQ-8 using a cutoff value of ten Tenfold cross-validation was applied.

Results: A cutoff value that yields an approximate sensitivity of 90% was selected to maximize the ability of the novel risk score to correctly identify subjects with depression symptoms. Sensitivity and specificity were estimated with a corresponding 95% confidence interval (95% CI). A novel depression risk score was computed as the linear predictor of the selected five variables in the LASSO regression analysis, as following: Risk score = -3.284 + 0.471*gender - 0.053*age + 0.049*BMI + 0.022*HDLmgdL - 0.072*HBA1c

Conclusions: We have shown that a novel depression risk score provides useful information for screening of depression. Further validation studies are needed to confirm the application of the risk score in daily practice.

Key messages:

- A novel depression risk score provides useful information for screening of depression.
- If the risk score can be verified in a different population, then it can improve the screening methods for depression.

Abstract citation ID: ckae144.1129
Digital Pathology: A Cost-Effective Solution For Healthcare Systems

Jonathan Chng Jia Hao

JJH Chng[1], *CZY Chong*[2]
[1]Pathology Department, National University Health System, Singapore, Singapore
[2]Primary and Community Care Division, Ministry of Health, Singapore, Singapore
Contact: chngjonathan@yahoo.com.sg

Background: Digital pathology represents a transformative technology in healthcare, utilizing digital analysis and interpretation of pathology microscopy images. While traditional light microscopy remains the standard, digital pathology offers potential advantages: improved diagnostic accuracy, increased efficiency, and enhanced collaboration. However, cost-effectiveness remains a crucial consideration for widespread adoption. This systematic review aims to evaluate the cost-effectiveness of digital pathology in various healthcare settings.

Methods: A literature search was conducted in PubMed, Scopus and Cochrane Library, using keywords "digital pathology", "telepathology" "cost", and "effectiveness". The search was limited to English-language studies discussing digital pathology and its cost effectiveness. Prior to inclusion, studies were evaluated for relevance and applicability. Included studies were analyzed for methodology, sample size, data collection methods, and key findings.

Results: Of 125 articles identified, 16 studies met inclusion criteria. Key findings included streamlined workflows allowing for smoother collaboration across institutions, enabling simultaneous evaluation of multiple slides, and utilizing image processing software to automate time-consuming tasks. Additionally, digital pathology reduces the need for physical slide transportation, reducing costs and enabling access to specialist expertise in remote or underserved areas. This combination of efficiency gains and potential cost savings suggests digital pathology's potential for long-term cost-effectiveness in healthcare systems.

Conclusions: Digital pathology has the potential to increase cost-effectiveness and improve quality and efficiency of pathology services. Further research is necessary to determine optimal implementation strategies, but the evidence suggests digital pathology warrants continued investment and adoption by healthcare systems to improve public health outcomes.

Key messages:

- Digital pathology demonstrates potential for cost-effectiveness.
- Despite the need to refine implementation, the efficiency and potential cost savings of digital pathology warrant further exploration.

Abstract citation ID: ckae144.1130
Using the innovative tool to prepare a quality national cancer control programme

Marjetka Jelenc

M Jelenc[1,2], *T Albreht*[1,3]
[1]Center for Health Care, NIJZ, Ljubljana, Slovenia
[2]University of Maribor, Faculty for Health Sciences, Maribor, Slovenia
[3]University of Ljubljana, Medical Faculty, Ljubljana, Slovenia
Contact: marjetka.jelenc@nijz.si

Issue: National cancer control programmes (NCCPs) are key documents in European Member States (MSs) used for the management of cancer policy. While some countries still have not prepared their NCCPs, there are several others, whose NCCP is not of high quality or not implemented.

Description of the problem: There is frequently a lack of knowledge in countries on how to prepare a quality NCCP or how to improve the existing one. Our objectives were: 1. To provide help in the preparation of an NCCPs and in cancer control to EU MSs 2. To enhance the availability of all the documents needed and provide best practices from other MSs. The development of an innovative tool was therefore the main objective of iPAAC Joint Action (JA). Streamlining of all NCCP-related documents prepared by the three JAs in cancer policy (EPAAC, CanCon, iPAAC) was central to the deliverables.

Results: The solution lied in the preparation of the interactive innovative tool called Roadmap on the Implementation and Sustainability of Cancer Control Actions (Roadmap). It was developed in a joint effort and collaboration between EU MSs and the European Commission. It is available online and can be used by all countries, including countries that are not part of EU, and who aim at preparing a high quality NCCP. The extensive content of the tool covers primary prevention, health promotion, screening, diagnosis, treatment, and health care, as well as a number of sub-areas with important contents, and over a hundred one-pagers, which include national and regional experiences. Among the latter, the European Guide for Quality NCCPs with instructions how to prepare a quality NCCP is presented as one pager.

Lessons: As the result of over 10 years of joint work in cancer control at EU level MSs have now both, the opportunity to learn from each other and the opportunity to access all key information they need for controlling cancer, including the instructions on the preparation of the key document, their NCCP.

Key messages:

- Using the Roadmap countries have access to instructions and guidance for the preparation of a quality NCCP.
- The Roadmap enables the access to all key documents for the management of cancer control in one place to all countries.

Abstract citation ID: ckae144.1131
Evaluation of Previous ECG Algorithms for Identifying the Culprit Artery in Inferior STEMI

Hela Ghali

S Fall[1]*, A Elhraiech*[1,3]*, H Ghali*[2,3,4]*, S Farhat*[1,3]*, M Slim*[1,3]*, S Ouennes*[1,3]*, I Ben Ali*[1,3]*, H Thabet*[1,3]*, R Gribaa*[1,3]*, I Neffati*[1,3]
[1]Department of Cardiology, Sahloul University Hospital, Sousse, Tunisia
[2]Department of Prevention and Security of Care, Sahloul University Hospital, Sousse, Tunisia
[3]Faculty of Medicine of Sousse, University of Sousse, Sousse, Tunisia
[4]LR20SP06, Sahloul University Hospital, Sousse, Tunisia
Contact: hela.ghali@outlook.com

Background: ST elevation myocardial infarction (STEMI) is the leading cause of cardiovascular related mortality. In the context of Inferior STEMI, the culprit artery is whether the right coronary artery (RCA) or left circumflex coronary artery (LCx). An accurate prediction of culprit artery prior to primary percutaneous coronary intervention (PCI) could improve the door-to-balloon time and could prevent contrast-induced-nephropathy. However algorithms established for that purpose were not evaluated within the Tunisian population. We aimed then to assess their performance in our population

Methods: We conducted a single-center hostorical cohort study from January 2014 to December 2022 on patients admitted at Sahloul university hospital Sousse Tunisia for PCI following an inferior STEMI. We analyzed the ST segment deviations at the J-point and 80 ms after the J-point then evaluated the performance of previous algorithms.

Results: We collected data from 156 patients, of which 130 (83.3%) hada RCA occlusion, and 26 (16.7%) a LCx occlusion. We evaluated 19 published algorithms. The criterion of zimetbaum et al (ST elevation in III> II and I and/or VL <-1 mm) had the highest AUC 0.77[0.66 - 0.88] YI = 52 accuracy = 0.81. The criterion of Herz et al (ST III > II) had AUC ROC of 0.71 [0.58 - 0.83] YI = 0.41 accuracy = 0.78, the algorithm of Tierala et al: AUC = 0.70[0.58 - 0.83] YI = 0.40 accuracy = 0.78. The algorithm og Fiol et al: AUC = 0.79 [0.58-0.83] YI = 0.59 accuracy = 0.73.

Conclusions: The Zimetbaum criterion had the highest performance in predicting the culprit artery and Fiol's algorithm was the most specific to the LCx occlusion in our population. Further study on the impact of these algorithms on patients outcome is necessary.

Key messages:

- The prediction of the culprit artery in inferior STEMI is challenging.
- The criterion of Zimetbaum et al had a good performance for that regard.

[9]Technical University, Varna, Bulgaria
Contact: vanko07@gmail.com

Background of the public health challenge: Excessive individual consumption of antibiotics (ABs) increases global antimicrobial resistance (AMR). Therefore, shaping consumers' behaviors towards responsible ABs use is an essential strategy in the battle with the silent pandemic of AMR. The EU One Health (OH) Action Plan against AMR targets making Europe a best-practice region. Overall consumption of ABs in the EU decreased significantly, especially during the COVID-19 pandemic. Bulgaria is the only EU country that has reported an annual increase in ABs use during this period (ECDC data). A growing part of Bulgarians, believe that 'ABs kill viruses' and is unaware that 'unnecessary use of ABs makes them ineffective' (Eurobarometer 2022). This limited understanding of adequate ABs use resulted in counterproductive behaviors that demand change. Introducing innovative policy instrument as a tool for behavioral change: Undeniably, drug prescription monitoring has the potential to change consumers' behaviors. In October 2023 mandatory electronic prescribing (e-Rx) for ABs was introduced in Bulgaria at a primary healthcare level. Consequently, there was an observed decline exceeding 30% in ABs sales (IQVIA Bulgaria data), evidencing a reduction in ABs consumption. However, there were negative reactions by the stakeholders, due to time-consuming procedures, nonoptimal IT infrastructure, etc., and that led to e-Rx-moratorium. Finally, in April 2024, the e-Rx is sustainably introduced.

Conclusions: Legislative measures, like e-Rx, can hinder the chaotic use of ABs. Moreover, Bulgarians need to reflect on their behaviors and values of solidarity which OH offers. Herewith, a multidisciplinary team of academic educators unite their OH efforts in raising awareness related to AMR and the rational use of ABs. Years of national endeavors toward healthcare digitalisation led to the introduction of e-Rx for ABs in Bulgaria. Research will prove its relevance for the rest of Europe.

Key messages:

- To the European community: The introduction of the innovative policy tool (e-Rx for antibiotics) in Bulgaria is a significant national effort in making Europe a best-practice region regarding AMR.
- To the Bulgarian society: Antibiotics are not bonbons! Responsible ABs use of every one of us can contribute to the EU efforts to manage AMR. In the context of AMR, every person is a stakeholder.

Abstract citation ID: ckae144.1133
Assessment of digital literacy and user experience in patients with cochlear implants

Maika Werminghaus

M Werminghaus[1], S Thyson[1], D Schatton[1], JG Richter[2], T Klenzner[1]
[1]Hearing Centre, Heinrich-Heine University Hospital Duesseldorf, Düsseldorf, Germany
[2]Department of Rheumatology, Heinrich-Heine University Hospital Duesseldorf, Düsseldorf, Germany
Contact: maika.werminghaus@hotmail.com

Introduction: The cochlear implant (CI) is the treatment of choice for people affected by deafness or profound hearing loss. Patients with cochlear implants (PwCIs) can enhance their hearing outcomes using digital hearing training programs (dHTPs). Current technological trends leans towards personalized, AI-driven dHTPs, aiming to optimize user experience (UX) and adherence. This study aims to investigate the digital literacy skills and UX of PwCI before and after testing a prototype of a dHTP with an AI-driven design (TraiCI).

Methods: Two research-specific questionnaires developed by the Hearing Center Düsseldorf (QDL and QUX) were used to assess digital literacy skills and user experience in TraiCI. Additionally, the User Experience Questionnaire (UEQ) was employed to evaluate general user experience. The UEQ assesses software quality across dimensions such as transparency and stimulation using paired opposites.

Results: 22 outpatient PwCIs the Hearing Center Düsseldorf with unilateral or bilateral CI (mean age 54 years; SD = 15) were included. In QDL, PmCI demonstrated high levels of digital literacy skills. The majority of PmCI (80.6%) reported prior experience with dHTP. Usage of these programs occurred daily to multiple times per week within the first six months after CI treatment, with session durations predominantly ranging from 10 to 30 minutes. QUX data indicated a smooth initiation process (70.8%) and seamless login experience (95.5%). The UEQ addressed various aspects of user experience, with ‘transparency’ receiving the highest scores (MW = 1.9; SD = 0.6), while ‘stimulation’ received the least positive ratings (MW = 0.0; SD = 2.1).

Conclusions: The results show a high degree of digital literacy among PwCIs. They encountered minimal challenges in operating hardware and software components. Further refinement is necessary to align with PwCI’s expectations and maximize benefits. Early and iterative involvement of PwCIs in future projects could optimize outcomes.

Key messages:

- The study highlights the proficient digital literacy skills of cochlear implant patients (PwCIs).
- Further refinement of dHTPs is needed to better align with PwCIs’ expectations and maximize benefits, emphasizing the importance of iterative involvement for optimized outcomes.

Abstract citation ID: ckae144.1134
Patients’ trust in health information sources as an antecedent of novel healthcare technology usage

Amit Gur

A Gur[1], R Avidar[1,2]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
[2]Communication, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
Contact: amitgu@yvc.ac.il

Background: As professional health information sources, healthcare maintenance organizations (HMOs) need to convince patients of the necessity, efficiency, and reliability of technology-based services to increase and optimize their usage. It raises the question of whether patients’ trust in health information sources shapes the use of technology-based services and, in return, increases their willingness to use novel healthcare services in the future.

Methods: Data were collected through an online close-ended survey among 668 adult Israeli citizens insured with Israeli health insurance (85% of them Jewish, 52.5% female, and in their early 40s, with half holding an academic degree). The survey explored actual use and willingness to use innovative healthcare technologies and the trust respondents attributed to various sources of health information. Data were analyzed by SPSS 28.

Results: Participants generally use healthcare technology primarily to schedule appointments, search for medical information, and make health-related requests. To quite an extent, they are willing to be treated with innovative healthcare technologies (e.g., for radiological purposes and personally tailored medication). Preliminary results suggest that trust in the measured formal health information sources (i.e., formal health providers, HMO, HMO online services) was positively associated with technology-based healthcare services usage (r=.14 - .20, p<.001). A positive association also emerged between the current use of healthcare technology and the willingness to use innovative medical technologies in the future (r=.23, p<.001).

Conclusions: HMOs, as key players, have the power to maximize the usage of advanced health services by establishing trusting relationships with their patients. This will increase the usage of healthcare technology-based services and generate positive patient experiences, which will result in the willingness to experience novel types of health services in the future.

Key messages:

- Encouraging patients to use technology-based health services will maximize the potential inherent in the use of innovative health services and treatments in the future.
- Nurturing trusting relationships with patients at any level in the health system will increase their compliance with health providers’ recommendations to use advanced health services.

Abstract citation ID: ckae144.1135
Debuting an innovative model for integrated child health care in the Southeast region, Bulgaria

Desislava Vankova

D Vankova[1,2], D Nikolov[3]
[1]Department of Social Medicine and Health Care Organization, Medical University of Varna, Bulgaria, Varna, Bulgaria
[2]Bulgarian Public Health Association, Pleven, Bulgaria
[3]Municipality of Burgas, Burgas, Bulgaria
Contact: vanko07@gmail.com

Background: Demographic indicators are fundamental drivers for health policy action. The Southeast Region (SER) is the largest statistical region (NUTS 2) in Bulgaria (BG), distinguished by the highest Infant mortality rates (IMR) and teenage crude fertility rates across the European Union (EU). For instance, the 2022 statistics reveal an IMR of 8.2 per 1000 live births in SER, notably higher than Bulgaria’s average of 4.8 and the EU’s average of 3.3. This disparity highlights the critical need for region-specific health initiatives aimed at curtailing IMR and harmonizing health outcomes throughout the EU territories. This report outlines such an initiative under the project code BG16FFPR003-2.001-012, recently funded by the EU. The novel SER initiative: This is the first presentation of the concept of integrated territory investments (CITI) and the innovative model for integrated child health care in SER, BG. The project impacts child health care across the four districts of SER - Burgas, Sliven, Yambol, Stara Zagora. The municipalities have collaboratively submitted 24 project proposals with educational bodies, NGOs, public institutions, and the Ministry of Health. The theoretical frame of the project’s model is underpinned by three foundational pillars: 1) Prevention in primary healthcare; 2) Child health care in hospitals; 3) Development of human resources, providers of health care. The forthcoming infrastructural, organisational, and capacity-building interventions will remain adaptable yet aligned with the overarching CITI framework.

Conclusions: A current phase of public discourse on the CITI concept and the innovative integrated model in SER is underway. Stakeholders are actively encouraged to provide input either through discussions or by participating in designated online surveys. Community engagement is instrumental in evaluating and prioritizing these initiatives, which aim to fundamentally transform the SER by leveraging its unique territorial potential.

Key messages:

- Demographic indicators drive health policy. Project BG16FFPR003-2.001-012 targets EU disparities, lowering IMR and balancing fertility rates.
- This is the first presentation of the “Innovative model for integrated child health care in SER”. The EPH Conference provides an ideal platform for sharing and discussion.

Assessing Academic Perspectives on Infodemic Management and Health Security: A Needs-Based Approach

Stefan Mandić-Rajčević

S Mandić-Rajčević[1,2,5], A Stevanović[1,2,5], A Rowland[3], M Zdujić[1,2,5], J Vidojević[1,2,5], I Sotirović[1,2,5], P Zelić[4], R Martin[3]

[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

[2]Laboratory for Infodemiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

[3]Emory Global Health Institute, Emory University, Atlanta, USA

[4]Managing Director’s Office, Medicines and Medical Devices Agency of Serbia, Belgrade, Serbia

[5]School of Public Health and Health Management, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Contact: stefan.mandicrajcevic@gmail.com

Background: The information environment significantly impacts public health decisions, behaviors, and health security. Misinformation and disinformation can compromise health interventions and undermine public trust, and this phenomenon, known as the infodemic, is increasingly challenging to address and requires innovation and transformation of public health and education of the health workforce. This study aimed to assess the relevance of infodemic management (IM) to different academic fields and training needs to create a competent workforce.

Methods: As part of the US Federal Assistance Award within the University Partnership Program between Emory University and the University of Belgrade, a mixed-methods study was conducted to evaluate the curricula of all 31 faculties at the University of Belgrade. An online survey was distributed to faculty deans to assess the current educational framework and opinions on IM in various academic fields. This approach provided a multidimensional view of how IM is perceived and integrated across diverse disciplines.

Results: The survey received 33 responses from different departments at the University of Belgrade. Over 75% of participants identified misinformation as prevalent in their respective fields. More than half of the respondents believe that students are not sufficiently familiar with the concept of the infodemic and its potential consequences, only 9% believe these topics are well covered in the current curriculum, and over 90% agree that additional content on IM is required to update study programs, indicating a gap in our current educational approach.

Conclusions: Academic circles have acknowledged the issue of misinformation and its negative impact on public health. Current gaps in academic curricula indicate the critical necessity of integrating IM into educational programs. This innovative approach will provide future specialists with the necessary skills to navigate the complexities of the modern information ecosystem.

Key messages:

- Over 75% of surveyed professors identify misinformation and disinformation as prevalent in their professional fields, indicating a widespread impact.
- Over half of professors feel academic programs do not sufficiently equip students to navigate the information ecosystem, with over 90% calling for additional infodemiology content.

Perspectives on intersectoral collaboration and citizen participation in community-based prevention

Jannemiek Sonneveld

JM Sonneveld[1,2], JE Bruijning[1], K Jerković-Ćosić[1,3], NJ de Wit[2]

[1]Research Group Innovations in Preventive Care, HU University of Applied Sciences, Utrecht, Netherlands

[2]Julius Center of Health Science, University Medical Center Utrecht, Utrecht, Netherlands

[3]Public Health and Oral Care Department, Academic Centre for Dentistry Amsterdam, Amsterdam, Netherlands

Contact: jannemiek.sonneveld@hu.nl

Background: Challenges in healthcare, such as rising healthcare costs, shortages of healthcare staff, and health disparities, have made many countries focus on intersectoral collaboration (IC) and citizen participation (CP) in community-based prevention (CBP) and health promotion (HP). Previous research on IC and CP has addressed the importance of exchanging perspectives to arrive at a shared vision and ambition. Our study is part of a long-term action research project conducted in two neighborhoods in the Netherlands. It aims to provide insight into stakeholders’ perspectives on IC and CP in CBP and HP to facilitate building partnerships.

Methods: Data collection takes place from March to June 2024. As part of a Q-study, we perform post-sort interviews. The Q-methodology is based on sorting statements concerning various aspects of IC and CP in CBP and HP (e.g., roles and tasks, involvement of citizens, communication, perceived barriers, etc.). We aim to include 40-50 participants from the aforementioned neighborhoods with diverse backgrounds. Participants sort 40 statements (Q-set) into a fixed-scaled framework ranging from -4 (disagree) to + 4 (agree). The interview is about individual sorting and perspectives on their own role within the collaboration.

Results: So far, the results of 10 participants with backgrounds in health care, social work, sports, local authority, volunteer work, and public health have been analyzed.Preliminary data synthesis shows six themes concerning shared purpose, collaboration partners, social collaboration competencies, personal motivation, conditions, and collaboration organization.

Conclusions: The preliminary themes overlap with findings from previous research. We will adapt existing models to reflect on our findings and enrich the literature with new themes or insights in the specific context. The interviews will help interpret the Q-sorts and develop follow-up actions in the action research projects in the participating neighborhoods.

Key messages:

- Insights in stakeholders’ perspectives are valuable for building local collaborative partnerships.
- Shared purpose, collaboration partners, social collaboration competencies, personal motivation, conditions, and collaboration organization are themes of interest to intersectoral collaboration.

A new digital model for Italian Integrated Home Care: strengths, barriers, and future implications

Andriy Melnyk

A Melnyk[1], *A Gentili*[1], *F Beccia*[1], *FA Causio*[1], *S Battilomo*[2], *S Paone*[3], *A Borghini*[3], *M Bartolo*[4], *E Chiarolla*[2], *F Cascini*[1,2]
[1]Catholic University of the Sacred Heart, Rome, Italy
[2]Health Information System and Statistics, Ministry of Health, Rome, Italy
[3]Italian National Agency for Regional Healthcare Services, Rome, Italy
[4]Telemedicine Department, San Giovanni Addolorata Hospital, Rome, Italy
Contact: andrymelnyk@yahoo.it

Issue/Problem: After the COVID-19 pandemic, Italy's National Health Service (NHS) is transforming by adopting telemedicine through its National Recovery and Resilience Plan, aiming to modernize healthcare delivery and ensure equity. In this plan Territorial Coordination Centers (COT) were designed to improve patient access and continuity of care. However, regulatory challenges hinder the widespread adoption of telemedicine. Our work describes the technical, structural, and operational aspects of the new Italian Integrated Home Care (IHC) digital model, addressing strengths, barriers, and future implications.

Description of the problem: The implementation of the IHC digital model faces multiple challenges. Italy's poor technical infrastructure, especially in rural areas, hampers access to critical services. Resistance to change among rural systems and the elderly, coupled with low digital literacy, inhibits telemedicine adoption. Fragmentation in the NHS leads to resource disparities, particularly disadvantaging southern regions. Italy also grapples with a severe shortage of healthcare professionals, posing a threat to the model's sustainability.

Results: The National Digital Health Agency enacts the IHC model by overseeing telemedicine services through a cloud-based protocol. Each Region provides "Basic Telemedicine Services": healthcare professionals' and patient teleconsultation, telemonitoring, teleassistance. Communication between services, infrastructures, and local health authorities is facilitated by a modular interoperability layer, ensuring data standards and quality. A national telemedicine dissemination portal will contain data on all telemedicine solutions provided.

Lessons: Clear communication is essential for telemedicine acceptance. COTs enhance coordination and management. Bridging the technology gap for disadvantaged groups, supporting frontline employees and addressing adoption factors is vital to overcome the challenges faced.

Key messages:

- The National Digital Health Agency drives telemedicine services under the IHC model. Each region offers Basic Telemedicine Services, ensuring data standards, quality and interoperability of data.
- Italy's telemedicine adoption faces poor infrastructure, resistance and workforce shortages. Focusing on equity, healthcare workers support and bridging the technology gap will be key.

[2]Department of Social Medicine and Public Health, Faculty of Public Health, Medical University of Plovdiv, Plovdiv, Bulgaria
Contact: gkpg21@yahoo.com

Background: This study investigates the manifestation of empathy among nursing students and teachers during virtual patient training with VR glasses at the Medical Simulation Training Centre of Medical University - Plovdiv. The pilot training, conducted from March 22 to April 12, 2024, was part of the Erasmus+ project 'Caring violent child safely in child psychiatric and residential units (Safe4Child) 2021-1-FI01-KA220-HED-000032106.' Participants were divided into two focus groups: third-year nursing students and lecturers teaching specialized academic disciplines in nursing.

Results: A total of 34 participants partook in the study, comprising 16 instructors with basic nursing education and 16 third-year nursing students. Students exhibited considerable empathy towards the virtual child patient, expressing an inclination to provide assistance, acknowledging the necessity for personalized care, and displaying a curiosity about the patient's experiences. They conveyed sentiments such as 'I felt the need to help the child/patient', 'the child needs individual work with a nurse' and 'I want to understand the child's experiences.' In contrast, instructors demonstrated more reserved emotional responses, characterized by professionalism and a focus on offering comfort. They expressed, 'Normal feelings...but you want to hug the child and comfort him.'

Conclusions: The study unveiled a marked difference in empathy expression between students and instructors, with students displaying stronger emotional reactions. These findings underscore the need to recognize and address individual variances in empathy expression within nursing education. Tailored strategies should be devised to bolster empathy development in both students and instructors during virtual patient training. Further investigation is warranted to explore effective methodologies for optimizing empathy development and fostering compassionate patient care in nursing education.

Key messages:

- A Comparative Analysis of Nursing Students and Instructors Using VR Glasses.
- Erasmus+ project (Safe4Child) 2021-1-FI01-KA220-HED-000032106.

Abstract citation ID: ckae144.1140
Future of nicotine pouches – users' perspective

Łukasz Balwicki

L Balwicki[1], *O Kalinowska-Beszczynska*[1], *A Wojtecka*[1], *M Basinska*[2]
[1]Department of Public Health and Social Medicine, Medical University of Gdansk, Gdansk, Poland
[2]Division of Quality of Life Research, Medical University of Gdansk, Gdansk, Poland
Contact: balwicki@gumed.edu.pl

Background: Nicotine pouches (NPs) are gaining popularity. They are a rapidly developing category with little research or regulatory oversight. Studies have shown that the descriptor 'tobacco-free' may impact risk perceptions and the appeal of nicotine pouches among young adults and thus shape their position on the market. The aim of the study was to broaden the knowledge on NP users' perspective about the future of this products.

Methods: Qualitative approach was utilized. In December 2022 there were seventeen structured In-depth Interviews (IDIs) conducted. The sample included of adults aged 18-22, both male and female. The respondents were asked how they see NPs in the context of aim group and competition with other nicotine products.

Results: We found that from NPs users' perspective, these products are aimed at those who want give up smoking, do not want to play with electronic devices (such us e-cigarettes of heated tobacco products) or just seek for discretion (such as office workers who do want to go outside for a smoke or vape). Special aim group are children who want to hide their nicotine product use. Respondents believe that they will not force traditional cigarettes out of the market but will be a popular alternative for young people. Some suggest they need popularization to help exclude products that produce smelly smoke or vape.

Conclusions: Nicotine pouches as smokeless products will probably fill the market space with product aimed at young people who seek discretion of their nicotine addiction as well as those who do not want to inhale smoke.

Key messages:

- Nicotine pouches users see value of these products.
- Nicotine pouches future seems to be bright unless regulations disrupt their market development.

Abstract citation ID: ckae144.1141
Future Finland – A nationwide Finnish multidisciplinary birth cohort initiative

Birgit Simell

B Simell[1], M Lonna[1], M Valtokari[1], E Kajantie[1], A Lundqvist[1]
[1]THL, Helsinki, Finland
Contact: birgit.simell@thl.fi

Increasing evidence suggests that early-life conditions may have substantial consequences on individual health and wellbeing throughout the lifecycle. Development of complex social and health issues may be best understood through longitudinal studies that combine the perspectives of social and health sciences. Future Finland aims to collect a nationwide lifelong data resource that through collaborative multidisciplinary research will strengthen future population welfare. Future Finland will be based on index children born in Finland (43.000/year) during a specific time period. National registers and other administrative data sources will provide data for the age cohort (children), their parents and siblings, with special effort on data from more rarely used sources (e.g., electronic health records, school records). Subsets of cohort members will be recruited in early pregnancy (consent) to undergo deeper data collection through questionnaires, biological and environmental samples and measurements, and digital monitoring data (e.g., physical activity, citizens digital footprint). The Future Finland preparatory phase started in 2023 at the Finnish Institute for Health and Welfare (THL). The Future Finland design and focus areas are currently being planned based on identified information gaps and with consultations of experts from other birth cohort studies. Data collection is planned to start in 2025 by piloting and foreseen to expand to full-scale in 2027-2028. The Future Finland data resource will be made available for the entire research community as openly as possible, at the same time maintaining the highest possible data security standards to protect privacy now and in the future. Future Finland enables novel interdisciplinary research and intervention setups, which will strengthen the knowledge base for societal decision-making and promote the future population welfare. Future Finland is funded by the Finnish Cultural Foundation.

Key messages:

- Future Finland initiative will collect a nationwide lifelong data resource enabling novel cross-disciplinary research designs to produce groundbreaking and impactful scientific results.
- A larger-scale use of data enables novel interdisciplinary research and intervention setups strengthening the knowledge base for societal decision-making and promoting the future population welfare.

Barriers and Facilitators in Implementation of Nutritional Benefit Transfer to Tuberculosis Patients

Manish Kumar Singh

MK Singh[1], A Mahapatra[2], SD Kandpal[1], H Salah[2], K Sharma[2]
[1]Community Medicine, RMLIMS, Lucknow, India
[2]Public Health, GRID Council, Noida, India
Contact: drmanishscbmc@yahoo.co.in

Background: Malnutrition & Tuberculosis (TB) form a vicious cycle. Nikshay Poshan Yojana (NPY) is a key strategy for a TB free India, that seeks to provide financial assistance for nutritional support to TB patients. The study is a qualitative study to identify operational challenges and facilitators in implementation of NPY

Methods: In Depth Interview (IDI) of 18 Senior Treatment Supervisor (STS) at Tuberculosis Unit (TU) and 19 Tuberculosis Health Visitor (TB HV) at Designated Microscopy Centre's (DMC) was done. For further insights, the STS, at District Tuberculosis Centre, Lucknow was also interviewed. Informal discussion was done with about 50 Tuberculosis patients. We explored providers perspective on impact of NPY on other duties/services, case load, hours dedicated to NPY, practice protocols, record keeping and data management, compliances, capacity building needs, quality protocols, key enablers, motivating factors, challenges, best practices and beneficiary's perspectives on quality of life, facilitators and challenges in availing services.

Results: Motivating leadership, supportive staff, good working relationship and seamless communication, teamwork, use of technology, supportive supervision & collaboration and support of NGO for private sector were the key facilitators. Barriers comprised system level barriers (Budget constraints, issues with NIKSHAY software and bank account), provider level barriers (shortage of human resource, nonfunctional tablets) and patient level barriers (stigma and bank account related challenges). The encouraging finding was majority of recipients, responding that they used the incentive to purchase ration, vitamin supplements etc.

Conclusions: NPY is having its intended benefit but there are barriers that need to be resolved for successful roll out. The study yield suggestions for removing barriers and found a set of innovations that can be replicated across other settings with high Tuberculosis burden

Key messages:

- Malnutrition and Tuberculosis form a vicious cycle. Nutritional support to TB patients improves treatment outcome and can save lives.
- Operational research on implementation of NPY offers insights for successful roll out of this key initiative across other resource limited settings in developing countries.

Abstract citation ID: ckae144.1143
Co-planning as a public health tool: the Milan Health Protection Agencies's Local Gambling Plan

Elisa Farchi

E Farchi[1], L Calloni[1], AP Capriulo[2], S Carraro[1], G Dodaro[1], R Albani[1], A Lamberti[1], C Celata[2]
[1]SC Promozione della Salute, ATS Milano Citta' Metropolitana, Milan, Italy
[2]SC Servizio Regionale Promozione della Salute, ATS Milano Citta' Metropolitana, Milan, Italy
Contact: efarchi@ats-milano.it

Issue/problem: Gambling represents a public health, social, and economic problem. Lombardy Region, according with national and regional law, has approved the Regional Plan for the prevention and contrast of Pathological Gambling. The Health Protection Agencies (HPA) of the Metropolitan City of Milan, as the other HPAs, implemented the Local Gambling Plan, based on a context analysis and in synergy with all the actors involved.

Description of the problem: Since 2019, the Milan HPA's Local Gambling Plan has been implemented through collaboration with non-profit entities (TSEs), which are involved via public tendering. The implementation of the new Italian 'Code of the Third Sector' changed the TSEs engagement modalities. For this reason, a complex co-planning process has been initiated in order to increase the level of active citizenship and to enhance public health, in line with horizontal subsidiarity principle.

Results: The Co-planning procedure promoted the integration among local health services, non-profit entities and municipalities with the aim of gambling prevention and contrast, ensuring the continuity of prevention programs and the involvement of local stakeholders in addressing a public health issue. During the co-planning, 9 working groups were established to define objectives, project actions, monitoring and evaluation methods, ensuring the common interest of all actors involved.

Lessons: For the health and social system, the co-planning procedure becomes an opportunity to translate what is foreseen by the regulations into local actions. It allow the active participation of local stakeholders involved into the co-construction and achievement of public health objectives and the promotion of communities' empowerment.

Key messages:

- Co-planning is both a process and a tool for local welfare.
- Co-planning involved multiple actors, among which the public institution that ensures satisfaction of health needs through governance actions.

Abstract citation ID: ckae144.1144
Health in Germany – A new panel infrastructure for Public Health Research in Germany: study design

Johannes Lemcke

I Öztürk[1], J Lemcke[1], S Damerow[1], M Hintze[1], T Kuttig[1], T Heller[1], M Wetzstein[1], J Allen[1], P Schmich[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch-Institute, Berlin, Germany
Contact: lemckej@rki.de

Background: The Robert Koch Institute (RKI) is developing a new panel infrastructure, 'Health in Germany,' to enhance public health research through continuous, rapid data collection from questionnaire surveys, measurements, and laboratory analyses. Using online and offline collection methods (CAWI and PAPI), the project aims to have 30,000 registered panelists by Spring 2024.

Methods: The sample of the recruitment study is based on address data from Germany's local registration offices, whereby a mixed-mode design is used for data collection. Individuals aged 16-69 receive an initial online-only invitation, followed by postal reminders that include a paper questionnaire. For those aged 70 and above, both online and paper options are available from the outset. Incentives include an unconditional €5 cash payment for all invitees and an additional €10 for successful registration into the panel infrastructure.

Results: The initial response rate of the recruitment study is 35%. Of the CAWI participants, approx. 90% expressed willingness to participate again, with approx. 80% completing the online registration. To date, over 42,000 panelists have been recruited. Further detailed results on response rates, non-response bias, and sample composition will be presented at the conference.

Conclusions: RKI's 'Health in Germany' is one of the largest probability panels in public health research, effectively gathering and analyzing data. The recruitment success and strong participant engagement highlight the infrastructure's efficiency and its significant contribution to epidemiological research in Germany.

Key messages:

- Successful recruitment of over 42,000 panelists demonstrates robust engagement and effective implementation.
- The push-to-web strategy (or web-push strategy) underscores the infrastructure's adaptability and efficiency.

Abstract citation ID: ckae144.1145
Evaluating a Novel Hospital-Integrated Vaccination Pathway: Enhancing Coverage among Frail Patients

Matteo Di Pumpo

M Di Pumpo[1], DM Tona[1], M Porcelli[1], A Lontano[1], L Regazzi[1], D Pascucci[1], S Bruno[1], C Cadeddu[2,1], P Laurenti[1], R Pastorino[1]
[1]Department of Life Sciences and Public Health, Catholic University of the Sacred Heart, Rome, Italy
[2]Erasmus School of Health Policy and Management, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: dipumpo.matteo@gmail.com

Background: The 2022-2025 Italian Plan for vaccine prevention (PNPV), recognizes vaccine-preventable diseases (VPDs) as significant contributors to mortality, morbidity, and healthcare expenditure. While the digitalization of the national vaccine registry is underway, initiatives aimed at enhancing digital integration between hospitals and territories are limited. There is still a gap in the development of automated systems for identifying patients who could benefit from vaccinations. The "Caring for frail patients through vaccination" (CareVax) Project aims to eliminate these gaps by providing new digital tools and integrated systems.

Methods: 1500 patients will be recruited at teaching hospital "A. Gemelli" over four years. With the assistance of an automated algorithm, electronic hospital and vaccination records will be utilised to assess eligibility for vaccinations against SARS-CoV-2, H. Zoster, Influenza, S.Pneumoniae and HBV. Eligible patients will be invited to schedule a vaccination appointment and will be asked to fill a questionnaire evaluating patient-reported experience measures (PREMs). The outcomes of interest include assessing the feasibility of the pathway, measuring patients' satisfaction and concerns, and evaluating its impact on vaccination coverage.

Results: It is expected that frail patients' vaccine coverage will improve, being offered an expedited booking process to get the vaccines either in the ambulatories of the Local Health Authority or in Hospital. The algorithm has already been successfully validated on a sample of anonymized patients. The results of the study will provide evidence on novel, hospital-integrating, vaccination pathways.

Conclusions: The results obtained from the intervention will help reduce VDPs and facilitate identification of the frail patients, ensuring easy access to vaccination and increasing vaccination coverage.

Key messages:

- Carevax will test their feasibility in an Italian teaching hospital, leveraging digital technologies to reduce the burden of VPDs novel approaches.
- Hospital-Territory integrated vaccination pathways represent a novel digital approach to reduce the burden of VPDs.

Abstract citation ID: ckae144.1146
Tobacco Free Advent Calendar: Evaluating innovative strategies in Public Health digital campaigns

Darius Lotrean

D Lotrean[1,4], Z Sargsyan[2], T Bonarrio[4,5], M Antinozzi[4,5], K Mocanu[3,4], C Radu-Loghin[3]
[1]University of Medicine and Pharmacy 'Iuliu Hațieganu', Cluj-Napoca, Romania
[2]Turpanjian College of Health Sciences, American University of Armenia, Yerevan, Armenia
[3]European Network for Smoking and Tobacco Prevention, Brussels, Belgium
[4]European Network for Smoking and Tobacco Prevention Youth Group, Brussels, Belgium
[5]Sapienza University of Rome, Rome, Italy
Contact: darius.lotrean@outlook.de

Introduction: Two editions, 2022 and 2023, of the Tobacco Free Advent Calendar (TFAC) built a large network of Organizations, Universities, Institutions, individual experts and medical students across Europe, coordinated by ENSPNext (European Network for Smoking and Tobacco Prevention Youth Group), to advocate for Youth and for Public Health. This study has 2 objectives: 1. Monitor the performance of TFAC 2023 vs TFAC 2022 for 31 days 2. Evaluate improvements in reach and engagement made for TFAC 2023.

Methods: For 24 days, TFAC 2023 featured thematic messages, embedded fact sheets, quizzes, videos and call-to-action buttons. New content was accessible daily starting on the first day of advent, ending on Christmas. TFAC was available in English and Armenian. AI was used to assist for various tasks and challenges during development and research. Comparative and Time Series Analysis were conducted in Excel and IBM SPSS26.

Results: TFAC 2023 was accessed 3764 times (8.8% increase), the doors were opened 1506 times (3.9% decrease), Call to action buttons were clicked 261 times (169% increase). For english version a strong variation in reach was observed, but not in engagement which remained relatively constant. In Armenian version both reach and engagement varied in 2023 vs 2022. A seasonal component was identified for both versions, particularly an increase at weekends and a decrease on weekdays. Similar to 2022, the reach and engagement were higher at the start and lower as time passed, although in 2023 the reach and engagement remained higher and more constant over time. Completion rates of interactive materials ranged between 21.4% to 100% in the English version and from 7.1% to 100% in the Armenian version. No interactive material remained unanswered.

Conclusions: Decrease of translations didn't lower the reach and engagement of TFAC. Engagement with TFAC 2023 was higher, possibly due to the implication of students organizations and collaboration with influencers.

Key messages:

- Targeted dissemination increased the reach and engagement of TFAC 2023 versus TFAC 2022.
- Members of the target group should be recruited for being members in the projects affecting them to increase engagement and impact of the campaign.

Abstract citation ID: ckae144.1147
Exploring Health Professionals' Views on Hive: A Digital collaborative space for Health Emergencies

Brian Yau

F Hang[1], M Farhat[1], B Yau[1], L Latinovic[1], K von Harbou[1], N Emiroglu[1], N Kovačev[2]
[1]Country Readiness Strengthening, WHO, Geneva, Switzerland
[2]HTEC, Belgrade, Serbia
Contact: byau@who.int

Background: The rapidly changing media landscape has significantly affected how information is consumed, particularly during health emergencies. Conflicting information shared or information lacking in scientific rigour can be exploited nefariously online to undermine the health response and damage trust. Digital platforms have become increasingly vital for facilitating communication, and in response, the WHO developed the Hive digital space to provide a safe environment for public health professionals to convene, share information, ask questions, and learn from each other. This study aims to explore the experiences of public health professionals in health emergencies to assess the added value of the Hive platform to coordinate and connect health expertise globally.

Methods: This study uses a cross-sectional online survey distributed to Hive users focusing on their experiences of working in health emergencies. The responses will undergo descriptive and thematic analysis, as well as inferential statistics such as one-way ANOVA and post-hoc analysis. The survey will emphasize the practical application, value, satisfaction, perceptions, and strategy for the Hive platform to be utilised for global health emergency coordination.

Expected Outcomes: Insights from this study will delineate how the Hive platform is used by public health experts at all levels in emergency management. It will also highlight the challenges, needs and demands for digital tools to connect skills, experience and knowledge in one place. These insights will demonstrate how the Hive can streamline these processes and provide a safe space for information exchange for a coordinated response to health emergencies.

Conclusions: Understanding the needs and perceptions of Hive users involved in health emergency prevention, preparedness, response, and resilience will provide critical insights into optimizing the platform's usability, connectiveness across emergency teams and sustainability of the platform.

Key messages:

- Connecting communities, fostering collaboration and co-creation for improved health emergency management.
- Hive enhances collaboration among health professionals, providing a safe environment for knowledge and information sharing.

Abstract citation ID: ckae144.1148
Collaborative development of open-source outbreak detection tools: Needs, concept and implementation

Paulina vom Felde genannt Imbusch

P vom Felde genannt Imbusch[1], A Vietor[1], A Ullrich[1], I Markus[1], M Diercke[1]
[1]Department for Infectious Disease Epidemiology, Robert Koch Institute, Berlin, Germany
Contact: vom-feldep@rki.de

Issue: The early detection of infectious disease outbreaks through surveillance is critical to initiate targeted public health interventions. Automated outbreak detection helps to identify trends and unusual events. Yet, there is no overview of how many EU countries use outbreak detection systems and what factors hindered their implementation.

Description of the problem: One aim of the Joint Action UNITED4Surveillance (U4S) is to identify EU countries' requirements for outbreak detection, and based on these, develop and deploy a tool for the timely and accurate detection of outbreaks. Through surveys, interviews and an in-person workshop involving public health experts, we identified uses cases, collected functional and technical requirements for a tool. Subsequently the tool development started in August 2023 as an open-source software process on GitHub.

Results: Despite high interest, only three of the 21 countries that took part in the survey have implemented outbreak detection tools, even though national surveillance systems offer the potential for their use. Reasons for this are limited resources and low prioritization. Experts identified gastrointestinal diseases as one major potential use case and emphasised the necessity of flexible outputs. Tailored to these requirements, data scientists from five European public health institutes developed an open-source R package for signal detection. The tool generates signals based on national surveillance data and enables the user to analyses these results using a dashboard with flexible exploration and generation of a report. The tool is now being piloted locally by ten European public health authorities and its use will be evaluated.

Lessons: There is a need to use automated outbreak detection tools for routine surveillance of infectious diseases in EU countries but often lack resources. Projects like U4S can bring together expertise to build sustainable tools and supporting material that can address the identified needs.

Key messages:

- Collaborative and open-source development leads to tools that are well tailored to the needs of the community and foster a high uptake in the usage of these tools.

- The tool enhances surveillance and outbreak detection in countries without the capacities to develop and implement outbreak detection methods for their surveillance systems.

Abstract citation ID: ckae144.1149
Developing a trustworthy national health data space: public needs and policy implications

Paola Daniore

P Daniore[1,2], *F Zavattaro*[1,2], *F Gille*[1,2]
[1]Institute for Implementation Science in Health, University of Zurich, Zürich, Switzerland
[2]Digital Society Initiative, University of Zurich, Zürich, Switzerland
Contact: paola.daniore@uzh.ch

Background: The ongoing development of a national health data space in Switzerland presents an opportunity to transform health delivery and care by enabling large-scale secondary health research. Central to this development is the Health2030 strategy, which calls for the establishment of public trust in the reliability and security of data collection, storage, and exchange.

Methods: We conducted four focus groups across the German, French and Italian-speaking regions of Switzerland to inform the development of the Swiss health data space that fosters public trust. To inform Swiss policy, we held a panel discussion with patient experts and healthcare professionals to translate the focus group findings into governance and public communication requirements. We synthesized our findings using a thematic analysis approach and proposed a guiding health policy strategy.

Results: Citizens perceive the health data space as trustworthy conditional on the delivery of its promised higher levels of transparency, security, and lower risk compared to other data sharing initiatives. To ensure its trustworthiness, citizens call for the provision of value-based consent to control data access based on the actors involved and research purposes, alongside implementing accountability measures for data misuse. Governance framework requirements entail establishing an advisory group for the health data space with sufficient representation of the Swiss population, including members of the public, patient advisory groups, and researchers. Public communication requirements call for ongoing monitoring of public opinion on health data space, alongside establishing public engagement initiatives, such as public fora, to inform ongoing progress.

Conclusions: Policy efforts should prioritize the meaningful involvement of relevant stakeholders throughout all stages of the health data space development to foster trust. Central to these efforts is balancing public expectations with their practical implementation.

Key messages:

- For the health data space to be trustworthy, citizens require transparency on their data use and the security measures taken, value-based consent for data access, and accountability measures.
- Diverse representation in governance and continuous public involvement are key policy measures to build public trust in the development of national health data spaces.

Abstract citation ID: ckae144.1150
Study tours as strategy in building multi-level public health system transformation in Ukraine (UA)

Jennifer Kolker

N Levkovich[1], *C Lasky*[2], *L Lieberman*[2], *M Melnyk*[3], *J Kolker*[4], *W Aaronson*[5]
[1]Executive, Health Federation of Philadelphia, Philadelphia, USA
[2]Health Federation of Philadelphia, Philadelphia, USA
[3]European Institute of Public Health Policy, Kyiv, Ukraine
[4]Health Management and Policy, Drexel University Dornsife School of Public Health, Philadelphia, USA
[5]Programs in Health Policy and Management, Temple University College of Public Health, Philadelphia, USA
Contact: jak682@drexel.edu

With 14 million Ukrainians in need of psychological aid (UNDP) and a strained health system, UA urgently requires mental health and psychological support services (MHPSS). As a TA partner on the USAID funded Public Health System Recovery and Resilience project in UA, the Philadelphia (PHL) team supports capacity building for population-based MHPSS at the community level with a study tour strategy. Such approaches apply to other countries interested in remodeling public health systems. The strategy aims to advance community based MHPSS through in person tours in PHL with remote follow up to stimulate vision, exchange ideas and accelerate action among governmental, community, and academic partners. The study tours presented overviews on health policy, system development, program services delivered to children and adults, community interventions, and workforce development of professionals and paraprofessionals. All included the foundational principles of trauma-informed practice. The June 2023 tour hosted 11 decision makers and regional officials who embraced the vision for system development and endorsed further engagement. The December 2023 tour hosted 13 practitioners and coordinators of health and social services to observe community programs. Results include development of PHL NGOs and UA social service hub partnerships to implement train the trainer programs for peers/people with lived experience and for mural arts programs to promote community engagement and empowerment. The September 2024 tour involves university partners from nursing, social work and psychology and PHL counterparts to strengthen curricula to include mental health competencies, support faculty development with potential for collaborative research and student exchange, and design post-graduate continuing education courses for upskilling the incumbent workforce. Study tours and direct exchange are an effective strategy for capacity building for MHPSS in Ukraine to address population health needs.

Key messages:

- The sequenced study tour strategy affects distinct levels of change makers in UA. The results are governmental buy-in, partnerships for programmatic development, and academic advancement.
- The study tour model promotes systematic change and offers solutions to MHPSS workforce shortages through information exchange, relationship building, and capacity development.

Abstract citation ID: ckae144.1151
How stop smoking outreach works: a co-inquiry informed, complex intervention model

Susie Sykes

T Mills[1], *L Dawkins*[1], *R Dean*[2], *E Lewis*[1], *J Wills*[1], *S Sykes*[1]
[1]PHIRST South Bank, London South Bank University, London, UK
[2]Hertfordshire County Council, Stevenage, UK
Contact: sykess@lsbu.ac.uk

Background: Across Europe, smoking prevalence is concentrating in underserved communities with high levels of deprivation. And yet, there is little research on how stop smoking services (SSS) can engage these communities. This study presents the findings of a 12-month collaboration involving an external public health research team and staff of an English SSS. Staff worked with community partners (e.g., schools) to raise awareness of the service, which included a newly introduced e-cigarette offer.

Methods: A complex intervention model was developed and refined through 6 facilitated co-inquiry sessions involving 13 SSS staff. Staff also completed 32 reflection forms on outreach events and rapid ethnography was conducted, by the research team, to evaluate staff's working assumptions. This included 8 observations of outreach events and interviews with 10 SSS staff and 8 community members, from the service target groups. Data were organised into themes.

Findings: The model presents a picture of stop smoking outreach as challenging, unpredictable and resource intensive yet often having great impact. The themes enrich this to highlight 1) the appreciation for yet unpredictability of outreach referrals for people disconnected from health services; 2) the importance of staff adopting a person-centred approach; 3) the challenges and opportunities presented by e-cigarettes; and 4) the role of strategic community partnerships in optimising staff time on outreach.

Conclusions: Stop smoking outreach can generate considerable interest in SSS, particularly when delivered in combination with an e-cigarette offer. Future research should explore the economic and social return on investment in community outreach: while time consuming, referrals generated proactively may become more important for SSS as smoking concentrates in underserved communities.

Key messages:

- Stop smoking outreach is an effective way to raise awareness and generate referrals but must be done non-judgementally and via effective community partnerships.
- Staff's careful discussion of an e-cigarette offer can change the perception of SSS without contributing to recreational normalization.

[4]Facultad de Nutrición Región Veracruz, Universidad Veracruzana, Veracruz, Mexico
[5]Centro de Estudios y Servicios de Salud, Universidad Veracruzana, Veracruz, Mexico
Contact: josue_eli@hotmail.com

Introduction: Prostate Cancer (PCa) represents a health problem in the world and its management is heterogeneous in care, depending on the resources each country has, modifying its effectiveness in prevention, diagnosis, treatment and follow-up.

Methods: The UROLATAM program was implemented based on the Design Thinking quadruple helix innovation model, consisting of the immersion, design, idea and prototype phases, characterized by being multidisciplinary and comprehensive. Teachers and students from different careers at the Universidad Veracruzana participated. Linkages were made with: Local government, government health institutions, colleges of specialist doctors, private institutions and civil society. This program was broadcast on radio, television and social networks inviting the population to participate in education and prevention activities, in addition to participating in diagnosis, treatment and follow-up actions for men over 40 years of age. The duration of the program was 4 days, including educational sessions for doctors, patients, family members and caregivers, as well as determination of prostate-specific antigen, urological consultation and prostate ultrasound, as well as rehabilitation exercises, diagnostic confirmation and treatment. who needed it.

Results: During the sessions, 944 patients aged 60.7 (±15.0) years were treated, 443 (47%) had never received a urological consultation, identifying a prevalence of 11.7% of Cap. The human team present with the patient was 25 specialist doctors, 16 medical residents, 38 undergraduate students, 3 rehabilitators and 6 administrative staff. None of the participants received a salary for participating in this project.

Conclusions: The multidisciplinary UROLATAM linkage project constitutes a useful educational, training and assistance tool for the population, as well as an educational element for the students who are part of the work team.

Key messages:

- The UROLATAM project is replicable in countries that require additional support in the prostate cancer approach.
- The structure of the UROLATAM project can be replicated to address other public health problems.

Abstract citation ID: ckae144.1153
Navigating complexity: an evaluation framework for assessing co-creation in public health

Danielle Agnello

DM Agnello[1], N Smith[1], A Steiner[2], M Vogelsang[1], S Chastin[1,3]
[1]School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
[2]Yunus Centre, Glasgow Caledonian University, Glasgow, UK
[3]Department of Movement and Sports Sciences, Ghent University, Ghent, Belgium
Contact: danielle.agnello@gcu.ac.uk

Background: Co-creation aims to democratize research and bridge the gap between research and practice. Key characteristics like empowerment and meaningful participation shape sustainable outcomes. However, existing frameworks like Arnstein's Ladder of Citizen Participation broadly overlook individual method contributions. This study aims to address this gap by creating and validating a framework for intrinsic evaluation, guiding stakeholders and researchers in genuine co-creation of public health interventions.

Methods: We systematically screened and extracted frameworks aligned with five key co-creation characteristics to identify and evaluate methods. Through iterative testing, we identified key features for distinguishing methods and integrated them into a novel framework. Co-creation experts validated and refined this framework using the closed card sort method, qualitative assessment, and group discussions.

Results: The Co-Creation Rainbow framework includes key features from 20 existing frameworks, with an Individual-to-Collective Continuum, five sections (Informing, Understanding, Stimulating, Collaborating, and Collective Decision-making), and three overarching themes (Engage, Participate, and Empower). Analysis showed successful categorization of 436 methods and revealed a significant disparity in co-creation practices between researchers and practitioners.

Conclusions: The Co-Creation Rainbow framework provides a structured approach to evaluating and reporting co-creation processes. Acknowledging co-creation's diversity, the framework aids in tailoring approaches for meaningful participation. By offering a unified language for diverse co-creation methods, the framework also facilitates transparent evaluation, enhancing the reliability and reproducibility of co-created public health interventions.

Key messages:

- Employing a universal language across diverse co-creation methods is pivotal in fostering transparent evaluation, thereby bolstering the reliability of co-created public health interventions.
- Effective collaboration of key stakeholders necessitates the use of suitable methods. By integrating diverse perspectives, public health interventions gain relevance, efficacy, and sustainability.

Population Health Management effectiveness in the primary healthcare setting: a systematic review

Rachel McNamara

R McNamara[1], N Nour[1], M Mannix[1], J Browne[2], S Donohue[1]
[1]Public Health Mid-West, Health Service Executive, Limerick, Ireland
[2]School of Public Health, University College Cork, Cork, Ireland
Contact: rachel.mcnamara@hse.ie

Background: Population Health Management (PHM) has shown promise as a tool in the improvement of health at scale. It works by; harnessing health-related datasets, allowing for population segmentation and risk stratification, and targeting interventions to yield positive health impact. Prior reviews on PHM, have sought to define PHM and assess feasibility. To date, there have been no systematic reviews that assess the effectiveness of PHM in achieving some or all of the quintuple aims of PHM (WHO 2023). The aim of this study is to determine the value and impact of a PHM approach in managing ambulatory care sensitive conditions (ACSCs) in the primary healthcare setting.

Methods: This systematic review is underpinned by a Population-Intervention-Comparator-Outcome (PICO) framework. The PROSPERO-registered study commenced in February 2024 for papers published since January 2000. Pubmed, Cinahl and Web of Science databases were used. Titles and abstracts of studies were reviewed using agreed eligibility criteria to select studies for inclusion and risk of bias assessment. Data abstraction and synthesis determined the effectiveness of PHM against agreed outcome measures.

Results: The search yielded 427 articles of which 19 were included. Studies addressed diabetes, hypertension, atrial fibrillation, asthma and comorbid conditions. Nearly all studies were based in the U.S.A. Almost 50% of studies showed a significant improvement in health outcomes following PHM. Study features that corresponded with positive health outcomes included; the use of population management tools, the employment of disease/population health managers and the mobilisation of medication reviews/education.

Conclusions: The challenges facing communities and health services require an alternative innovative approach to health such as a PHM approach. The results of this study will inform a larger body of work which seeks to establish a PHM approach to the delivery of services in the Mid-West region of Ireland.

Key messages:

- Population health management (PHM) could be a viable mechanism for health services to serve increasing need and multi-morbid populations.
- This is the first systematic review of PHM against the quintuple aims of PHM, specifically in the management of ambulatory care sensitive conditions in primary healthcare.

Abstract citation ID: ckae144.1155
Effects of a multidisciplinary program with physical exercise in pediatric obesity

Carlos Meneses

C Meneses[1], A Lopes[2], F Fonseca[2], A Eusébio[2], R Peixoto[3], J Vilaça-Alves[3,4], C Santos[1,5,6], T Moreira[1,5]

[5]Research Center, Polytechnic Institute of Maia N2i, Maia, Portugal
[6]University Lusófona, CIDEFES, Lisbon, Portugal
Contact: carlosmiguelmeneses@hotmail.com

Background: Childhood obesity is a growing public health concern worldwide, with prevalence rates increasing in recent decades. This epidemic not only predisposes children to immediate health risks such as cardiovascular disease and musculoskeletal problems but also significantly increases their risk of obesity-related comorbidities in adulthood. Recognizing the multifactorial nature of pediatric obesity, interventions targeting lifestyle modifications are crucial to its control. Among these interventions, physical exercise emerges as a cornerstone in combating pediatric obesity.

Purpose: Our study examines the effectiveness of a twelve-week online physical exercise program on body composition and functional capacity in children and adolescents with obesity.

Methods: The sample consists of 30 participants (9 girls and 21 boys, aged 11-17 y) from the Pediatrics Department of Senhora da Oliveira Hospital in Guimarães (HSOG). Using standardized protocols, anthropometric measures (body weight and waist circumference) were measured. Functional capacity was assessed through squats, push-ups, and elbow plank tests (maximum repetitions in 60 seconds). All analyses were done using SPSS software, and the alpha level was 5%.

Results: Significant impacts of the exercise program were observed in body weight and waist circumference variables. Multivariate tests indicated a statistically significant interaction between the Moment*Groups factors (weight $p = 0.040$; waist circumference $p = 0.007$). Moreover, functional capacity was also influenced by the exercise program (squat $p = 0.034$; push-ups $p = 0.013$; and elbow plank $p = 0.025$).

Conclusions: Our results underscore the significant public health impact of integrating physical exercise into a multidisciplinary program for pediatric obesity. Innovative use of online interventions facilitated broader reach and accessibility, resulting in measurable improvements in body weight, waist circumference, and functional capacity among participants.

Key messages:

- Integrating exercise into multidisciplinary programs improves pediatric obesity outcomes.
- Online interventions broaden accessibility and effectiveness in preventing childhood obesity.

Abstract citation ID: ckae144.1156
Predicting diabetes prognosis using machine learning techniques in a Hungarian clinical database

Attila Nagy

A Nagy[1], R Bata[1], A Ghanem[1], M Móré[2]
[1]Department of Health Informatics, Faculty of Health Sciences, University of Debrecen, Debrecen, Hungary
[2]Institute of Social and Sociological Sciences, Faculty of Health Sciences, University of Debrecen, Nyíregyháza, Hungary
Contact: nagy.attila@sph.unideb.hu

Background: Chronic conditions such as type 2 diabetes mellitus have great impact on patients' quality of life. Although clinical databases provide a perfect base for research aimed at improving diabetes care, analyzing such databases requires extensive preprocessing, mainly due to the large amount of unstructured data. Our study aimed to present the steps of generating a dataset from a large clinical database, and to apply machine learning-based analytical techniques regarding.

Methods: Data of the Clinical Center of University of Debrecen was used. To structure the unstructured data, regular expressions and natural language processing methods were used. The main machine learning models were as follows: Gradient Boosting Machines to predict the risk of complication development; Long Short-Term Memory Networks to forecast future health outcomes. All analysis and procedures were done using Python.

Results: The database contains approximately 1600 tables, with a total size of 1.9 terabytes, where the largest table is 21.07 gigabytes with approximately 44.64 million rows. The final dataset consisted of 40,332 patients. Most variables originate from the unstructured data, including complications and comorbidities of diabetes, as well as physical and laboratory parameters. Related to laboratory parameters, the number of measurements and the median value for every half-year were available. The diagnosis time of the complications' occurrence is also presented. Machine learning methods were more accurate compared with traditional statistical methods in predicting the prognosis ($p < 0.05$).

Discussion: Our research highlights the importance of clinical data in chronic disease management. There are challenges in pre-processing and managing datasets, but machine learning-based methods are very efficient not only in extracting useful information from unstructured data but also in predicting the prognosis and identifying potential intervention points for better care.

Key messages:

- Natural language processing can be used to obtain useful information from unstructured clinical data.
- Using machine learning techniques on clinical data could improve diabates care.

Abstract citation ID: ckae144.1157
'Freeze the measles': how to improve backward tracing with a new digital tool

Alessandro Daole

A Daole[1], S Giorgi[2], L Bonaldo[1], G Cruschelli[1], G Spagnolo[3], A Gallo[2], C Rizzo[1]
[1]Department of Translational Research and New Surgical and Medical Technologies, University of Pisa, Pisa, Italy
[2]Unità Funzionale Igiene Pubblica e Nutrizione, Azienda USL Toscana Nord Ovest, Pisa, Italy
[3]ISTI, CNR, Pisa, Italy
Contact: aledaole@icloud.com

Background: A measles outbreak occurred in Tuscany, between January and April 2024. There were 37 cases (Incidence: 40,5 per million) with 32 cases (24 confirmed) in the Health District of Pisa. Even if bidirectional tracing showed a better effectiveness in pandemics, there aren't ready-to-use standardized tools for backward tracing.

Methods: Pisa Public Health Unit created a digital tool based on a spreadsheet and called "Freeze the measles" which records measles cases and the locations where they passed through (hotspots). These were uploaded on a cloud shared with all the tracers. Hotspots have an expiry date of 21 days. Hotspots and home address case were plotted on a digital map. In a new investigation, tracers could find out if the case visited some hotspots before getting sick and check the distance between home address and hotspots, reducing recall bias. Every case was interviewed about 21 days before rash onset (backward) and plus or minus 4 days of rash onset (forward). The tool matched data to identify contacts and exposure.

Results: Since the index case wasn't found, the first 5 unrelated cases were considered index cases for this outbreak. Second and third wave involved 17 cases. The tool allows to find an epidemiological link for 16 of them, while 1 case remained unrelated. A super-spreader was identified with 12 secondary cases occurred at hospital emergency room (7), at a near home minimarket (4) and in a large furniture store (1). In second and third waves, tool was able to link 94% of cases. 2 additional cases were imported. When the last hotspot became frozen without new cases occurring, the outbreak was considered ended. The outbreak lasted 33 days.

Conclusions: The "Freeze the measles" tool allows to identify transmission chains through an interactive map built on cases and their mobility.

Key messages:

- Contact tracing needs an appropriate backward investigation to be more effective.
- New digital tools as 'Freeze the measles' could improve preparedness and management of outbreaks.

International projects such as the Joint Action on strengthening eHealth including telemedicine and remote monitoring for health care systems for cancer prevention and care (eCAN) are implemented in countries with different languages, requiring validation of translations of standardized tools. Evaluation frameworks for telemedicine services necessarily include the patient's perspective, i.a. on the service usability. Due to the lack of validated questionnaires in multiple European languages we sought to develop translation for the languages of the eCAN pilot countries. Based on literature review, we selected mHealth App Usability Questionnaire (MAUQ) and Telehealth Usability Questionnaire (TUQ) and developed a conceptual definition for each item. Next, we performed forward and back translation from English into the target languages, expert review, cognitive interview (CI) with 5-10 cancer or chronic disease patients per language/per questionnaire. Qualitative CI results were scored by 2 independent researchers for consistence of each item with conceptual definitions for final review by native speaker expert. We chose 8 languages (ES, GR, HU, IT, LT, NL, PT, SI) for validation. CI involved 48 respondents (29 females, 60%; 18 aged>60, 38%;23 higher education, 48%) for TUQ and 48 (22 females, 46%; 16 aged>60, 33%; 23 higher education, 48%) for MAUQ. Overall 872 (87%) of TUQ and 728 (84%) of MAUQ item answers were classified as consistent. In more than one language we identified concepts difficult to understand: consistent navigation when moving between screens, distinction between easy to use/learn, social settings. The validation process allowed us to identify opportunities to improve translation and highlighted concepts generally more difficult to understand. We provided validated translation of MAUQ and TUQ in 8 European languages for use in eCAN pilots and future telemedicine evaluation studies.

Key messages:

- eCAN successfully validated translations of telemedicine usability questionnaires for 8 languages.
- Multilingual translation validation can provide insights into concepts difficult across languages.

Abstract citation ID: ckae144.1159
Syndemic vulnerability in Dutch urban cities: investigating health disparities and intersectionality

Eveline Dubbeldeman

EM Dubbeldeman[1], HMM Vos[1], M Bussemaker[1], MN Slagboom[1], DO Mook-Kanamori[1], MR Crone[2]
[1]Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands
[2]Department of Health Promotion, Maastricht University, Maastricht, Netherlands
Contact: e.m.dubbeldeman@lumc.nl

Background: Syndemics, the clustering of health and social issues, disproportionately affect marginalized communities. While prior research indicates sex-specific variations in syndemic vulnerability, current research often overlooks other sociodemographic characteristics and their interaction. An intersectionality-informed syndemic approach could offer more insights into the mechanisms in syndemic suffering, providing a deeper understanding and identifying groups most affected by structural inequalities.

Methods: Our study focused on adult residents in Leiden and The Hague, the Netherlands, registered at different general practices. Using existing routine health data linked with Central Bureau for Statistics information, we included adults who were registered with a general practitioner in 2018 and 2019, had a minimum of two registered health conditions documented by their general practitioner, lived in Leiden or The Hague, and were at least 18 years old in 2018.

Results: A total of 43340 adults were included for analyses. Distinct health condition clusters were observed within sex and age groups. Women experiences a broader range of health issues, often characterized by mental and psychosomatic symptoms like mood/anxiety disorders and abdominal complaints. Conversely, men exhibited a higher prevalence of specific physical conditions, including hypertension, diabetes, and cardiovascular diseases.

Conclusions: The findings align with previous research, suggesting the importance of further exploration into the role of intersectionality in syndemics. Currently, we are investigating the foundations of these disparities, including interaction analyses and Multilevel Analysis of Individual Heterogeneity and Discriminatory Accuracy (MAIHDA). Using MAIHDA, we will examine the relationship between intersectionality and syndemic vulnerability, quantifying intersecting factors (sex, ethnicity, SES) and exploring their impact at individual and group levels.

Key messages:

- Understanding intersectionality in health disparities is crucial for addressing syndemic vulnerabilities.
- Tailored interventions informed by intersectionality may promote equitable health outcomes.

Abstract citation ID: ckae144.1160
Pediatric tonsilitis: modern tactics against an old foe

Afonso Herdeiro Cachim

A Cachim[1], MM Santos[1], A Luz Fortes[1], MM Paixão[1]
[1]USP Francisco George, ULS Santa Maria, Lisbon, Portugal
Contact: afonsocachim@gmail.com

Background: Pediatric tonsillitis (PT) impacts public health due to its widespread incidence and the prevalent overprescription of antibiotics driven by concerns over Group A β-hemolytic streptococcus (SGA) complications. Rapid antigen diagnostic tests (RADT) serve as vital tools for promptly identifying SGA infections in PT cases. However, despite their widespread availability, healthcare professionals often underutilize RADT, leading to inappropriate antibiotic prescriptions. Clinical audits and feedback to professionals emerge as solutions to this issue.

Methods: An audit was conducted on clinical cases of PT during 2023 to evaluate the correct usage of RADT and subsequent antibiotic prescription across various primary care practices in Lisbon, Portugal. Afterwards, a pilot practice was selected to assess the feasibility and utility of an online tool designed specifically to report RADT results and create a real-time surveillance system of incidence of SGA with feedback to prescribing clinicians. Following the revision of the reporting tool after the pilot, its implementation was extended to multiple practices across the Lisbon region.

Results: From the 1050 clinical cases analyzed, 992 had an indication to do a RADT according to the Portuguese guidelines, however only 282 (28.4%) tests were done. Overall, only 19.6% of PT cases were considered fully compliant. During the pilot, the introduction of the online tool led to a 3.259 increase in reporting (from 0.574 RADT/day to 1.872 RADT/day) for the same time period between February and March.

Conclusions: The implementation of an online reporting tool represents a significant advancement in SGA surveillance efforts, detecting cases promptly for public health interventions. This initiative underscores the importance of continuous quality improvement in diagnostics and shows digital tools' potential for better disease surveillance in clinical settings.

Key messages:

- Underutilization of RADT in PT cases contributes to inappropriate antibiotic prescriptions, compromising patient care.
- Introduction of an online reporting tool significantly enhances RADT usage, aiding prompt SGA detection for improved public health interventions.

Abstract citation ID: ckae144.1161
Needs Assessment for Primary Care for Best Practice Implementation: The CIRCE Joint Action

Sophia Papadakis

S Papadakis[1,2], E Petelos[1,2,3], A Angelaki[1,2], M Anastasaki[1,2], M Vafeiadi[1,2], E Magkanaraki[2], S Tornero Patricio[4], A Carriazo[4], C Lionis[1,2]
[1]7th Health Region of Crete, Heraklion, Greece
[2]School of Medicine, University of Crete, Heraklion, Greece
[3]CAPHRI, Maastricht University, Maastricht, Netherlands
[4]Andalusian Health Service, Seville, Spain
Contact: sophiapapadakis@gmail.com

Introduction: CIRCE is a Joint Action (JA) supporting the transfer of six best practices (BPs) to new primary care settings in Europe. High-quality needs assessment can set the foundation for strong planning and implementation of the CIRCE-JA best practices in these new primary care settings.

Methods: A needs assessment tool was developed based on the TO-REACH knowledge transfer framework and learnings from a scoping review of international knowledge transfer frameworks. The needs assessment provides structured tool for local sites to self-assess the alignment of the BP with local priorities, readiness of the local site to successfully implement the BP, the availability of necessary leadership, resources and partnerships, and an examination of barriers to local BP implementation and mitigation strategies.

Results: Twenty-six CIRCE-JA teams completed the needs assessments. Local teams identified the CIRCE-JA BPs were value-adding and aligned with local priorities. Cross-cutting barriers were identified which were common among the six CIRCE-JA best practices across five thematic areas: (1) provider level, (2) intervention level, (3) health system/policy level, (4) partnership and physical resources and (5) information technology. The needs assessment supported primary care sites with a structured approach to planning for transfer of BPs to their local setting that is based on established international best practices and knowledge transfer frameworks including early identification of barriers and mitigating strategies.

Conclusions: The needs assessment has supported teams with conducting a self-assessment and informing initial planning for adoption of the BP in their local primary care practice. Given the importance of the local needs assessment to high quality implementation of BP the CIRCE-JA experience with local needs assessment may provide learnings for future BP transfer initiatives.

Key messages:

- Local needs assessment supports the transfer of best practices to primary care settings, which is a critical component of service transformation during the post-COVID-19 period.
- For successful transfer of best practices in primary care, it is vital to give to examine such as provider capacity, available human resources, health policy, and information technology.

Adoption and Utilization of Telemedicine and Digital Health Services among Older Adults in Israel

Motti Haimi

M Haimi[1,2], *R Sergienko*[3]
[1]Health Administration, Yezreel Valey Academic College, Emek Yezreel, Israel
[2]Faculty of Medicine, Technion- Israel Institute of Technology, Haifa, Israel
[3]Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel
Contact: morx@netvision.net.il

Background: As the population ages and the prevalence of long-term diseases rises, telecare is being used increasingly frequently to aid elderly people.

Aims: We aimed to explore the usage and adoption of 3 types of telehealth services among the senior population in Israel- prior, during, and after the COVID-19 pandemic rise in Israel.

Methods: We explored the usage characteristics of older adults (age 65 and above) belonging to 'Clalit', in the use of three types of telehealth services: digital services for administrative tasks, synchronous 'online visits' with the patient's personal physician during clinic business hours, and 'afterhours' consultations during evenings, nights, and weekends. The data was collected and analyzed throughout three distinct time periods in Israel: before the COVID-19 pandemic, during the onset of the COVID-19 pandemic and following the COVID-19 'peak'.

Results: Data of 618850 patients who met the inclusion criteria was extracted. Telehealth services utilized for administrative purposes were the most popular. The older population significantly increased their use of all types of telehealth services during the COVID-19 period, and in the majority of types, this usage decreased after the COVID-19 peak, but to a level that was higher than the baseline level prior to the COVID-19 period. Prior to the COVID-19 period, 23.1% of the study population used 'online visits', and 2.2% used 'afterhours' consultations, at least once. The percentage of usage for these services increased during the COVID-19 period to 59.2% and 5.0%, and then decreased during the third period to 39.5% and 2.4%, respectively ($P < 0.001$). Multiple patient variables have been found to be associated with the use of the different telehealth services, in each time-period.

Conclusions: The senior population uses telehealth services, and can increase their consumption, when they are needed. Suitable and straightforward telehealth solutions tailored for this population should be created.

Key messages:

- The senior population uses telehealth services, and can increase their consumption, when they are needed.
- Suitable and straightforward telehealth solutions tailored for this population should be created.

Abstract citation ID: ckae144.1163

Barriers and challenges to telemedicine usage among the elderly population in Israel

Motti Haimi

M Haimi[1,2,3], *U Goren*[4], *Z Grossman*[5]
[1]Health Administration, Yezreel Valey Academic College, Emek Yezreel, Israel
[2]Faculty of Medicine, Technion- Israel Institute of Technology, Haifa, Israel
[3]Department of Digital Medical Technologies, Holon Institute of Technology, Holon, Israel
[4]Innovation Center, Meir Medical Center, Kfar Saba, Israel
[5]Adelson School of Medicine, Ariel University, Ariel, Israel
Contact: morx@netvision.net.il

Background: Despite the challenges to its adoption, telemedicine is becoming more and more popular for helping elderly people preserve their independence and continue to live in their own homes.

Aims: We investigated the challenges and barriers experienced by the elderly population when using telemedicine services in Israel.

Methods: Fourteen elderly people were recruited for the study and interviewed in person using a semi structured interview protocol, using a qualitative technique. Participants' replies were evaluated and analyzed thematically. The participants were questioned regarding their usage of telehealth services, the benefits they perceive in them, any potential difficulties to use, and suggestions they had for making these services more readily available and simpler to use for the elderly.

Results: Most participants recognized the advantages of telehealth services, particularly for the elderly population during pandemics and normal times. However, most of them also expressed various challenges that face the elderly population in using these services. Many participants were concerned that the quality of telemedicine sessions may not be good enough compared to in-person sessions, and expressed a lack of confidence in telemedicine services, and frustration from the absence of in person interaction. Many participants highlighted the technological challenges in the use of computers and applications in general and in the context of healthcare, in particular, in addition to physiological and literacy difficulties. Finally, the participants suggested several ways to increase the accessibility and usage of telemedicine solutions by elderly people.

Conclusions: A proactive approach to identifying and resolving telehealth barriers can maximize virtual interactions for the older population and alleviate care inequities. There is a need to increase awareness of the availability, benefits, and uses of each telehealth service in comparison to in-person consultations.

Key messages:

- A proactive approach to identifying and resolving telehealth barriers can maximize virtual interactions for the older population and alleviate care inequities.

- There is a need to increase awareness of the availability, benefits, and uses of each telehealth service in comparison to in-person consultations.

Abstract citation ID: ckae144.1164
Integrating telemedicine in European healthcare settings: Key enablers for healthcare professionals

Tugce Schmitt

T Schmitt[1]*, K Habimana*[2]*, A Gottlob*[2]*, C Habl*[2]*, M Rosińska*[3]*, M Sønderskov Frydensberg*[4]*, S Anker Gents*[4]*, V Leclercq*[1]*, M Delnord*[1]*, M Van den Bulcke*[1]
[1]Cancer Centre, Sciensano, Brussels, Belgium
[2]IPED, Austrian National Public Health Institute, Vienna, Austria
[3]Department of Computational Oncology, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland
[4]Department of Digital Innovation, Health Innovation Centre of Southern Denmark, Odense, Denmark
Contact: Tugce.Schmitt@sciensano.be

Background: Conducted as part of WP4 (Sustainability) of the eCAN Joint Action (JA), we aimed to understand the facilitating factors for the use of telemedicine services in healthcare organisations (HCOs) involved in cancer care, such as comprehensive cancer centres and hospitals. eCAN JA runs pilot studies in 18 HCOs across 10 EU Member States (MS) to test the integration of telemedicine into the daily practice of healthcare professionals.

Methods: Based on a literature review, we identified 26 facilitators to implement telemedicine services at the organisational level; these were integrated to an online survey and sent to healthcare professionals working in cancer care. Next, they were invited to a foresight workshop to complement the quantitative survey data with qualitative insights.

Results: 24 healthcare professionals across 12 EU MS, predominantly from the pilot sites of the eCAN JA, responded to the survey. They advocate for trainings on telemedicine, emphasising the importance of user-friendly and interoperable platforms, alongside sufficient technological support, time, and financial resources to effectively implement telemedicine in HCOs. Trial periods for both healthcare professionals and patients should offer first-hand experience, while harmonising telemedicine protocols ensure consistency. In addition, promoting digital literacy among physicians and providing IT education from an early age could facilitate adoption. These strategies, coupled with awareness campaigns and infrastructure investments in HCOs, can pave the way for telemedicine adoption.

Conclusions: Based on the quantitative and qualitative outcomes, it can be concluded that policies should establish telemedicine training for healthcare professionals, support interoperability and user-friendliness of these services in HCOs. They should also address hospital workload challenges, create harmonised protocols, provide incentives, and invest in digital infrastructure in HCOs for telemedicine adoption.

Key messages:

- Telemedicine implementation in HCOs requires equipping healthcare professionals with the necessary skills, ensuring system compatibility, and addressing resource constraints in HCOs for success.
- Financial and infrastructural support to HCOs is crucial for the seamless integration of telemedicine services into the daily workflows of healthcare professionals, enhancing health service delivery.

Contact: dipumpomarcello@gmail.com

Background: Physical activity (PA) is key for the well-being of the elderly. Despite its proven efficacy, many older adults remain sedentary. Digital health interventions offer promising results. The study aimed to appraise scientific literature evidence regarding digital interventions to improve physical activity levels among community-dwelling adults aged 60 years or older.

Methods: A systematic review and semiquantitative analysis were performed. Digital interventions were included if using eHealth/mHealth tools, app-based technologies and text messaging. An intervention control was required. Main outcomes consisted in physical activity levels and related measures. A semiquantitative approach was chosen for evidence synthesis, using a harvest plot to visually facilitate the weighing of results with sample size and quality assessment.

Results: A total of 10 studies (13 publications) were included, from which five main intervention types were identified (2 studies per each intervention type). A semiquantitative evidence synthesis via a harvest plot was performed, to base the studies evaluation on the simultaneous consideration of sample size, study quality by type and effectiveness of intervention. Interventions adopting dynamically-adjusted exercise plans via wearables and app-based digital peer-support resulted the most successful, whereas PA digital coaching interventions resulted the least recommendable for adoption. Motivating interventions through digital platforms and digital diaries showed inconclusive results.

Conclusions: Personalized interventions using dynamically-adjusted wearable-based technology and app-based digital peer-support ones resulted as the most promising. Their ability to provide real-time, personalized feedback and foster social support is key for health promotion. It is crucial to leverage these promising tools for enhancing population health, integrating them into comprehensive, equitable, sustainable and engaging public health interventions.

Key messages:

- Interventions using personalized and dynamically-adjusted plans result as the most effective to increase physical activity amond the elderly.
- It is key to integrate effective digital health tools into comprehensive, equitable, sustainable and engaging public health interventions to enhance population health.

Inequities to the access to and use of telemedicine among cancer patients in Europe: A scoping review

Robbe Saesen

V Leclercq[1]*, L Vandervliet*[1]*, T Schmitt*[1]*, M Van den Bulcke*[1]*, M Delnord*[1]
[1]Cancer Center, Sciensano, Brussels, Belgium
Contact: Robbe.Saesen@sciensano.be

Background: Over the last few years, telemedicine services (TMs) have increasingly been used in European health and care systems. TMs include remote assistance with teleconsultation and telemonitoring. The expected benefits to individuals include easier access to information and personalized care. However, while the effectiveness and utility of TMs among cancer patients are well-established in Europe, several evidences highlighted the fact that TMs may widen existing inequities in health. Therefore, the aim of this study is to identify barriers and facilitators contributing to inequities to TMs among cancer patients in Europe.

Methods: Medline (via Ovid) and Scopus databases were searched in March 2023 for all publications providing evidence on factors influencing the access to and use of TMs services among cancer patients aged 18 and over in Europe published between January 2018 and March 2023. The PROGRESS-plus framework was used to stratify health opportunities, patients characteristics and outcomes.

Results: A total of 1683 peer reviewed publications were identified and after screening, 26 articles were retained in our scoping review. All included studies focused on TMs used by cancer patients through mobile or web-based applications. On one hand, socioeconomic status and language were the most cited influential factors as well as having an internet connection and a (mobile) device to the access to TMs. On the other hand, factors that influence the use of TMs are the level of education with digital skills and (e-)health literacy, social support, age and presence of comorbidities.

Conclusions: Identifying and addressing factors influencing access to and use of TMs among cancer patients will enable the development and tailoring of TMs that align more effectively with the needs and expectations of cancer patients. Integration of patient-centered care in TMs is necessary to enhance equity and allow a better implementation of TMs in European health and care systems.

Key messages:

- The main factors influencing the access to and use of TMs are socioeconomic status and level of education respectively.
- TMs must be developed and used to tackle inequities already present among cancer patients instead of widening the gap.

Abstract citation ID: ckae144.1167

An Artificial Intelligence approach to monitor infectious diseases: lessons learned from COVID-19

Luigi Palla

M Antinozzi[1], D del Re[2,3], L Palla[1], P Meridiani[3], L Soffi[3], MT Loiudice[4], MS Cattaruzza[1]
[1]Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy

Contact: luigi.palla@uniroma1.it

Background: The World Health Organization declared the start (March 11th 2020) and the end (May 5th 2023) of COVID19 pandemic, while in Italy it has been present since February 2020. Indicators such as number of new positive cases, deaths and hospitalizations are used to monitor epidemiological trends, but they suffer from biases limiting their effectiveness.

Methods: We used data from the Emergency Medical Services Activities as an alternative and studied three types of contributions: COVID19, flu and baseline during three time frames: -period 1 (July 1st-Oct 11th 2016; Feb 10th-May 20th 2017) used to model the baseline, when flu contribution should be negligible. -Period 2: (Dec 15th-Feb 14th 2017), when flu in 2017 is very evident. -Period 3: (March 11th-31st 2020), when the first COVID19 wave is dominant. To extract the pure contribution from flu and COVID19, the baseline contribution was properly subtracted.

Results: From these data we developed a machine learning approach (MLA) that offers a simple and powerful tool to monitor COVID19 or future infectious diseases. To maximize the identification power of COVID19, we used the Toolkit for multivariate analysis package. An artificial neural network, multilayer perceptron, deep neural network and boosted decision tree methods have been trained, considering the events in period 3 as signal and period 1 as background. To avoid overtraining, the samples were divided in two: one half to train the algorithm, and the other to check the performance. The results are stable over time and able to efficiently discriminate COVID19. With 50% efficiency of accepting COVID19 patients, roughly 95% of baseline patients can be rejected.

Conclusions: MLA can be used to early assign a probability of COVID19 without specific test, only relying on standard triage and emergency call details. This tool could be very useful to early detect the presence of new pandemics and tag positive patients before the official healthcare reporting system.

Key messages:

- AI model using data from Emergency Medical Services Activities can be a useful tool to early detect new pandemics and tag positive patients before the official healthcare reporting system.
- Covid19 pandemic gave us the possibility to develop new digital tools to use in the analysis of epidemiological trends.

Abstract citation ID: ckae144.1168

A Comparative Study of Sensor Quantity and Data Granularity in AAL Systems for Activity Recognition

Ashish Saragadam

A Saragadam[1,3], P Morita[1,2,3], J Kaur[1]

[3]Research Institute for Aging, University of Waterloo, Waterloo, Canada
Contact: asaragad@uwaterloo.ca

As populations age, the demand for non-intrusive elderly care solutions increases, highlighting the need for efficient AAL systems. Current research predominantly focuses on wearable sensors at high data frequencies. There is a critical gap in research in understanding the effectiveness of model performance using ambient sensors operating at varied granularities and with varied numbers of sensors. This study addresses this gap by investigating how sensor quantity and data frequency affect an artificial intelligence model's ability to detect various activities of daily living. The methodology employs a quantitative, experimental design to systematically assess the performance of artificial intelligence models across sensor quantity and data frequencies. This assessment will be conducted through a multi-study approach involving different populations to ensure robust and generalizable findings. Each model's efficacy will be evaluated using 5-fold cross-validation and GridSearchCV for rigorous hyperparameter tuning, employing diverse data aggregation and imputations techniques to maintain comprehensive analysis integrity. The primary goal of this research is to determine the optimal data granularity and number of sensors that maximize AI models' ability to detect daily living activities while minimizing resource demands, thereby enhancing the sustainability and scalability of AAL systems. This work aims to advance the field of ambient sensing in elderly care, offering significant implications for designing and implementing future AAL technologies and potentially improving the quality of life for the elderly population.

Key messages:

- The study explores the optimal configuration of data granularity and sensor quantity to maximize AI model efficiency in detecting activities of daily living among older adults.

- The study investigates the impact of data frequency and sensor count on AI model performance in detecting daily activities, aiming to optimize Ambient Assisted Living systems for the elderly.

[2]SEVERA, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg im Breisgau, Germany
Contact: Urs.Fichtner@uniklinik-freiburg.de

Background: Artificial intelligence (AI) has experienced an explosive growth in the healthcare sector and the scientific field. Large Language Models (LLMs) are investigated as potential tool to be used in medical treatment, by e.g. producing doctor's reports, supporting personalized medicine or educating patients. However, limitations are broadly discussed addressing patient safety and ethical concerns due to false and misleading content. Therefore, LLMs face criticism among users not only towards their integration in the patient-provider-interaction, but also in its use in medical research and health care education. In the ongoing EXPOLS (Exploring the Potential of LLMs in Statistical Consulting) study, we address the question 'What are the attitudes, fears and experiences regarding the integration of AI tools in the clinical/scientific work routine?'

Methods: We implemented an online survey that will be accessible in 07/2024. All employees at the University and Medical Center Freiburg will be asked to participate in the survey via online media. We expect a sample size of n = 600-1,200. The survey combines published measurements (e.g. TRI 2.0, result expectation measure), as well as a self-designed instrument with 15 items aiming to measure fears and attitudes towards AI. Latter was developed within a multidisciplinary team making use of ChatGPT as item generator. We will investigate its psychometric properties using exploratory factor analysis and describe distribution characteristics.

Results: At the time of the conference, the project will be completed and both psychometric insights and content-related results will be reported. The results could have important public health implications, since attitudes towards AI will steer its integration in the medical and clinical routine.

Conclusions: The EXPOLS study makes a current inventory among medical scientists in Freiburg following a modern approach in instrument development by including ChatGPT as collegial advisor.

Key messages:

- This study explores attitudes, fears and experiences towards the integration of AI tools in the work routine from medical and scientific staff at the University of Freiburg.
- The findings might be crucial in determining the integration of AI based tools in the medical and clinical work routine.

Abstract citation ID: ckae144.1170
Optimizing elderly care: a data-driven AI model for predicting polypharmacy risk using SHARE data

Aliaa Elhosseiny Elsayed

A Elhosseiny Elsayed[1,2], S Eldawlatly[3,4], E Ramadan[2], A Börsch-Supan[5], M Salama[1,6]

Contact: aliaa.elhosseiny@aucegypt.edu

Background: Polypharmacy (PP), which rises with age, is a growing public health challenge, affecting health outcomes and escalating healthcare expenditure. Leveraging the comprehensive European coverage and longitudinality of the Survey of Health, Ageing, and Retirement in Europe (SHARE) study, we aim to assess PP prevalence patterns and identify the most effective machine learning (ML) model for predicting long-term PP risk, as a foundation for a scalable predictive tool.

Methods: We used data from participants aged above 50 who were present in wave 6 and at least one of the subsequent three waves of the SHARE study, aiming to predict PP risk at 2, 4, and 6-year intervals. PP was defined as the concurrent use of five or more medications. We analyzed PP prevalence trends and selected the predictor variables from wave 6 using LASSO regression analysis. We evaluated eight ML models, namely, ANN, SVM, DT, RF, GB, XGBoost, LightGBM, and CatBoost, using a rigorous cross-validation strategy to ensure robustness and reliability.

Results: Our analysis reveals an upward trend in PP prevalence across the surveyed countries, with aggregate figures rising from 34.03% (95% CI 33.1-34.9) in wave 7 to 36.75% (95% CI 35.6-37.9) in wave 8, reaching 39.91 (95% CI 38.9-40.9) in wave 9. Additionally, using the Categorical Boosting ML model to predict PP resulted in overall accuracies of 75.08%, 73.7%, and 71.65% and recall rates of 72.83%, 70.48%, and 67.96% for the 2, 4, and 6-year intervals, respectively.

Conclusions: This study reveals a rising trend of PP across European countries and demonstrates the potential of using longitudinal data and ML to enhance PP prediction. The tool developed represents a step forward in risk stratification, which would be particularly beneficial in practical settings where family physicians or pharmacists could employ the tool to monitor elderly patients, predict and thus prevent PP, and reduce the negative health and economic impact associated with it.

Key messages:

- The integration of machine learning with longitudinal data presents a significant advance in polypharmacy risk prediction.
- The tool we developed highlights the potential translational impact of our findings.

Abstract citation ID: ckae144.1171
Cardio Policy Optimiser: an integrated public health approach to enhancing cardiovascular health

Henrique Lopes

H Lopes[1], R Baptista-Leite[1], P Simões Coelho[2,3], J Mendes[2,3], J Diogo[1], M Castro[1]
[1]Center for Global Health, NOVA-IMS, NOVA University, Lisbon, Portugal
[2]NOVA Information Management School, NOVA University, Lisbon, Portugal
[3]Information Management Research Center, NOVA University, Lisbon, Portugal
Contact: hlopes@novaims.unl.pt

Background: Cardiovascular diseases (CVDs) remain a leading cause of mortality in Europe, with atherosclerotic-related conditions accounting for 80% of CVD deaths - a third of them premature. Despite extensive efforts over the past five decades, the decline in these deaths over the last 20-25 years has plateaued, highlighting the need for innovative approaches. Additionally, the co-occurrence of CVDs with other chronic conditions such as diabetes, hypertension, and renal and hepatic diseases, adds complexity to their management and prevention.

Methods: In Portugal, the pilot phase implemented a novel integrated approach combining a Bayesian epidemiological model - which incorporates genetic, sociodemographic, comorbidity, and lifestyle data - with an adaptive conjoint analysis model focusing on atherosclerosis policy intervention. These models are part of a comprehensive response framework that incorporates health outcomes and associated costs resulting from better prevention and diagnosis.

Results: Currently in the development and calibration stage, the model is expected to yield initial results by early September.

Conclusions: This modeling approach offers new opportunities for public health to intervene at early stages in the natural history of CVDs. It emphasizes enhancing prevention and early diagnosis to potentially reduce the incidence of acute episodes and associated mortalities. Moreover, the model facilitates rapid evaluation of the economic benefits derived from preventive policies, thereby supporting more informed public health decision-making.

Key messages:

- The CPO model combines epidemiological and policy models to address cardiovascular morbidity and mortality.
- It boosts early diagnosis and prevention, and assesses economic benefits from policies.

Abstract citation ID: ckae144.1172
What to expect when generating data through the use of a mobile health application

Isabella Schwab

I Schwab[1], *T Ohnhäuser*[1], *N Scholten*[1]
[1]IMVR, University of Cologne, Cologne, Germany
Contact: isabella.schwab@uk-koeln.de

Background: Digitalization has significantly expanded the possibilities for collecting health data. Besides options such as online surveys, data can be collected through the use of digital applications (apps). Once users have given their consent, contact information from the app registration can be accessed to invite the relevant target group for further surveys. To generate a sufficient amount of data, a high level of willingness to participate and long-term involvement are required. This study aims to illustrate the willingness to share data and what can be expected from it by means of the Neo-MILK app, which supports mothers during lactation.

Methods: The willingness to share data and the data resulting from the use of the app is shown by the frequency of consent to the different data use options and the users' participation.

Results: While over 68% of the $n = 1079$ registered app users consented to the use of their app data, 47% agreed to be contacted again for scientific purposes. Data from $n = 421$ active users were available for analysis. From $n = 220$ mothers, milk pumping data was available. In 36% of cases, little (<10) or no information on pumping was provided. Of the users who agreed to be contacted again for scientific purposes, $n = 300$ were invited to participate in another survey and 23% ($n = 69$) participated.

Conclusions: In this example, the general willingness to share data and participate in further studies shows great potential for data collection. However, the data collection methods differ primarily in the motivation to participate. When collecting data through app usage, ensuring that the design of the app meets the needs of the user is essential to optimize the user experience and thereby generating complete data. If the use of contact information has been agreed to, incentives may be considered to increase the willingness to participate. Required ethics approvals and data protection regulations should also be ensured for app-based data collection.

Key messages:

- Generating data via app usage as well as the collection of data through the use of users' contact information shows great potential for health research.
- App-based data collection should be considered when planning future health research projects.

Contact: julia.nadine.doetsch@gmail.com

Chronicity, comorbidities, and social context influence COVID-19 risk and prognosis, drawing attention to a syndemic dimension. We discuss how linking routinely collected data and data collected through observational population-based cohorts can contribute to advance knowledge on the association between COVID-19 and chronic diseases and social indicators. Record linkage as a multidimensional tool may ultimately enable defining and optimizing of integrated strategies, which may create multilevel public health measures to foster solidarity on health in all policies when ethical and legal barriers under prerequisite data protection and privacy can be overcome. Legal discrepancies have been proving detrimental to research in member states, including those which already had established a margin for research for the common good without explicit consent. We hence call for further harmonization of data protection requirements for scientific research activities in the EU/EEA, focusing in particular on health-related research. A proposed framework demonstrates the role of record linkage as a trailblazing key player in research optimization due to its multidimensional possibilities calling for harmonization.

Key messages:

- Further harmonization of data protection requirements for scientific research may create multilevel public health measures.
- As a multidimensional tool, it optimizes integrated strategies and fosters solidarity on Health in All Policies (HiAP).

Abstract citation ID: ckae144.1174
Impact of AI on public health emergency communication in Europe and Central Asia: A Delphi study

Stefan Adrian Voinea

D Mahl[1], *MS Schäfer*[1], *SA Voinea*[2], *K Adib*[2], *B Duncan*[2], *C Salvi*[2], *D Ortiz*[2]
[1]IKMZ, University of Zurich, Zurich, Switzerland
[2]WHO/Europe, Copenhagen, Denmark
Contact: svoinea@gmail.com

Background: Artificial Intelligence (AI) holds the potential to fundamentally transform public health communication - presenting promising opportunities alongside profound challenges and risks. This two-wave Delphi study therefore invited practitioners and scholars to assess the potential impact of AI on the risk communication, community engagement, and infodemic management

(RCCE-IM) of public health authorities in European and Central Asian countries.

Methods: In two successive online surveys, 54 experts - both RCCE-IM practitioners and scholars with expertise in (digital) health communication, risk communication, and AI - from 28 countries provided their assessment of the following analytical dimensions: (1) opportunities, challenges, and risks of AI, (2) conditions for the responsible use of AI, (3) potential future scenarios, and (4) prioritized actions. The first Delphi wave followed an open and exploratory approach, while the second wave sought to prioritize and rank key findings from the previous round. The survey instruments included open-ended and closed-ended questions that were analyzed through statistical analysis, inductive and deductive coding.

Results: Results showed that AI holds various opportunities for the RCCE-IM of public health communicators. Challenges and risks, such as algorithmic bias or concerns about inclusivity, equally affect RCCE-IM efforts. Experts identified seven principles for the responsible use of AI (e.g., fair, human-centered) and predicted optimistic (e.g., optimized workflows) and pessimistic (e.g., flood of (mis)information) scenarios for the future impact of AI. Prioritized actions range from regulation, resource allocation, and feedback to capacity building, public trust, and education.

Conclusions: To responsibly navigate the opportunities, challenges, and risks of AI for public health emergency communication, clear guiding principles, ongoing critical evaluation, and multi-sectoral collaboration are needed.

Key messages:

- AI is likely to transform public health emergency communication.
- A set of agreed-upon principles will support public health authorities in the responsible management of the opportunities, challenges, and risks of AI.

Abstract citation ID: ckae144.1175
Development of a Medical Device Lifecycle Research Database at the MFDS

Hee Soo Yang

HS Yang[1], SW Jeon[1,2], CH Park[4], SY Kim[1,3], JH Park[1,2,3]
[1]Institute of Health & Science Convergence, Chungbuk National University, Cheongju-si, South Korea
[2]College of Medicine, Chungbuk National University, Cheongju-si, South Korea
[3]Department of Public Health and Preventive Medicine, Chungbuk National University Hospital, Cheongju-si, South Korea
[4]Big Data-based Policy Analysis Team, Ministry of Food and Drug Safety, Cheongju-si, South Korea
Contact: gmltndid1234@gmail.com

So-called big data are potentially useful in the healthcare field and are of interest to researchers, industry, and government agencies. Over the past 10 years, Europe, the United States, and Asia have been making efforts to collect and systematically manage information on the entire process from clinical trials to follow-up management of medical devices (MD). We developed MD lifecycle research database at the Ministry of Food and Drug Safety (MFDS) of the Republic of Korea, consisting of 61 tables and 2,053 variables. The MFDS possesses statistical information on all MD, pharmaceuticals, foods, and human tissues produced and distributed. The information in the database is categorized according to four MD lifecycle phases-clinical trial, approval, production, and post-approval. For the clinical trial phase, the database contains information on planning and approval of clinical trial and non-clinical trial. The approval phase includes information on models, raw materials, quality, and changes, while the production phase stores information on production, import, export, supply and use. For the last step, follow-up management phase, provide information on post-marketing safety management, risk management, and administrative disposition. All four steps are linked based on primary key, so it is possible to understand information on the overall MD lifecycle. The MD Lifecycle Research Database will help strengthen the industry's competitiveness in terms of cost-effectiveness in MD development and facilitate policy monitoring by improving its utilization in the public interest. This database contains information on all MD produced and distributed in Korea depending on the phases of the MD lifecycle, and data is easily accessible due to the lack risk of personal information exposure, so it can be widely used by individual researchers, industries, academia, and governments.

Funding This research was supported by a grant (22063MFDS498) from ministry of food and drug safety in 2024.

Key messages:

- We developed a medical device lifecycle database that enables tracking management according to the medical device lifecycle.
- This database can be used as a scientific basis to ensure the safety, effectiveness, and efficiency of medical devices.

Abstract citation ID: ckae144.1176
Public Perceptions and Engagement in mHealth Across Eight European Countries

Diego Maria Tona

DM Tona[1], FA Causio[1], F Beccia[1], A Cristiano[1], A Verduchi[1], M Porcelli[1], C Van El[2], GE Calabrò[1], R Pastorino[1], S Boccia[1]
[1]Università Cattolica del Sacro Cuore, Rome, Italy
[2]Vrije Universiteit Amsterdam, Amsterdam, Netherlands
Contact: diegomaria.tona@gmail.com

Background: Mobile health technologies have the potential to revolutionize healthcare delivery and patient engagement. This study explores public attitudes toward health app usage and data sharing across eight European countries, addressing a significant gap in understanding the public's perspective on mHealth adoption.

Methods: A cross-sectional survey was conducted involving 6,581 participants from Italy, the Netherlands, France, Germany, Spain, Poland, Romania, and Hungary. The survey assessed current health app usage, future interest, willingness to share health data, and concerns about data privacy and security.

Results: 21.87% of respondents currently use health apps, with 42.71% expressing interest in future use. Regarding data sharing, 52.82% are willing to share health data with healthcare providers, and 25.48% would share data with research institutions. However, 53.18% fear unauthorized use or hacking of their health data. Significant generational and geographical differences in mHealth engagement were observed, with older generations showing higher willingness to adopt health apps OR 1.22 (CI 1.03 - 1.46) for Baby Boomers, OR 1.45 (CI 0.97 - 2.16) for Silent Generation. Education level emerged as a crucial factor, with tertiary-educated individuals more likely to use health apps (OR 1.41 CI 1.24 - 1.58) and demand transparency (OR 1.61 CI 1.45 -1.78).

Conclusions: The findings underscore the need for targeted strategies to enhance digital literacy, ensure data privacy, and promote equitable access to mHealth technologies across Europe. Policymakers and healthcare stakeholders should prioritize these areas to foster greater public trust and engagement in mHealth, ultimately improving health outcomes and patient care.

Key messages:

- Public attitudes toward mHealth vary significantly across generations, countries, and education levels in Europe.
- Addressing data privacy concerns and enhancing digital literacy are crucial for widespread mHealth adoption.

Abstract citation ID: ckae144.1177
Trust in sources of information about digital health technologies: The User's Perspective

Birgit Babitsch

N Hannemann[1], *B Babitsch*[1]
[1]New Public Health, Osnabrück University, Osnabrück, Germany
Contact: bbabitsch@uos.de

Background: Trust is key to healthcare, including all types of health information. This applies not only to the process of healthcare delivery, but also to health-related behaviors and the utilization of healthcare services. Trust in health information sources has been shown to vary by social and health characteristics. Therefore, the research question is: Are there social and health-related differences in perceptions of trust in sources of information (government agencies or physicians) about digital health technologies?

Methods: The analysis is based on a cross-sectional online survey (STELLAR) conducted in 2022 (N = 1,200), Participants were asked whether they perceive trust (1= fully agree- 4= not at all) in information about digital health technologies provided by government agencies (institutional trust) or physicians (interpersonal trust). For the analysis, binary logistic regressions (references: traditionalists, low education level, poor self-perceived health) were used.

Results: Institutional Trust. Overall, 43.9% of the participants perceived trust in this information source. Baby Boomers (OR 2.022), Generation Y (OR 2.544), and Generation Z (OR 2.566), as well as medium (OR 2.526) and high (OR 3.823) educational level, increased the odds of perceived trust; the same was found for better self-perceived health (OR 1.569). Interpersonal Trust. In general, 94.8 % of the participants expressed trust physicians. Belonging to Generation Z decreased the chance (OR 0.097) and a better subjective health status increased the chance (OR 4.250) of perceiving trust. Education did not emerge as a significant determinant.

Conclusions: The study confirmed that interpersonal and institutional trust varies by social and health characteristics. There seems to be a need to strengthen efforts to explain the process of trust building in different population groups., e.g. to find explanations for why educational level was only relevant for institutional trust but not for interpersonal trust.

Key messages:

- Trust in sources of information about digital health technologies differ by generation, educational level, and subjective health status.
- Given the existing differences in perceptions of trust, it is worthwhile to explore the unknown mechanisms of the trust-building process among different population groups.

Abstract citation ID: ckae144.1178
Evaluating healthcare inequalities using ChatGPT4 – The case of potentially inappropriate medication

Johan Öberg

J Öberg[1,2], *K Khalaf*[1,2], *P Midlöv*[3,4], *R Perez*[1], *J Merlo*[1,3]
[1]Unit for Social Epidemiology, Lund University, Malmö, Sweden
[2]Department of Healthcare Management, Region Skåne, Malmö, Sweden
[3]Centre for Primary Health Care Research, Region Skåne, Malmö, Sweden
[4]Family Medicine and Community Medicine, Lund University, Malmö, Sweden
Contact: johan.oberg@med.lu.se

Issue/problem: Regular and standardized monitoring of healthcare is necessary to inform decision makers and clinicians about healthcare quality. Equity is a fundamental dimension in such evaluations. We aimed to investigate if artificial intelligence (AI) large language models (LLM), such as ChatGPT4, may facilitate routine monitoring of healthcare inequalities using an established framework for healthcare quality and equity evaluation, analysis of individual heterogeneity and discriminatory accuracy (AIHDA).

Description of the problem: We have previously demonstrated that compared to traditional methods, AIHDA improves the evaluation of healthcare inequity. We asked ourselves if ChatGPT4 could facilitate the standardized application of the AIHDA approach in routine monitoring of healthcare.

Results: Using strict guidelines, we instructed a GPT model, based on ChatGPT 4, to utilize the AIHDA framework for evaluating healthcare inequalities. To demonstrate the analysis, we used the quality indicator potentially inappropriate medication among elderly and analyzed simulated data of individuals >75-year-old belonging to 36 socioeconomic strata and residing in 21 Swedish regions. The GPT performed an accurate analysis, correctly interpretated the results and formulated an informative short rapport with illustrative tables and figures.

Lessons: AI appears to facilitate routine monitoring of health care inequity using the AIHDA approach. AI also allows a constructive interaction with the user but, so far, it needs be closely supervised.

Key messages:

- ChatGPT 4 can improve the standardized evaluation of healthcare inequity.
- Although the technology is under development and must be used with caution.

Abstract citation ID: ckae144.1179
Tracing applications for the control of virus dispersal - COVID-19 experience

Olga Kalinowska-Beszczynska

O Kalinowska-Beszczynska[1], *A Wojtecka*[1], *P Tymosiewicz*[2]
[1]Department of Public Health and Social Medicie, Medical University of Gdansk, Gdansk, Poland
[2]Department of Pedagogy and Psychology, Jozef Pilsudski University of Physical Education in Warsaw, Biała Podlaska, Poland
Contact: o.kalinowska-beszczynska@gumed.edu.pl

Tracing apps have been promoted as an effective tool for the monitoring and control of the spread of COVID-19. Although the correlation between the use of mobile tracking apps and reducing the spread of the virus has been demonstrated, the success of these apps depends on a number of factors, such as the number of app users, the rate at which new systems get adopted, as well as concerns related to anonymity and privacy. The aim of the research was to analyse the pattern of adaptation and use of a COVID-19 tracing app in the context of Polish society. The research used a qualitative approach, data were collected through focus group and individual interviews. The sample consisted of 34 respondents, aged 23-61, with different educational levels and backgrounds. The study followed two phases. First, a model with a set of questions was proposed on the basis of the unified theory of technology acceptance and use. Secondly, using the set of questions, interviews were conducted. In order to examine the data, thematic analysis was applied. To summarise the results of the survey, the respondents have clear expectations towards the app, which are not fulfilled. They are afraid of new technologies. However, they use them frequently and willingly without thinking about the security of their personal data. They expect applications to provide reliable information, but at the same time do not want to enter necessary data that they consider sensitive. They are negative about government actions without losing trust in government applications. It can also be speculated that a lack of information and understanding of the app may have contributed to some of the objections. In conclusion, we need to better understand users and be able to accommodate often conflicting characteristics in order to design more effective tracking applications in the future.

Key messages:

- Technology offers ways to successfully prevent viruses from spreading.
- Getting the technology right, based on customer behaviour, is key to the effectiveness of tracking applications.

Abstract citation ID: ckae144.1180
The interplay of technology anxiety and digital health literacy in determining e-health readiness

Mariusz Duplaga

[1]Department of Health Promotion and e-Health, Jagiellonian University Medical College, Cracow, Poland
Contact: mariusz.duplaga@uj.edu.pl

Background: The assessment of e-health readiness (eHR) is used to assess the ability of selected groups of citizens and patients, as well as society as a whole, to adopt e-health support. This study aimed to understand the main determinants of eHR in adult Internet users in Poland.

Methods: The analysis was conducted using data from a computer-based web-based interviewing (CAWI) survey carried out in June 2023 in a representative sample of 1661 Polish Internet users. The eHR score was established based on the e-Health Readiness Scale. Uni- (ULRM) and multivariable (MLRM) models were developed for eHR. Independent variables included technology anxiety (TA), digital health literacy (DHL), Internet (IU) and social media use (SMU), self-assessed health status, and sociodemographic variables.

Results: ULRMs revealed that TA, DHL, IU, SMU, an array of sociodemographic variables, and self-assessed health status (SAHS) were significant predictors of eHL. ULRMs with TA and DHL explained, respectively, 30.1% and 23.9% of the eHR variability. In MLRM developed with all predictors confirmed in ULRMs, only TA, DHL SMU, age, and income level maintained their significant effect on eHR. MLRM explained 42.8% of TA variability. Higher TA was associated with lower eHR (B, 95% confidentiality interval (95%CI): -0.30, -0.33 - -0.27). Respondents with higher DHL demonstrated higher eHR (B, 95%CI: 0.42, 0.37 - 0.48). Older persons were more likely to accept e-health solutions (B, 95%CI: 0.03, 0.003 - 0.05). More frequent SMU was associated with higher eHR (B, 95%CI: 1.87, 0.94 - 2.80). Finally, those who refused to reveal their level of income showed significantly lower eHR than those who revealed it (B, 95%CI: -0.84, -1.58 - -0.10).

Conclusions: TA and DHL are the main predictors of eHR. SMU also accounts for eHR. Unexpectedly, older age is a positive predictor of eHR. Finally, variables reflecting health status do not exert a significant effect on eHR.

Key messages:

- Technology anxiety should be treated as an important determinant of the successful implementation of e health solutions.
- The development of society's digital health literacy may be a countermeasure to the unfavorable effect of technology anxiety on e-health readiness.

Abstract citation ID: ckae144.1181
Two decades of electronic nicotine delivery systems discussions in Türkiye: AI-driven text analysis

Nadiye Pinar Ay

S Doğan Jamil[1], H Jamil[2], P Ay[1]
[1]Public Health, Marmara University, Faculty of Medicine, Istanbul, Türkiye
[2]Materials Science and Nano-Engineering, Sabancı University, Faculty of Engineering and Natural Sciences, Istanbul, Türkiye
Contact: npay@marmara.edu.tr

Background: As Turkiye ranks second in cigarette consumption in Europe, the increasing shift to Electronic Nicotine Delivery Systems (ENDS) presents emerging public health concerns. This study aims to introduce a hybrid approach by combining AI-driven large language models (LLM) with traditional thematic analysis to explore 20 years of ENDS discourse on Eksisozluk, a popular Turkish social media platform, using the Health Belief Model (HBM).

Methods: This mixed-methods study, analyzed 5,907 comments about ENDS from 2003 to 2023, sourced from a renowned online user-generated forum in Turkiye. Utilizing an LLM, comments were first categorized according to the HBM. Subsequently, the LLM's generative capabilities were employed to identify sub-themes through thematic analysis. A temporal analysis was then conducted to examine the evolving trends over the 20-year span.

Results: ENDS popularity peaked in 2017, dipped during the COVID-19 pandemic, and later rebounded. Using an LLM with 70% accuracy, validated by a manually labeled sample, we discerned two main themes: perceived benefits (40.5%) - primarily using ENDS as for harm reduction (32.8%) and smoking cessation tools (21.6%)- and perceived barriers (27.7%), with cost and accessibility (21.9%) being the most significant throughout the period. Initially, the focus was on cessation, but shifted to harm reduction post-pandemic.

Conclusions: Our study indicates that consumers in Turkiye initially used ENDS for cessation but recognized their ineffectiveness over time. During the COVID-19 pandemic, usage shifted towards harm reduction, likely influenced by the rhetoric of the Tobacco Industry. Despite a national ban, ENDS remain widely used in Turkiye.

Key messages:

- Turkiye should develop a social marketing strategy to raise awareness that ENDS is not a valid tool for harm reduction.
- Although the sale of ENDS is prohibited in Turkiye, enforcement of bans should be strengthened as part of an effective control strategy.

Abstract citation ID: ckae144.1182
Exploring the Impacts of Artificial Intelligence Interventions on Provider Practice practice

Joe Lintz

J Lintz[1]
[1]Health Information Management Department, Parker University, Allen, Texas, USA
Contact: cclintz@hotmail.com

Background: Despite the growing prevalence of AI in healthcare, there has been a lack of recent studies exploring its impact on providers' practices and patient outcomes. This study investigates healthcare providers' perceptions of AI interventions' influence on their practice efficiency and patient outcomes, as well as the correlation between providers' perceptions of AI and its effects on patient outcomes.

Methods: A self-administered questionnaire was mailed to 38 healthcare providers at a rural medical center in north Texas, with a 70% percent response rate ($n = 27$). In addition to descriptive statistics, multivariable logistic regression test was conducted to discern the relationship between their perceptions of AI and its impact on patient outcomes.

Results: The findings revealed that a majority of providers perceived AI to still be in its early stages, posing challenges for practice and having a limited impact on patient outcomes. Additionally, various factors such as age, gender, a user-centered design approach, AI experience, along with perceptions of workplace support and stress, significantly shape providers' attitudes toward AI and ultimately affecting patient outcomes.

Conclusions: Before AI technology can fulfill its promise of transforming healthcare through integration with other technologies, the healthcare sector must address numerous hurdles. It is crucial to approach the development and testing of intricate systems like AI-integrated electronic health record (EHR) systems with caution to ensure their reliability and dependability in clinical decision-making. Additionally, navigating medico-legal responsibilities and pursuing fair distribution of benefits are equally crucial.

Key messages:

- This study offers insights into the extent of AI interventions' impact on healthcare.
- This study specifically focuses on enhancing patient care, reducing costs, and improving the efficiency of the healthcare system.

Abstract citation ID: ckae144.1183
User technology for AI-supported objective measurement of Work-related Quality of Life (MI-LQ)

Carsta Militzer-Horstmann

C Schreiber[1,2], M Geisler[2], J Voigt[3], H Kosakyan[4], J Hohn[3], A Hamm[2], E Mut[5], JM Burkhardt[6], UD Braumann[5], C Militzer-Horstmann[1,2]

[4]Appsfactory GmbH, Leipzig, Germany
[5]Institute for Applied Informatics, InfAI e.V., Leipzig, Germany
[6]Information Systems, University of Leipzig, Leipzig, Germany
Contact: militzer-horstmann@wifa.uni-leipzig.de

Background: Understanding and enhancing job satisfaction is crucial for improving Work-Related Quality of Life (WrQoL) in today's office work environments. Our work uses multimodal data collection and analysis techniques to objectively assess WrQoL, thus mitigating respondent bias and survey fatigue. Leveraging machine learning (ML) and automated methods measuring WrQoL presents a promising approach in public health research, particularly concerning stress-related health outcomes.

Methods: Through a systematic literature search of 9,242 publications to identify WrQoL indicators, we selected over 100 publications for data extraction. A base model, including workload, commute, overtime, valence, and arousal was formulated. To amass a wide data set, Objective measurement tools (computers, smartphones, and wearables) complemented by questionnaire data. This data will inform ML algorithms to predict individual WrQoL indicators. Developed as an input/output data platform, an app-prototype will objectively assess WrQoL, facilitating a field study with office workers to refine the model. A mobile app prototype serves as a user interface and data relay for WrQoL metric analysis.

Results: Our research develops instruments for measuring WrQoL using smartphones, wearables, and specialized trackers for heart rate variability (HRV) analysis, alongside a software prototype for keyboard and mouse tracking for workload assessment of valence and arousal. Fitness trackers with photoplethysmography functionality are favored for HRV assessment.

Conclusions: The systematic search identified influences on WrQoL, translated into measurable indicators in a base model. Leveraging user tech for assessment and a ML and mobile app framework, this approach facilitates objective WrQoL determination. By presenting the relationship between digital service use and WrQoL indicators, this methodology promises new insights, informing stress and burnout prevention strategies within public health initiatives.

Key messages:

- Progressive approach: ML-driven WrQoL assessment offers promising avenues for stress prevention in workplace health research.
- Methodological Advancement: The novel framework for WrQoL assessment using digital tools contributes to effective workplace health promotion strategies, with potential for tailored interventions.

Abstract citation ID: ckae144.1184
Digital communication and techno-stress among health professionals: a cross-sectional study in Italy

Andreea Mihaela Butnaru

AM Butnaru[1], G Scaioli[1], M Lodin[1], C Toffanin[1], A Cataldo[1], G Lo Moro[1], F Bert[1,2], R Siliquini[1,3]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Infection Control Unit, ASL TO3, Turin, Italy
[3]AOU City of Health and Science of Turin, Turin, Italy
Contact: andreeamihaela.butnaru@unito.it

Background: Digital technologies are increasingly indispensable in physicians' clinical practice. Despite their advantages, they are also linked to information overload and constant availability, which might affect healthcare professionals' quality of life. The study aims to investigate the utilisation of digital technologies among healthcare providers and to identify possible predictors of techno-stress associated with these technologies.

Methods: A cross-sectional study was conducted through an anonymous questionnaire distributed to Medical Doctors (MDs) via social media. The main outcomes were "Impact of digital technologies" and "E-mail overload" (EO), and "Whatsapp overload" (WO) as indicators of techno-stress. Univariable and multivariable regression models analyzed the association between the outcome variables and selected independent variables.

Results: Preliminary results were conducted on 246 MDs. Most respondents declared that using digital technologies positively impacted their relationship with patients and colleagues (67.1% and 56.7%, respectively). Multivariable linear regression analyses highlighted that variables associated with a higher or lower EO and/or WO were age (WO: adjusted coefficient (adjCoeff)=0.24, $p = 0.004$), being a specialist compared to a General Practitioner (GP) (EO: adjCoeff -8.42, $p = 0.000$; WO: adjCoeff=-5.2, $p = 0.02$), the number of patients visited each day (EO: adjCoef=16.10, $p = 0.000$; WO: adjCoeff=10.43, $p = 0.001$), working in a town with a larger population (EO: adjCoeff=-8.22, $p = 0.001$).

Conclusions: In agreement with the literature, GPs were the medical category most affected by techno-stress. Doctors with a higher volume of patients and who work in smaller towns have a higher likelihood of techno-stress. These findings underscore the necessity of interventions to address the issue, specifically through increased MD education and enhanced EU-wide regulations on digital technology use in healthcare.

Key messages:

- Digital technologies positively impact physicians' relationships with patients and colleagues, but also contribute to techno-stress, especially among General Practitioners and those with more patients.
- Interventions like improved Medical Doctors' education and stronger European regulations are needed to manage techno-stress and optimize the use of digital technologies in healthcare.

Usability of an AI-based independent pedestrian navigation device designed for blind people

Marina Denisa Dascal

M Dascal[1,2], O Blaga[1,2], M Padure[1,3], C Amariei[1]
[1]DOTLUMEN S.R.L, Cluj-Napoca, Romania
[2]Department of Public Health, Babes-Bolyai University, Cluj-Napoca, Romania
[3]Special Education Department, Babes-Bolyai University, Cluj-Napoca, Romania
Contact: marina.dascal@ubbcluj.ro

Background: 2.2 billion people live with visual impairment (VI) worldwide and face orientation and mobility challenges in various aspects of their lives. Despite technological advancements, the most used mobility solutions for VI are still the walking cane and the guide dog. The objective of this research is to assess the system usability of an AI-based independent pedestrian navigation device (.lumen glasses), designed for blind people.

Methods: During 31st of October and 2nd of November 2023, 27 visually impaired people living in Bucharest, Romania, tested the . lumen glasses for 1-3 hours during an outdoor navigation task. The glasses use AI to recognize the user's environment and haptic and audio feedback to guide them. The System Usability Scale (SUS), a 10-item instrument, was used to evaluate the level of usability the participants ascribe to the .lumen glasses. Qualitative feedback was collected as part of the post-test survey and analyzed using thematic analysis. Data were triangulated to identify usability issues.

Results: The mean age of the participants was 30.3 years old (SD = 12.07, min=21 max =56, range: 48), 55.6% (N = 15) of the participants were male, 96,3% (N = 26) were completely blind, and 81.5% were using a white cane for orientation and mobility. Our findings reveal a mean SUS score of 83.65 (SD = 15.23, range 47.5, min=52.5, max=100) indicating high usability. The thematic analysis revealed 5 themes: (1) auditive and (2) haptic feedback in navigation, (3) hardware (adjustment system & buttons), (4) tutorial & presentation of how the device works and (5) other aspects (usage in combination with other assistive technologies etc.). The participants declared that the glasses are intuitive to use and promote the feeling of safety and independence.

Conclusions: Data suggest that the .lumen glasses area promising assistive technology for the mobility of VI. Findings are currently used to steer the development and implementation of the AI-based system.

Key messages:

- According to participants' feedback, .lumen glasses are a scalable AI-based mobility solution that can make navigation and orientation easier for visually impaired individuals.
- .lumen glasses designed for the visually impaired individuals are one of the current and limited assistive technology improving the mobility and orientation.

Abstract citation ID: ckae144.1186
Digital health and some thematic shifts in bioethics in academic publications after the pandemic

Martin Mirchev

M Mirchev[1], I Mircheva[1]
[1]MU- Varna, Varna, Bulgaria
Contact: mart_mirchev@abv.bg

Background: Digital health (DH) presents vast opportunities, but also dynamic shift in viewpoints, which is reflected in academic works. Since DH concerns patient data, a major issue is complying with the bioethical principles, and ensuring patients' privacy and security. The aim of this research is to explore avenues, in which ethics and privacy are reflected in DH, especially in terms of research, legislation, artificial intelligence (AI) and blockchain applications in medicine and public health.

Methods: Literature search for full text publications in PubMed, Scopus and ScienceDirect focused on ethics and privacy in DH in the period 2019-2023 found 325 articles in English authored by academicians. Six thematic categories were identified: ethics (fundamental principles; ethics in using novel DH tools); privacy (in use of apps/wearables; as a challenge/barrier to DH interventions/technologies); ethics/privacy in: DH research (data gathering, use, sharing); policy and legislation (for DH applications); AI and blockchains (in medicine and public health).

Results: Articles were from 32 countries: USA-24.3%; UK-13.5%; Germany-7.7%; Canada-7.4%; Australia-6.7%; Netherlands, Italy, Switzerland-4.7% each; China, India-3.0% each and 20.3% from 22 other countries; 86.5% in medical/DH journals. Only 10.2% were published in 2019; 17.8% - 2020; 19.4% - 2021; 27.1% - 2022 and 25.5% - 2023. Privacy was discussed in 26.5%; ethics-23.7%; research-19.4%; AI-15.1%; policy and legislation-9.5% and blockchains-5.5% of the articles. The publication activity of all six categories increased after the unfold of the pandemic in 2020. In 2023 publications for ethics (13%), privacy (5.8%) and research (6.3%) decreased; for legislation (12.9%), AI (14.3%) and blockchains in healthcare (16.8%) increased.

Conclusions: The pandemic and its aftermath present a change in academic interest. Traditional ethical fundaments in DH slightly lose position in favor of top notch technologies and apt legislation.

Key messages:

- The pandemic and modern technologies enforced new digital health applications. Further research will reveal the needs of AI and blockchain applications respecting privacy and the ethical principles.
- Besides existing legislation and regulations, in order to catch up with the dynamic developments in DH, the legal base needs to become more flexible. Technologies change, privacy importance does not.

Abstract citation ID: ckae144.1187
The effects of weather and mobility on respiratory viruses before and during the COVID-19 pandemic

Lília Perfeito

L Perfeito[1], I Varela-Lasheras[2], S Mesquita[1,3], J Gonçalves-Sá[1,2]
[1]Social Physics and Complexity, Laboratório de Instrumentação e Física Experimental de Partículas, Lisbon, Portugal
[2]School of Business and Economics, Universidade Nova de Lisboa, Lisbon, Portugal
[3]Nova Medical School, Universidade Nova de Lisboa, Lisbon, Portugal
Contact: lperfeito@lip.pt

Background: The flu season is caused by a combination of different pathogens, including influenza viruses, which cause the flu, and non-influenza respiratory viruses, that cause common colds or influenza-like illness. These viruses exhibit similar dynamics and, given that outbreaks occur mostly in the winter and there is almost no circulation during the summer, in temperate regions, meteorological conditions have historically been regarded as a principal modulator of their epidemiology. However, after the emergence of SARS-CoV2, in late 2019, the dynamics of these respiratory viruses were strongly perturbed worldwide: some infections displayed near-eradication, while others experienced temporal shifts or occurred "off-season". This disruption raised questions regarding the dominant role of weather while also providing an unique opportunity to investigate the roles of other determinants in their epidemiological dynamics.

Methods: Weather, mobility and epidemiological surveillance data was collected for Influenza, RSV, hCOV and hMPV, from Canada and the USA, from 2016 to 2023. Statistical analysis and modeling were employed to test the effects of weather and mobility on viral dynamics, before and during the COVID-19 pandemic.

Results: Using Beta Regressions, we found that whereas in the pre-COVID-19 pandemic period, weather had a strong effect, in the pandemic period, this effect was strongly reduced post-pandemic with mobility playing a more significant role.

Conclusions: These results, together with previous studies, dispute the general belief that respiratory viral dynamics are mostly dictated by weather and indicate that behavioral changes resulting from the non-pharmacological interventions implemented to control SARS-CoV2, played a key role. This disruption of past dynamical equilibrium raises important questions regarding the factors that modulate them, particularly in a context of climate change.

Key messages:

- We took advantage of the disruption caused by COVID-19 to study dynamics of other respiratory viruses and to disentangle the effects of weather from those of human behavior.
- While before 2020 cold temperatures were highly correlated with incidence, afterwards cold weather was no longer a necessary condition and human mobility became central.

Abstract citation ID: ckae144.1188

Using marketing strategies to promote maternal health: an international students' collaboration

Dziyana Nazaruk

D Nazaruk[1], *L Pardo*[2], *A Palacios*[1], *J Chopak-Foss*[1]
[1]Health Policy and Community Health, Georgia Southern University, Savannah, USA
[2]Academy for Games and Media, Breda University of Applied Science, Breda, Netherlands
Contact: dnazaruk@georgiasouthern.edu

Purpose: About 1 in 8 birth parents experience symptoms of perinatal mood and anxiety disorders (PMADs). The purpose of this collaborative project was to create a social media deliverable to lower the risk of postpartum depression in pregnant and postpartum parents in Georgia, USA.

Methods: Using the SM 10-step model, Master of Public Health Students from Georgia Southern University (GSU), Georgia in collaboration with Creative Business students from Breda University of Applied Science (BUas), the Netherlands, designed an evidence-based SM product. They were mentored by public health and media faculty from both institutions. Roles and responsibilities according to the skill sets were divided, but briefly: students 1) identified a target audience; 2) conducted tertiary data collection; 3) set goals and objectives; 4) developed 4 P's (product, price, place, and promotion) 5) developed marketing strategies.; 6) and used the strategy to create a specific social media deliverable.

Results: Utilizing the 10-step model social marketing strategy used state-of-the-art marketing and digital media techniques and evidence-based strategies to create a digital electronic booklet that focused on reducing the stigma associated with help seeking behaviors with the ultimate goal to reduce the incidence and prevalence of PMADs. The digital interactive booklet will be pilot tested in selected OBGYN offices and health departments in Southeast Georgia in July 2024.

Conclusions: This collaborative project demonstrates effective collaboration between disciplines from different world regions utilizing strengths from both teams: public health and digital media skills to create an SM product that will be utilized to promote social engagement among postpartum parents.

Key messages:

- Students utilized social marketing strategies to create an electronic booklet to address postpartum depression using state-of-the-art digital media techniques and evidence-based strategies.
- This collaborative project demonstrates effective collaboration between disciplines from different world regions and utilizes strengths from both teams.

Abstract citation ID: ckae144.1189

Video consultations among registered nurses in public sector and associated factors

Emma Kainiemi

E Kainiemi[1], *L Virtanen*[1], *T Heponiemi*[1], *T Vehko*[1], *A-M Kaihlanen*[1]
[1]THL, Helsinki, Finland
Contact: emma.kainiemi@thl.fi

Background: In digital health services, including services for older people, video consultations can enhance access to care while enabling interaction through audio and visual means. Registered nurses are pivotal in digital care delivery and there is a need for more understanding regarding the use of video consultations in nursing. This study aims to examine factors associated with nurses' video consultations in the public sector.

Methods: The Finnish 'Survey on information systems for registered nurses' was delivered for registered nurses in March 2023. The respondents were asked whether their work had included video consultations in the past six months. Binary logistic regression was used to examine if career stage and digital skills (basic IT-skills, proficiency in data security, skills in digital working environments) were associated with nurses' video consultations, adjusted for working unit and location of employment.

Results: The study included 2,525 public sector nurses (92.7% female, mean age 47.34, SD 10.47). Of them, twelve percent had used video consultations with patients. Most nurses used video consultations in outpatient units (63.3%), whereas they were less used among those working in acute care (3.3%), housing services (3.3%) and home-based services (8.2%). Early-career nurses had lower odds (OR .38, 95% CI .19-.73) of video consultations compared to mid-career nurses. Nurses who had good skills in working in digital environments (OR 2.07, 95% CI 1.26-3.39) had greater odds of video consultations than those with poorer skills.

Conclusions: The study suggests a limited adoption of video consultations among public sector nurses, particularly among early-career professionals. Increasing targeted support and training, and the availability of tools for various patient service needs in video consultations, are needed. By recognizing the importance of nurses' digital skills, digital care delivery could be enhanced and potential public health benefits promoted.

Key messages:

- Relatively few registered nurses used video consultations in the public sector. More research is needed to explore if their usage could be increased safely for patients, also in early nursing careers.
- Proficiency in digital work environments is imperative for ensuring the quality of care in video consultations. Therefore, collaborative efforts are required to enhance professionals' digital skills.

Abstract citation ID: ckae144.1190

Leveraging digital adherence technologies to enhance public health: insights from TB care in Ukraine

Roman Rodyna

V Kochanov[1], *A Bogdanov*[1], *K Karpiuk*[1], *R Rodyna*[1], *M Germanovych*[1], *G Dravniece*[1]
[1]PATH, Kyiv, Ukraine
Contact: rrodyna@path.org

Background: Effective tuberculosis (TB) care is vital for public health, especially in war-affected Ukraine. In response to the complex healthcare delivery landscape, where traditional directly observation treatment methods became impractical, digital adherence technologies (DATs) emerged as a promising solution, offering more autonomy for people, and remote monitoring capabilities for healthcare providers.

Intervention: The PATH-led USAID-funded Support TB Control Efforts in Ukraine (STBCEU) project implemented smart pill boxes in eleven Ukrainian regions. These devices equipped with built-in reminders helped people adhere to their medication regimen, and signaled healthcare providers when the box was opened.

Results: Since April 2022, STBCEU has supported 2,022 people with TB who used smart pill boxes during their treatment, including 489 (24%) with drug-resistant TB (DR-TB). A total of 482 people continue utilizing boxes. Of 1,540 people with TB who completed the use of boxes, 1,207 people (78%) successfully completed TB treatment with an average of 84% treatment adherence rate digitally reported by the technology.

Conclusions: The integration of smart pill boxes in TB management has enhanced people-centered care, ensuring treatment continuity even in challenging circumstances and providing healthcare providers with real-time adherence data. The innovation contributed to TB control efforts and health equity through expanding opportunities for people to choose their treatment model based on their needs, available resources and community support programs. Leveraging digital solutions proved to be essential in strengthening healthcare systems. In the realm of TB management, DATs enhance differentiated care, embodying a harmonious integration of technology automation and provider interventions.

Key messages:

- Integration of smart pill boxes enhanced patient-centered care, providing real-time adherence data and empowering individuals to choose personalized treatment models.
- Digital technologies like smart pill boxes transformed TB care, offering tailored support for patients and remote monitoring capabilities for healthcare providers even in challenging circumstances.

Abstract citation ID: ckae144.1191
A mixed-methods evaluation of a virtual coach for smoking cessation and physical activity in adults

Milon van Vliet

MHM van Vliet[1,2], A Versluis[1,2], NH Chavannes[1,2], BL Scheltinga[3,4], N Albers[5], KM Penfornis[6], W Baccinelli[7], E Meijer[1,2], on behalf of the Perfect Fit consortium[3,5,6]

[1]Department of Public Health and Primary Care, Leiden University Medical Centre, Leiden, Netherlands
[2]National eHealth Living Lab, Leiden University Medical Centre, Leiden, Netherlands
[3]Biomedical Signals and Systems, University of Twente, Enschede, Netherlands
[4]Roessingh Research and Development, Enschede, Netherlands
[5]Intelligent Systems, Delft University of Technology, Delft, Netherlands
[6]Unit Health, Medical and Neuropsychology, Leiden University, Leiden, Netherlands
[7]Netherlands eScience Center, Amsterdam, Netherlands
Contact: m.h.m.van_vliet@lumc.nl

Background: Mobile health (mHealth) interventions with virtual coaches (i.e. AI conversational agents) offer scalable and cost-effective solutions for health behavior change. We developed Perfect Fit, an mHealth intervention with a virtual coach providing personalized feedback to promote smoking cessation and physical activity simultaneously. Through innovative techniques (e.g. sensor technology) and iterative development involving end-users, we aim to overcome challenges faced by mHealth interventions, like insufficient personalization. This study examines Perfect Fit's feasibility and acceptability.

Methods: A single-arm, mixed-method, real-world evaluation study was conducted with 100 adult smokers in the Netherlands. The intervention lasted approximately 16 weeks. Data were collected at baseline and post-intervention. Quantitative data included usage data and self-report questionnaires on feasibility, acceptability and participant characteristics (e.g. eHealth literacy). Qualitative data included semi-structured post-intervention interviews with a subsample of 12 participants. Descriptive analyses (quantitative) and the Framework Approach (qualitative) were used for data analysis, and quantitative and qualitative data were integrated during interpretation.

Preliminary results: Participants adapted the use of Perfect Fit to their preferences. Many participants were satisfied with the content but missed variations in conversations with the virtual coach. The coach offered anonymity, positively experienced by some (e.g. non-judgemental), but negatively by others (e.g. lower accountability). Many participants liked the combination of smoking cessation and physical activity enhancement.

Conclusions: Findings show the potential of interventions like Perfect Fit as a multiple health behavior change strategy in promoting public health and preventing chronic disease. Findings can inform intervention development and identify methods to foster feasibility and acceptability.

Key messages:

- mHealth interventions with virtual coaches, like Perfect Fit, could promote public health.
- Targeting multiple behaviors, like low physical activity and smoking, simultaneously seems beneficial.

Abstract citation ID: ckae144.1192
Digital Health in Croatia: Key stakeholders' perspective of societal and institutional readiness

Anamaria Malešević

A Malešević[1], A Čartolovni[1,2]

[1]Digital Healthcare Ethics Laboratory, Catholic University Croatia, Zagreb, Croatia
[2]School of Medicine, Catholic University Croatia, Zagreb, Croatia
Contact: anamaria.malesevic@unicath.hr

Background: According to the literature, digital health brings an innovative approach to healthcare and an inevitable transformation and disruption. The potential of digital technologies is far-reaching, from preventive medicine to addressing public health challenges. However, the implementation also significantly depends on the social & cultural context.

Methods: To research Croatia's expectations, challenges, and readiness for implementing digital health, interviews were conducted with physicians, patients, hospital managers, policymakers, jurists, and engineers (n = 75). Following identifying key themes, a survey was conducted among Croatian medical students (n = 775) at the end of 2022.

Results: Key stakeholders believe implementation preparedness is demonstrated through institutional and societal readiness. Prominent characteristics of societal readiness include appropriate infrastructure and legal and financial frameworks. Societal readiness is assessed through digital and health literacy and existing social practices within Croatian society. Only 4.6% of medical students believe Croatia's healthcare system is ready to implement digital technologies. They perceive the highest readiness regarding digital education (63.7%) and the digital literacy of physicians (60.9%) while negatively evaluating healthcare infrastructure, financial resources, and patient literacy. The results highlight numerous aspects that must be addressed for successful implementation, many of which have been neglected in previous periods.

Conclusions: The research identifies critical aspects of the social context and presents valuable implications for the digital health transformation. Key stakeholders assess that institutional and societal readiness is not at the level required for the sustainable implementation of digital health, thus necessitating specific actions, ranging from governmental bodies and international organisations to the health system, education system, and media.

Key messages:

- It's crucial to align digital health implementation with the social & cultural context and capabilities.
- The prerequisites for successful implementation necessitate engagement across various societal domains beyond the healthcare system.

Abstract citation ID: ckae144.1193
International case studies: success and failure factors for digital transformation in healthcare

Lena Kraft

L Kraft[1]*, AL Brecher*[1]*, S Sgraja*[1]*, VE Amelung*[1]
[1]Hannover Medical School, Hanover, Germany
Contact: kraft.lena@mh-hannover.de

Background: The digitalization of healthcare systems is expected to lead to improvements in the quality and efficiency of healthcare services. Despite Germany's leading economic and technological position, the implementation and utilization of digital health solutions is lagging far behind internationally. A look at other countries shows that the digital transformation in healthcare can be successful, and that financial resources and available technologies are not the only determining factors. Rather, it is a matter of political processes, the interests of different stakeholders and the acceptance of patients and HCPs.

Methods: While the impression often arises that the selection of countries in case studies is random, eight international case studies were identified using a scientific method. A systematic and multistage process was developed to select the case studies, taking into account various relevant criteria (e.g. degree of digitalization, geography, economy). The implementation and use of various digital health tools will be examined in selected countries and healthcare systems, in which the digitalization of the healthcare system is particularly advanced. Semi-structured interviews will be conducted with experts from the international healthcare systems between fall 2024 and summer 2025. The findings will inform the development of recommendations for actions for policymakers in Germany.

Conclusions: This study aims to provide new insights into the key success and failure factors for the digital transformation of healthcare systems. Recommendations for action, tailored specifically to the German healthcare system and aimed at policymakers, are intended to support decision-makers in setting the course for a successful further transformation towards digital health.

Key messages:

- International case studies will be used to identify factors that contribute to the success or failure of digital transformation in healthcare systems.
- Based on the findings of this research, recommendations for action will be developed for policymakers in Germany to set the course for the successful further digitalization of healthcare.

Knowledge and attitudes of the Italian population on sharing health data: a cross-sectional study

Carola Toffanin

C Toffanin[1]*, G Scaioli*[1]*, G Lo Moro*[1]*, A Mara*[1]*, MG Varì*[1]*, AM Butnaru*[1]*,*
A Cataldo[1]*, M Lodin*[1]*, F Bert*[1,2]*, R Siliquini*[1,3]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Infection Control Unit, ASL TO3, Turin, Italy
[3]AOU City of Health and Science of Turin, Turin, Italy
Contact: carola.toffanin@gmail.com

Background: Healthcare digitization enhances data accessibility but faces data management and privacy challenges. The study sought to explore the Italian public's understanding and views on storing and sharing health data for treatment and research purposes, as well as factors influencing their attitudes toward health data management and sharing.

Methods: A cross-sectional questionnaire assessed socio-demographic information, knowledge about health data sharing, and attitudes toward sharing data for treatment and scientific purposes. Descriptive analyses and multivariable logistic regressions were performed to examine the associations between sociodemographic factors and knowledge/attitudes about data storage and sharing.

Results: A total of 1,389 citizens participated. Most respondents (65.4%) thought that healthcare providers could access personal health data nationwide, while 94% expressed willingness to share personal health data nationwide. A high percentage of respondents (73%) fully agreed that storing and sharing personal health-related data could improve research and quality of care. Males and younger individuals (<41 years) were likelier to have higher data-sharing knowledge (adjusted Odds Ratio [adjOR] 1.50, 95% Confidence Interval (CI) 1.03 - 2.18, and adjOR 1.99, 95% CI 1.29 - 3.08 respectively). Lower educational-level respondents exhibited lower positive attitudes towards sharing health data for treatment and research purposes (adjOR 0.18, 95% CI 0.05-0.58 for high school, and adjOR 0.11, 95% CI 0.03-0.41 for middle school or lower, compared to those with a university degree).

Conclusions: The findings offer valuable perspectives for European policymakers, healthcare practitioners, and researchers who aim to enhance data handling, foster cooperation, and maximize the benefits of health data for tailored care and scientific progress.

Key messages:

- Italian citizens show strong willingness to share health data nationwide for treatment and research, suggesting a favorable environment for collaborative healthcare initiatives.
- Sociodemographic factors such as age and education level influence attitudes towards health data sharing, stressing interventions to ensure equitable access and participation in data-driven healthcare.

Abstract citation ID: ckae144.1195
Enhancing Public Health: training an AI chatbot for complex tasks support

Giuseppe Migliara

I Aloise[1]*, G Migliara*[2]*, A Franceschetti*[1]*, A Pistollato*[1]*, C Mancini*[1]*, C Forcella*[1]*,*
V Baccolini[1]*, C De Vito*[1]
[1]Department of Public Health and Infectious Diseases, Sapienza - University of Rome, Rome, Italy
[2]Department of Life Sciences, Health, and Health Professions, Link Campus University, Rome, Italy
Contact: gmigliara@gmail.com

Background: The evolution of Large Language Models (LLMs) such as GPT-4, Gemini, and Copilot has transformed the field of Natural Language Processing, demonstrating human-level capabilities and potential applications in Public Health. Here, we report on the training of a chatbot model based on GPT-4 designed to assist operators with relevant and complex public health tasks.

Methods: A scoping review of existing studies on the application of LLMs in Public Health settings was conducted to understand the landscape and identify gaps in their current implementations. We then proceeded to analyse the necessary skills and competencies required for public health professionals to adequately instruct the model on required tasks. Finally, we selected the Italian regulations and guidelines with the greatest relevance in the public health field to provide the knowledge base to the model.

Results: The review revealed no relevant documents on the use of LLMs in areas related to Public Health. Skills and competencies were retrieved from the Guidelines of the Italian Society of Hygiene for Public Health operators and used to instruct the model on how to address public health tasks. As for the knowledge base, we retrieved 25 documents regulating specific areas of the public health field, such as vaccinations, hygiene and safety at work, infection prevention, and school hygiene. Such documents were used to train the model, after formatting them appropriately.

Conclusions: Despite challenges with non-standardized and technically complex documentation, preliminary testing of our model has shown its versatility and utility in supporting daily public health operations. A validation phase is under definition and will involve a DELPHI process, in which products of the custom GPT model will be evaluated by a panel of public health operators to evaluate its performance in real-world settings, ensuring compliance with national health regulations.

Key messages:

- Training a GPT-4-based chatbot to support complex tasks in Public Health, tailored by relevant national guidelines.
- Our custom model, informed by public health guidelines, showed potential in preliminary tests.

Abstract citation ID: ckae144.1196

Discrepancies in breast cancer screening and hypothesis of artificial intelligence support

Maria Teresa Riccardi

MT Riccardi[1], V Rosca[2], F Forestiero[3], T Rudniki[3], A Testa[1], G Cerone[1], E Rossi[1], MO Trinito[1]
[1]Local Health Authority Roma 2, Rome, Italy
[2]Tor Vergata University, Rome, Italy
[3]Sapienza University, Rome, Italy
Contact: mt.riccardi@gmail.com

In Italy,the National Breast Screening Programme offers mammography as the 1st level examination, blindly assessed by two radiologists.In the context of continuous quality control,discrepancies in the assessment of mammograms between the 1st and 2nd reader have been studied,focusing on the most significant ones.The aims of the present study are:to evaluate the outcome of women sent to the 2nd level of review;to evaluate the possibility of using artificial intelligence (AI) software to assist radiologists in case of discrepancies. In the Local Health Authority Roma2,radiologists use a standardised classification that rates radiographs on a five-level scale from R1 to R5:R1=no abnormalities,R2=benign findings,R3=equivocal findings,R4=suspected cancer,R5=strongly suspected cancer.Data were extracted from the mammograms performed in 2023 that showed discrepancies (R1/R2 vs. R4/R5).2nd level mammography≥R4 and 2nd level histology≥B4 were considered positive. For the second aim,"IA Lunit INSIGHT" software was used to create specific target groups using the following cut-offs:G1<10%, G2 11-29%; G3 30-59%; G4 60-85%; G5 86-100%(groups ≥G3 were considered positive). Of the 36,339 mammograms,524(1.5%) were discordant:347 (66.2%) were considered suspicious by the second radiologist.49 (9.4%) were confirmed positive by Level II mammography and 23 (4.4%) reported histology≥B4. The AI red a random sample of 247 mammograms and classified 34 women as positive (1 G5, 6 G4, 9 G3), of whom 11 (4.5%) were confirmed positive by Level II mammography and 6 (2.4%) were histologically positive. Of the negative women, 2 had histology≥B4. Discrepancies may be one of the factors leading to inappropriate referral to second level investigation. In such cases, the use of AI may improve the appropriateness of further investigation, although this hypothesis needs to be tested in larger numbers, with additional comparisons with experienced radiologists and consideration of retraining.

Key messages:

- Continuous monitoring in cancer screening programs are vital to assure a sustainability of the process.
- Artificial Intelligence software are promising in aiding health care professionals in case of discrepancies.

Abstract citation ID: ckae144.1197

Evaluating Accuracy of AI-Generated Travel Vaccine Recommendations: GPTs in Public Health

Marín Rodríguez

JA Marin-Rodriguez[1], M Rodriguez[1], L Leyva[1], C Torralba[1], F Agustin[1], F Enriquez[1]
[1]Preventive Medicine and Public Health, Virgen de las Nieves, Granada, Spain
Contact: jmarinrq@gmail.com

Introduction: Artificial intelligence (AI), particularly generative pre-trained transformers (GPTs), holds promise for enhancing public health strategies like travel vaccine recommendations. This pilot study evaluated GPTs' accuracy in delivering tailored vaccine advisories compared to standards set by public health professionals. Integrating AI's data analysis capabilities into healthcare decision-making could improve recommendation precision and personalization.

Methods: This retrospective study analyzed GPT travel vaccine recommendation accuracy against a gold standard from health professionals for 90 travelers visiting various countries. Sociodemographic data and vaccine recommendation outcomes were examined. Accuracy assessments were stratified by age, sex, country of travel, duration of travel, type of travel, and specific vaccines.

Results: Preliminary results showed an 77.43% overall accuracy across all vaccine recommendations. Specific vaccine accuracies varied, with 97.78% alignment for hepatitis A, 93.51% for typhoid fever and 89.36% for rabies. However, lower accuracies were observed for cholera (33.33%) and encephalitis (56.25%). Moderate accuracies were noted for yellow fever (75%), 74.07% for malaria prophylaxis, diphtheria and tetanus (63.33%), and dengue (57.58%). Stratified analyses are expected to provide more realistic results and highlight discrepancies in certain groups.

Conclusions: This pilot demonstrates GPTs can be a valuable tool for supporting international vaccination professionals, but they are still not a substitute for these professionals, achieving 77.43% overall accuracy. Recommendations include: a) Educate health professionals in the use of GPTs, b) Developing guidelines for ethical and accurate AI use in public health, c) Using AI to strengthen surveillance and response systems. Combining AI with traditional strategies aims to optimize international traveler health outcomes.

Key messages:

- Using artificial intelligence can optimize and facilitate the task of clinical consultancy in traveler's advice.
- It is necessary to establish guidelines for AI use to ensure ethical and accurate applications.

Abstract citation ID: ckae144.1198

Application of artificial intelligence to study the causality in public health: a systematic review

Martina Barchitta

C La Mastra[1], M Barchitta[1], A Maugeri[1], A Agodi[1]
[1]Department GF Ingrassia, University of Catania, Catania, Italy
Contact: mbarchitta@unict.it

Introduction: In epidemiology, establishing causation requires meeting rigorous criteria beyond mere association. Traditional methodologies often struggle to provide definitive causal conclusions due to confounding variables. However, leveraging artificial

Intelligence (AI) and machine Learning (ML) offers a promising solution by modeling complex interactions among relevant factors. This systematic review explores the AI techniques utilized to uncover causal relationships in public health applications.

Methods: A literature search was conducted in Pubmed, Web of Science, and Scopus, employing the following search strategy: (Causalit*[Title/abstract] OR Causation*[Title/abstract] OR Causal [Title/abstract]) AND ('Machine Learning'[Title/abstract] OR "Deep Learning" [Title/abstract] OR 'Artificial Intelligence' [Title/abstract] OR Algorithm* [Title/abstract]). The search aimed to identify studies encompassing causal inference techniques utilizing ML and AI methodologies in public health.

Results: From a total of 28,230 articles published up to August 2023, after removing duplicates (11,158) and articles that did not meet the inclusion criteria (16,168 post title/abstract screening, and 856 post full-text screening), the systematic review included 48 articles. Bayesian additive regression trees, Bayesian network models, causal forests analysis, and graphical causal models emerged as the prevailing causal methodologies. AI-driven causal methodologies have been investigated across various domains within public health, encompassing disease prediction, evaluation of treatment efficacy, identification of risk factors, analysis of health behaviors, precision Public Health initiatives, and environmental health assessment.

Discussion: While our systematic review affirms the potential of AI-driven causal approaches across several public health domains, further research is warranted before these emerging techniques can be effectively integrated into real settings.

Key messages:

- In epidemiology, establishing causation requires meeting rigorous criteria beyond mere association and traditional methodologies often struggle to provide definitive causal conclusions.
- This systematic review explores the AI techniques utilized to uncover causal relationships in public health applications.

Abstract citation ID: ckae144.1199
Exploring Meditron-7b performance on a small-scale purpose made dataset in human nutrition queries

Nicolò Scarsi

N Scarsi[1], *B Büsser*[2]
[1]Section of Hygiene, Department of Life Sciences, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Security Research Department, IBM Research Europe, Rüschlikon, Zürich, Switzerland
Contact: nicolo.scarsi@unicatt.it

The interest in Large Languages Models (LLMs) has been rapidly evolving over the last years, boosting concerns about their potential to improve the efficiency and effectiveness of clinical, educational and research work in medicine. In this study, we aimed to test the performance of MEDITRON, a recently released suite of open-source LLMs with 7B parameters adapted to the medical domain, on a small sample of human nutrition queries. To facilitate our assessment, we curated a specialized dataset comprising a diverse range of human nutrition-related queries, which have been manually collected from various medical databases and nutrition exams. The dataset was adapted for the scope of our analysis to encompass variations in language complexity, query types, and semantic nuances commonly encountered in real-world settings. Additionally, to ensure a standardized and clinically relevant context for our evaluations, we engineered a specialized prompt designed to mimic interactions with a highly esteemed physician specializing in nutrition, food science, and diet-related disorders. The prompt guided the generation of nutrition-related queries in a structured format, enabling MEDITRON to provide responses consistent with the latest advancements in medical research. Our preliminary findings revealed promising capabilities of MEDITRON in understanding medical language, providing contextually appropriate responses to several human nutrition related questions. Through this study, we add valuable insights to the ongoing discussion around the deployment of LLMs in public health, highlighting their potential to improve access to essential human nutrition literacy.

Key messages:

- Design of LLMs tools holds the potential to improve healthcare in clinical, research and education applications.
- Further evidence is needed to foster their actual integration in real world settings.

Abstract citation ID: ckae144.1200
Different approaches to regulate digital health applications in seven European countries

Lea Koisser

M Riedel[1], *L Koisser*[1], *T Czypionka*[1]
[1]Health Economics and Health Policy, IHS, Vienna, Austria
Contact: koisser@ihs.ac.at

Background: Demographic ageing, shortages in health workforce and increased use of digital tools in daily life kindle decision makers' interest to utilize digital health applications (DHA). While there are several reviews that provide an overview across remuneration frameworks, no synthesis between additional regulatory aspects and frequency of remuneration approval has been conducted.

Methods: European countries with either strong status in digital health in general or regulation for health apps in particular were chosen for analysis (BE, DK, DE, EE, EN, FR, NL). Country specific information was collected from scientific and grey literature, legal and stakeholder webpages. Semi-structured interviews were conducted with country experts via video call or e-mail and analyzed using Mayring's structured, qualitative content analysis.

Preliminary results: We find three approaches concerning DHT-definitions: For BE, DE, FR, specific regulations define national remuneration requirements. EN and NL define only minimum requirements while decentralized payors make financing decisions. DK and EE fit DHTs into existing financing schemes. Among countries with a national financing framework, DE achieved the largest number of approvals, followed by FR, while BE has not yet issued a (lasting) financing approval. Evaluation requirements focus on clinical and economic outcomes, largely ignoring non-clinical improvements for patients.

Conclusions: The German regulation stands out with a peculiar definition that might help clarify evaluation criteria, increase the number of financing approvals but also empower patients while reducing the role of health workforce in their application. BE and NL regulations necessitate involvement of health workers, thus addressing structurally different applications.

Key messages:

- Drawing lessons for DHT regulations across countries needs to address differences in national definitions and evaluation criteria.
- A standardization system for DHT may help to speed utilization of effective tools and clarify evaluation requirements.

Abstract citation ID: ckae144.1201
Digital Health Interventions' Impact on Health Literacy: A Systematic Review

In the digital era, health literacy is crucial for informed health decisions and outcomes. This systematic review evaluates the effectiveness of digital health interventions (DHIs) in enhancing health literacy, as defined by the World Health Organization. We included a variety of studies, such as cross-sectional studies, surveys, and case reports, focusing on interventions like mobile health apps, online platforms, and telehealth services. Our search, adhering to PRISMA guidelines, spanned databases like PubMed, IEEE, and ACM, covering publications from 2013 to 2023. From 1,029 initial articles, 58 met our inclusion criteria after rigorous screening and duplicates removal. Our findings highlight that DHIs, including multimedia tools and remote sessions, significantly bolster health literacy across diverse populations. However, the impact varies due to the digital divide, influenced by factors like age and socioeconomic status. This review underscores the potential of DHIs in public health and the necessity to address accessibility to reduce health disparities. The full synthesis of data and methodological details will be discussed in the presentation, aiming to guide future digital health strategies and policies.

Key messages:

- Digital Interventions Enhance Health Literacy Across Diverse Populations.
- Addressing the Digital Divide to Ensure Equitable Access to Health Benefits.

Abstract citation ID: ckae144.1202
Multi-objective Symbolic Regression for Clinician-in-the-loop Machine Learning algorithms

Davide Ferrari

D Ferrari[1], Y Wang[1], J Edgeworth[2], V Curcin[1]
[1]Department of Population Health Sciences, King's College London, London, UK
[2]Department of Infections, Guy's and St. Thomas' NHS Foundation Trust, London, UK
Contact: davide.ferrari@kcl.ac.uk

Background: The power of machine learning (ML) in medicine is further enhanced by input from clinical experts with detailed knowledge of phenomena explored and the organization in which the ML models will be deployed. This input is needed not only in the problem conception and evaluation, but also in the training itself using the clinician-in-the-loop approach. We explore the applicability of such an approach to Multi-objective Symbolic Regression (MOSR) and compare it with state-of-the-art methodologies.

Methods: This is a retrospective study based on the admission data of 22576 patients routinely collected by the intensive care units (ICU) of Guy's and St. Thomas' NHS Foundation Trust in central London between April 1st, 2008, and December 31st, 2022. Patient-level data was used, including blood tests, urine tests, medical history, signs, symptoms, and common clinical scores. The outcome was modelled as a binary classification; four experiments were executed predicting mortality at 7 days (4.5% of patients), 30 days (10.2%), 6 months (17.4%) and 12 months (21.2%). A random train-test split of 80/20% ratio was performed. Clinician-in-the-loop approach used a Multi-objective Symbolic Regression algorithm bespoke designed to also optimize for the F1-score.

Results: For all four experiments, MOSR outperformed all other available ML algorithms providing significantly higher F1-scores and AUC. This makes MOSR the most competitive algorithm, particularly for imbalanced datasets such as typical ICU admission data.

Conclusions: We have demonstrated how ML algorithms designed for a clinician-in-the-loop approach outperform standard off-the-shelf alternatives and note the role of the application environment and clinical knowledge in the training itself enhancing the model performance. We therefore champion the adoption of approaches that, like MOSR, enable clinical input also in shaping the training behaviour.

Key messages:

- The input of clinical knowledge and understanding of the application domain dynamics are crucial for ML development in healthcare.
- In Health Data Science we need ML algorithms like MOSR capable of receiving clinical input also in shaping the training behaviour.

Abstract citation ID: ckae144.1203
AI-Enhanced Allergy Diagnostics: Streamlining Healthcare and Reducing Costs

Paweł Łukasiewicz

PJ Łukasiewicz[1,2]
[1]Health Digitisation Centre, Kozminski University, Warsaw, Poland
[2]R&D Department, Milton Essex SA, Warsaw, Poland
Contact: plukasiewicz@kozminski.edu.pl

Issue/Problem: WHO projects a shortfall of 10 million health workers by 2030. One area particularly lacking technological support is allergy diagnostics. The World Allergy Organization recognizes skin tests as the gold standard for allergy diagnostics, yet these tests are still manually assessed. General practitioners lack the time and tools, leading them to focus on treating the symptoms without addressing the causes.

Description of the problem: Symptomatic treatment of allergy can lead to the development of asthma in 30-40% of patients, increasing healthcare costs and causing lost productivity. The shortage of allergists further exacerbates this issue in many countries.

Results: Research conducted by the Military Institute of Medicine in Warsaw, in collaboration with a company producing automated allergy testing systems, explored a solution for allergy diagnostics, analyzing the entire process from the patient's initial visit to desensitization therapy. The solution uses AI algorithms to reusable existing patient data and analyze patient history, correlate symptoms, medications, and allergen exposure, streamlining diagnostics and treatment. Patients at high risk undergo a computer-assisted interview to determine allergen panels. The only manual step is applying allergens to the skin, after which AI performs the reading and diagnosis.

Clinical trials involving around 300 patients demonstrated high sensitivity and specificity, along with significant time savings for allergists and other medical staff, averaging 40 minutes per patient. The HTA evidence base will be ready by the end of this year.

Lessons: The integration of this AI-supported diagnostic method can eliminate bottlenecks in allergy diagnostics, improving health outcomes and reducing healthcare costs. However, its effectiveness depends on having at least few years of patient treatment data available. Without access to patient data, the method can be used in part to objectify PRICK test readings.

Key messages:

- AI-supported diagnostics streamline allergy testing, reducing time and costs in the healthcare system.
- The most accurate technique currently available for the automated reading of test results is that which evaluates the response to an allergen in the dermis in two spectra.

Abstract citation ID: ckae144.1204
Investigating the impact of the WHO Hive platform for health emergencies preparedness and response

Brian Yau

M Farhat[1], L Latinovic[1], K von Harbou[1], N Emiroglu[1], F Hang[1], B Yau[1], N Kovačev[2]
[1]Community Readiness and Resilience Unit/Department, WHO, Geneva, Switzerland
[2]HTEC, Serbia, Serbia
Contact: byau@who.int

Background: Recent global health emergencies, such as the COVID-19 pandemic, showed there is a growing need for enhanced collaboration and knowledge sharing across global health communities. The WHO Hive platform provides a centralized hub for public health experts to connect, share and access valuable resources. This study aims to analyze the impact of the Hive following its launch of 4 tools within the Hive to enhance engagement and collaboration: Community space, Chat and discussion forum, Video conferencing, Hive drive document repository. The study will explore further technological and structural needs required to increase its usage in health emergency preparedness and response.

Methods: This study employs a structured survey for users of the Hive that will be anonymized and stratified by non-identifying data such as professional roles and geographic locations to highlight trends and patterns within specific subgroups. This approach ensures that the analysis is representative of the diverse user base on the Hive platform, with currently over 700 public health experts from more than 200 organizations across 105 countries.

Expected Outcomes: The study is expected to provide a comprehensive evaluation of Hive's operational effectiveness in enhancing community collaboration, engagement, and knowledge-sharing, and highlighting its strengths and areas for improvement. The results will help inform future development to enhance collaboration and engagement.

Conclusions: The WHO Hive offers a unique value proposition as a platform developed by a trusted global health authority, enhancing credibility and fostering greater participation between health professionals. Feedback from the users is crucial to optimize future development to sustain it as a resource for health emergencies preparedness, readiness and response.

Key messages:

- Digital tools for stronger health emergency preparedness and response to enhance collaboration and engagement.
- Highlighting key areas for digital integration to strengthen health emergency preparedness and response.

Abstract citation ID: ckae144.1205
GPT models classify free text from emergency department accesses in children with medical complexity

Gloria Brigiari

G Brigiari[1], M Franzoi[1], C La Piana[2], A Zanin[3], F Benini[3], D Gregori[1]
[1]UBEP, University of Padua, Padua, Italy
[2]University of Padua, Padua, Italy
[3]Palliative Care and Pain Service, Department, University of Padua, Padua, Italy
Contact: gloria.brigiari@ubep.unipd.it

Background: Emergency Department (ED) management software often collects clinical information as free text, but its unstructured nature limits routine use. While Machine Learning (ML) techniques have been employed to classify such information, they demand substantial data and computational resources. GPT-based models, using direct text prompts, offer a solution without requiring retraining, potentially simplifying clinical practice.

Aims: To assess OpenAI GPT's performance in automating data extraction from ED medical records of complex pediatric patients.

Methods: Electronic admission records of children and young adults referring to the pediatric ED of Padova University Hospital (2007-2023) were analyzed. Principal variables of interest were discharge diagnosis, reason for ED access, required medical procedures, color code at triage, color code at discharge/hospitalization, outcome of the access. GPT-4 classification, via OpenAI API, was compared with manual classification by an expert pediatrician on sample of 791 records.

Results: Preliminary results of this study analyzed 107 records, showing a correct classification of discharge diagnosis in 95% of records. The reason for access to the ED was correctly identified in 97% of cases, while outcome of admission and color code, both at triage and discharge/hospitalization, were correctly classified in all given cases. Misclassification occurred mainly in cases where classification made by the model was incomplete (e.g., in the case of a trauma, abbreviated site of lesion was not identified by the model).

Conclusions: GPT-based models demonstrate feasibility, accuracy, and efficiency in transforming unstructured data into structured formats. Ultimately, GPT-based models could provide aid to the medical personnel in decision-making processes.

Key messages:

- Emergency departments often collect clinical data in unstructured free text format, resulting in usability limitations.
- GPT-powered models efficiently convert unstructured data to structured formats, offering potential support for medical decision-making.

Abstract citation ID: ckae144.1206
National implementation of telehealth in Denmark: A case study

Stina Bollerup

S Bollerup[1,2], LG Jensen[1], CB Jacobsen[3], CP Nielsen[1,2]
[1]DEFACTUM, Public Health Research, Central Denmark Region, Aarhus, Denmark
[2]Department of Public Health, Aarhus University, Aarhus, Denmark
[3]Department of Political Science, Aarhus University, Aarhus, Denmark
Contact: stibol@rm.dk

Background: With a growing number of chronic patients and a shortage of healthcare professionals, modern health systems face mounting economic pressures. Telehealth has emerged as a promising solution to address these challenges and is considered a critical component of future healthcare provision. However, implementing telehealth on a large scale is complex and challenging. To fully grasp these challenges, it is essential to look beyond the technology and delve into the processes and actors involved in its implementation. Actors on a political-administrative level are pivotal in large-scale implementation, yet this level remains understudied. Thus, this study investigates the dynamics of large-scale implementation at a political-administrative level through a case study of the national implementation of TeleCOPD in Denmark - a home-monitoring intervention targeting patients with Chronic Obstructive Pulmonary Disease (COPD).

Methods: An in-depth qualitative study of the implementation process at the political-administrative level was undertaken. Data consisted of comprehensive documentary material, including policy documents and meeting minutes and 12 semi-structured interviews with 16 key stakeholders across all levels of the implementation process. Data was analysed in accordance with thematic analysis using an abductive strategy.

Results: The analysis shows that large-scale implementation of telehealth is a profoundly complex process, necessitating the collaboration of various stakeholders across organisational hierarchies. Substantial translational work is required at the political-administrative level to implement telehealth across diverse organisational contexts. Moreover, understanding the role of context in this translation process is essential.

Conclusions: This study generates valuable knowledge about large-scale implementation of telemedicine in addition to insights into the role of the political-administrative level in the implementation process.

Key messages:

- Implementing telehealth nationally involves intricate translation processes at multiple levels.
- Balancing local adjustments with degrees of fidelity is crucial in large-scale implementation.

Abstract citation ID: ckae144.1207
Inferring diagnoses from prescription data: a machine-learning approach

Tiago Miranda

AS Pinto[1], L Perfeito[1], T Miranda[1,2], S Mesquita[1,3], N Pereira[1], J Gonçalves-Sá[1]
[1]Social Physics and Complexity Lab - SPAC, LIP - Laboratório de Instrumentação e Física Experimental de Part, Lisbon, Portugal
[2]Instituto Superior Técnico, Lisbon, Portugal
[3]Nova Medical School, Lisbon, Portugal
Contact: tiagomiranda@lip.pt

Estimating disease prevalence is a fundamental while challenging public-health goal: in the absence of solid diagnostic data, it typically requires expensive and time intensive studies. Analyzing existing medical records is an alternative, complementary approach. In particular, prescription records offer a glimpse into the health status of populations, prescribing patterns, and operational dynamics. We asked whether these could be used to infer diagnostics and, therefore, estimate disease prevalence. We used the Portuguese electronic medical prescriptions dataset (ADD NUMBERS) and trained a machine learning model that captures the probability that specific drugs are prescribed for the same or related medical conditions. We 1) constructed a manually-curated dataset of diseases and associated medications; 2) used this dataset to train embeddings models; 3) tested these models against human-classified data; 4) used the trained/tested model to uncover comorbidities associated with a) antibiotic prescription (to validate the model), and b) the impact of COVID-19 in prescription patterns of chronic-diseases. The model was able to accurately identify drugs used for targeting ten specific diseases, with few false positives and false negatives. Our analysis showed that the COVID-19 pandemic had almost no effect on the number of prescriptions for some chronic diseases (such as diabetes and depression), but, importantly, had a strong impact on the number of new diagnoses, with new users of diabetes medication in 2019 dropping by more than 16.8% in 2020. Medical prescriptions offer a promising tool to quickly assess disease prevalence, underdiagnosis, and allow a broad overview of the medical status of the population, especially in the face of health emergencies that strongly pressure the medical system.

Key messages:

- We propose a new approach to infer diagnostics from prescription data with several promising applications.
- We propose a new approach to infer diagnostics from prescription data with several promising applications.

Abstract citation ID: ckae144.1208
Clustering Portuguese municipalities based on population health indicators

Background: The large number of publicly available health-related indicators poses challenges in health planning to policymakers. Identifying patterns among municipalities may assist these processes, by grouping similar contexts and pointing out relevant differences among neighbouring locations. The aim of this work was to define clusters of municipalities based on health-related indicators.
Methods: All health-related indicators available at municipality level for the year 2021 were obtained from the Portuguese National Statistics Office website. Missing values were imputed with the closest available year or excluded. Indicators were standardized and K-means clustering was applied. Elbow criterion was used to select the optimal number of clusters. Sensitivity analysis was performed with a priori exclusion of indicators less directly associated with health outcomes.
Results: The clustering analysis revealed five distinct clusters of municipalities. Clusters were associated with specific socio-demographic patterns, providing insights into common health challenges and strengths within each group. Interestingly, geographic profiles emerged (e.g. coastal vs inland), despite no geographic information being specifically provided. One outlier municipality was identified (Lisbon), highlighting a need for special consideration.
Conclusions: Clustering techniques provide a data-driven approach to inform public health planning. Our findings show previously unrecognized patterns and relationships between municipalities. Using these clusters, policymakers may implement interventions based on what has been proven to work in similar contexts, enhance collaboration opportunities and promote a tailored policy development, contributing to an overall improvement of public health outcomes.

Key messages:

- Clustering machine learning techniques provide a data-driven approach to inform public health planning.
- Identifying comparable municipalities based on health-related indicators allows targeted public health interventions.

Abstract citation ID: ckae144.1209
AI-Powered Post-Discharge Monitoring to Prevent Patients Readmissions and Reduce Workforce Burden

Matilde Santos

M Santos[4], M Peyroteo[1,2], L Lapão[1,2,3]
[1]UNIDEMI, NOVA School of Science & Technology, Caparica, Portugal

[3]WHO Collaborating Center on Health Workforce, IHMT, Lisbon, Portugal
[4]Physics Department, NOVA School of Science & Technology, Caparica, Portugal
Contact: mma.santos@campus.fct.unl.pt

Background: Patient readmission poses a significant burden on healthcare systems, straining resources, negatively impacting patient treatment, and it is often a Public Health problem. Traditional post-discharge follow-up methods, such as phone calls, often lack efficiency and personalization. Artificial intelligence (e.g., Machine Learning (ML)) offers a transformative approach that can potentially improve post-discharge care.
Methods: This scoping review aimed to map existing research on AI-powered solutions for post-discharge monitoring, focusing on their application in risk stratification and their potential for reducing hospital readmissions within a public health framework. Following PRISMA-ScR guidelines, a search was conducted across four databases using keywords related to AI, post-discharge, and risk stratification.
Results: Studies published between 2018 and January 2024 were included if they described the development and application of an

ML model in a post-discharge setting for risk stratification. Sixteen studies met the inclusion criteria. Tree-based algorithms, particularly XGBoost, were the predominant ML approach, with promising performance metrics for readmission risk prediction.

Conclusions: However, limitations were identified, including restricted generalizability due to data source limitations and a lack of real-time implementation in many studies. This review highlights the potential of AI in post-discharge monitoring, particularly the use of ML for risk stratification, as a promising tool for public health contact tracing. While challenges remain regarding generalizability and real-world implementation, the findings suggest AI holds immense promise for improving post-discharge care, potentially reducing readmissions, and optimizing resource allocation. Future research with broader datasets and real-time applications can further solidify the role of AI in revolutionizing post-discharge care within public health systems.

Key messages:

- This study shows the potential of AI and risk stratification in post-discharge monitoring, improving public health outcomes by reducing hospital readmissions and optimizing the healthcare workforce.
- This review highlights the value of AI in public health, particularly for improving post-discharge care through effective prediction of high-risk readmissions.

Abstract citation ID: ckae144.1210
Impact of in-silico technologies in the development of high-risk medical devices on healthcare

David Roesler

D Roesler[1], *T Czypionka*[1,2], *S Eisenberg*[1], *M Kraus*[1], *M Reiss*[1], *C Zech*[1]
[1]Institute for Advanced Studies, Vienna, Austria
[2]LSE, London, UK
Contact: david-roesler@outlook.com

This study examines the impact of in-silico technologies (IST), such as virtual cohorts and digital twins, on the development of high-risk medical devices within the healthcare sector. An iterative empirical approach combining a literature review, exploratory and in-depth interviews with stakeholders from academia, industry, regulators, healthcare professionals, and focus groups with patients across Europe, Japan, and the USA was employed to gain insight into the implications of IST on healthcare. The findings indicate that IST can reduce the time to market for medical devices, thereby facilitating faster, broader, and more equitable access for patients. The implementation of extensive early testing, optimized study designs and increased sample sizes in trials can facilitate the achievement of enhanced safety. The early identification of adverse effects can enhance the safety of medical devices and improve patient outcomes. Furthermore, IST may facilitate the inclusion of underrepresented groups, such as children, in clinical trials, thereby enhancing their representation in medical research. The reduction in costs associated with IST may facilitate innovation cycles. However, the impact on prices is contingent on competition. Furthermore, IST have the potential to reduce the need for animal testing. Nevertheless, several uncertainties and potential adverse effects have been identified. Physician training on new devices remains a bottleneck, which may limit the benefits of new products. Despite the advancements, a complete replacement of traditional clinical and preclinical trials with IST is not seen to be feasible. From a policy perspective, it is crucial to promote regulatory clarity by providing guidance for the usage of IST, to offer incentives for the adoption of IST, and to foster competition. These findings demonstrate the multifaceted potential benefits and challenges of IST, including enhanced safety, accessibility, and innovation in healthcare.

Key messages:

- In-silico technologies can reduce time-to market of medical devices up medical device and improve safety for patients.
- Challenges like physician training and regulatory guidance must be addressed to fully realize benefits of in silico technologies.

Abstract citation ID: ckae144.1211
Using electronic health records in assessing the prevalence of hypertension in Kyrgyzstan

Aidana Arykova

A Arykova[1,2,4], *T Laatikainen*[3], *M Borubaev*[4], *M Duishenalieva*[2], *A Altymysheva*[5], *A Polupanov*[2]
[1]Kyrgyz-Russian Slavic University, Bishkek, Kyrgyzstan
[2]National Center of Cardiology and Internal Medicine n.a. M. Mirrakhimov, Bishkek, Kyrgyzstan
[3]Institute of Public Health and Clinical Nutrition, Kuopio, Finland
[4]E-health Center under Ministry of Health of the Kyrgyz Republic, Bishkek, Kyrgyzstan
[5]WHO Country Office of Kyrgyzstan, Bishkek, Kyrgyzstan
Contact: arykova.aidana98@gmail.com

Background: Non-communicable diseases are an increasing challenge in Kyrgyzstan as well as in other parts of Central Asia. However, there is very little epidemiological data on disease burden in the country. The development of electronic health records in primary health care provides an opportunity to assess the disease incidence and prevalence among patient population.

Methods: All patients with hypertension (HT) diagnoses (ICD-10 I10-I15) were identified from electronic health records used in primary health care in Kyrgyzstan from years 2021, 2022 and 2023 from all 7 regions and Bishkek and Osh cities ($n = 132621$-152743). Each year, all patients diagnosed with HT during that year or in previous years were included, while those who had passed away were excluded. The incidence and prevalence of patients was calculated using as denominator both the patients who had visited the services as well as registered patients.

Results: The prevalence of patients with hypertension calculated using patients with service use as denominator varied by region between 10.2% to 14.0% and was pretty stable during the observed period. The prevalence was the lowest in Chui region and the highest in Bishkek city. When the prevalence was calculated using the registered patient population the prevalence was only between 1.5% to 3.1%.

Conclusions: The observed prevalences were notably lower compared with data from WHO Steps surveys, which have reported a hypertension prevalence more than 40% among individuals aged 25 to 64. It is known that only approximately 25% of the population in Kyrgyzstan utilize primary healthcare services, with maternity care comprising the largest portion. This factor, coupled with cases that go undiagnosed, could potentially account for the observed low prevalence in electronic patient data. However, the electronic patient records provide useful information on diagnostics and disease burden in the country that can be used in developing the services.

Key messages:

- Electronic health records have developed quickly in Kyrgyzstan and enable extraction of patient data from primary health care.
- The low use of primary health care services complicates the use of register data in assessing the disease prevalences.

Abstract citation ID: ckae144.1212
Developing an mpox risk assessment matrix for social listening and infodemic insights generation

Sandra Machiri

A Pereira Ibrahim[1], *S Machiri*[1], *A Ishizumi*[2], *T Nguyen*[2], *L Latinovic*[1], *S Bezbaruah*[1], *T Purnat*[2], *K Von Harbou*[1], *N Emiroglu*[1], *S Varaidzo Machiri*[1]
[1]Country Readiness and Strengthening, WHO, Geneva, Switzerland
[2]Epidemic and Pandemic Preparedness and Prevention, WHO, Geneva, Switzerland
Contact: machiris@who.int

Issue: Any effective response to an infodemic, requires prioritizing public health response on identified narrative themes that pose highest risk to health and well-being of populations. High-risk narratives often require more swift and far-reaching action and low-risk narratives require little or no response.

Description of the problem: Different countries are assigned different levels of risk to specific narratives or concerns, recognizing that for some issues there may be a large gap between the true public health threat and what is generating lots of conversations, concerns and press coverage that indicate a high degree of risk perception that may be unwarranted. WHO developed a risk matrix to apply to global analysis of questions, concerns and narratives about mpox, which resulted in biweekly infodemic intelligence reports that risk-assessed identified infodemic themes and corresponding recommendations for action.

Results: Risk assessment criteria were defined in the context of WHO's global infodemic insights analysis for low, medium and high risk and positive sentiment in mpox global outbreak context before conducting the integrated analysis so that insights were reproducible and infodemic response actions were prioritized. This implemented the WHO/UNICEF training manual on 6 steps to produce an infodemic insights report, which includes tools on how to develop and apply a risk matrix for a specific public health question of concern and apply it in analysis.

Lessons: The approach resulted in rapid, systematic, reproducible and evidence-driven decision-making to respond to the infodemic accompanying the mpox global outbreak. Risk matrices must be adapted to the context of the public health event and the mandate of the health authority taking action. An mpox risk matrix for narratives included adaptation to reflect high-risk from stigmatizing narratives, as well as narratives circulating around or within LGBTQI+ communities.

Key messages:

- A risk matrix must be developed and adapted to the context of each health emergency and level of health authority action.
- Prioritization for rapid infodemic response based on a risk assessment is that it facilitates more effective response in a health emergency.

Abstract citation ID: ckae144.1213
Development of an assessment process for digital medical devices in Austria

Anja Laschkolnig

A Laschkolnig[1], E Tanriverdi[1], D Dick[1], A Herzog[2]
[1]IPED, Austrian Public Health Institute, Vienna, Austria
[2]AGES, Vienna, Austria
Contact: Laschkolnig@yahoo.de

Issue/problem: Digital medical devices have experienced a rapid development in recent years and are playing an increasingly important role in healthcare. These devices offer numerous benefits and can improve patient care. However, despite their potential benefits, the use of digital medical devices also poses risks and regulation from governmental side is needed from a Public Health Perspective. This is why some countries already implemented assessment processes for Digital Medical Devices (e.g. Germany and France) leading to the question how such a process could be established in Austria too.

Description of the problem: While digital medical devices must fulfil requirements set by the medical device regulation to enter market, several other aspects are of interests when offering digital medical devices in routine care. These include e.g. medical effectiveness, data security and interoperability. The objective of the ongoing pilot project is to develop a process for the assessment of quality-assured digital medical devices in Austria in 2024. For this, a combination of literature research, interviews and workshops with relevant stakeholders is used in order to gain all necessary information. Process and assessment criteria will be tested and revised in a pilot phase with several digital medical devices.

Results: At the end of the project, an assessment framework as well as a potential evaluation process will be designed in accordance with relevant stakeholders. Moreover, legals aspects and the potential integration into the austrian health telematics infrastrucutur will be assessed. This will form a basis for implementing digital medical devices within the austrian healthcare system.

Key messages:

- The result of this project aims to build the basis for implementing an evaluation process for digital medical devices in Austria.
- The establishment of an evaluation process for digital medical devices supports the integration of quality assured digital medical devices in healthcare.

[3]NOVA National School of Public Health, CHRC, NOVA University Lisbon, Lisbon
Contact: Susana.Viegas@ensp.unl.pt

In poultry production environments, particulate matter (PM) is considered one of the harmful air pollutants [2]. Considering potential biological pathogens, the genus Aspergillus in particular, Aspergillus fumigatus, is a widely recognized human and animal pathogen [3]. Hot-humid farm environments could contribute to the proliferation of these fungi [4]. Therefore, poultry production workers, besides animals [4], may be at a higher risk of inhaling fungi spores [4,5]. This study aimed to determine particulate matter (PM) contamination and analyze the prevalence of Aspergillus section Fumigati in air samples from poultry pavilions. Indoor and outdoor air samples were taken in the 1st, 2nd and 3rd weeks of birds growth cycle ($n = 58$). Air was collected through the impaction method (MAS-100) onto polycarbonate filters, set at 100 L/min, for 5 min. Followed by DNA extraction, and real-time PCR detection of Aspergillus section Fumigati. For PM evaluation, portable direct-reading equipment (Lighthouse, model 3016 IAQ) was used. Particle concentrations were measured ($n = 67$) at five distinct fractions during 5 min. Considering particles fractions, PM10 and PM5 where prevalent in 1st (58% PM10; 28% PM5), 2nd (63% PM10; 26% PM5) and 3rd (64% PM10; 25% PM5) weeks. These results evidence that coarse particles (between 2.5 and 10 µm) are the most relevant PM present in this setting. Regarding fungal detection, Aspergillus section Fumigati was widespread inside poultry pavilions (62%, 26 out of 42), highlighting this environment has a potential reservoir of microbial pathogens [7]. Furthermore, PM can act as a host of biological fragments [6]. Overall, in addition to molecular analysis, future studies should consider using culture-based methods to assess the viability of pathogenic microorganisms and their infection potential [3]. From a One Health perspective, quantitative and qualitative research is required to fully understand this environment.

Key messages:

- This study evidence that coarse particles (between 2.5 and 10 µm) are the most relevant PM present and Aspergillus section Fumigati is widespread in poultry pavilions.
- A One health intervention should be considered in future studies.

Abstract citation ID: ckae144.1215
Global health resource distribution during COVID-19 and in future pandemics: Here's what people say

Friedemann Trutzenberg

F Trutzenberg[1], *ML Hagel*[2], *M Eid*[1]
[1]Department of Education and Psychology, Freie Universität Berlin, Berlin, Germany
[2]Department of Psychology, Humboldt University of Berlin, Berlin, Germany
Contact: friedemann.trutzenberg@fu-berlin.de

During the COVID-19 pandemic, countless individuals across the world needed novel and sophisticated health care resources simultaneously, leading to dramatic global shortages. How to distribute resources in such situations? This dilemma is neither new nor understudied: Its complexity is well known to medical ethicists, public health scientists and philosophers. Building on this knowledge, powerful global distribution frameworks were proposed already early into the pandemic. Despite this knowledge, no globally consensual regulations existed (and exist) on the political sphere. Worse still, numerous countries hoarded resources for themselves, increasing global inequalities and prolonging the pandemic for everyone. For future emergencies, it is thus necessary to develop immediately applicable strategies. Because public acceptance is key for such interventions, evidence on the public opinion towards allocation principles is strongly needed. In 2021, we asked representative samples of $N = 2694$ adults in England and Germany to rate seven COVID-19-specific global allocation principles. In line with literature on justice attitudes in general, extensions of bifactor(S-1) models showed that participants would have preferred a more equity- or equality-based global resource distribution during the pandemic, presenting themselves as more cosmopolitan than global leaders. Trying to understand these attitudes better, we tested pre-registered hypotheses on relations with other constructs and found positive associations between equity- and equality-directed preferences and global human identification, among others. To ensure generalisability on future pandemics, we collected data from a second cohort in spring 2024. All results will be presented in detail. With their responses, European citizens call upon the development of fairer and more efficient global distribution mechanisms. This global public health perspective could inform preparations for future global emergencies.

Key messages:

- European citizens would have preferred a more equity- or equality-based global distribution of scarce health care resources during the COVID-19 pandemic than global leaders organised.
- Citizens' global perspective on public health and their strong emphasis on global fairness should inform preparations for future pandemics and other global emergencies.

Abstract citation ID: ckae144.1216
What are the health system impacts of engaging with global health activity? A qualitative study

Jack Haywood

J Haywood[1], *J Smyth*[2], *R Goldstone*[1]
[1]Global Unit, NHS England, London, UK
[2]Royal Free NHS Foundation Trust, London, UK
Contact: jack.haywood@doctors.org.uk

Background: Global health partnerships between high-income health systems and low- and middle-income countries (LMICs) are becoming more common as there is an appreciation of the need for collaboration to solve global health issues through knowledge and skill exchange. However, partnership evaluations largely focus on the benefits to individual participants and recipient systems, with little evidence of the impacts on the high-income system. Therefore, the aim of this study was to explore the health system-wide impacts of engaging with global health activity and consider the arguments for and against adopting these partnerships.

Methods: We carried out semi-structured interviews with individuals from three UK health systems that engage with global health activity to explore their motivations to in doing so. Transcripts were thematically analysed.

Results: We found that engagement in global health activity can contribute to workforce recruitment, retention, development, and upskilling, benefiting the system. Examples were also given of system-wide clinical, reputational, and economic benefits. However, this activity impacts short term staffing and can cause personal emotional issues that systems need to support.

We also explored facilitators of engaging in global health work which included operational support, supporting healthcare staff to engage, and system acceptance. Barriers included lack of senior buy-in, opportunity access inequities, operational challenges, and the current UK health system challenges.

Conclusions: This study demonstrated the potentially significant system-level benefits of engaging in global health activity. These focused on improved workforce, which is a major public health issue worldwide. We have also identified system characteristics, such as buy-in and operational support, which influence success. We hope this work provides a building block demonstrating there are benefits to be had for donor health systems, but barriers must be overcome.

Key messages:

- The potential benefits and drawbacks that may arise from high-income health systems engaging in global health, as well as facilitators and barriers, are explored.
- This study creates a foundation to understand donor-system benefits and encourages further research, particularly in systems who do not engage with global health activity to understand why this is.

Abstract citation ID: ckae144.1217
Sailing along the global tobacco supply chain: public health insights of innovative database project

Britta K Matthes

R Hiscock[1], *F Dunwoodie Stirton*[1], *BK Matthes*[1,2], *J Mehegan*[1], *H Alaouie*[1,3], *AWA Gallagher*[1], *MJ Bloomfield*[1,2,3]
[1]Tobacco Control Research Group, University of Bath, Bath, UK
[2]Centre for Development Studies, University of Bath, Bath, UK
[3]Department of Social Policy Sciences, University of Bath, Bath, UK
Contact: bkm28@bath.ac.uk

Background: Tobacco control commonly focuses on reducing tobacco demand rather than tobacco supply. This paper presents findings from a major four-year project on the tobacco supply chain. Transnational Tobacco and Leaf Companies (TTLCs) and other tobacco supply chain companies argue that provision of livelihoods, exports and corporate social responsibility (CSR) exonerates tobacco. Our objective was to consider these claims.

Methods: This paper presents the results of three studies: a literature review and two analyses of data from the innovative Tobacco Supply Chain Database (TSCD). Study 1: A scoping review of academic literature (n = 124 papers) reviewing how the tobacco supply chain embeds the tobacco industry as a development actor. Study 2: The statistical association between countries hosting TTLC subsidiaries (TSCD) and TTLC interference in health policy (Global Tobacco Industry Interference Index) was analysed (n = 76 countries). Study 3: Document and website analysis of TSCD non-TTLC tobacco supply chain companies comparing descriptions of CSR and tobacco supply chain involvement (n = 80 companies).

Results: Study 1: Although there are instances of advantages of involvement in the tobacco supply chain, TTLCs tends to be associated with declines in tobacco workers' income, equality, quality of life (cultural and health and wellbeing) and nations' environment and economy. Study 2: Countries that hosted more TTLCs had more policy interference (farming subsidiaries p=.046, tobacco product manufacturing subsidiaries p=.008). Study 3: Non-TTLC companies often lack transparency regarding their connection to tobacco. For example, 68% linked to CSR activity on their homepage whereas only 16% linked to involvement in the tobacco supply chain.

Conclusions: Tobacco supply chain involvement is detrimental to public health, the environment and governance. Countries and companies should seek to extricate themselves from the tobacco supply chain.

Key messages:

- Tobacco supply chain involvement weakens public health governance despite CSR activities. Lack of transparency on supply chain involvement by companies is thus a concern.
- The new Tobacco Supply Chain Database illuminates previously hidden areas of the tobacco supply chain: the location of tobacco industry subsidiaries and presence of independent companies.

Abstract citation ID: ckae144.1218
Occupational Hazards: The Impact of Streptococcus suis Infections in Portuguese Pig Farming

Silvia Salvador

S Salvador[1,5], *S Sousa*[2], *D Sousa-Gomes*[3], *R Ferreira*[4]
[1]Unidade de Saúde Pública, Unidade Local de Saúde do Nordeste, Bragança, Portugal
[2]Divisão de Saúde Militar, Ministério da Defesa Nacional, Lisbon, Portugal
[3]Unidade de Saúde Pública, Unidade Local de Saúde do Litoral Alentejano, Santiago do Cacém, Portugal
[4]Faculdade de Medicina Veterinária, Universidade de Lisboa, Lisbon, Portugal
[5]Instituto Politécnico de Bragança, Instituto Politécnico de Bragança, Bragança, Portugal
Contact: silvia.salvador@ulsne.min-saude.pt

Background: In Portugal, the commensal and opportunistic bacteria Streptococcus suis is prevalent among pigs. Recognizing its public health significance, this systematic review investigates the relationship between occupational exposure in pig farming and the incidence of S. suis infections among workers. The importance of this study is to identify high-risk occupational activities and formulate effective public health interventions.

Methods: This review analyzed 20 scientific studies from 1986 to 2023 on human infections with S. suis in Portugal. The primary sources included articles in Portuguese from databases like MedLine, Scopus, and Pubmed. Studies were selected based on their focus on occupational exposure and the details provided on epidemiological context, clinical presentations, and outcomes.

Results: The review found that 85% of infection cases occurred in occupational settings, particularly among butchers (53%) and pig breeders or handlers (29%). Clinical manifestations predominantly included acute bacterial meningitis, with significant occurrences of neurosensory hearing loss as a sequelae. The average age of affected individuals was 44, predominantly male.

Conclusions: The study confirms a significant correlation between occupational exposure in pig farming and S. suis infections in humans. The findings underscore the need for stringent occupational health measures and integrated approaches encompassing human, animal, and environmental health under the One Health initiative. Innovations in public health interventions recommended include enhanced surveillance, improved workplace hygiene, and targeted health education for at-risk populations.

Key messages:

- Occupational exposure in pig farming is a significant risk factor for S. suis infections in humans.
- Integrative One Health approaches are essential for preventing S. suis infections in occupational settings.

Abstract citation ID: ckae144.1219
BELCOHORT: towards a population-based cohort for health research and policy support in Belgium

Pierre Smith

P Smith[1,2], *H Bruggeman*[1], *J Van der Heyden*[1]
[1]Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Institute of Health & Society, Université Catholique de Louvain, Brussels, Belgium
Contact: pierre.smith@sciensano.be

Background: In the past decades much progress has been made in Belgium in the development and valorisation of population-based data collections which are directly or indirectly related to health. New surveys have been set up and the use of medico-administrative and environmental data for public health research gained momentum. However, no infrastructure is currently in place to link survey data with existing sources in a longitudinal perspective to address research questions directly relevant to health policy. BELCOHORT is a three-year pilot project aimed at developing a population based cohort enriched with these different data sources. The project is considered as a step towards a large population cohort in Belgium.

Methods: A first wave of participant recruitment was organized in February 2024 using the Belgian national register as a sampling frame, and 41,153 households were invited (targeted sample of 5000 individuals aged 18-69). A first baseline survey (online and paper) was organized and an annual follow-up is planned. Linkages procedures will be implemented with administrative data and geospatial data on air pollution and green space. The inclusion of data from physical examinations and biological samples will be explored.

Results: In the first recruitment wave the individual response rate was only 2.5%, leading to a sample of 1,947 participants. The sample showed an under-representation of women (45%), people aged 18-24 years (2%) and low educated people (21%). In total, 23% of participants opted to complete the first baseline questionnaire on paper. Stakeholder meetings have been started to implement the individual and geospatial linkages.

Conclusions: This project generate insights that will assist in methodological choices in the development of a large population cohort in Belgium. In the second recruitment lessons learned from the first data collection will be used to improve the response rate as well as the participation of under-represented groups.

Key messages:

- This study provides insights on how existing population-based data collections including administrative and environmental data can be valorized in setting up a population cohort.

- Recruitment strategies for a population cohort should be tested thoroughly and adapted in order to obtain a well-balanced sample composition.

Abstract citation ID: ckae144.1220
Born in Ethiopia

Elena Capitani

E Capitani[1], M Cozzolino[2], N Nante[1,3], L Alaimo[2]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Degree Course in Obstetrics, University of Siena, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: ecapitani89@gmail.com

Background: Goal 3 of the United Nation 2030 Agenda states that we want to ensure health and well-being for all. This is even more true for countries in the IV World. The aim of our study is to investigate the timing of childbirth in Ethiopia.

Methods: The stages of our ethnographic study include: choosing the study topic and location, participating in group life, collecting and analysing data. The field experience, led by a midwife, took place from September 2023 to October 2023 in Ethiopia, within the Saint Luke Catholic Hospital in Wolisso.

Results: The instruments that the midwives have at their disposal are few and obsolete: the most is Pinard's stethoscope. The mothers are all very young: the youngest woman was fourteen years old while the oldest woman was thirty-eight years old. As for parity, the fertility rate is around 4.6 live births per woman. Women's family members take care of them in all aspects of care. Pregnant and new mothers receive support from their attendants, an all-female network. Pregnancy monitoring is almost non-existent. There is no prenatal diagnosis. In 2022, St. Luke's hospital saw a 20% caesarean section rate, an increase from the previous two years. Poverty and the lack of government facilities that can support a problem child are two of the reasons why many of these children are abandoned. In terms of maternal and child health, mortality indicators are still too high for mothers and children. There are 353 mothers dying per 100,000 live births and 41 babies dying per 1,000 live births.

Conclusions: The biomedical model exported from the Western world, as shown for example by the increase in caesarean sections, has led to a slow but progressive hospitalisation of childbirth in the search for safety from maternal and neonatal mortality.

Key messages:

- Poverty, malnutrition, lack of sanitation and drinking water, as well as early pregnancies and high parity remain among the leading causes of mortality in Ethiopia.
- The biomedical model exported from the Western world has led to a slow but progressive hospitalisation of childbirth in the search for safety.

Abstract citation ID: ckae144.1221
Global health at local level: characterization of tropical diseases in northern Portugal, 2020-2024

Daniela Lima

F Malcata[1], D Silva[1], R Guedes[1], M Mendes[1], R Teixeira[1], A Ferreira[1]
[1]Public Health Unit, Local Health Unit São João, Maia, Portugal
Contact: dani.dslima@gmail.com

Background: The escalating global prevalence and geographic spread of tropical diseases pose significant global health risks worldwide, with local implications. In Portugal, these diseases require mandatory notification. Concerns were raised following the detection of Aedes albopictus mosquitoes in mainland Portugal in 2017, alongside a Dengue outbreak in Madeira in 2012. Despite Portugal being declared malaria-free, the detection of Anopheles mosquitoes also raises concerns. This study aims at characterizing notified cases of tropical diseases in two cities in Northern Portugal since 2020.

Methods: A retrospective study of Malaria, Dengue, Zika, and Chikungunya cases in the Maia & Valongo's Public Health Unit included data from the National Epidemiological Surveillance System covering January 2020 to April 2024. Descriptive analysis was conducted using SPSS IBM for iOS® v29. Results are presented as mean ± standard deviation for continuous variables and proportions for categorical ones.

Results: Five malaria cases were reported, predominantly affecting males (80%), with an average age of 34±16.96 years. Four were Portuguese and one Angolan. All cases were imported, mostly from Angola (80%). Etiological analysis revealed two cases of Plasmodium malariae and three of Plasmodium falciparum. All were hospitalized, no deaths. Four dengue cases were documented, 50% in males, averaged 33±24.73 years. Three were Portuguese and one Mozambican. One was hospitalized with no deaths. All cases were imported from Brazil, Cuba, Indonesia, and islands of Saint Martin/Saint-Barthélemy. No Zika or Chikungunya confirmed cases were identified during this period.

Conclusions: The increasing incidence of Dengue and Malaria underscores the critical connection between infectious diseases, vector ecology, and global health security. This study highlights the risk of imported Dengue and Malaria cases, emphasizing the imperative for surveillance and preventive actions to protect public health.

Key messages:

- Dengue and Malaria cases in Portugal underline the importance of international collaboration and robust strategies.
- Stepped-up surveillance is key to protecting vulnerable groups from imported infections.

Abstract citation ID: ckae144.1222
One Health literacy and governance of health leaders across three countries following the pandemic

Saskia De Gani

Contact: saskia.degani@careum.ch

Background: To address health threats and promoting health of all, One Health is an important approach. To foster the implementation of One Health, a framework proposed by Blankart et al. (2024) postulates a reinforcing relationship between One Health literacy and governance after being triggered by an external event. We build on this model and aim to explore how the postulated mechanism differs among health policy and practice leaders across the UK, Germany, and Switzerland after the external triggering event of the COVID-19 pandemic.

Methods: We developed an online survey instrument for each of the 5 elements of the framework and conducted it in April 2024. We targeted mid- and end-career leaders and senior experts from the Sciana network that reported about their personal experiences and perceived changes (scale from -5 to + 5). We performed descriptive and inferential statistics to analyse the data. The survey was complemented by structured interviews to gather contextual information.

Results: Leaders and experts (N = 30, response rate: 30%) increased their One Health literacy (mean: 2.2), increasingly engaged with One Health principles (mean: 1.0), which resulted in more calls for optimized One Health governance (mean: 2.4). The interviewees reported that they adopted and implemented a more consistent One Health governance (mean: 2.6), which led to more familiarity with One Health principles (mean: 2.3). According to the results, the average effect on One Health literacy and Governance was stronger in Germany, followed by Switzerland and the UK.

Conclusions: We have demonstrated that triggering events such as the COVID-19 pandemic have led to improvements in One Health literacy and subsequently One Health governance. We therefore suggest that the postulated framework holds in practice and have showed that there are important differences in uptake between leaders in the three countries. Further research may build on these findings and develop more effective health policy.

Key messages:

- We have contributed to the understanding of how pandemics improve One Health literacy and subsequent One Health governance using the example through a survey of leaders in health policy and practice.
- Based on the understanding of triggering events' effect on One Health literacy and governance specific recommendations for the implementation of One Health in public health can be developed.

Abstract citation ID: ckae144.1223
Key competencies for global health research: systematic literature review and mapping

Bianka Detering

V Saint[1], *B Detering*[1], *A Franke*[1], *H Eger*[1], *J Oppenberg*[1], *S Rohleder*[1], *K Bozorgmehr*[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: bianka.detering@uni-bielefeld.de

Background: Despite a boom in global health programmes and trainings, there is a lack of clarity and standardisation about which competencies are essential for researchers in global health, who stem from diverse disciplines and backgrounds. The objective was to map key competencies for global health research and approaches to progressively develop them in education and training.

Methods: We performed a systematic review in English in PubMed/MEDLINE, Web of Science, and Psychinfo/EBCSO host of literature published since 1 January 2010. 1827 articles were screened in duplicate. Data was extracted from 84 publications about focus in global health, recommended competencies and educational approaches, with two researchers giving a relevancy rating. AI-assisted extraction was conducted on 40 high-relevance publications to garner further information, informing development and application of a coding framework to these articles.

Results: Emerging results point to eight main domains and numerous subdomains related to competencies seen as critical for global health research. In addition to traditionally emphasised cognitive competencies (e.g. methodological), the literature underlined the importance of critical analyse of how systems related to globalisation, political economy and structural injustice shape health at local level. Also highlighted was the need for more focus on affective and practical competencies for conducting global health research in alignment with equity principles, including through innovative pedagogical approaches.

Conclusions: Our review identifies competencies seen as essential for global health researchers, including skills to critically analyse geopolitical, colonial and structural drivers, as well as self-reflexivity, (cultural) humility and other key affective competencies. It also highlights, however, the significant diversity of perspectives, lack of consensus, and ongoing disconnect between principles and practice.

Key messages:

- Greater clarity and consensus is needed around the specific competencies required to work as a researcher in global health, taking account of diversity across disciplines, sectors and stages.
- Global health researchers require skills to critically analyse geopolitical, colonial and structural drivers, as well as self-reflexivity, (cultural) humility and other key affective competencies.

Abstract citation ID: ckae144.1224
Barriers to a sustainable living in Italy: results of a national survey

Background: Sustainable living plays a crucial role in creating a fairer society, but various constraints prevent consumers from adopting sustainable behaviours. This study investigated the reasons for non-adoption of sustainable products or behaviours among the Italian population.

Methods: From January to June 2023, we surveyed the Italian population using a 40-question online survey that asked about knowledge, awareness, and attitudes toward sustainable behaviours and products. Participants were asked about the reasons why they did not engage in a certain behaviour or did not use a selected product. Descriptive statistics, t-test and chi-square tests were performed to assess association with participant characteristics.

Results: The 420 participants had a median age of 39 years (interquartile range: 32-56), 66% were female. The largest discrepancy between knowledge of sustainability impacts and implementation was in the personal care (92% knowledge, 31% implementation) and transportation (85% knowledge, 48% implementation) domains. In general, the main reasons for not using the surveyed products were practical complications in everyday life (25%), the difficulty of finding or producing them (23%) and their cost (13%). Specifically, practical complications (42%) were the main reason for not adopting sustainable behaviours in the transport domain. In the personal care domain, low confidence in product quality or ignorance of their existence accounted for only 26% of reasons for non-use, while supply problems, practical complications in everyday life and existence unawareness accounted for 61%.

Conclusions: Targeted measures are needed to address the reasons for non-use or adoption of sustainable products and behaviours. In this way, these actions will help to promote healthy living, protect our planet, support socio-economic development, and ensure global prosperity.

Key messages:

- A greater sustainability- implementation awareness gap was found in personal care and transportation domains.
- The main reasons for not implementing sustainable living were practical complications in daily life, supply difficulties and product cost.

Abstract citation ID: ckae144.1225
A Multidisciplinary One Health Approach to Addressing Unsanitary Conditions: The Case of Cascais

Carlos Quelhas

C Quelhas[1], M Lopes[1], J Silva[1], R Nunes[1], M Fernandes[1]
[1]Cascais Public Health Unit, Western Lisbon Local Health Unit, Cascais, Portugal
Contact: carlos.quelhas@ulslo.min-saude.pt

Unsanitary conditions in domiciles often stem from complex social and health-related issues, involving the elderly and/or individuals with mental health problems. These situations typically lead to a decreased quality of life for those involved, directly and indirectly, and may pose a risk to public health depending on their magnitude. In Cascais municipality, identified cases of unsanitary conditions undergo a multidisciplinary analysis. It has been established a Local Technical Group for Domiciliary Unsanitary Situations, comprising various institutions such as local authorities, law enforcement agencies, civil protection, health and social security ministries, and the animal rescue center. This group operates under a One Health approach, encompassing human health, environmental health, and animal health. Interventions are determined by the working group, with the aim of promoting health and enhancing citizens' quality of life. Cases of unsanitary conditions reported are subsequently discussed within the technical group, which has regular meetings, and may organize joint assessment visits and appropriate actions. This social and environmental initiative responds to the growing need to address unsanitary and cluttered living conditions, which significantly impact individuals' physical, emotional, and social well-being. The objective is to restore housing conditions in homes by removing waste and unnecessary items, contributing to general individual well-being. While international studies suggest a correlation between unsanitary conditions and hoarding disorder, it's crucial to differentiate between distinct and independent situations caused by various physical, psychological, and cognitive processes. The establishment of a Local Technical Group for Domiciliary Unsanitary Situations exemplifies a proactive approach to addressing complex health and social challenges, emphasizing collaboration, and holistic intervention strategies, always with a One Health approach.

Key messages:

- Addressing unsanitary conditions is crucial for safeguarding public health, impacting physical, emotional, and social well-being.
- The establishment of a Local Technical Group for Domiciliary Unsanitary Situations, under a One Health framework, reflects a collaborative approach to addressing complex health and social challenges.

Abstract citation ID: ckae144.1226
Beneficial effect of honey from algae extract-fed bees on quality of life

Zsuzsa Emma Hajzer

[8]Food and Health Sciences, University of Debrecen, Debrecen, Hungary
Contact: hajzer.zsuzsa@etk.unideb.hu

Background: Our team has been researching and developing special honeys from bees fed with syrups containing natural plant extracts for decades. Several pre-clinical studies have demonstrated that honey from bees fed with Chlorella algae extract contains a number of algal active ingredients with beneficial effects on the human body.

Methods: We conducted a prospective double-blind functional food study with 30 healthy volunteers with ethical approval. Based on strict inclusion and exclusion criteria, 30 gramms of honey has been eaten twice a day for 3 weeks under 150 ml of yoghurt. 15 people were fed honey from bees with special algae extract, while 15 concerned - as a control group - consumed acacia honey. Before and after the study, sleep quality was assessed by the SQS questionnaire, and quality of life by the SF-36, EORTC Q-C30 and EQ-5D tests.

Results: The specific algae extract contained honey improved the people's sleep quality, their EQRTC parameters, their appetite, their digestion, and it also significantly reduced pain ($p = 0.01$), boosted the patients cognitive function, and reduced both constipation and diarrhoea. Significant differences in SF-36 parameters: pain decreased (12.9±1.6vs 6.6±1.1; $p = 0.01$), physical function (21.2± 6.3vs 27.1±3.6; $p = 0.01$) and energy (11.2±2.7vs 13.9±1.4; $p = 0.01$) improved. No such changes occurred in control group.

Conclusions: Honey from bees fed with algae extract has a number of beneficial physiological effects on the human body, improving many parameters of quality of life.

Key messages:

- The consumption of honey from bees fed with algae extract improves sleep, reduces pain, and has a positive effect on digestive and gastrointestinal symptoms.
- Within public health, quality of life is an increasingly important issue and improving it with functional foods is an important area of research.

Abstract citation ID: ckae144.1227
What works in global health partnerships? Reflections on a Nigerian-German project collaboration

Chinedu Okoroafor

C Okoroafor[1], F Haderer[2], J Terpase Dooga[1], U Zocher[3], O Okafor[1], T Okwor[1]
[1]Nigeria Centre for Disease Control and Prevention, Abuja, Nigeria
[2]Robert Koch-Institute, Berlin, Germany
[3]Independent Consultant, Heidelberg, Germany
Contact: chinedu.okoroafor@ncdc.gov.ng

Background: Global health partnerships for project implementation is a frequent way to address health challenges. Bringing stakeholders from different disciplines, professions, settings and countries together provides opportunity to look at health challenges from different perspectives, develop suitable ideas to tackle them and leverage diverse capacities.

Problem: In such diverse partnerships, cultural norms, practical realities and institutional practices create challenges for the development of good and equitable relationships.

Methods: In our project collaboration between the Nigerian Centre for Disease Control and Prevention and the German Robert Koch Institute on developing and implementing trainings in infection prevention and control, we demonstrated how a partnership can function. The collaboration followed a participatory approach and was informed by the following principles: - Plan, revise, adapt and implement all project activities as well as its contents participatorily; - A well-coordinated teamwork is key to facilitate operational performance; - Consider everyone as expert in its own domain of influence; - Constant and inclusive communication: maintaining transparency on all aspects and steps both in contents and organization and applying non-violent communication and active listening; - Provide space for reflection on roles and functions and for open discussion on needs and misunderstandings; - Appreciate team work as constantly evolving process of interaction and learning.

Results: We built a strong resilient team and could leverage team diversity to deliver on project objectives with exceptional quality, adaptability in a highly complex and frequently changing implementation setting.

Lessons: Working across cultures, disciplines, professions and countries means to develop a joint communication language and an understanding of the other. It is challenging and dynamic, requires additional space/time and attention, but offers personal growth and self-realization.

Key messages:

- Using a participatory approach in teams can leverage team diversity to deliver on project objectives and bring about a high professional and personal self-realization.
- There are concrete implementable ways of teamwork in international interdisciplinary global health collaborations that enhance quality of results in complex implementation settings.

Abstract citation ID: ckae144.1228
Antimicrobial resistance trends in Italian hospitals: insights from two point prevalence surveys

Antonino Russotto

A Russotto[1]*, C Vicentini*[1]*, R Bussolino*[1]*, M Castagnotto*[1]*, C Gastaldo*[1]*, L Bresciano*[1]*, S Bazzolo*[2]*, D Gamba*[3]*, CM Zotti*[1]
[1]Department of Public Health and Paediatrics, University of Turin, Turin, Italy
[2]Department of Environment, Land and Infrastructure Engineering, Polytechnic of Turin, Turin, Italy
[3]Department of Surgical Sciences, University of Turin, Turin, Italy
Contact: antonino.russotto@unito.it

Background: Antimicrobial resistance (AMR) presents a critical challenge to global healthcare systems, necessitating vigilant surveillance efforts. The European Centre for Disease Prevention and Control (ECDC) conducts point prevalence surveys (PPSs) to monitor AMR trends across European hospitals. This study focuses on comparing AMR patterns in Italian hospitals using data from two surveys: PPS2 (2016-2017) and PPS3 (2022-2023).

Methods: A total of 140 hospitals enrolling 28991 patients participated in PPS2, while 325 hospitals with 58506 patients contributed data to PPS3. Microbiological samples were collected and tested for antimicrobial susceptibility. Prevalence ratios (PR) with corresponding 95% confidence intervals (CI) were calculated to assess changes in resistance patterns between PPS2 and PPS3. Statistical significance was determined with p-value <0.05.

Results: Staphylococcus aureus showed a trend towards decreased oxacillin resistance, (PR: 0.77, 95% CI: 0.60 - 0.99). Enterococcus faecalis exhibited a non-significant decrease in glycopeptide resistance. Pseudomonas aeruginosa and Acinetobacter baumannii maintained stable carbapenem resistance between the two surveys. Escherichia coli and Klebsiella pneumoniae showed a decreasing trend in resistance to carbapenems and third-generation cephalosporins, but only Klebsiella pneumoniae was found to be significant (PR: 0.69, 95% CI: 0.55 - 0.88, p 0.004 and PR: 0.78, 95% CI: 0.66 - 0.94, p 0.01, respectively).

Conclusions: These findings underscore the importance of surveillance in monitoring AMR trends. Observed decreases, especially in Klebsiella pneumoniae, suggest potential improvements. However, the overall stability of resistance highlights the ongoing challenge of combating AMR. A multifaceted approach, including antimicrobial stewardship and One Health initiatives, is crucial to address this global health threat effectively.

Key messages:

- Surveillance efforts are crucial to understand antimicrobial resistance (AMR) trends, as demonstrated by comparing data from two surveys in Italian hospital.
- Results highlight the need for data-driven interventions, guiding future strategies within a One Health framework to address antimicrobial resistance comprehensively.

Abstract citation ID: ckae144.1229
A monitoring framework for reinforcing policies against antimicrobial resistance in Europe

Mariana Dates

M Dates[1]*, M Davies*[1]
[1]Tetra Tech International Development, Amsterdam, Netherlands
Contact: mariana.dates@tetratech.com

In an attempt to overcome barriers to the effective implementation of policies against antimicrobial resistance (AMR) in the EU Member States, Norway and Iceland, One Health national action plans (NAPs) need to show improvements in both their formulation and their implementation. Research conducted by Tetra Tech, funded by the EU4Health Programme, has identified shortcomings to One Health national policies across all countries, such as limited political focus and awareness of the challenges brought by AMR; lack of operational plans for delivering on the NAPs; and lack of harmonised indicators and inadequate information systems for monitoring the implementation of plans. On this last issue, subsequent reseach by Tetra Tech has supported the design and development of monitoring indicators for reinforcing the expected improvements of NAPs and the implementation of policies aimed at EU Member States in the 2023 "Council Recommendation on stepping up EU actions to combat antimicrobial resistance in a One Health approach". While drawing on existing data sources at EU and global level, the study has also worked with Member States representatives in identifying indicators for the monitoring framework and proposed new data collection activities at the national level.

Key messages:

- EU countries face common barriers to the effective implementation of One health policies against AMR, and need to reinforce their national action plans.
- Stepping up the fight against AMR in the EU requires a strong monitoring framework for following up on EU recommendations.

Abstract citation ID: ckae144.1230
One Health Perspectives on Food System Transformation: Insights from the InsectERA Agenda

Ricardo Assunção

R Assunção[1]*, P Quinteiro*[2]
[1]CiiEM, Egas Moniz School of Health & Science, Almada, Portugal
[2]CESAM, Department of Environment and Planning, University of Aveiro, Aveiro, Portugal
Contact: ric.assuncao@gmail.com

Background: One Health framework recognises the interconnectedness of human, animal, plant and environmental health. With this understanding, it becomes imperative to address challenges such as those posed by food systems through a One Health lens. Food systems pose significant public health challenges, particularly in terms of food safety and security. Pressures from factors such as population growth, changing consumption patterns and intensified production systems, particularly animal-based protein production, contribute to environmental pressures. In addition, environmental changes, including climate change, further threaten food safety and access to healthy food.

Methods: Through the InsectERA agenda, funded as part of the Recovery and Resilience Plan, stakeholders collaborated across sectors to explore the potential of insects as bioindustrial tools to address food system challenges. A structured, integrated approach combining health and sustainability considerations was matured and applied to pilot food products developed through this initiative. Recognising the potential health and sustainability impacts of these products, a comprehensive assessment was carried out.

Results: This study defined a structured, integrated approach to assessing the health and sustainability impacts of foods developed under the InsectERA agenda. Key steps included i) identifying critical issues and questions, ii) prioritising considerations, iii) defining methodologies, iv) collecting and analysing data, and v) integrating results for communication.

Conclusions: The study highlights the importance of integrated approaches in addressing food system transitions. Integrated approaches, guided by the One Health framework, play a critical role in informing policy decisions by providing policy makers with robust evidence. There is an urgent need for food system transformation based on decisions that holistically consider health and sustainability impacts, to ensure the protection of Public Health.

Key messages:

- Integrating health and sustainability into the transition of food systems, within the One Health framework, is crucial for identifying options that safeguard Public Health.
- A structured, integrated approach within a multi-stakeholder environment offers robust insights for policy decisions, advancing sustainable food systems.

Curricular innovations to address inequalities in global health education

Mariam Sbaiti

M Sbaiti[1], A Abbara[2], M Al-Haffar[3], S Budhathoki[1], K Wihba[4], A Cardoso Pinto[4], M Streule[5]
[1]Department of Primary Care and Public Health, Faculty of Medicine, School of Public Health, Imperial College London, London, UK
[2]Department of Infectious Disease, Faculty of Medicine, School of Public Health, Imperial College London, London, UK
[3]Faculty of Epidemiology and Population Health, LSHTM, London, UK
[4]Faculty of Medicine, Imperial College London, London, UK
[5]Faculty of Engineering, Imperial College London, London, UK
Contact: m.sbaiti@imperial.ac.uk

Background: Global Health education (GHE) has expanded dramatically, with new degrees and expanded competencies in medical curricula. Yet, Global Health (GH) is also going through significant reckoning and debate around inequalities in the field. GH degrees are predominantly based in high-income countries and inaccessible to most global majority students. Some suggest GH education itself contributes to reproducing inequalities in GH. Thus, both educators and policy-makers require evidence and tools to support more representative and authentic educational experiences which can adequately equip our future graduates.

Objectives: To present educational innovations which gesture towards responding to the stark inequalities in Global/Public Health education. These include a unique project that experiments with disrupting current power dynamics through co-design and co-delivery of a curriculum on Syrian healthcare by colleagues with lived experience, and a student-staff partnership to integrate self-reflexivity and positionality (SRP) in curricula at Imperial College London (UK).

Results: Qualitative data shows that the Syrian Curriculum has resulted in enhanced student experience, being consistently cited as a highlight of the curriculum, whilst alsoenhancing inclusivity for many students. SRP supplemented this by providing students with tools to engage in open, respectful discussions and critically reflect on personal biases that impact class dynamics.

Conclusions: These projects provide tools for educators and policy-makers across European universities to address current challenges in GH education. Nonetheless, these innovations should principally be seen as tools to reflect and advocate for fundamental changes towards more representative structures in GH.

Key messages:

- Curriculum innovations offer key tools to address inequalities in GHE, enhancing student experience/inclusivity.
- Yet, these remain limited without fundamental change towards a more representative sector.

Abstract citation ID: ckae144.1232

Developing an infodemic management toolkit for immunization: An iterative consultation process

Brian Yau

B White[1], L Menning[2], JR Orbina[2], S Abeyesekera[3], T Purnat[4], K Von Harbou[1], N Emiroglu[1], S Varaidzo Machiri[1], B Yau[1]
[1]CCR, WHO, Geneva, Switzerland
[2]UHC, WHO, Geneva, Switzerland
[3]UNICEF, New York, USA
[4]EPP, WHO, Geneva, Switzerland
Contact: byau@who.int

Issue: An infodemic is an overwhelming amount of information, accurate and otherwise, that accompanies health emergencies such as outbreaks and other health crises. Infodemic management work is done by people from different positions and professions, with differing resources at their disposal, and applied to a range of health issues. An infodemic insights report can help identify questions, concerns, information voids and circulating mis- disinformation to help inform an emergency response. Health issue specific guidance can be useful for those who may have infodemic management as part of their regular work but want to identify infodemic insights and contextualize these insights in relation to other programme data.

Description: The WHO and UNICEF 'how to build an infodemic insights report in 6 steps' document provides general guidance. A more immunization specific document, with practical and specific tools in standalone short focus areas was developed to guide infodemic managers or those working on vaccine demand and acceptance, and by vaccination field workers. The toolkit is intended for vaccines across the life course, including for children, adolescents, pregnant people, adults, and people with pre-existing conditions or have other vulnerabilities.

Results: Rounds of iteration with experts both internal and external to WHO provided useful feedback, review and suggestions. The toolkit provides information targeted at different resource and capacity levels.

Lessons: The consultative process resulted in a toolkit informed by experts and those who are likely end-users of the document. The consultations sought to align the toolkit with immunization programme processes and with other tools and interventions for improving vaccine uptake. Having health issue specific guidance is a useful addition to the infodemic manager toolbox and tools such as these can be an important component of community resilience and health security initiatives.

Key messages:

- For immunization, infodemic management can support programme activities to build vaccine confidence and improve uptake, and manage vaccine-related events.
- Expert informed guidance on health topic specific areas can be a useful addition to the infodemic manager toolbox.

[3]Education, Municipal Department of Education, Rio Claro, Brazil
[4]Research Center for Child Studies, University of Minho, Braga, Portugal
[5]University Rovuma, Nampula, Mozambique
[6]Department of Nursing, University of Évora, Évora, Portugal
Contact: roberto.iaochite@unesp.br

Background: The reopening of schools during the COVID-19 pandemic has had a profound global impact, affecting millions of students, educators, and families worldwide. This organisation study, conducted in collaboration with professionals from Brazil, Mozambique, and Portugal, focuses on the organisation of school environments to ensure education safety and continuity, underscoring the global relevance of our findings.

Methods: A consortium of 12 countries developed a script for the semi-structured online interviews used in this study, which took place between March and December 2021. Focusing on the reorganisation of schools during lockdowns in the classroom, we interviewed 12 native Portuguese speakers involved in this process. We applied thematic analysis using NVivo v.22.0 to transcript interviews.

Results: Results revealed complexities in school reopening during the public health crisis. Key barriers were disparities between public and private schools and inadequate infrastructure. Facilitators included thorough preparation of staff, community engagement, and strong collaboration between the educational and health sectors, along with classroom and school space adaptations.

Conclusions: This study highlighted significant barriers and facilitating factors affecting school reopening during the pandemic. Challenges such as educational inequalities and infrastructure gaps were evident, while effective facilitation involved comprehensive planning and stakeholder engagement. These findings offer valuable insights for strategic planning and professional practice in ensuring safe and continuous education during pandemics.

Key messages:

- Global collaboration in this study spotlights the complex challenges and necessary strategies for safely reopening schools amid a pandemic.
- Research underscores the critical role of thorough preparation and community engagement in overcoming educational disparities during crises.

Abstract citation ID: ckae144.1234
Temporal Analysis of Sanitation and Water Development Indicators in Tunisia: 2012-2023

Chahida Harizi

S Fitouri[1], C Harizi[1], Y Ayedi[1], A Skhiri[1], K Besbes[1], R Fakhfakh[1]
[1]Department of Epidemiology and Biostatistics, Abderrahmen Mami University Hospital, Ariana, Tunis, Tunisia
Contact: chahidaharizi@hotmail.fr

Background: Access to sanitation and water resources is a cornerstone of the 'One Health' approach, which encompasses the holistic integration of human, animal and environmental health considerations. We aimed to elucidate the temporal trajectory of sanitation and water resource development in Tunisia across successive years.

Methods: Data from the Multiple Indicator Cluster Survey in Tunisia, a UNICEF-conducted repeated cross-sectional survey, was used to compare trends in access to improved water sources, utilization of improved sanitation facilities, and handwashing practices across 2012, 2018, and 2023.

Results: In 2023, we observed that 20.9% of households did not have access to drinking water on site, compared with 12.7% in 2018 ($p = 0.15$). The availability of drinking water in sufficient quantity was 69.8% in 2023 and 80.6% in 2018 ($p = 0.37$). In 2023, 78.1% of the population had access to an improved water source, compared with 86.3% in 2018 and 95.7% in 2012 ($p = 0.4$), 80% in urban areas and 73% in rural areas ($p = 0.57$). In 2023, 12.5% of the population consumed water from sources contaminated with Escherichia coli, compared with 20.5% in 2018 ($p = 0.16$). Disparities in Escherichia coli detection were observed between rural (21%) and urban (8.3%) areas ($p = 0.01$). In 2023, 92.1% of households had access to handwashing facilities equipped with soap and water, compared with 89.9% in 2018 and 91.5% in 2012 ($p = 0.98$). The breakdown between urban and rural areas was 95.1% and 86.4% respectively ($p = 0.51$).

Conclusions: Access to improved water sources, sanitation, and handwashing practices remains high over time, but regional disparities persist. Improved water quality directly reduces the transmission of waterborne pathogens, emphasizing the need to address regional disparities and socio-economic inequalities to promote public health nationwide.

Key messages:

- Challenges persist in tunisia regarding sanitation and access to water.
- Regional disparities threaten public health.

Abstract citation ID: ckae144.1235
Health literacy of pregnant women in Hungary

Anita Molnárné Grestyák

A Molnárné Grestyák[1], T Ratkó[2], Á Barabás[1], P Takács[1], R Jávorné Erdei[1]
[1]Faculty of Health Sciences, University of Debrecen, Debrecen, Hungary
[2]Trimester Company, Budapest, Hungary
Contact: grestyak.anita@etk.unideb.hu

Health literacy determines our state of health and through this our quality of life. The health behavior of women of reproductive age should be treated with priority, since the lifestyle of pregnant women shows a correlation with the occurrence of premature birth and intrauterine development, and also between fetal development and the occurrence of chronic diseases in adulthood. The aim of our research is to explore the factors influencing the health behavior of pregnant women, to analyze regional differences, and to identify the causes of regional differences and inequalities. During a prospective, cross-sectional study, the health behavior of pregnant women living in Hungary was assessed using a questionnaire. In the course of our research, we examined health literacy using two measuring instruments, the Chew questionnaire and The Newest Vital Sign test. A total of 2,000 questionnaires were distributed of which 1,655 evaluable questionnaires were returned, the willingness to answer was 75%. The most people considered their own health to be good or very good (59.7%). 59.5% of the respondents changed their health behavior because of their pregnancy, mainly for the sake of the health of the fetus. 18.1% of pregnant women most likely have insufficient, 15.0% probably limited and 48.1% most likely have adequate functional health literacy. Age, education, place of residence and financial situation of pregnant women show a significant correlation with health literacy. Our results confirmed that sociodemographic factors, especially age and education, significantly influence the health literacy, perceived health status and health behavior of pregnant women. The two health literacy questionnaires we use can be combined well with each other and complement each other. The results greatly contribute to the development of health literacy, and thus to the development of individual and community-level strategies for improving health behavior in the field of pregnant women's care.

Key messages:

- Health literacy of pregnant women in Hungary.
- Health literacy in health promotion.

Abstract citation ID: ckae144.1236
A canine onchocercosis report from the portuguese west region in 2024: implications for Public Health

Diogo Neves

D Neves[1], *M Ourique*[2], *T Magalhães*[2], *N Rodrigues*[1]
[1]Public Health Unit, Oeste Local Health Unit, Torres Vedras, Portugal
[2]Public Health Unit, Santa Maria Local Health Unit, Mafra, Portugal
Contact: diogofvneves@gmail.com

Issue/problem: Onchocerca lupi parasitosis, known as onchocercosis, affects dogs, sporadically cats and humans, posing a public health concern due to possible vectors in the environment. This neglected tropical disease(NTD), has no known human cases outside endemic areas. However, recent reports in non-endemic areas raise concerns about future implications. Climate change has increased the potential risk of disease vectors establishing themselves in previously unaffected areas.

Description of the problem: A case of canine onchocercosis in the West Region of Portugal, made the pet owner look for medical counselling. Primary health care providers contacted the Public Health Unit(PHU) for guidance and actions. There had been no previous reports in this region. In this case report, we explore the potential public health implications, through a one-health approach.

Results: History of the disease was collected, and travel history of the dog revealed that he had lived in the Algarve during 11 years with only a one-and-a-half-month travel to Italy in this period. Literature review revealed reports of previous cases of oncochercosis in the Iberian Peninsula. Collaboration between the PHU, research institutes, and veterinary authorities led to the assumption of probable transmission in the Algarve.

Lessons: Increased vector surveillance is needed, especially in areas associated with animal onchocercosis. Proactive measures reduce transmission risks, protecting both humans and animals. Tracking animal cases is vital for understanding regional environmental factors. PHU's must conduct thorough risk evaluations and maintain assertive risk communication strategies to address public and pet owner concerns effectively. Adopting a One Health approach improves the understanding of the disease dynamics and enables targeted interventions.

Key messages:

- NTD's transmitted by vectors pose a potential future challenge. This report underscores the need for a One Health approach, with collaborative multidisciplinary efforts to address these challenges.
- Furthermore, systematic interaction and reporting between human, animal, and environmental health authorities are crucial to ensure comprehensive surveillance and mitigation strategies.

Abstract citation ID: ckae144.1237
Food insecurity is associated with poor mental health and health risk behaviors in Czechia

Maika Ohno

M Ohno[1], *D Dzúrová*[1]
[1]Charles University, Department of Social Geography and Regional Development, Prague, Czechia
Contact: ohnoma@natur.cuni.cz

Background: Food insecurity (FI) is one of social determinants of health and a profound public health concern because it leads to malnutrition and hence poor health. COVID-19 impacted people disproportionately and exacerbated preexisting social and health inequalities. The aim of this study was to understand how socioeconomic and health conditions affected one's FI in Czechia during the pandemic using a representative panel of Czech adults from a longitudinal survey, Life During the Pandemic collected in October 2022 as part of a Czech longitudinal survey.

Methods: A study sample of 1,499 respondents was included in our multiple logistic regression models. Depressive symptoms and anxiety symptoms were assessed using validated questionnaires PHQ-2 and DAG-2.

Results: Approximately one third of the study sample (32.4%) reported being food insecure. In the fully-adjusted model, adults with depressive symptoms (OR 2.37, CI 1.49, 5.02), problems with sleeping (OR 2.20, CI 1.64, 2.96), smoking habit (OR 2.27, CI 1.68, 3.07), lower fruit and vegetable consumption (OR 1.50, CI 1.04, 2.17) had greater odds of experiencing FI. The lowest income group was associated with 6.2 times greater odds of reporting FI as compared to the high-income group (CI 3.96, 9.67). Lower education attainment also had higher odds of experiencing FI (OR 2.15, CI 1.40, 3.31). Anxiety was not a significant predictor for FI.

Conclusions: Our study highlights that food insecurity is associated with depressive symptoms, poor quality of sleep and lower consumption of fruit and vegetables among adults. Food insecurity was also evident among lower income and lower education attainment.

Funding source: This study was supported by The Charles University Grant Agency (GA UK).

Key messages:

- Our study suggests that adults with poor mental health and diet quality experience food insecurity.
- Given the established link between a balanced diet and mental well-being, interventions should encompass not only food security but also the quality of dietary intake.

Abstract citation ID: ckae144.1238
Impact of spilanthol supplementation with balance training on neuromuscular performance

Kumar Mishra

KG Mishra[1], *N Patnaik*[2], *NR Pradhan*[3]
[1]Community Medicine, Apollo Institute of Medical Sciences & Research, Hyderabad, India
[2]Obstetrics and Gynaecology, AIIMS Bibinagar, Hyderabad, India
[3]Vascular Surgery, AIG Hospitals, Gachibowli, Hyderabad, India
Contact: drguru1990@gmail.com

Background: Age-related reductions in muscle mass, muscle contraction power, force, and coordination contribute to an elevated risk of falls and associated consequences. Research suggests that the enhancement of neuromuscular function is attainable through a regimen of targeted exercises and the strategic inclusion of certain supplements like spilanthol. This randomized controlled trial investigated the effect of resistance exercise with either spilanthol plus coordination/ balance training (BAL) or BAL-alone on neuromuscular function (countermovement jump, multiple one-leg hopping, and sit-to-stand test).

Materials and methods: In the course of this study, a cohort of 68 healthy male participants, aged 40 to 50 years, completed a rigorous 6-month intervention, from the initial 75 recruits. In the spilanthol-plus-BAL group, participants engaged in 30 minutes of resistance exercise sessions four times a week, complemented by daily supplementation of 17.5 mg of spilanthol.

Results: The analysis of the results showed significant improvements in the spilanthol-plus-BAL group, particularly evident in the peak countermovement power ($p < 0.01$). The mean effect size for this parameter was a + 1.5[0.9 to 2.1] W/kg greater change in spilanthol-plus-BAL group than BAL-alone group after six months. Moreover, multiple one-leg hopping performance showed significant enhancement in the spilanthol-plus-BAL group post-intervention. The parameters of sit-to-stand duration (1.04 s vs. 1.95 s; $p = 0.03$) and average acceleration (1.54 g vs. 1.06 g; $p = 0.04$) both exhibited substantial improvements in the spilanthol-plus-BAL group compared to the BAL-alone group.

Conclusions: The findings of this investigation contribute empirical evidence supporting the proposition that spilanthol supplementation, when integrated with BAL training, can exert a more pronounced impact on select facets of neuromuscular function.

Key messages:

- Spilanthol supplementation with balance training can exert a pronounced impact on neuromuscular function.
- Spilanthol supplementation with balance training demonstrates potential in mitigating sarcopenia and other degenerative conditions.

Abstract citation ID: ckae144.1239

The association between trajectories of structural disadvantage and mental wellbeing for Māori youth

Denise Neumann

D Neumann[1], *SJ Paine*[1,2], *E Yao*[1]
[1]School of Population Health, Waipapa Taumata Rau - The University of Auckland, Auckland, New Zealand
[2]Te Kupenga Hauora Māori, Waipapa Taumata Rau - The University of Auckland, Auckland, New Zealand
Contact: d.neumann@auckland.ac.nz

Background: Youth mental health is a major global concern with substantial inequities for Indigenous and other young people from minoritised ethnic groups. In New Zealand, Māori, the Indigenous people, experience poorer mental health than other young people, especially those living in high deprivation. Cultural connectedness is related to positive mental wellbeing, however, its potential to buffer against the harms of structural disadvantage for young Māori mental health has not been investigated.

Methods: We used data from 1224 Māori young people in the longitudinal Growing Up in New Zealand study. Structural disadvantage measures included material hardship, deprivation, employment, residential mobility. We conducted Latent Class Analysis and Social Sequence Analysis to identify clusters and longitudinal patterns of structural disadvantage. Cultural connectedness and mental wellbeing (depression & anxiety symptoms, quality of life) were measured at age 12. Linear regression analysis was used to determine associations between structural disadvantage, cultural connectedness and mental health.

Results: We identified 3 trajectories of structural disadvantage for Māori youth: 21% experienced persistent high structural disadvantage, 35% intermittent high structural disadvantage and 44% persistent relatively low structural disadvantage. Few differences in mental health were found between groups. Cultural connectedness was independently associated with positive mental wellbeing, yet there was mixed evidence it might buffer the impacts of structural disadvantage on mental health.

Conclusions: Our results highlight the importance of policies that uphold Indigenous rights to health and address structural disadvantage as a persistent threat to Indigenous wellbeing. Our findings call for holistic, early-life, family-centred strategies and to reduce barriers to accessing support. We highlight the need for policies that enable young people to flourish in their identity and culture.

Key messages:

- Many Māori young people experience pervasive structural disadvantage starting before they are born, persisting throughout childhood and adolescence which is an omnipresent threat to their wellbeing.
- Supporting cultural connectedness for Indigenous youth is important but cannot substitute for policies addressing structural disadvantages that contribute to health inequities.

Inequalities in access to healthcare for older adults during COVID-19 pandemics in Lithuania

Ramune Kalediene

R Kalediene[1], *S Kaseliene*[1], *S Sauliune*[1], *O Mesceriakova*[1], *R Zutautiene*[1], *V Kalibatas*[1]
[1]Faculty of Public Health, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: ramunekalediene@gmail.com

Background: During COVID-19 pandemic, healthcare systems experienced unprecedented shock. Older adults were the most vulnerable group of Lithuanian society, facing distinctive health challenges and highest mortality rates. The aim of the study was to examine perceived inequalities and challenges in access to healthcare of Lithuanian population over 65 years old during COVID-19 pandemic.

Methods: Representative sample of Lithuanian population over 65 years old (1503 individuals) was involved in the anonymous questionnaire survey, performed in January, 2024.

Results: 22 % of respondents reported not using healthcare services during COVID-19 pandemics. Among them, 76% did not have any need for healthcare services, while 13.6% did not approach healthcare due to fear of getting infected by Covid-19, and the other 10.4% had various accessibility challenges. 15.8% reported frequent problems in registering with family doctors, and 20.0% - with the specialist appointment. There was a clear social gradient observed among those underserved: it was associated with educational level and place of residence. Those with lower education and living in smaller towns and rural areas reported more common healthcare accessibility problems. Higher education, income and better self-perceived health correlated with higher satisfaction with travel time reaching health care services and registering for the appointment ($p < 0.05$).

Conclusions: Health system resilience reflects the ability to continue service delivery in the face of extraordinary shocks. Limited health care accessibility and clear social gradient could increase vulnerability of older adults, which resulted in exceptionally high mortality rates during COVID-19 pandemics. Results of the survey will be used for further development of transformative capabilities of healthcare system, responding to public health disasters and protection of the vulnerable groups of the society.

Key messages:

- Limited health care accessibility and clear social gradient could increase vulnerability of older adults, which resulted in exceptionally high mortality rates during COVID-19 pandemics.
- Results of the survey will be used for further development of transformative capabilities of healthcare system, responding to public health disasters.

Abstract citation ID: ckae144.1241
Inequalities in prevalence rate of edentulism in the European Union between 1990 and 2019

Carlos Alexandre Soares Andrade

CAS Andrade[1], N Mahrouseh[1], E von der Lippe[2], CM Baravelli[3], O Varga[1]
[1]Department of Public Health, University of Debrecen, Debrecen, Hungary
[2]Department of Epidemiology, Robert Koch Institute, Berlin, Germany
[3]Department of Disease Burden, Norwegian Institute of Public Health, Bergen, Norway
Contact: soares.andrade@med.unideb.hu

Background: Edentulism, characterized by tooth loss, serves as a global indicator of oral health burden, particularly affecting older and economically disadvantaged populations. We aimed to assess health inequalities in age-standardized prevalence rate (ASPR) of edentulism across 28 EU member states and EU as a whole between 1990 and 2019.

Methods: We retrieved ASPR, annual rate of change (ARC) and 95% uncertainty interval from the Global Burden of Disease (GBD) 2019 study. We calculated the ASPR ratio between 1990 and 2019 and country-paired ASPR for 2019. To estimate the inequalities between countries between 1990 and 2019, we used the Gini Coefficient (GC) and Slope Index of Inequality (SII).

Results: The EU ASPR for edentulism was 5912 (95% UI: 4751-7473) in 1990 while in 2019 it was 5048 (95% UI: 3970-6485). Sweden had the lowest ASPR in 1990, while Spain held this position in 2019. The highest rates in 1990 were observed in Poland and the Netherlands, with the Netherlands maintaining the highest ASPR in 2019. Spain exhibited the lowest ARC at -0.325 (95% UI: -0.477–0.193), while Sweden was the sole country with a positive value, at 0.034 (95% UI: -0.009-0.075). The ASPR ratio across all EU member states exhibited a range of values for males, from 1.00-2.16, and for females, from 1.00 to 1.87. The ASPR ratios ranged between 1.81 and 2.16 from 1990 to 2000. The GC was 0.097 (95% UI: 0.076-0.117) in 1990 and subsequently decreased-0.084 (95% UI: 0.063-0.105) by 2019. The SII exhibited a range from 0.062 (95% UI: 0.051-0.072) in 1990-0.046 (95% UI: 0.038-0.054) in 2019.

Conclusions: Inequalities in edentulism in the EU were similarly low when comparing 1990 and 2019. However, there was an alarming increase in inequalities between 2005 and 2010. This underscores the need for targeted interventions and policy measures-address oral health inequalities, considering socio-economic factors, healthcare policies, sex disparities, and public awareness initiatives.

Key messages:

- Edentulism is a significant public health concern within the EU for approximately 30 years.
- It has demonstrated comparable disparities in prevalence at both the beginning and end of the period, with a noticeable intensification in the interim.

Abstract citation ID: ckae144.1242
Nationwide prevalence and trends in high-risk drinking among adult men the disabled and non-disabled

Bohui Park

BH Park[1], SY Kim[2,3], JH Park[1,2]
[1]Department of Biomedical Convergence, Chungbuk National University, Cheongju-si, South Korea
[2]College of Medicine, Chungbuk National University, Cheongju-si, South Korea
[3]Department of Public Health and Preventive Medicine, Chungbuk National University Hospital, Cheongju-si, South Korea
Contact: pbhmail26@gmail.com

Background: Excessive drinking is an important public issue that causes various levels of physical, psychological, behavioral problems. Especially for the disabled, it matters in that it could lead to poor health and secondary health conditions.

Methods: This study analyzed high-risk drinking (HRD) behaviors over a 9-year period in adult South Korean men according to disability presence, severity, type. We linked national disability registration data with the National Health Insurance claims data. Age-standardized prevalence of HRD were analyzed for each year and the odds of current HRD were determined by multivariate logistic regression after adjusting for income level, residence, insurance type, Charlson comorbidity index.

Results: The age-standardized HRD prevalence of the mildly disabled was higher than that among the non-disabled. Among the mildly disabled and physically disabled, younger aged group showed higher prevalence of HRD than that of non-disabled. In multivariate logistic regression analysis, the mildly (aOR=1.26, 95% CI = 1.24-1.29), physically (aOR=1.31, 95% CI = 1.28-1.33), communication disabled (aOR=1.12, 95% CI = 1.07-1.17) had higher prevalence of HRD than the non-disabled.

Conclusions: The prevalence of HRD was higher among the young mildly disabled than the non-disabled, this was more evident in young men physically disabled, communication disabled. This may be a result of the physical and social limitations of severely disabled and should be interpreted with caution. Social activities should be supported, and health policies on alcohol consumption should be implemented to prevent secondary conditions and reduce health disparities. Funding: This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Ministry of Education (No. 2022R1I1A3070074) and by a grant of Patient-Centered Clinical Research Coordinating Center (PACEN) funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HC23C0165).

Key messages:

- The prevalence of high-risk drinking was highest among the mild disabled, especially the mild, physical, communication disabled in younger aged men.
- Health policies and efforts to improve health disparities aimed at reducing alcohol consumption among people with disabilities are needed.

Abstract citation ID: ckae144.1243
Social patterning of health misinformation in two Eastern Mediterranean populations

Alexandros Heraclides

A Heraclides[1], K Kouvari[1], A Hadjikou[1], A Gkoutzourelas[1]
[1]Health Sciences, European University Cyprus, Nicosia, Cyprus
Contact: a.heraclides@euc.ac.cy

Background: Health misinformation, the spread of false or misleading information relevant to health, has been proposed as a major global public health thread by the WHO. We aimed to identify the major social determinants of health misinformation in the general Greek and Cypriot populations.

Methods: Following proportional quota sampling we recruited a nationwide sample of 585 adults from Greece and Cyprus between January 2022 and May 2023. A newly developed, culturally adopted questionnaire comprising 48 items, was used to assess misinformation on COVID-19 vaccines and the pandemic. Sociodemographic determinants of interest included gender, age, marital status, area of residence, educational attainment, and income. Multiple linear regression was used to determine associations between the aforementioned social factors and the two dimensions of health misinformation, applying mutual adjustment.

Results: Misinformation about both vaccination and the pandemic was higher in younger age groups (p-trend 0.026 and 0.007, respectively), among those separated, divorced, or widowed (mean difference, 95% CI compared to those single: 9.73, 0.45, 19.01), and among those living in semi-urban compared to urban areas (11.14, 1.32; 20.97 and 9.44, 1.96; 16.92, respectively). We also detected strong inverse socioeconomic gradients in health misinformation based on educational attainment and income (p-trend <0.001, for both).

Conclusions: Younger individuals, those living alone, those residing in semi-urban areas, and those with lower educational attainment and income are particularly prone to health misinformation. Our adjusted models show that this social phenomenon is not simply explained by differences in education, hence more complex, cultural, political, perceptual, and psychosocial dynamics might be in place. Addressing the social patterning of health misinformation would help manage the issue more effectively and also reduce health inequalities.

Key messages:

- Health misinformation is strongly socially patterned in two Eastern Mediterranean European populations.
- Targeting efforts to tackle health misinformation to those more vulnerable, would render such programmes more effective, also helping reduce social inequalities in health.

Abstract citation ID: ckae144.1244
Determinants of willingness to vaccinate against HPV among adults: an Italian cross-sectional study

Riccardo Mimmo

R Mimmo[1], *G Lo Moro*[1], *F Golzio*[1], *G Campi*[1], *G Scaioli*[1], *F Bert*[1,2], *R Siliquini*[1,3]
[1]Department of Public Health Sciences and Pediatrics, University of Turin, Turin, Italy
[2]Local Health Unit ASL TO3, Turin, Italy
[3]University Hospital City of Health and Science of Turin, Turin, Italy
Contact: riccardo.mimmo@unito.it

Background: In Italy, heterosexual males over the age of 18 do not participate in the free-of-charge HPV vaccine offer, nor do women over the age of 26, with regional differences; however, they can vaccinate for a fee. This survey aims to assess the vaccination readiness of the 18-40 year old population group, their perceived need with respect to the vaccine, and the determinants of the vaccination choice.

Methods: A questionnaire-based cross-sectional study targeting the general population in the 18-40 age group has been ongoing since March 2024. Recruitment occurs through social media and flyers. Demographic characteristics, social determinants, deprivation index by area via HAZ (health action zone) method (SR: -15;25), risk factors, main barriers to vaccination are assessed. Our main outcome is HPV vaccination willingness. People already vaccinated were excluded from the analysis. Descriptive and logistic regression analyses were performed with Jamovi.

Results: Our preliminary results included 159 individuals of whom 57.2% would like to receive HPV vaccine. The main characteristics of the sample were: median age 30 years (IQR:26.5;34), 47.2% female gender, median deprivation index 3.7 (IQR:-0.2;7.1), 75% working, 11.9% from the LGBTQ+ community. Regarding barriers, 31.9% rated fatigue in accessing the vaccine as significant, 10.4% feared a risk in receiving the vaccine. Among the people who did not want to vaccinate or did not know, 75% would do so by paying less than the normal amount, 21.6% if free, and 3.4% would not vaccinate anyway. Vaccination willingness was positively associated with female gender (OR:3.1; $p = 0.026$) and belonging to the LGBTQ+ community (OR:10.0; p:0.050) and negatively associated with working status (OR:0.19; $p = 0.013$).

Conclusions: Socioeconomic barriers appeared to play a significant role in the choice to vaccinate. Policies to reduce economic barriers could increase vaccination in an uncovered but still potentially sexually active population.

Key messages:

- Coverage of HPV vaccine is not yet at optimal thresholds, yet people excluded from free vaccination programs could benefit from vaccination incentive policies.
- Vaccination intention among heterosexual men is significantly lower than among women in the same age group, a symptom that there would still be room for awareness-raising interventions on the issue.

Contact: v.bempi@prolepsis.gr

Issue: In Europe, over 80 million people experience mental ill-health and there are 4 million new cancer diagnoses each year. Individuals experiencing mental ill-health exhibit higher rates of cancer morbidity and mortality, with this excess attributed to risky health behaviors and obstacles encountered when accessing often fragmented healthcare systems.

Description of the problem: The aim of Co-CAPTAIN is the pilot implementation and evaluation of the Patient Navigation Model (PNM) for the improvement of primary cancer prevention in individuals with mental ill-health, adapted through participatory co-design in the European context. The project will adopt a cohort-based study design, commencing data collection at baseline and succeeded by three follow-ups (6 weeks, 9 months, 18 months). It will utilize a mixed-methods approach, combining quantitative and qualitative methodologies to assess diverse outcomes of PNM, facilitating both exploratory and confirmatory research. Qualitative data will be obtained through semi-structured interviews, while quantitative data will be collected using validated questionnaires and items developed ad hoc. The project will involve four pilot sites in Europe (Austria, Greece, Poland and Spain), where the PNM will be adapted to the specificities of national healthcare and support systems. The implementation phase is expected to begin in June 2024.

Results: During implementation, gathering both quantitative and qualitative data will offer valuable insights into feasibility and effectiveness, establishing a baseline for reshaping health and social care policies for individuals with mental ill-health across Europe.

Lessons: Co-CAPTAIN project aims to reduce health disparities for individuals with mental ill-health by improving overall health and reducing cancer burdens, leading to cost reductions in European health and social care systems.

Key messages:

- The project aims to deliver an innovative solution based on the PNM, to address health disparities among individuals with mental ill-health by reducing cancer burden.
- Combination of qualitative and quantitative methodologies to assess diverse outcomes.

Abstract citation ID: ckae144.1246
Closing the gap: introducing the EQUALS MAP framework for equity-focused evidence synthesis

Lucy McCannn

L McCann[1], L Johnson[1], A Gkiouleka[2], H Pearce[2], J Ford[1]
[1]Wolfson Institute of Population Health, Queen Mary University of London, London, UK
[2]Department of Public Health & Primary Care, University of Cambridge, Cambridge, UK
Contact: Lucy.mccann@nhs.net

Background: Equity-focused analysis is vital to understanding how interventions affect disadvantaged groups and prevent widening inequalities via intervention-generated inequalities. We reviewed PROGRESS-Plus usage - a commonly used framework in equity-focused reviews and proposed a novel framework.

Methods: First, we re-analysed articles from the EQUALISE study, a review of interventions that increase or decrease inequalities in general practice, to explore the various domains of disadvantage examined in the included studies. We then compared these domains of disadvantage with the existing PROGRESS-Plus framework. Finally, we propose a new framework to support equity-focused evidence synthesis.

Results: From the 325 studies included, the PROGRESS-Plus dimensions most assessed were sex(52%), ethnicity/race(49%), and age(44%). The PROGRESS-Plus framework missed context-specific groups, those with multiple intersecting disadvantage, and people who experience disability. Our new framework EQUALS MAP includes: Ethnicity (and culture and race); Qualifications (and other socioeconomic factors of household or individual); Underprivileged areas; Age; Lesbian, gay and other sexual identities; Sex and gender; Multiple disadvantages; Additional groups experiencing significant disadvantage; and Physical and mental disability.

Conclusions: EQUALS MAP encapsulates the key dimensions of health inequities whilst for allowing context-specific flexibility. Examining the effectiveness of policy and practice interventions by disadvantaged groups is paramount to prioritise actions.

Key messages:

- PROGRESS-Plus - a commonly used framework for equity-focuses evidence synthesis - misses context-specific groups, those with multiple intersecting disadvantage, and people who experience disability.
- EQUALS MAP is a novel framework which encapsulates the key dimensions of health inequalities whilst allowing for context-specific flexibility.

Abstract citation ID: ckae144.1247
Post-operative Mortality Trends for Complicated Appendicitis: Adults with and without Disabilities

YuJin Kim

YJ Kim[1], KE Yeob[2], SY Kim[2,3], JH Park[1,2,4]
[1]College of Medicine, Chungbuk National University, Cheongju, South Korea

[3]Health Policy and Management, Chungbuk National University, Cheongju, South Korea
[4]Public Health and Preventive Medicine, Chungbuk National University Hospital, Cheongju, South Korea
Contact: althqhfl97@gmail.com

Background: Even for the same complicated appendicitis, the prognosis may vary if appropriate post-operative care and follow-up are not provided. We aimed to investigate the 10-year trend of complicated appendicitis mortality among disabilities and non-disabilities peoples in Korea, recognizing potential disparities in post-surgical outcomes and the importance of adequate post-operative care.

Methods: Patients with complicated appendicitis were classified by severity using DRG codes. Causes of death were categorized into infectious, respiratory, cardiovascular, and digestive diseases using ICD-10 data. Age-adjusted mortality rates were calculated annually from 2008 to 2017 based on disability presence, severity, and type. Factors associated complicated appendicitis mortality were analyzed using multivariate logistic regression models.

Results: The mortality of complicated appendicitis was 10.2 times (40.8% vs. 413.9%) higher in people with disabilities, especially those with severe disabilities. This difference was more evident in patients with a severe disability (aOR=2.12, 95% CI:1.58-2.86), intellectual or psychological disability (aOR=2.95, 95% CI:1.49-5.85) and internal organ problems (aOR=2.05, 95% CI:1.28-3.28).

Conclusions: Our findings suggest that insufficient post-operative care among disabled peoples, especially those with severe disabilities, internal organ problems, and intellectual or psychological disabilities, may impact outcomes. This is exacerbated by poor healthcare facilities and limited disability awareness among healthcare workers. Additionally, further research is required to uncover unexplained mortality causes. Funding: This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Ministry of Education (No. 2022R1I1A3070074) and by a grant of Patient-Centered Clinical Research Coordinating Center (PACEN) funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HC23C0165).

Key messages:

- Complicated appendicitis mortality rates show a stark 10.2-fold disparity between people with and without disabilities.
- Severe disabilities, intellectual or psychological disabilities, and internal organ problems heighten the risk, emphasizing the importance of disability-inclusive healthcare practices.

Background: The Health Navigator Model (HNM) is a newly developed skill-mixed model that may improve access to cancer prevention services for over 895,000 People who are currently Experiencing Homelessness (PEH) in Europe. The aim of this study was to assess the feasibility and implementation of the model in European settings.

Methods: A co-designed pilot implementation study was undertaken in Austria, Spain, Greece and the United Kingdom. A total of 20 trained health navigators were appointed at support centres for PEH and facilitated PEH's access to cancer prevention activities based on a comprehensive and tailored needs assessment. The study duration was 19 months, with two follow-ups. Feasibility data (recruitment/retention/participation rates, barriers, facilitators) were monitored throughout the study.

Results: More than 1,981 PEH were informed about the study and 652 of them participated. Most participants were male (64%), with low or no income (42%) and had previously experienced homelessness (51.7%). The mean age of participants was 47.4 years old. Overall, 69% of participants completed the first, and 42.5% completed the second follow-up. Main dropout reasons were loss of contact, loss of interest or having other priorities. Participants undertook a range of cancer prevention activities, including education (n = 494), workshops (n = 280), health consultations (n = 251), referrals for specialist care (n = 212) and cancer screening tests (n = 169). Difficulties in accessing the healthcare system, de-prioritising cancer and PEH's complex needs were identified as the main barriers. Building trusting relationships with PEH, increasing cancer awareness and coordinating social and health services were identified as the main facilitators.

Conclusions: Implementing the Health Navigator Model was a feasible and dynamic process leading to improved equity and inclusion of people experiencing homelessness in cancer preventive services.

Key messages:

- The Health Navigator Model is a feasible model to enhance cancer prevention among people experiencing homelessness following a person-centred, destigmatising approach.
- Effective liaison between health and social services under the Health Navigator Model plays a critical role in facilitating access to cancer preventive care among people experiencing homelessness.

The Welsh Health Equity Solutions Platform – a mechanism for health equity solutions

Jo Peden

D Stewart[1], *L Couzens*[1]
[1]Policy and International Health WHO CC, Public Health Wales, Cardiff, UK
Contact: jo.peden@wales.nhs.uk

Health inequities are a longstanding issue in Wales, as they are across the globe. They disproportionately affect the health and wellbeing outcomes of disadvantaged groups, restricting opportunities to live full and prosperous lives. Post COVID-19 new groups are emerging with disproportionately higher risk of poor health and premature death and disease, especially those with unmet needs and vulnerabilities, with the rising cost of living amplifying health inequities. Despite their prevalence, health inequities are avoidable. Efforts to reduce health inequities require action on all the social determinants of health across the life course. Improved understanding of the key drivers of health gaps is needed to address the problem and provide support for solutions-driven action to break down the barriers to health equity. The Welsh Health Equity Solutions Platform (WHESP) launched on 22nd June 2023, a collaboration between Public Health Wales, Welsh Government and WHO European Office for Investment in Health and Development. The WHESP is an innovative digital tool developed around the WHO Health Equity Status Report initiative framework of the 'five essential conditions' for healthy, prosperous lives for all. It is a mechanism for health equity solutions and aims to inform and facilitate policy and decision making to improve population health and address the increasing health gap through an online gateway to data, health economics, policies, and innovative health equity tools. Emerging evidence is highlighted to identify solutions for achieving healthy equity, which informs evidence-based decision making to reduce the health gap, improve overall population health and wellbeing, and achieve inclusive and sustainable economic growth and prosperity for all. Collating and sharing health equity solutions, evidence, data and best practice both across Wales and globally supports equitable, long-term action to improve the health and wellbeing of the population.

Key messages:

- Highlighting health equity solutions informs best practice on tackling health inequalities.
- WHESP provides extensive evidence to facilitate cross-sectoral action and policy change.

[7]Mental Health Europe, Brussels, Belgium
Contact: katrin.schaefer@meduniwien.ac.at

Introduction: People experiencing mental ill-health have greater disparities in cancer specific morbidity and mortality. Factors influencing cancer prevention include increased risk behaviours and frequent encounters with barriers to health care utilization. The Patient Navigation Model (PNM) has been proven to reduce barriers in accessing cancer preventive care in vulnerable populations. To facilitate successful implementation, the conceptual features of the PNM were co-designed with patients and other relevant stakeholders.

Methods: Twelve focus groups were conducted in January 2024 at four pilot sites in Austria, Greece, Poland, and Spain. Iterative focus group discussions were carried out following key considerations for the PNM as outlined by DeGroff et al., audio recorded and transcribed verbatim. Transcripts were analysed deductively using a directed content analysis while allowing for potential inductive emergence of codes and topics. A total of 50 participants attended, representing five groups (individuals with mental ill-health, care givers, care team members, representatives of mental health organizations, and representatives of service managers).

Results: The co-design focus groups allowed for the PNM to be contextually adapted to each pilot site, but similarities in the approach emerged within the following four themes: 1) the requirement for a person-centred approach, 2) consideration of both person-specific and context-specific needs, 3) flexibility and

competencies of navigators and 4) variation of navigation services (e.g., improving health literacy, promoting a healthy lifestyle, and providing practical support).

Conclusions: Participatory approaches in co-designing interventions allow for context specific development of interventions to meet the requirements of people with complex needs. Co-designing the PNM is part of activities of the CO-CAPTAIN project funded by the European Union's Horizon Europe Programme (GA 101104784).

Key messages:

- The Patient Navigation Model for Primary Cancer Prevention is a tailored intervention aiming to meet the needs of individuals experiencing mental ill-health.
- The conceptual features of the Patient Navigation Model for Primary Cancer Prevention were co-designed with patients and other relevant stakeholders.

Abstract citation ID: ckae144.1251
Quality of life in people with multiple sclerosis vs general population: differences increase by age

Lara Marleen Fricke

LM Fricke[1,2], *K Krüger*[1,2], *C Krauth*[1,2]
[1]Institute for Epidemiology, Hannover Medical School, Hannover, Germany
[2]CHERH - Center for Health Economics Research Hannover, Hannover, Germany
Contact: fricke.lara@mh-hannover.de

Background: To enhance health care for chronically ill people, it is crucial to understand the impact of their disease on health-related quality of life (HRQoL). More than 240,000 people in Germany live with multiple sclerosis (PwMS), the most common immune-mediated neurodegenerative disease of the central nervous system. Little is known about HRQoL in PwMS in comparison to the general population and by subgroups.

Methods: In 2021, 6,928 statutorily-insured PwMS aged ≥18 years and living in the federal state of Lower Saxony, Germany, were invited to take part in an online survey. The German EQ-5D-5L value set was used to analyse HRQoL by index values. Descriptive subgroup analyses were conducted (age, sex) and compared to a general German reference population (Grochtdreis et al. 2019, DOI: 10.1007/s10198-019-01054-1). Mann-Whitney-U- or Kruskal-Wallis-tests were performed as appropriate.

Results: Of 1,935 respondents (response rate 27.9%), 1,916 PwMS were included in the current preliminary complete case analysis. HRQoL is reduced in PwMS compared to the general population: Mean (M) 0.67 vs. M 0.88, respectively. While no significant differences by sex were found in PwMS (male: M 0.66 vs. female: M 0.68, $p = 0.1$), HRQoL decreased with increasing age ($p < 0.001$). The reduction in HRQoL is more pronounced in PwMS than in the general population (difference between means 0.53 in 18-24 years old to ≥ 75 years old PwMS vs. 0.14 in the reference population, respectively).

Conclusions: PwMS report an overall lower level of HRQoL compared to the general population. Increasing age correlates with a substantial decrease of HRQoL in PwMS. Targeted research is needed to improve HRQoL of this vulnerable population.

Key messages:

- The decline in HRQoL with increasing age is more pronounced in PwMS than in the general population in Germany.
- Further research should focus particularly on the extent to which MS-related factors are solely attributable for the considerable decline of HRQoL in PwMS.

Factor Influencing Unmet Healthcare Needs among the disabled

Bohui Park

BH Park[1], *SY Kim*[2,3], *JH Park*[1,2]
[1]Department of Biomedical Convergence, Chungbuk National University, Cheongju-si, South Korea
[2]College of Medicine, Chungbuk National University, Cheongju-si, South Korea
[3]Department of Public Health and Preventive Medicine, Chungbuk National University Hospital, Cheongju-si, South Korea
Contact: pbhmail26@gmail.com

Background: The unmet Healthcare needs (UHNs) of the disabled are not only detrimental to their quality of life but also can lead to serious health outcome including death. A variety of factors including socioeconomic, personal, environmental factors affect UHNs for the disabled.

Methods: We analyzed the UHNs status and influencing factors among 4,326 adult the disabled using Korea disability Life Data. Chi-square analysis was conducted to identify differences in UHNs according to characteristics of general, disability, environmental of the disabled. Logistic regression analysis was conducted to determine factors affecting UHNs.

Results: Those with low educational level (aOR=1.23, 95% CI = 1.02-1.48), those enrolled in private insurance (aOR=1.23, 95% CI = 1.02-1.50), those need help with daily living (aOR=1.30, 95% CI = 1.06-1.59), those who rarely go out (aOR=1.57, 95% CI = 1.27-1.92), those who use taxis (aOR=1.41, 95% CI = 1.05-1.89) or call taxi for the disabled when going to the hospital (aOR=1.37, 95% CI = 1.01-1.88), the communication disabled (aOR=1.30, 95% CI = 1.03-1.65), those with poor subjective health status (aOR=1.25, 95% CI = 1.04-1.49), those felt the explanation of treatment results was insufficient (aOR=4.04, 95% CI = 1.37-11.93), and those dissatisfied with healthcare services (aOR=3.52, 95% CI = 2.74-4.51) were more likely to experience UHNs.

Conclusions: Effective healthcare service provision for the disabled requires not only financial assistance but also social support, along with education for healthcare staff, policies with the characteristics of disabilities. Funding: This research was supported by a grant of Patient-Centered Clinical Research Coordinating Center (PACEN) funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HC23C0165) and by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No. RS-2024-00394642)

Key messages:

- The disabled need not only financial support when using healthcare services, but also support from society, such as accompanying them to the hospital and providing transportation.
- Education for healthcare staff who communicate with the disabled and provision policy to provide appropriate healthcare services according to the characteristics of disabilities are needed.

Abstract citation ID: ckae144.1253
Equity of continuous glucose monitoring in young people with type 1 diabetes: a systematic review

James Howard Dicks

J Howard Dicks[1], *L McCann*[2], *AL Tolley*[1], *A Barrell*[3], *L Johnson*[2], *I Kuhn*[4], *J Ford*[2]
[1]School of Clinical Medicine, University of Cambridge, Cambridge, UK
[2]Wolfson Institute of Population Health, Queen Mary University of London, London, UK
[3]School of the Biomedical Sciences, University of Cambridge, Cambridge, UK
[4]University of Cambridge Medical Library, University of Cambridge, Cambridge, UK
Contact: james.howarddicks1@nhs.net

Background: Socioeconomic (SES) and ethnic inequalities in type 1 diabetes (T1D) outcomes are widespread. There is concern that unequal access to technologies, such as continuous glucose monitoring (CGM), may increase disparities. This systematic review summarises the evidence for inequalities in access to CGM for children and young people (CYP) and outcomes for CGM users.

Methods: MEDLINE, Embase, and Web of Science were searched for observational studies published between January 2020 and July 2023 which report CGM use stratified by any PROGRESS-plus criteria for T1D patients under 26. Reports based in low- or middle-income countries or ≤ 500 participants were excluded. Primary outcomes were the proportion of patients using CGM and HbA1c of CGM users. Quality assessment was performed using the Newcastle-Ottawa Scale. Unadjusted odds ratios were calculated from extracted data, though heterogeneity precluded meta-analysis. The protocol was pre-registered with PROSPERO (CRD42023438139).

Results: Of the 3,369 unique studies identified, 27 met inclusion criteria. We found decreased CGM use and higher discontinuation for low SES, low education, publicly insured, and minority ethnic, especially black, CYP. These associations were generally robust to adjustment for other sociodemographic variables, suggesting an independent effect. Lower SES inequalities were seen in countries where CGM is reimbursed. Although low SES and minority ethnicity were generally associated with poorer outcomes, there was no significant association between domains of disadvantage and higher HbA1c for CGM users, excepting parental education.

Conclusions: There are significant SES, ethnic, and education inequalities in CGM use for CYP with T1D, particularly when reimbursement is limited. This is contributing to outcome inequalities. However, evidence suggests CYP benefit equally from CGM use, irrespective of ethnicity and SES. Increasing CGM funding and use is likely to reduce outcome inequalities.

Key messages:

- There are significant SES, ethnic, and education inequalities in continuous glucose monitoring use for young people with T1D. Inequalities are more marked when technology is not reimbursed.
- Increasing access to CGM may reduce outcome inequalities, as evidence suggests that young people benefit equally from CGM use, regardless of ethnicity or SES.

Abstract citation ID: ckae144.1254
Welfare regimes and socioeconomic inequalities in edentulism: A multilevel analysis of 40 countries

Roger Keller Celeste

R Keller Celeste[1,2], *C Guarnizo-Herreño*[3], *F Costa*[4], *O Ayo-Yusuf*[5], *AJ Barros*[4], *J Fritzell*[2], *MA Peres*[6], *RG Watt*[7]

[6]National Dental Research Institute, Duke-NUS Medical School, Singapore, Singapore
[7]Department Epidemiology and Public Health, University College London, London, UK
Contact: roger.keller@ufrgs.br

Aim: To evaluate the association between welfare regimes with edentulism and to investigate if it modifies the magnitude of socioeconomic inequalities in edentulism.

Methods: We analysed data from 40 high-, middle- and low-income countries collected between 2007 and 2018, encompassing 117397 individuals 20 years or older. The main outcome was edentulism and welfare regimes were the main exposure and effect modifier. Individual level variables were sex, age and quintiles of the wealth score. Multilevel logistic regression was used to estimate the odds of being edentulous and cross-level interaction terms between individual wealth and country factors were tested.

Findings: Individuals at the lowest wealth quintile had a consistently higher prevalence of edentulism. The highest age-sex standardised prevalence of edentulism was found in Eastern European countries (9.9%) followed by Informal Security (9.4%), while the lowest was among the Insecurity regime (1.4%) followed by the Social Democratic regime (4.7%). Liberal countries presented the highest magnitude of absolute and relative inequalities, where the lowest quintile had OR = 16.7 (95%CI: 10.5-26.5) times more chances of being edentulous and 14.4 percentage points higher prevalence. Low-income countries in the Insecurity Regime in social and labour market presented the lowest level of inequalities. Among HIC and upper-middle income countries, Social Democratic regime had the lowest absolute inequalities (4.0 percentage points difference between highest and lowest quintiles) and the Informal Security regime had the lowest relative differences between the highest and lowest quintiles (OR = 3.21, 95%CI: 2.83-3.63).

Interpretation: Our findings suggest that policies in some welfare regimes might improve oral health while reducing inequalities. High and upper-middle-income countries presented a high level of edentulism and inequalities.

Key messages:

- Larger socioeconomic inequalities in edentulism were found in high-income countries with liberal policies.
- A possible benefit of welfare policies on prevalence and inequalities in edentulism may be only evident among industrialised countries.

Abstract citation ID: ckae144.1255
Lesson learned from a co-designed vaccination initiative with undocumented people in the Netherlands

Louise De Vos Klootwijk

L De Vos Klootwijk[1,2], *CA Kersten*[1]
[1]Department of Infectious Disease, Public Health Service Haaglanden, The Hague, Netherlands
[2]Infectious Disease Control, Academic Collaborative Centre for Public Health Lumens, The Hague and Leiden, Netherlands
Contact: louise.devosklootwijk@ggdhaaglanden.nl

Issue/ problem: ‘The coronavirus does not take document status into account’. The COVID-19 pandemic highlighted the importance of equal healthcare access for all. Yet, undocumented people face numerous personal and practical barriers in accessing health. Ensuring the protection of the most vulnerable is a global concern.

Description of the problem: In 2021, a regional initiative aimed to remove barriers and create a trusted environment for undocumented people to receive vaccinations. This collaborative effort included public health departments, NGO’s, community groups, (self) organized migrant organizations, GP’s and embassies. Regular meetings identified the population’s needs. A medical doctor was made available 24/7 to address questions and concerns. Actions were undertaken to build trust, foster collaborations between health authorities and communities and to improve vaccine service access and design.

Results: Working in partnership fostered trusted, multi-sectorial relationships, resulting in a vaccination initiative that met the diverse needs of the undocumented people. Widespread community-driven outreach through flyers and social media reached those who normally are not reached. Supported by over 40 volunteers, three vaccination events were organized in which 693 doses were administered. All parties made their contribution, e.g. with different migrant communities providing hot meals. The initiative began at the grassroots level in the communities and was then executed in partnership with the involved parties, making it highly successful.

Lessons: Inclusive engagement, addressing concerns and sharing clear information not only supports trusted relationships but also strengthens social cohesion. Collaborating directly with the communities ensured the initiative was tailored to their needs, thereby lowering the barriers for accessing healthcare. Achieving this success required a foundation of trust, mutual respect and a collective commitment from all involved.

Key messages:

- Codesigning vaccination initiatives with the communities is essential for success.
- Trusted partnerships, community involvement and mutual commitment were key elements for lowering barriers to accessing health.

Abstract citation ID: ckae144.1256
The Role of Faith in Medical Decision-Making

Aviad Tur-Sinai

A Tur-Sinai[1], R Neriya-Ben Shahar[2], F Yuval[3]
[1]School of Public Health, University of Haifa, Haifa, Israel
[2]Department of Communications, Sapir Academic College, Sderot, Israel
[3]Department of Public Policy and Management, Ben-Gurion University of the Negev, Beer-Sheva, Israel
Contact: atursinai@univ.haifa.ac.il

Background: Ultra-Orthodox Israeli Jews face complex decisions when their doctors' instructions contradict their rabbis' advice. This study examines how their belief system affects their trust and decision-making in such situations, using socio-economic club theory and Gilligan's listening guide.

Methods: Excerpts from 16 focus groups with 128 ultra-Orthodox Jews were analyzed to understand their perspectives on the relationship between doctors and rabbis. The socio-economic approach of Berman's club theory was applied to explain their behavior, and Gilligan's listening guide was used to analyze the focus group results.

Results: The strict behaviors in the relationships between doctors, rabbis, and patients function as social capital, raising the status of ultra-Orthodox Jews as members of an exclusive club. They balance critical health decisions with the social demand to obey religious leaders. However, listening to different voices ('I,' 'we,' and 'they') provides nuanced insights into their decisions, revealing dynamic changes in the community's perceptions of the doctor-rabbi relationship and varying perspectives within the heterogeneous ultra-Orthodox community.

Conclusions: Combining Berman's theory with Gilligan's listening guide is an effective method for conducting in-depth qualitative research on sensitive issues with religiously strict groups. Understanding the belief systems underlying healthcare decisions is essential for providing culturally sensitive medical care to religious communities and training medical staff serving these communities.

Key messages:

- Ultra-Orthodox Jews balance complex health decisions with social demands, revealing nuanced perspectives through strict doctor-rabbi relationships.
- Combining theories and qualitative methods effectively studies sensitive issues in religious groups, informing culturally sensitive healthcare.

Abstract citation ID: ckae144.1257
The role of sociodemographic factors on herpes zoster vaccine uptake among hard-to-reach populations

Giacomo Diedenhofen

G Diedenhofen[1], G Colaiocco[2], G Adamo[2], P Amoriello Lamberti[2], SM Gherardi[2], F Trani[2], O Zuccaro[2], C Isidori[2], G De Angelis[2], V Fano[2,3]
[1]Specialization School for Medical Statistics, Department for Public Health - Sapienza University of Rome, Rome, Italy
[2]Department of Prevention, Azienda Sanitaria Locale Roma 2, Rome, Italy
[3]Unit for Epidemiology and Tumor Registries, IRCCS Istituti Fisioterapici Ospedalieri, Rome, Italy
Contact: diedenhofen@agenas.it

Background: The anti-Herpes Zoster (HZ) vaccination program was expanded with the adjuvated recombinant vaccine (HZR) in the Lazio Region, Italy, in 2022, restricting its use only to certain categories at risk due to pathological conditions, such as dialysis patients or immunocompromised individuals. This study focuses on the role of clinical and socio-demographic factors on HZR vaccine uptake within the fragile resident population of the Local Health Authority Rome 2 (ASL RM2).

Methods: This population-based, retrospective cohort study leveraged data from various registries and databases. The study population comprised 835,779 individuals aged $\geq$18 years who were both RM2 residents and registered with an RM2 general practitioner (GP). Among these, 143,242 individuals with at least one chronic condition were assessed for vaccination uptake using a multivariate logistic model, exploring associations with gender, age, nationality, marital status, household size, and level of deprivation.

Results: At the conclusion of the study period, a small fraction (1.5%) of the fragile subjects had received at least one dose of the HZR vaccine, and a majority (78%) completed the vaccination course of two doses. The analysis indicated that vaccine adherence was significantly higher in males ($OR = 1.15$) and individuals aged $65+$ ($OR = 1.13$) while lower among residents in areas of medium ($OR = 0.61$) and high deprivation ($OR = 0.44$) and with specific living arrangements - widowed people living alone ($OR = 0.66$) and families $\geq$ 6 people ($OR = 0.63$).

Conclusions: The ASL RM2 vaccination strategy for hard-to-reach individuals includes an integrated approach, with the engagement of local healthcare facilities and hospitals. Despite these efforts, lower adherence in socioeconomically disadvantaged fragile patients suggests a pressing need for targeted communication strategies and interventions to ensure equitable access to the HZ vaccine, as these groups are more vulnerable to developing chronic diseases.

Key messages:

- Socio-demographic factors significantly influence Herpes Zoster vaccine uptake in hard-to-reach populations, with lower adherence in socially deprived groups.
- Tailored, equity-driven approaches are essential for enhancing vaccine coverage among hard-to-reach fragile individuals, mitigating the higher disease risks in these communities.

Abstract citation ID: ckae144.1258
Children with disabilities and inclusive education in general schools: pricipals' attitudes

Donatas Austys

D Austys[1], N Bartkutė[1,2]
[1]Department of Public Health, Institute of Health Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania
[2]Public Health Bureau of Vilnius City Municipality, Vilnius, Lithuania
Contact: donatas.austys@mf.vu.lt

Background: As inclusive education is being implemented nationwide in Lithuania, various attitudes towards education of children with disabilities in general schools are observed. We aimed to assess the attitudes of heads of general schools towards the provision of education to children with disabilities in general education schools of Lithuania.

Methods: Heads of all schools in the Lithuanian capital and its surrounding municipalities implementing general education programmes were invited to take part in this study. 115 persons agreed to participate and completed the questionnaire in spring of 2024. The distribution of the respondents by their answers to the questions about the attitudes towards the provision of inclusive education was compared according to gender, age, education level, work experience, school location (municipality), language of education, type of school, subordination, number of pupils, teachers, teaching assistants and pupils with disabilities.

Results: The most frequently indicated barriers for inclusive education provision were the lack of specialists, compensatory measures, methodological tools, adaptation of the physical environment, and high number of pupils (87.8%, 84.3%, 78.8% and 76.6% respectively). Attitudes of the respondents were similar in most of the cases when compared according to socio-demographic factors (p more than 0.05). Negative attitudes towards the possibilities for provision of inclusive education were more common among respondents from schools with fewer pupils and higher relative number of teachers, positive attitudes - among those from schools located in municipalities with lower number of residents and schools with more teaching assistants (p less than 0.05).

Conclusions: While attitudes of heads of general schools towards the provision of inclusive education for children with disabilities are similar in most of the cases, negative attitudes are more common among those from schools with fewer pupils and more teachers.

Key messages:

- While attitudes of heads of general schools towards the inclusive education are similar in most of the cases, negative attitudes are more common among those from smaller schools.
- Higher number of teaching assistants and smaller municipalities were associated with positive attitudes towards inclusive education of children with disabilies in general schools.

Abstract citation ID: ckae144.1259
Deafness and Inclusion: Perceived Communicative Barriers in the Area of Rehabilitation in Italy

Marise Sabato

M Sabato[1]*, S Sandroni*[2]*, M Marceca*[1]
[1]Department of Public Health, Sapienza University of Rome, Rome, Italy
[2]Speech Therapy, ASL Roma 6, Ariccia (Rome), Italy
Contact: marise.sabato@uniroma1.it

Introduction: Deafness can create a communication deficit/barrier between the Deaf or Hard of Hearing patient and the Healthcare Workers (HWs), with negative outcomes for diagnostic and therapeutic success. As underlined by the COVID-19 pandemic, there is a need to train HWs in effective communication strategies in order to avoid marginalising or excluding the Deaf Community by denying them access to healthcare services. This study highlights the urgent need and desire of Healthcare staff for training in effective communication strategies, such as sign language, to help the Deaf community gain equal access to Healthcare.

Materials and methods: A cross-sectional survey was carried out between May and July 2022 using the Google Forms platform. An anonymous questionnaire was given to Rehabilitation HWs (RHWs) at a national level to collect information from the HWs of the various areas of rehabilitation, identifying their knowledge, training, and experience with regard to deafness. Data analysis was then carried out using the Google Forms program, SPSS program Windows7 Excel Spreadsheet.

Results: 252 RHWs belonging to 8 different profiles answered this survey. 89% were women. 46% were younger than 30. 57% of these 252 had deaf patients, but 54.6% of these had no prior training. 33% of the RHWs had followed courses or seminars on deafness at least once. When asked, 94% were interested in courses or training in communication with deaf people.

Conclusions: HWs recognize the gap in communication and are willing to learn more in the matter for effective communication with their patients to gain a better therapeutic success. They also consider a program that imparts such knowledge and training to be highly important.

Key messages:

- Therapeutic success is increased if there are effective communication strategies, such as sign language, between the Deaf and Healthcare provider.
- This study shows the importance of training all health workers in effective communication strategies with deaf people to allow an all-inclusive healthcare.

Abstract citation ID: ckae144.1260
We are wales: taking the hospital to the community - an engagement experiment

Joanne Hopkins

J Hopkins[1,2,3]*, M Abdul Waheed*[3,4]*, B Parry*[4]*, J Bromwelll*[1,3]*,*
N Blakeborough[1,3]
[1]Policy and International Health, Public Health Wales, Cardiff, UK

[3]ACE Hub Wales, Public Health Wales, Cardiff, UK
[4]Violence Prevention Unit, Public Heath Wales/South Wales Police, Cardiff, UK
Contact: joanne.hopkins2@wales.nhs.uk

In Wales we are facing two major barriers to public health engagement. The first is describing our communities as 'hard to reach' when in public service we make little effort to reach them, and second, we do not consider in population level research or practice how we are perpetuating the sense of, and real, inequality in our communities that our work on social determinants of health and health inequalities seeks to address. In Wales we want to take the 'hospital to the community'; to meet people where they are at, where they live and work and where they experience barriers to inclusion, discrimination, lack of trust and fear. 'We are Wales' is is built on the Museum of the United Nations concept of a global we - except we will start small with a small nation that as yet has not worked out how to include and involve everyone in our communities in the policy and practice decisions that may help, or hinder us all from leading a healthier, happier life. 'We are Wales' is a simple concept; it is about amplifying and connecting people who would not normally do so, because they do not have the resources or capacity to travel or take time out. It is about equal power in a connection to find solutions to adversity and trauma caused by structural inequality; it is about relationships, inclusion, kindness and compassion - and listening, sharing and taking action without judgement. We have taken a dome to communities in economically deprived areas of Wales and stimulated conversation between politicians, young people and communities around the concept of home. Using a virtual reality dome to project images to encourage discussion we have provided a safe space to amplify and include the voices of those who want to be heard and deserve to be listened to.

Key messages:

- 'Take the hospital to the community' - meet people where they are at and feel safe.
- power sharing and an equal place at the table stimulates ideas and knowledge change in a trauma-informed way.

Problem: The Eastern Shore of Maryland is a beautiful region that boasts a multicultural community of 455,000 year-round residents. Despite its rural location, the coastal lifestyle attracts retirees, making it the state's oldest population. Unfortunately, the region also has the highest socioeconomic disparities in the state, which creates difficulties in accessing healthcare. This is a significant public health issue that results in costly barriers to preventive care and timely, accounting for $320 billion in unnecessary healthcare spending.

Description of the problem: Maryland's healthcare funding formulas favor larger health systems in urban areas, leading to health inequities. To address this, we propose an innovative scenario analysis model partially based on European public health approaches. This model will adjust funding formulas based on each region's specific needs and challenges, promoting fairness and equity in healthcare funding.

Results: Adopting this population health management approach would have built-in efficiencies: In the United States, healthcare spending tends to be higher among underserved populations due to delayed care, access challenges, missed diagnoses, and limited access to the latest scientific advances as well as proper preventive services.

Lessons: The proposed scenario-based public health funding approach targeting the needs of the underserved population on the Eastern Shore of Maryland could yield significant positive health outcomes and health savings generating a ripple effect across the state, and perhaps even the country. The lessons learned in how other countries handle public health funding could lead to global collaboration.

Key messages:

- Our approach aims to provide a practical solution to unnecessary healthcare spending.
- We must adapt to the changing tides to stay on course.

Decoding healthcare strategies: providing comprehensive care for type II diabetes in Ecuador

Lucy Parker

A Bravo Díaz[1], *J Pinto Delgado*[1], *F Barrera Guarderas*[1], *A Torres*[1], *A Peralta*[1], *C Blanes*[2], *L Parker*[2,3]
[1]Institute of Public Health, PUCE, Quito, Ecuador
[2]Department of Public Health, University Miguel Hernández, Elche, Spain
[3]CIBER Epidemiología y Salud Pública, CIBER, Madrid, Spain
Contact: lparker@umh.es

Background: Diabetes is a major global health challenge, impacting millions and disproportionately affecting low- and middle-income countries (LMICs), where approximately three-quarters of affected individuals reside. Despite abundant guidance on diabetes management, most evidence is derived from high-resource settings, potentially impeding effective application in low-resource settings. This study explored issues related to the application of the current clinical practice guidelines (CPG) for diabetes management in Ecuador, from the perspective of local health professionals.

Methods: We developed 5 focus groups in Quito, the capital of Ecuador, in a low-income district. The groups included doctors, nurses, and health promoters; they discussed four sections of the CPG concerning their daily practice. Qualitative results are contrasted with quantitative research based on patient records.

Results: The Ecuadorian health system considers patients with diabetes a priority group, yet a patient may wait up to 4 months to receive their first appointments and once they receive their diagnosis several criteria set out in the CPG are not followed due to lack of time and resources, particularly the delivery of multidisciplinary attention. Access to specialized consultations, such as an ophthalmological assessment is severely restricted, and it can take up to a year to get an appointment. Clinicians expressed difficulties in adapting the nonpharmacological recommendations to different socioeconomic backgrounds, while at times, prescription choices are determined by medicine stock regardless of the patient's actual needs.

Conclusions: Healthcare professionals have developed a series of ad-hoc strategies to ensure healthcare for their patients, pointing out the difficulties of applying CPG within a health system that lacks basic resources. Healthcare is intertwined with social inequalities among the Ecuadorian population that have worsened since the covid19 pandemic.

Key messages:

- We identified significant challenges in applying the CPG in low resource settings. Clinicians adapt by introducing novel ways to overcome limitations at times to the detriment of the patient's health.
- CPGs need to be tailored to the context considering socioeconomic realities of the population and limited resources in the health setting.

Abstract citation ID: ckae144.1263
What Makes a Home.Evaluating a Novel Low Support Homeless Accommodation Model Using Co-design Methods

Kate Frazer

K Frazer[1], *A Darley*[1], *C Duffy*[2], *O Doyle*[2], *T Kroll*[1], *N Bhardwaj*[1]
[1]University College Dublin, Dublin, Ireland
[2]Dundalk Simon Community, Dundalk, Ireland
Contact: kathleen.frazer@ucd.ie

Background: Homelessness is a global challenge, with a prevalence of 4%; the problem is underestimated due to limitations in data collection. In Ireland, 1% of the population, including children, adults, and families, experience homelessness due to housing shortages and systemic complexities. Homeless accommodation is defined as emergency and temporary; the wording is used interchangeably. The ETHOS typology of homelessness comprises two dimensions - housing-focused and support-focused. Supports range from high to low levels. This study evaluated an emergency housing accommodation with low support to assess its feasibility and impact.

Methods: Previous residents of an urban residential area with low support [introduced in August 2021] and key stakeholders, including policymakers and health and social care professionals, were invited to collaborate in a half-day co-design workshop [February 2024]. The workshop modified Stanford D's five-stage design thinking processes to consider 'How might we harness strengths and abilities to create a home and beyond'. Qualitative data were captured on flip charts, post-its, and via photographs over three rounds of activities following initial reflection regarding 1) identifying emerging challenges, 2) exploring potential solutions, and 3) considering resources for advocacy and success.

Results: Data analyses from 16 participants highlight 1)Personal insights: silence, freedom in decision-making, feeling overwhelmed, valuing independence and understanding accommodation transitions; 2)Organisational insights: developing and promoting independent skills, managing resident preferences and personalities, balancing regulations within emergency accommodation, and staff training. Space was critical in fostering therapeutic well-being and a sense of home environment.

Conclusions: Effective organisational structures are required to facilitate coherent transfers and transitions. Using co-design methods enabled real-world partnerships and engagement.

Key messages:

- Homelessness is a significant public health challenge, and a model of low support emergency accommodation has value in supporting transition through and out of services.
- Engaging with people with lived experience of homelessness is essential for developing supported accommodation models.

Nationwide trends in the suicide mortality among the disabled in Korea from 2006 to 2017

Kyoung Eun Yeob

KE Yeob[1], SY Kim[1,2], JH Park[1,2]
[1]Institute of Health & Science Convergence, Chungbuk National University, Cheongju-si, South Korea
[2]Public Health and Preventive Medicine, Chungbuk National University Hospital, Cheongju-si, South Korea
Contact: gy10060624@gmail.com

Aims: The disabled are one of the priority populations at risk of suicide, but there has been no study of the factors influencing suicide mortality among the disabled in South Korea.

Methods: To analyze age-standardized suicide mortality (ICD-10 Codes, X60-84) for each year according to the presence, severity and type of disability, we linked three population datasets (National Health Insurance Claims Database, Disability Registry, and Deaths by Cause). Our dataset covers the entire population of South Korea, extended over a 12-year period from 2006 to 2017. The analyses were stratified by sex, and hazard ratios for suicide were determined by multivariate logistic regression after adjustment for socio-demographic and clinical variables.

Results: The suicide rate among the disabled was 2.24 times higher than among the non-disabled in 2017. The highest suicide rates were observed among intellectual or mental disabled, and severe disabled. In the disabled group, suicide rates were higher among those with medical benefits, older age (over 70 years), and depressive disorders in both male and female.

Conclusions: Although the disabled people's suicide is often seen as an individual problem, it actually affects their families, communities and society. Therefore, government must strive to emphasize the broad view of the disabled population - not just the health of individuals, and track suicide trends and identifying risk and protective factors for suicidal behavior. From this information, suicide prevention strategies for the disabled people should be evaluated to identify the most effective interventions. Financial support: This research was supported by the Basic Science Research Program through the National Research Foundation of Korea funded by the Ministry of Education (No. 2022R1I1A3070074, and 2022R1I1A1A01068449), and a grant of Patient-Centered Clinical Research Coordinating Center funded by the Ministry of Health & Welfare, Republic of Korea (No. HC23C016500).

Key messages:

- The suicide rate among the disabled was 2.24 times higher than among the non-disabled in 2017.
- In the disabled group, suicide rates were higher among those with medical benefits, older age (over 70 years), and depressive disorders in both male and female.

Abstract citation ID: ckae144.1265
Formalizing the role of community key individuals in Utrecht, the Netherlands

Putri Hintaran

P Hintaran[1,2], C Sarolea[2], M El Loukili[2], M Bah[2]
[1]Infectieziektebestrijding, GGD regio Utrecht, Zeist, Netherlands
[2]Stichting Sleutelpersonen Utrecht, Utrecht, Netherlands
Contact: phintaran@ggdru.nl

Issue: The disconnect between (underserved) communities and governmental bodies in Utrecht, The Netherlands, has led to uneven access to (essential) healthcare services, increasing health inequalities. This gap is often bridged by key community individuals, whose roles have historically been informal. Key individuals are often seen as volunteers who are necessary to gain access to certain communities but are rarely seen as equals in a project team, resulting in mistrust and reduced collaboration on the long term on the side of the key individuals.

Description of the problem: This practice describes the start of a new foundation in Utrecht that formalizes and compensates key individuals' roles in public (health) projects. The aim was to empower them and to encourage continued participation.

Effects: In 2024, the foundation supported key individuals in three government projects, including a childhood vaccination awareness campaign. Interviews revealed that key individuals felt more empowered and equally valued compared to other project members. They also felt a strong responsibility for project success. However, some noted that formal structures could be restrictive. The government felt more convenience working with a formal foundation.

Lessons: Empowering key individuals is crucial for effective collaboration in public health. There needs to be a balance between formal structures and the flexibility of informal approaches to prevent barriers for key individuals to participate in government projects.

Key messages:

- Formalizing key individual roles enhances public health interventions.
- Fair compensation to key individuals fosters sustainable collaboration.

Abstract citation ID: ckae144.1266
Mobile street clinics and harm reduction: pathways to provide care to homeless people in Brazil

Rômulo Paes de Sousa

MCA Araujo[1], AA Souza[1,2], PVR Fraga[1], ACMTV Dantas[1], RA Marinho[1], ALJ Martins[1], HMM Junior[1], RP Sousa[1]
[1]Health and Social Protection Policies Research, Instituto René Rachou/Fiocruz Minas, Belo Horizonte, Brazil
[2]School of Nutrition, Federal University of Ouro Preto, Ouro Preto, Brazil
Contact: romulo.paes@fiocruz.br

Homeless people (HP) are defined as a heterogeneous group that lives in extreme poverty, with weakened or severed family ties, lacking access to conventional housing, and using public spaces as residence. In terms of health, mental health conditions are prominent as a primary treatment demand, with care aimed at addressing needs arising from the use of alcohol and other drugs being a priority in serving HP. In this context, mobile street clinics (MSC) provide health services directly in street environments, focusing on individuals who use alcohol and other substances through harm reduction approaches. Harm reduction is defined as a set of practices aimed at minimizing the adverse health effects of alcohol and drug use without necessarily eliminating usage. Moreover, it represents an ethical and political direction in care, confronting the logic of criminalization and compulsory abstinence, enhancing access to health care for alcohol and other drug users through strategies that foster autonomy development. In the current study, we conducted an integrative review assessing the facilitators and barriers for HP access to mental health services. Preliminary results indicated that MSC, the connection between healthcare workers and the HP they serve, and the implementation of local street-based actions were the main facilitators of access for individuals who engage in harmful use of alcohol and other drugs to mental health services. Conversely, stigma, services' lack of adjustment to the lifestyles of homeless people, and excessive bureaucracy were identified as the principal barriers of access. MSC, through their harm reduction activities, have emerged as a potential care technology to facilitate access to health services for homeless people. This research aims to present harm reduction as an ethical and political direction of care through the actions of mobile street clinics, as a way to facilitate access to health services for the homeless people.

Key messages:

- Homeless people require mental health care tailored to the use of alcohol and other drugs, and harm reduction strategies implemented through mobile street clinics prove to be an effective form of care.
- Mobile street clinics and harm reduction are important care technologies that enhance access to health services for the homeless population.

Abstract citation ID: ckae144.1267
Regional variations in breast cancer screening uptake and its associated factors in Ghana

Florence Gyembuzie Wongnaah

Introduction: Timely identification of breast cancer is critical for successful treatment and prevention, reducing its burden. Despite its significance, breast cancer screening services in Ghana are underutilized, with considerable regional variations in uptake rates. We examined the regional differences in breast cancer screening uptake and its associated factors in Ghana.

Methods: We analyzed data from 15,014 women of reproductive age from the 2022 Ghana Demographic and Health Survey. Spatial mapping illustrated regional variations in screening uptake. Multilevel logistic regression was employed to examine the factors associated with breast cancer screening uptake.

Results: National breast cancer screening prevalence was 18.4%, with regional variations observed across the 16 regions. Eastern, Western, Brong Ahafo, and Greater Accra had the highest screening uptake. The likelihood of breast cancer screening was higher among women aged 45-49 (aOR = 3.59; 95% CI = 12.52, 5.12), Married women (aOR = 1.44; 95% CI = 1.17-1.77), Higher education, employment, health insurance, recent health facility visits, media access, and wealth index (middle: aOR = 1.45, 95% CI = 1.08, 1.94; richest: aOR = 1.91, 95% CI = 1.36, 2.70). Islamic and African Traditional affiliations decrease screening likelihood (aOR = 0.77; 95% CI = 0.63, 0.95; aOR = 0.46; 95% CI = 0.22, 0.97). Rural residence and specific regions (Ashanti, Oti, Savannah, Upper West) reduce odds, while living in North East increases odds (aOR: 1.86; 95% CI = 1.14-3.03).

Conclusions: Cost-effective breast cancer screening services are crucial, particularly in rural areas with geographical disparities. Culturally and religiously sensitive protocols are needed to address regional and religious differences. Expanding Ghana's national health insurance to cover preventive measures like breast cancer screening is essential. Promoting awareness through conventional and digital platforms is crucial for advocating screening.

Key messages:

- Addressing geographical and cultural differences crucial for equitable breast cancer screening in Ghana.
- Expanding health insurance and raising awareness vital to promote screening access and reduce disparities.

Prioritizing health, well-being, active ageing needs in Lithuania: insights from stakeholders

Aukse Domeikiene

A Domeikiene[1,2]*, L Danuseviciene*[3]*, L Sileikiene*[1,4]*, J Paulauskiene*[1]
[1]Department of Preventive Medicine, Faculty of Public Health, Lithuanian University of Health Sciences, Kaunas, Lithuania
[2]Department of Family Medicine, Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Kaunas, Lithuania
[3]Department of Bioethics, Faculty of Public Health, Lithuanian University of Health Sciences, Kaunas, Lithuania
[4]Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: aukse.domeikiene@lsmu.lt

Background: The rate of aging in Lithuania is faster than the EU average. The number of long-term health problems in older (65+yrs) people increases, posing changes in societal needs. The aim of our study was to identify the most important needs of older people in Lithuania.

Methods: Generic qualitative inquiry employed purposeful sampling of stakeholders in Lithuania: policymakers, administration, academia, civil society, health care, social service, public health, organizations of elderly. 43 experts, engaged in online focus groups, generated a list of needs for health, wellbeing, active ageing in elderly; they deliberated to prioritize top 5; scientific team condensed a list of 10 for voting to determine final 5 national needs. Research was done within project "Roadmap to improve the health and well-being of the ageing population in the Baltic Sea Region (AgeFLAG)", 2020.

Results: Top needs identified were: shaping healthy lifestyle habits and motivation for change (72%) / age friendly environment and virtual assistive technologies (72%); person centred care (domiciliary care, residential care and nursing, social activities and etc. depending on the needs and wishes of the older person) (58%); increasing and maintaining physical capacity (56%); intersectoral collaboration and integration of social and health services (53%); establishment of positive public attitudes towards elderly people (50%). All stakeholders indicated that "Establishment of positive public attitudes towards elderly people" is the corner stone of all priorities for action to healthy ageing in Lithuania.

Conclusions: The main issue hindering active and healthy ageing in Lithuania - negative image of ageing in the society. Recommendations on the public health actions included promoting intergenerational conversation, reducing stigmas around ageing, strengthening social inclusion, generating age-friendly environments, and creating a safe space for self-realization and development.

Key messages:

- The main issue hindering active and healthy ageing in Lithuania – negative image of ageing in the society.
- The change in the population requires the transformation of health care and social care systems building age friendly environments in Lithuania.

Abstract citation ID: ckae144.1269
Promoting ownership in local community health promotion interventions

Louise Lund Holm Thomsen

L Lund Holm Thomsen[1], *CG Andersen*[1], *C Overgaard*[1]
[1]Department of Public Health, University of Southern Denmark, Esbjerg, Denmark
Contact: louiselundthomsen@health.sdu.dk

Background: A prerequisite for successful and sustainable implementation of local community health interventions is strong community ownership. Ownership is related to the level of perceived control of an intervention and its program components. Facilitation of community ownership involves engagement of the stakeholders within the community, e.g. in deciding what the problem is to whom and how to solve it. Much is known about methods to facilitate community engagement at a continuum between informing the community and community control. However, less is known about how different methods for community engagement work to foster and sustain ownership among local stakeholders.

Aim: To generate knowledge about how ownership is fostered or hindered among stakeholders across three different communities in a local community intervention with whole-of-community characteristics implemented to reduce overweight among children. The study also explores how synergies of ownership between various types of stakeholders at different organizational levels influence overall ownership and implementation of the intervention.

Methods: The study is designed as a multiple case study based on Robert K. Yin's principles for case study evaluation. The study takes place in three different Danish Municipalities with different local contextual conditions. Various data sources are collected including sources of qualitative data comprising document analysis, observations, and interviews with key stakeholders.

Preliminary results: An influential contextual factor on local ownership is that implementation of the intervention and commitment to this in 10 years is a top-down decision at the policy level. Local stakeholders find the goals of the intervention meaningful to their day-to-day practices. However, they also experience a shortage of resources for participating and lack trust in higher management stakeholders to take shared leadership when the implementation phase ends.

Key messages:

- Ownership is influenced by the degree of engagement.
- Ownership is influence by the synergy of ownership between different stakeholders.

Abstract citation ID: ckae144.1270
Co-producing evidence to inform universal health coverage implementation in Ireland: 2019-2024

Sarah Parker

S Burke[1], *S Parker*[1], *C Bruen*[1], *K Schulmann*[1], *R Siersbaek*[1], *L Mac Conghail*[1]
[1]Centre for Health Policy and Management, Trinity College Dublin, Dublin, Ireland
Contact: saparker@tcd.ie

Background: In 2017, Ireland's parliamentary health committee published a ten-year health reform plan, entitled Sláintecare, with the aim of delivering universal healthcare. Endorsed by government in 2018, progressing Sláintecare remains government policy in 2024. In 2019, Prof Burke was awarded public funding to co-produce knowledge for the design and implementation of the regions, a key aspect of Sláintecare. In 2020, with the arrival of COVID-19, regional reform was paused and the research pivoted to capture the learning from the COVID-19 health system response to inform Sláintecare. In 2022/3, the research returned to focus on the regions.

Methods: Foundations' research resulted in 14 peer-reviewed publications between 2019 and 2023. These were mixed-methods using qualitative and quantitative data and analysis. Coproduction with health system leaders that were devising and implementing the regions and the COVID-19 health system response underpinned the research.

Results: There are 14 academic publications from the Foundations Research (2019-2023). At the core of co-production is trust and good working relationships. Co-producing research with senior policy makers and implementers has benefits and drawbacks. The benefits include access to resources and data and that the data and knowledge generated are more likely to be adopted. Drawbacks include control over areas researched, denial of access to data and lack of openness to research findings. Producing controversial findings, unpopular with government, minister or health system leaders can also lead to difficulties for the research team.

Discussion/conclusions: Details of the coproduction process with senior health system and policy leaders will be presented. It will detail specific examples of the research which were initiated by the health system and those that came from the academic research team. It will give examples of how the research influenced the policy making and implementation processes.

Key messages:

- Co-producing research between academics and health system and policy leaders leads to better use of evidence.
- Trust and good workign relationships are key to co-producing research that is used in policy making and implementation processes.

Abstract citation ID: ckae144.1271
Implementing a pilot primary care program: Armenia's steps toward universal health coverage

Shivani Dayal

S Dayal[1], *L Libaridian*[2]
[1]David Geffen School of Medicine, University of California, Los Angeles, USA
[2]Community Health Programs, The Children of Armenia Fund, Yerevan, Armenia
Contact: shivanidayal@gmail.com

Problem: Armenia has struggled to transform its ineffective primary healthcare (PHC) system into one that can address the non-communicable disease burden, which causes 93% of mortality. To address this issue, Armenia aims to establish universal health coverage and invest in high-quality primary care.

Description: In 2023, the Armenian Ministry of Health signed a multisectoral policy to implement a pilot primary care program to trial a multitude of reforms related to diabetes (DM) and hypertension (HTN). Pilot interventions include pathways for screening/diagnosis, provider training, free medications and diagnostics, and new provider financial incentives. The key question to be answered is if these pilot interventions cause DM and HTN health outcomes to improve. Beginning in 2024, the program is being piloted in a primary care clinic in Dsegh.

Results: As a result of the 2023 Ministerial policy, multisectoral stakeholders designed and implemented this pilot program. Baseline focus groups found that the pilot addresses the financial barriers that community members noted lead to delays in seeking care and that providers perceive the pilot to be beneficial to their patients. Although final results are not yet available, the pilot has already positively changed features in the national EMR and brought together stakeholders in a way never done before.

Lessons: The pilot's innovation comes from it being the first time that hypertension and cholesterol medications are provided by the government for free, provider bonuses are based on outcome indicators, indicator targets are set this high, a point-of-care A1c machine is utilized, and a robust monitoring and evaluation (M&E) plan is implemented, all of which are currently shaping discussions on national policy. For countries similarly working on strengthening primary care, it is recommended to pilot specific reforms and establish mechanisms through M&E systems that allow pilots to inform evidence-based decision making.

Key messages:

- To move towards universal health coverage, pilot programs designed with multi-sectoral stakeholders are needed to trial suggested healthcare reforms.
- It is essential to invest in monitoring and evaluations systems to generate the data necessary to develop evidence-based policies.

Abstract citation ID: ckae144.1272
Perinatal mortality in women in minority ethnic groups in Ireland (2011-2021)

Sara Leitao

S Leitao[1,2], *L Robinson*[2], *K O'Donoghue*[2]
[1]National Perinatal Epidemiology Centre, UCC Department of Obstetrics and Gynaecology, Cork, Ireland
[2]Pregnancy Loss Research Group, UCC, Cork, Ireland
Contact: s.leitao@ucc.ie

Women in minority ethnic groups (MEG) have been consistently overrepresented in the National Perinatal Epidemiology Centre (NPEC) Perinatal Mortality (PM) reports in Ireland (IE). International research, report similar findings. A secondary analysis of NPEC PM national clinical audit data (2011-21) examined factors associated with PM in women in MEG and differences between these and white women. Maternal sociodemographic and obstetric characteristics, maternal medical history, infant characteristics and PM outcomes of women in MEG were analysed and compared with women of white ethnicity with $\chi 2$ tests. There were 4314 PMs in IE from 2011-21; 2896 stillbirths (SB) and 1418 early neonatal deaths (ENND). Women in MEG who experienced PM were younger ($p < 0.001$) and 46% were employed (vs 75% of white women, $p < 0.001$). A greater proportion of women in MEG had previous pregnancies (77% vs 68%, $p < 0.001$), and more than twice as many had ≥ 3 previous completed pregnancies versus white women (26% vs. 12%, $p < 0.001$). Women in MEG also had more previous pregnancy medical issues (49% vs 38%, $p = 0.001$). Twice as many women in MEG had their first prenatal appointment after 20 weeks' gestation or never received prenatal care ($p < 0.001$). Analysing by type of PM, statistically significant differences persisted for all these variables in both SB and ENND groups. Women in MEG experienced more placental conditions and obstetric factors as causes of PM, but fewer congenital anomalies compared to white women ($p = 0.047$). These differences only persisted in the SB group when data was analysed by type of PM. Factors highlighted in this study such as employment, parity, and prenatal care access may explain the over-representation of women in MEG in PM. These findings provide further knowledge useful to create targeted interventions (e.g. initiatives to improve maternal health literacy for women in MEG). Further studies are needed to promote change that would specifically address these systemic inequities.

Key messages:

- Data shows systemic inequities that may contribute to the over-representation of women in minority ethic groups in perinatal mortalities. Clear and tangible changes are needed to address these issues.
- Further research needs to clarify factors restricting access of women in minority ethic groups to prenatal care and promote interventions to ensure adequate prenatal care is available and accessible.

Strategies to improve recruitment to multimodal group programmes for obesity: a systematic review

Inanna Reinsperger

I Reinsperger[1], *S Wolf*[1], *I Zechmeister-Koss*[1]
[1]Austrian Institute for Health Technology Assessment GmbH, Vienna, Austria
Contact: inanna.reinsperger@aihta.at

Background: The World Health Organization describes obesity as one of the greatest public health challenges in the 21st century. Possible therapies include multimodal (group) programmes with nutrition, exercise, and behavioural therapy elements. However, programme providers often have difficulties recruiting the target groups and motivating them to participate. This systematic review aimed to identify barriers and facilitators as well as strategies to improve recruitment.

Methods: We systematically searched five databases (Medline, CINAHL, Cochrane, PsycInfo, Web of Science). Based on predefined inclusion criteria, we selected primary studies of different study designs (e.g. [randomised] controlled trials, qualitative studies). We extracted barriers and facilitators as well as recruitment strategies into predefined tables, assessed the quality of the studies and summarised the results narratively.

Results: Of the 1,082 articles identified, 16 met the inclusion criteria. The main active recruitment strategies were writing directly to potential participants and referrals from health professionals. The most frequently reported passive strategies included media adverts, websites, flyers, social media, and word of mouth. The information on how many people approached actually participated was heterogeneous, which illustrates that recruitment depends on the setting/context and the people involved. Some studies came to contradictory results, e.g., regarding whether passive or active methods are more successful. In most cases, a combination of strategies was recommended. The studies reported numerous recruitment barriers, e.g., lack of staff time, lack of motivation, or fear of discrimination.

Conclusions: The review provides a broad overview of recruitment methods that can be applied depending on the framework conditions and target groups. The summary of possible barriers can serve as an overview of which aspects could be considered when designing or adapting a programme.

Key messages:

- To improve recruitment to obesity programmes, a combination of several recruitment strategies, including active and passive methods, should be applied.

- Results on the "effectiveness" of the strategies were inconclusive, which indicates that the success of methods depends on the context, setting and the people involved.

Abstract citation ID: ckae144.1274
Housing items and amenities a non-traditional risk factors for all-cause and cardiovascular mortality

Dalia Luksiene

D Luksiene[1,2], A Tamosiunas[1], G Aukstakalniene[2], R Radisauskas[1,2], M Bobak[3]
[1]Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania
[2]Public Health Faculty, Lithuanian University of Health Sciences, Kaunas, Lithuania
[3]Institute of Epidemiology and Health Care, University College London, London, UK
Contact: dalia.luksiene@lsmu.lt

Background: Higher satisfaction levels are associated with improved psychological well-being (PWB), such as housing amenities being a determinant of health. However, their potentially influencing effect on mortality risk at this moment is not enough. For this reason, searching for non-traditional risk factors that could reduce all-cause and cardiovascular disease (CVD) mortality risk is our primary objective of this study.
Methods: The cohort study was based on the framework of the international study Health, Alcohol and Psychosocial Factors in Eastern Europe (HAPIEE). Data from the Official Lithuanian Mortality Register were used to evaluate mortality from the baseline survey (2006- 2008) to 31 December 2022. The 20 housing items and amenities were used. The items were categorized into three groups: basic needs, socially oriented needs, and luxury.
Results: A total of 6472 participants aged 45-72 years were examined in the baseline survey. Cox proportional hazards regression analysis results show that increasing the number of housing items per 1 unit decreased the risk of all-cause mortality by 8% (Hazard ratio (HR)=0.92;95%CI 0.90-0.94) in males and by 7% (HR = 0.93;95%CI 0.91-0.96) in females. Increasing the number of housing items per 1 unit decreased the risk of mortality from CVD by 10% (HR = 0.90;95%CI 0.87-0.93) in males and by 9% (HR = 0.91;95% CI 0.87-0.95) in females (data adjusted by age, education, smoking, metabolic syndrome, PWB, CVD at baseline survey). Once more, the increased number of items from the luxury group (4-7 vs. 0-1) significantly decreased all-cause and CVD mortality risk (respectively in males HR = 0.74(95%CI 0.60-0.91) and HR = 0.71(95%CI 0.52-0.96); in females HR = 0.66(95%CI 0.48-0.91) and HR = 0.57(95%CI 0.33-0.96).
Conclusions: These data suggest that the increasing number of household items and amenities, as an essential aspect of people's lives, may be used as non-traditional risk factors in assessing the risk of all-cause mortality and CVD.
Key messages:
- Household items and amenities may be used as non-traditional risk factors in assessing the risk of all-cause mortality and CVD.
- Increasing the number of housing items decreased the risk of all-cause and CVD mortality.

Abstract citation ID: ckae144.1275
Blood pressure and its control in adults: the Italian Health Examination Survey 2023-CUORE Project

Luigi Palmieri

B Marcozzi[1], C Lo Noce[1], A Di Lonardo[1], S Vannucchi[1], C Damiano[1], D Galeone[2], P Bellisario[2], L Palmieri[1], C Donfrancesco[1]
[1]ISS, Rome, Italy
[2]Italian Ministry of Health, Rome, Italy
Contact: luigi.palmieri@iss.it

Background: The WHO recommends a 25% relative reduction in the prevalence of raised blood pressure (RBP) by 2025, considering 2010 as baseline. To monitor the achievement of this target, prevalence of RBP and mean blood pressure were measured in the Italian general adult population within periodic health examination surveys (HESs) conducted within the CUORE Project.
Methods: In 2023 a new HES started including, up to now, data from random samples of residents aged 35-74 years (706 men, 727 women) in 7 Regions (of 20 regions) distributed in North, Centre and South of Italy. Blood pressure was measured at the right arm, in sitting position, by automated oscillometric device using standardized procedures and methods; the average of two measurements performed with 1 minute interval was used for the analysis. RBP is defined as systolic and/or diastolic blood pressure equal or greater than 140/90 mmHg. The survey is funded by the Italian Ministry of Health-CCM.
Results: Preliminary analysis shows that prevalence of RBP is 37% (95% Confidence Interval-CI: 30-46%) in men and 23% (17-29%) in women. Mean value of systolic blood pressure is 134 mmHg (133-136 mmHg) in men and 126 mmHg (125-127 mmHg) in women. Mean value of diastolic blood pressure is 80 mmHg (78-81 mmHg) in men and 75 mmHg (74-76 mmHg) in women. Among those with RBP and/or in treatment (49% of men and 39% of women), 35% of men and 19% women are unaware they could have BP control problems, 8% and 9% are aware but not in treatment, 24% and 40% are under treatment and at target, 33% and 22% are under treatment but not at target, respectively.
Conclusions: These preliminary data underline that RBP is still high in the Italian adult population. Significant reductions in RBP prevalence occurred in comparison to previous HES data, 20% from 25 years ago, about 10% from 15 year ago, while a stable trend was found in comparison to 5 years ago. Improvements on RBP awareness and control are still necessary.
Key messages:
- Raised blood pressure is still high in the Italian general adult population.
- Implementing periodic HES is fundamental to measure blood pressure and estimate awareness and control of hypertension in the general population.

Educational inequalities in cervical cancer mortality: A systematic review and meta-analysis

Monica Machado

M Machado[1,2], TA Eikemo[2], T Mohammad[2], M Balaj[2]
[1]Department of Public Health and Nursing, Norwegian University of Science and Technology, Trondheim, Norway
[2]CHAIN, Norwegian University of Science and Technology, Trondheim, Norway
Contact: monica.machado@tum.de

Background: Educational inequalities in mortality continue to persist. We aimed to systematically analyse the association between level of education and cervical cancer mortality.
Methods: We conducted a systematic review and meta-analysis. We systematically searched Pub-Med, Web of Science, Scopus, EMBASE and Global Health (CAB), EconLit and Sociology Source Ultimate databases. A protocol has been registered with PROSPERO (CRD42023411757). We included studies that measured the association between level of education and cervical cancer mortality using individual level data. Included articles were assessed for study quality and risk of bias using the Joanna Briggs Institute critical appraisal checklists. A random-effects meta-analysis was conducted to evaluate the overall and stratified effects of education on mortality.

Findings: Our literature search resulted in over 47,000 articles. 30 studies mentioned cervical cancer as a cause of death, and of these, 11 were eligible for the meta-analysis. Results showed an overall risk ratio of 2.41 (95% CI 1.81-3.20) for low education (ISCED 0-2) and 1.62 (95% CI 1.18-2.24) for medium education (ISCED 3-4). Those aged 25-64 with low education had more than twice the risk of cervical cancer (RR = 5.73; 95% CI 5.04-6.51) compared to those aged 25 and above (RR = 2.11; 95% CI 1.82-2.45). Besides, the impact of an additional level of education on reducing risk of cervical cancer mortality was higher in Northern Europe, compared to the South.

Interpretation: Lower educational attainment is associated with an increase in the risk of cervical cancer mortality, with an additional level of education greatly reducing this risk in Northern Europe. Younger cohorts with low education have a higher risk of cervical cancer mortality. This study provides important information for evidence-based policy seeking to reduce health inequities and inequalities in both the health and education sector.

Key messages:

- Lower educational attainment is linked to a higher risk of cervical cancer mortality.
- Younger cohorts (aged 25-64) with low education are at a particularly heightened risk compared to those aged 25 and above.

[7]CIBERNED, Instituto de Salud Carlos III, Madrid, Spain
Contact: crodb@isciii.es

Background: Health outcomes of patients with multimorbidity are associated with the satisfaction with the care received. The objective of this study is to describe and compare the needs, adequacy of and satisfaction with the received healthcare in patients with complex chronic diseases in Spain.

Methods: Data from a convenience sample of patients participating in the Access to Diagnosis and Treatment and Healthcare Survey (Spanish Patient Organizations Platform, 2022). The chronic conditions were grouped into osteoarticular, cardiovascular, neurological, respiratory, diabetes, rare diseases, digestive, vision diseases, cancer and others. The main variables included were satisfaction with the received care (0-10), perceived adequacy of care (1-5) and unmet needs (yes/no). Bivariate analyses (chi-squared and Mann-Whitney tests and correlation coefficients) were performed.

Results: 1133 patients answered the survey: mean age 49.5 years (standard deviation, SD: 14.8), 55.1% women, mean of 2.9 chronic health conditions (SD: 1.7). Participants showed higher levels of satisfaction with routine follow-ups and control of diseases than with access to rehabilitation and specialized care. Satisfaction with healthcare was associated with perceived adequacy of follow-ups (r= -0.79, $p < 0.01$). Patients with osteoarticular pathologies reported a higher number of unmet needs (57%), rated the care received as less adequate (mean 3.4; SD: 0.9) and less satisfactory (mean 4.2; SD: 2.8). Patients with cancer reported fewer unmet needs (6%), considered the care adequate (mean 2.9; SD: 0.9) and satisfactory (mean 6.8; SD: 3.1). Similar figures were also seen in patients with cardiovascular diseases.

Conclusions: Knowledge on patients' perceived unmet needs and demands may lead to improving satisfaction with the health system. Comprehensive care for people with multimorbidity, including assessing patients' perception, is a challenge that must be addressed by healthcare systems.

Key messages:

- The analysis of the differences between pathologies in their demands will better describe the reality of patients with multimorbidity in Spain.
- The perception of healthcare adequacy and satisfaction greatly varies across the type of chronic condition.

Abstract citation ID: ckae144.1278
Associations between diabesity and mortality over 7 years: a Maltese population-level case study

Elizabeth Grech

S Cuschieri[1], *E Grech*[2], *A Cuschieri*[1]
[1]Faculty of Medicine and Surgery, University of Malta, Msida, Malta
[2]Mater Dei Hospital, Msida, Malta
Contact: elizabeth.v.grech.18@um.edu.mt

Introduction: Diabesity presents a growing global epidemic. Demographic and socioeconomic associations have been documented, yet, the literature on mortality risk associated with diabesity is scarce. The aim of this study was to assess whether diabetes and/or diabesity increas the risk of all-cause mortality across a period of 7 years at a population level.

Methods: A nation-wide health examination survey in Malta was conducted between 2014 and 2016. This collected sociodemographic information, bio-anthropometric measurements (waist circumference, body mass index [BMI], body adiposity index [BAI]) and blood samples. Mortality information was acquired in 2021 by cross-referencing with the national mortality register. Statistical analysis was conducted using chi-square tests and Cox proportional hazard models.

Results: A mortality rate of 1.67% was observed ($n = 3947$), with diabetes and obesity being responsible for 6.06% and 3.03% of deaths, respectively. Examining the deceased individuals alongside their baseline characteristics (2014-2015) revealed that 25.76% (CI95%: 16.75 - 37.44) had diabetes, and 30.30% (CI95%: 20.55 - 42.22) were obese. Diabetes was associated with significant mortality risk (HR: 2.65 CI95%: 1.20 - 5.85; $p = 0.02$), while diabesity showed borderline significance ($p = 0.06$). After adjustment for potential confounding factors the mortality risk linked to diabetes remained significant and BAI was the only anthropometric measurement positively associated with mortality.

Conclusions: These findings emphasise the urgency for comprehensive public health policies targeting the concurrent prevention and management of diabetes and obesity at a population level. Our results also indicate that incorporating body adiposity index (BAI) into risk assessment protocols may provide valuable insights into mortality risk prediction and inform tailored interventions.

Key messages:

- Diabetes and a high BAI score were significantly associated with mortality in the Maltese population, while diabesity had moderate significance, emphasising the urgency of tackling this epidemic.
- These findings call for broad health policies to address diabesity at a population level and suggest integrating BAI into risk assessment for better mortality prediction and tailored interventions.

Cardiovascular diseases risk assessment: the Italian Health Examination Survey 2023 - CUORE Project

Chiara Donfrancesco

C Donfrancesco[1]*, C Lo Noce*[1]*, A Di Lonardo*[1]*, B Marcozzi*[1]*, S Vannucchi*[1]*, M Morello*[2]*, S Bernardini*[2]*, D Galeone*[3]*, P Bellisario*[3]*, L Palmieri*[1]
[1]ISS, Rome, Italy
[2]Tor Vergata University Hospital, Rome, Italy
[3]Italian Ministry of Health, Rome, Italy
Contact: chiara.donfrancesco@iss.it

Background: The reduction of NCDs premature mortality is pursued by the WHO; risk conditions targets are recommended as well as population-level monitoring of cardiovascular disease (CVD) risk. The Italian Ministry of Health (MoH) has strengthened prevention/health promotion and supported periodic CVD risk assessment through national health examination surveys (HESs), funded by the MoH-CCM and conducted within the CUORE Project.

Methods: In 2023 a new HES started including the 10-year fatal and non-fatal CVD risk assessment based on knowledge of sex, age, smoking habit, measured systolic blood pressure and fasting total and HDL serum cholesterol, and presence of diabetes (on measured fasting serum glycemia and/or treatment) and anti-hypertensive therapy. Up to now, data from random samples of residents in 7 Regions (of 20 regions) distributed in North, Centre and South of Italy, aged 35-69 years, without previous CVD, are available (585 men, 617 women). Determinations were assayed by a central lab. CUORE Project functions developed on and for the Italian adults were used.

Results: Mean values of the CVD risk assessment resulted 6.9% (95% CI: 6.3-7.4) in men and 2.3% (2.1-2.5) in women. For men aged 35-44 years risk was 1.6% (1.5-1.8), for 45-54 years 3.8% (3.5-4.2), for 55-64 years 10.0% (9.0-10.9), for 65-69 years 17.6% (16.4-18.9); for women was 0.5% (0.4-0.6), 1.0% (0.9-1.1), 3.3% (2.9-3.7) and 6.0% (5.5-6.6) respectively. Prevalence of CVD risk less than 5% was 57% (49-64) in men and 88% (84-93) in women, of 10-15% risk were 22% (15-28) of men and 9% (5-14) of women, of 15-20% risk were 5% (1.6-8.0) of men and 0% of women, of over 20% risk were 2% (0-3.6) of men and 0% of women.

Conclusions: Compared to 2008, these data showed stable mean levels of CVD risk both in men and women at any age-classes and stable prevalence of CVD risk classes. CVD risk perception represents a challenge in primary prevention especially for young age groups and women.

Key messages:

- In the Italian general population, CVD risk assessment remained stable compared to 15 years ago.
- CVD risk perception represents a challenge in primary prevention.

Adapting a cultural dance program to prevent cognitive decline: insights from experts and educators

Mele Look

MA Look[1,2]*, M de Silva*[2]*, A Hermosura*[1]*, JK Agard*[1]*, JKW Antonio*[1]*, D Iseri*[1]*, S Haumea*[3]*, C Solatorio*[4]*, S Yoshimura*[5]*, JK Kaholokula*[1]

[4]Kula no nā Po'e Hawai'i, Honolulu, USA
[5]Kōkua Kalihi Valley, Honolulu, USA
Contact: mele@hawaii.edu

Leveraging activities such as cultural dance shows promise as an effective basis for chronic disease prevention and management with at-risk populations. In fact, recent WHO reports and resolutions advocate utilizing cultural context to achieve health equality. Hula, the Native Hawaiian indigenous dance has been successfully utilized in interventions with statistically significant improvement in medication resistant hypertension management and heart disease prevention. In this study, Alzheimer's Disease and Related Dementia (ADRD) experts and kumu hula (hula experts and educators) provide insights to developing a hula-based lifestyle program for prevention of cognitive decline. Informant interviews were used to collect information for developing a hula-based program for individuals with mild cognitive impairment from 4 ADRD experts and clinicians, and 4 kumu hula. The 60-90 minute semi-structured interviews were conducted, recorded, then transcribed. Separate thematic analysis allowed distinct themes for each group to emerge. Themes with greatest between group alignment informed the adaptation of an existing hula-based chronic disease intervention. The clinical and cultural experts were unanimous on multiple themes. First, a hula-based program was well positioned to promote social functioning. Second, hula facilitated integrated multi-dimensional benefits including physical, cognitive, social, and cultural. Third, facilitating learning included: repetition done in creative forms; utilization of aids such as dance notation and audio recordings; and educational approaches such as project-based learning. Cultural activities such as dance have been underutilized in health promotion initiatives. A significant challenge in health promotion programs is engagement and retention of participants. Cultural dance programs are popular and can be effective interventions, particularly when both clinical and cultural experts are engaged in program development.

Key messages:

- Inclusion of clinical and cultural experts in health promotion program development leads to unique collaboration and impactful insights.
- ADRD clinicians and Hawaiian cultural dance educators identify social, cultural, physical, and cognitive benefits of hula as instrumental for individuals with mild cognitive impairment.

Abstract citation ID: ckae144.1281
Joint Action JACARDI: a context analysis on CVDs and diabetes policies and practices

Issue/problem: Non-communicable diseases are the leading cause of death and disability in Europe, with 63 million people living with cardiovascular diseases (CVDs) and 32 million with diabetes (DM) in 2019. The EU-co-funded Joint Action on CVDs and diabetes (JACARDI), with 76 partners from 21 countries, aims to reduce CVDs and DM burden at European level through 142 pilot projects.

Description of the problem: For an effective and tailored pilots' implementation, a preliminary step is to assess the current state of strategies and services for CVDs and DM prevention and management in Europe. We adopt the Gap Analysis methodology aiming to evaluate the gap between the current and the ideal state, the latter defined according to scientific evidence, best-practices, guidelines, and expert's opinions. For this purpose, 12 questionnaires, one for CVDs and one for DM for six different thematic areas, were developed through a participatory approach that fostered the collaboration between the scientific coordination team and the project members.

Results: Questionnaires were sent to National Focal Points for health covering 29 European countries. We anticipate receiving responses from each country covering aspects related to the legal and strategic framework, the intersectoral and equity-oriented approaches, the funding and the service delivery and capacity for CVDs and DM. This information will be collected across each of the six thematic areas corresponding to six technical Work Packages (WP): health literacy, data, screening, integrated-care pathways, patients self-management, labour participation. The survey will be completed by June 2024, and results by WP and country will be presented.

Lessons: The context analysis, based on the Gap Analysis methodology, allows to identify gaps between the current and ideal state in CVDs and DM prevention and management. This will guide JACARDI's pilots to address gaps and serve as a roadmap to inform European policy-makers.

Key messages:

- The context analysis will provide an invaluable overview of the current European state of CVDs and DM prevention and management.
- The context analysis will support JACARDI's pilots in addressing identified gaps and policy-makers in shaping public health responses.

Abstract citation ID: ckae144.1282
Association of physical activity with health-related quality of life in rectal cancer survivors

Tatjana Gazibara

T Gazibara[1], *N Grubor*[2,3], *N Pavic*[2], *I Grubor*[4], *M Ceranic*[2,3]

[2]Clinic for Emergency Surgery, University of Clinical Center of Serbia, Belgrade, Serbia
[3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[4]Department of Health Promotion, Institute of Public Health of Serbia, Belgrade, Serbia
Contact: tatjanagazibara@yahoo.com

Background: Health-related quality of life (HRQoL) in rectal cancer survivors after completion of surgical treatment may be influenced by various factors including physical activity. The purpose of this study was to examine the association between regular exercise and physical and mental health in rectal cancer survivors.

Methods: People who underwent surgical resection of rectal cancer with temporary ileostomy from 2018 to 2021 were invited to participate. Participants were drawn from the Clinic for Digestive Surgery and the Clinic for Emergency Surgery of the University Clinical Center of Serbia, as well as the nationwide laparoscopic program - LapSerb consortium. Data were collected through interviews in late 2022 and early 2023. The HRQoL was evaluated using the physical composite score (PCS) and mental composite score (MCS) of the Short Form-36 (SF-36) questionnaire. Socio-demographic, clinical and behavioral characteristics including the frequency of exercise were analyzed in multiple linear regression models.

Results: A total of 134 rectal cancer survivors were tested. Few participants (18.7%) exercised regularly, while most of the study population occasionally (41.8%) or never engaged (39.5%) in physical activity. Rectal cancer survivors who exercised regularly had significantly higher scores of physical (75.5 vs. 62.8, $p = 0.019$) and mental quality of life (78.9 vs. 63.8, $p = 0.008$). Regular exercise remained associated with better physical and mental health after the adjustment for demographic, clinical and behavioral characteristics.

Conclusions: Consistent physical exercise seems to be significant contributor of better physical and mental quality of life in rectal cancer survivors after completion of surgical treatment.

Key messages:

- Physical exercise may help rectal cancer survivors improve their physical and mental health.
- Promotion of physcial activity in rectal cancer survivors could optimize recovery after surgery.

Contact: asmasmams@yahoo.fr

Introduction: Therapeutic education is a patient-centered, approach aimed at addressing the patient's needs and resources. It is intended not only to help the patient understand their illness and treatment but also to empower them to become autonomous. So far, in Tunisia, we lack structures for therapeutic education specifically tailored for coronary patients. In this context, we implemented a Therapeutic Education Program (TEP) for coronary patients visiting the cardiology department at Sahloul University Hospital with the aim of assessing the impact of this program in the short, medium (3 months), and long term (12 months).

Methods: We conducted a quasi-experimental study on TEP for patients with coronary artery disease over one year at Sahloul University Hospital. Patients were divided into two groups, intervention, and control. Outcome measures included major cardiovascular events, improvement in knowledge, and biological indicators, with statistical analysis performed using SPSS in accordance with ethical considerations.

Results: The study included 129 patients, of whom 38 underwent a therapeutic education program. TEP demonstrated a significant improvement in knowledge about coronary artery disease, with program satisfaction rated ≥ 8 on a scale of 0 to 10.Our program also showed improvement in biological parameters, particularly lipid profiles, within the educated group before and after 3 months, such as LDL cholesterol levels (2.53 vs 1.88, $P < 0.001$), and compared to the control group (1.88 vs 2.9, $P = 0.001$).Moreover, it led to a significant reduction in long-term cardiovascular events compared to the control group (21.1% vs 59.3%, $p < 0.001$).

Conclusions: this study underscores the crucial importance of therapeutic education in enhancing the care and quality of life of coronary patients, highlighting its central role in a proactive, personalized approach to medical management.

Key messages:

- The significance of therapeutic education in empowering patients to understand their condition and become self-reliant.
- Need for Structured Programs specifically for coronary patients in Tunisia.

Primary prevention of type 2 diabetes in the EU: A systematic review of interventional studies

Szabolcs Lovas

S Lovas[1], *CA Soares Andrade*[1,2], *N Mahrouseh*[1], *G Chamouni*[1], *B Shahin*[1,2], *D Wangeshi Njuguna*[3], *F Israel*[1,2], *O Awad Mustafa Eltayeb*[1,2], *AN Aisul Muhlis*[1,2], *O Varga*[1]
[1]Department of Public Health and Epidemiology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary
[2]Doctoral School of Health Sciences, University of Debrecen, Debrecen, Hungary
[3]Medical Surgical Department, Dedan Kimathi University of Technology, School of Nursing, Nyeri, Kenya
Contact: lovas.szabolcs@med.unideb.hu

Background: The GBD 2019 study revealed that type 2 diabetes caused over 109.000 deaths and accounted for 5.3 million Disability Adjusted Life Years in the EU, with an estimated annual cost of EUR 300 billion in 2014. Interventions for primary prevention are pivotal in preventing diabetes, providing a structured approach to implementing lifestyle modifications or community-based programs. The objective of this study was to demonstrate the effectiveness of primary prevention interventions to prevent or delay the onset of type 2 diabetes in the EU member states.

Methods: A systematic review on six databases was conducted for relevant interventional studies carried out in the EU-28. The main outcome of the studies was determined by changes in the incidence of type 2 diabetes.

Results: The search yielded 18.885 records, of which 18 met the eligibility criteria. The following studies reported significant incidence reduction in the intervention groups: The Finnish Diabetes Prevention Study by individualised lifestyle intervention (HR: 0.614, 95%CI: 0.478-0.789), the Spanish CORDIOPREV Study through increased plant protein intake (HR: 0.64, 95%CI: 0.43-0.96), the Spanish PreDE trial by promoting healthy diet and physical exercise (RR: 0.68, 95%CI: 0.47-0.99), the Norfolk Diabetes Prevention Study with intensive diet-exercise counselling (OR: 0.57, 95%CI: 0.38-0.87), the Spanish PREDIMED and PREDIMED-Reus trials by mediterranean diet supplemented with extra virgin olive oil or mixed nuts (HR: 0.60, 95%CI: 0.43-0.85; HR: 0.49, 95%CI: 0.25-0.97; HR: 0.48, 95%CI: 0.24-0.96), and the Dutch SLIM Study with advices on diet and physical activity (RR: 0.53, 95%CI: 0.29-0.97).

Conclusions: Significantly decreasing the incidence of diabetes is feasible within primary healthcare settings through intensive lifestyle interventions targeting individuals at high risk. Therefore, it would be beneficial to incorporate these findings into the European guidelines for preventing type 2 diabetes.

Key messages:

- Primary care plays an important role in the prevention of type 2 diabetes.
- Well-defined primary lifestyle interventions are capable of slowing the progression from prediabetes to diabetes.

Abstract citation ID: ckae144.1285
Measurements and medication data are indispensable for population blood pressure monitoring

Hannelore Neuhauser

H Neuhauser[1,2], *J Büschges*[1,2], *G Sarganas*[1,2], *B Gärtner*[1,2], *H Perlitz*[1], *J Fuchs*[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Institut, Berlin, Germany
[2]German Center of Cardiovascular Research, Berlin, Germany
Contact: neuhauserH@rki.de

Background: The National Study on Health of Older People in Germany "Gesundheit 65+" included blood pressure (BP) measurements at home by a study nurse and classification of all current medication.

Methods: Nationally representative examination survey of the population aged 65 years and older residing in Germany using two-stage population registry sampling from 128 sample points, with a standardized examination at home from June 2022 to April 2023. Three standardized blood pressure measurements at two-minute intervals were taken after 5 minutes rest with an oscillometric device (Mobil-O-Graph) using one of five cuffs according to upper arm circumference. The mean of the second and third measurement was used for analysis. Hypertension was defined as mean systolic BP (SBP) at or above 140 mmHg, or mean diastolic BP (DBP) at or above 90 mmHg, or the use of antihypertensives (antihypertensives, diuretics, beta-blockers, calcium-channel blockers, ACEI and ARB) in participants with self-reported hypertension diagnosis. Provisional weights account for unequal sampling and participation probabilities.

Results: The "Gesundheit 65+" examination part included 1,493 participants of whom 1,475 (98.8%) had successful BP measurements (763 men and 712 women, aged 66 to 101 years). Based on self-reported diagnoses alone, the prevalence of hypertension would be 58.3% [95% CI 53.2-63.3] in men and 59.5% [53.8-64.9] in women. However, overall hypertension prevalence was estimated at 70.4% [65.8-74.7] in men and 72.3% [66.9-77.1] in women based on the study definition which combines self-reported diagnoses, standardized BP measurements and medication.

Conclusions: The prevalence of hypertension is greatly underestimated in the absence of examination survey data with standardized measurements and recording of medication use. In addition, measurement and medication data are needed for monitoring the hypertension cascade, i.e. awareness, treatment and control of hypertension.

Key messages:

- Hypertension prevalence is underestimated in the absence of health examination surveys with measurements and medication data.
- The hypertension cascade, i.e. assessment of awareness, treatment and control of hypertension needs population surveys with measurements and medication assessment.

Thirty-five years of personalized promotion. The contribution of medicine in the workplace

Giacomo Viti

N Magnavita[1,2], *U Iannaccone*[2], *E Di Stasio*[1], *I Meraglia*[1,2], *G Viti*[1,2], *L Borghese*[2]
[1]Occupational Health, Università Cattolica del Sacro Cuore, Rome, Italy
[2]San Giovanni Battista Hospital, Acismom, Rome, Italy
Contact: giacomo.viti.med@gmail.com

Issue/problem: Occupational medicine has always had the task of identifying and solving problems caused by exposure to occupational risks and improving the health conditions of workers. This traditional prevention task can be advantageously associated with promotional activities to reduce the incidence of non-communicable diseases.

Description of the problem: Since the end of the 1980s we have conducted health promotion interventions in the workplace, integrated into the company's occupational prevention plan. The results, discussed internationally, have allowed the improvement of projects such as the one presented here, aimed at the prevention of cardiovascular and metabolic risks.

Results: Workers carry out a clinical check integrated with blood chemistry tests, actigraphic measurement of physical activity and sleep, bioimpedance measurement and plicometry, to objectify the data of interest. Furthermore, they keep a food diary and answer questionnaires on lifestyle, stress, and sleep. They receive personalized non-pharmacological treatment aimed at making salutogenic changes to diet, sleep, physical activity, and relaxation methods. They are monitored monthly and carry out a follow-up after six months. The pilot study, conducted on 20 healthcare workers with previously undiagnosed metabolic problems, indicates a significant improvement in abdominal circumference, systolic blood pressure and sleep duration in the third month. Workers report a high level of satisfaction with the initiative, a lower level of occupational stress and a higher quality of sleep.

Lessons: Accumulated experience demonstrates that projects of this type are feasible, sustainable, and advantageous and can be applied to companies of all sizes, regardless of the quantity of resources available.

Key messages:

- Health promotion in the workplace can contribute to the reduction of chronic non-communicable diseases.
- The active participation of workers in health promotion activities contributes to improving job engagement and satisfaction derived from work.

Advancing Dementia Care in Austria: developing a Dementia Registry using a multimethod approach

Ana Cartaxo

A Cartaxo[1], T Herz[1], B Juraszovich[1], E Rappold[1]
[1]Health Professions and Long Term Care, Austrian National Public Health Institute, Vienna, Austria
Contact: ana.cartaxo@goeg.at

Background: Austria faces an increasing demand for dementia care in an ageing population. However, a lack of representative data hampers evidence-based policy development and evaluation of care. To address this gap, the Austrian National Institute of Public Health is undertaking the task of developing the Austrian Dementia Quality Registry (ÖDQR).

Methods: Based on the AIHTA Good Practice Framework for Dementia Registries, the development and testing of the ÖDQR has unfolded in 4 distinct phases: 1) planning; 2) registry design (including definition of quality indicators and minimum data set, recruitment, and governance); 3) definition of data collection, sources, and management; 4) pilot testing. A steering committee of government representatives and dementia care experts was convened to oversee the project. A scientific committee provided oversight and ensured methodological rigor. Working groups of national and international dementia care experts focused on standards for diagnosis and therapy, activities of daily living and quality of life, legal aspects, and technical implementation, thus contributing to the content development of the ÖDQR.

Results: An initial systematic literature review informed the selection of quality indicators in the working groups. A conceptual framework of 15 descriptive and 30 quality indicators was developed. Preliminary results of pilot testing indicate feasibility and content validity. As a result, the ÖDQR will be established as a longitudinal survey-based registry, based on an instrument comprising 163 variables and emphasizing data collection across care settings. Legal and technical frameworks are being developed.

Conclusions: The öDQR holds the promise of informing evidence-based policy and improving the quality of dementia care in Austria. Careful planning and collaboration have laid the foundation for a data repository that will inform policy and improve care for people with dementia and their caregivers.

Key messages:

- Dementia registries require a complex development to assure validity and adherence.
- The Austrian Dementia Registry aims to establish best practice by focusing on the life situation of those affected by this condition.

Implementing a chronic disease self-management program in Moldova: a roadmap for sustainability

Florence Secula

F Secula[1,2], D Berari[3], N Holm Faber[4], C Rimis[3], N Silitrari[5], A Curteanu[3], H Prytherch[1,2]

[5]National Institute for Public Health, Chisinau, Moldova
Contact: florence.secula@swisstph.ch

Chronic disease self-management programs are evidence-based interventions but achieving their sustainability can be challenging. We propose a roadmap to sustainability that examines the transferability of intervention components and fosters multi-level and multisectoral partnerships.

Since 2019, the Swiss Agency for Development and Cooperation's Healthy Life project, in cooperation with the Ministry of Health of Moldova, has implemented a self-management program in rural communities. At pilot stage, we achieved a 53% increase in participants' self-efficacy (Palmeirim et al, 2024). To date, the program has reached 1432 beneficiaries in 70 communities. The intervention cost per participant was approximately 74 Euros. Our evidence supported the inclusion of self-management in the national non-communicable disease program 2023-2027. We designed a roadmap to hand over this innovation to Moldovan public health institutions. Firstly, we unpacked the intervention into transferable resources, processes and roles. These included human resources (a network of 140 facilitators), pedagogical resources (culturally adapted facilitator training and self-management workshop content) and key operational processes (coordination, resource management, partnership building, monitoring and evaluation). Then, we convened a national workshop to discuss the transfer of these components to relevant institutions. We emphasized working in a coordinated partnership across institutions for intervention delivery. Finally, we launched a national working group that will work on the operational modalities of this multi-stakeholder partnership. Achieving an enabling policy environment for self-management created favorable conditions and accountability for institutional partnership building. A strategic reflection on our partner ecosystem was key to leverage local and national interests in continuing self-management approaches.

Key messages:

- We have established priorities among transferable intervention components to match country stakeholders' ability and readiness to sustain innovative approaches.
- We are building an institutional partnership across sectors based on complementarity of experience to sustain the delivery of a self-management intervention.

Oral health related cardiovascular disease risk factors: a cross-sectional study

Amr Ghanem

NO Németh[2], MM Móré[1], AN Nagy[1]
[1]Faculty of Health Sciences, University of Debrecen, Debrecen, Hungary
[2]Faculty of Dentistry, Semmelweis University, Budapest, Hungary
Contact: aghanem@etk.unideb.hu

Background: Hypertension, cardiovascular disorders, and hypercholesterolemia represent significant public health concerns. This research presentation examines the impact of various oral health indicators, such as bleeding gums, untreated dental decay, loose teeth, and missing teeth, on these conditions within Hungary.

Materials and methods: This study utilized data from 5,603 individuals participating in the 2019 Hungarian European Health Interview Survey. Predictor variables were chosen using elastic net regularization and k-fold cross-validation to enhance the performance of weighted logistic regression models. Sensitivity analysis underpinned the robustness of the results.

Results: Significant associations emerged between deteriorating oral health and the prevalence of various cardiovascular conditions. An increased likelihood of hypertension was observed in individuals with multiple tooth removals, showing an odds ratio (OR) of 1.67 with a 95% confidence interval (CI) of [1.01-2.77]. The use of dental prosthetics presented an OR of 1.45 [1.20-1.75]. Additionally, presence of gum bleeding corresponded to elevated odds for both cardiovascular disease (OR = 1.69 [1.30-2.21]) and hypercholesterolemia (OR = 1.40 [1.09-1.81]).

Conclusions: enhancing oral health could potentially mitigate chronic cardiac conditions, highlighting the importance of integrating dental care in comprehensive disease management strategies.

Key messages:

- Poor oral health is linked to higher hypertension and heart disease odds.
- Dental care is crucial in cardiac disease prevention and management.

Abstract citation ID: ckae144.1290
Toothbrushing habits are associated with self perceived stress

Martin Ranfl

N Vinder[1]
[1]NIJZ, Ljubljana, Slovenia
Contact: martin.ranfl@nijz.si

Background: Personal self-care is one of the most important factors in maintaining and improving oral health. Public health guidelines are recommending tooth brushing at least twice daily, once before bed time and at least on one occasion. On the other hand, our regular routines and caring for our own health is influenced by different factors including stress. We wanted to research how much does daily stress influencing tooth brushing habits.

Methods: We analyzed data from 2020 CINDI nationwide cross-sectional survey in Slovenia. Tooth brushing once a day or less was assessed as inadequate. Stress was assessed with question >>How often in the last 14 days have you felt tense, stressed or under a lot of pressure? << Participants who chose often or always as an answer were assessed as persons under stress. Method of binary logistic regression was used for statistical analysis of association between tooth brushing frequency and self-perceived stress, modified for some socioeconomic factors.

Results: Prevalence of inadequate frequency of tooth brushing was present in 31,6 % of sample, 31,5% in participants who were not feeling tense and 31,8% in participants who often felt tense or stressed. At first it seemed stress is not associated with tooth brushing habits. We adjusted this association for gender, education level and age and this association became clearer. Participants who felt stress and/or under pressure had higher odds for poor tooth brushing habits, their odds ratio was 1,283 ($p < 0,001$; 95% CI 1,124; 1,464) when adjusted for aforementioned factors.

Conclusions: Oral health is integral part of general health. Association between oral and mental health is often overlooked even though psycho-social aspects are part of modern oral health definition. As personal self-care is cornerstone of maintaining and improving oral health, implementation of mental health aspects should be incorporated in public health advises and programmes for promoting oral health.

Key messages:

- Self-perceived stress is associated with toothbrushing habits.
- People who are under stress less regularly brush their teeth.

Abstract citation ID: ckae144.1291
Type 2 diabetes risk is associated with poorer general health and mental health in women and men

Laura Neuperdt

L Neuperdt[1], *Y Du*[1], *J Nuebel*[1], *U Hapke*[1], *L Walther*[1], *GBM Mensink*[1], *A Richter*[1], *C Scheidt-Nave*[1], *J Baumert*[1], *C Heidemann*[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
Contact: neuperdtl@rki.de

Background: Increasing evidence points to a relation between cardiometabolic and mental health, but population-based data are scarce. We investigated the association of type 2 diabetes (T2D) risk to general and mental health with a focus on potential differences between women and men.

Methods: The study population comprised 5,192 adults (18+ years) without known diabetes based on data of the German Health Update (GEDA) 2022. T2D risk was assessed by the German Diabetes Risk Score (GDRS), that estimates the 5-year probability of developing T2D and was categorized into low, still low, elevated, and high risk. Sex-specific Poisson regression analyses were conducted including self-rated health (SRH), self-rated mental health (SRMH), depressive symptoms (PHQ-2) and anxiety symptoms (GAD-2) as dichotomous dependent variables and age, educational level, living alone, region of residence, and social support as covariables.

Results: Women had a higher prevalence of low T2D risk (66.1%) and a lower prevalence of high T2D risk (9.4 %) than men (55.3% vs. 16.3%). Compared to those with low T2D risk, women and men with a high T2D risk were less likely to report very good/good SRH (women: prevalence ratio: 0.63; 95% confidence interval: 0.51-0.79; men: 0.69; 0.57-0.84) or excellent/very good SRMH (women: 0.53, 0.39-0.73; men: 0.85, 0.63-1.15). Further, those with a high T2D risk had a higher risk of depressive symptoms (women: 1.71, 1.05-2.81; men: 2.23, 1.22-4.05) and anxiety symptoms (women: 1.84, 1.03-3.29; men: 2.73, 1.09-6.81). No statistically significant interactions between sex and T2D risk were observed regarding the included health outcomes.

Conclusions: A high T2D risk is associated with a lower probability of a favourable SRH and SRMH and a higher risk of depressive and anxiety symptoms in men and women. The underlying mechanisms need further identification, in order to design synergistically beneficial health promotion for cardiometabolic and mental health.

Key messages:

- No sex-specific differences in general and mental health were found in people at high T2D risk.
- Further research is needed to identify the underlying mechanism to improve general and mental health.

Abstract citation ID: ckae144.1292
Prediction of subsequent CKD according to eGFR decline slope varies by the presence of hypertension

Naomi Miyamatsu

N Miyamatsu[1], *A Shima*[1,2], *F Matsuno*[1,3], *H Segawa*[4], *Y Tatsumi*[5], *A Morino*[1,2], *M Kiyohara*[1], *A Yamaguchi*[1], *Y Kawatsu*[2]
[1]Department of Clinical Nursing, Shiga University of Medical Science, Otsu, Japan

[4]Department of Nephrology, Omihachiman Community Medical Center, Omihachiman, Japan
[5]Department of Hygiene and Public Health, Teikyo University School of Medicine, Tokyo, Japan
Contact: miyan@belle.shiga-med.ac.jp

Background: We reported that a declining slope in eGFR evaluated from 3-year observation could predict subsequent CKD among the relatively healthy population, even adjusted for baseline eGFR. However, its certainty may vary depending on the presence of comorbidities such as diabetes and hypertension, which are also recognized as the risk factors of CKD.

Methods: Annual health check-up data from a Japanese company spanning from 2009 to 2022 was used. The analyses included participants having 4 times continuous eGFR measurements for 3 years, undergoing health checkups at least once during a follow-up period, with negative for urinary protein (UP), and non-diabetic. Individual 'eGFR slopes' were calculated by the regression line with 4 times eGFR measurements. Participants with slopes of < -5 per year were categorized as the "decreased" group and -5 or more were categorized as the "stable" group. The cases of positive UP or less than 45mL/min/1.73m2 in eGFR during a follow-up period were defined as CKD. Cox regression analyses adjusted for sex, age, and eGFR at baseline were performed to calculate the hazard ratios and 95% CIs for CKD in the decreased group (reference; stable), stratified by hypertension.

Results: Out of 5598 study participants(men 36%, mean age 48.2± 10.1years, mean follow-up period 4.3 years), 260 CKD cases (4.6%) were observed. CKD cases accounted for 4.5% (235/5218) in the stable group and 6.6% (25/380) in the decreased group. Multivariate-adjusted hazard ratios [95%CIs] of CKD by eGFR decline was 1.50[0.99-2.27]. The eGFR decline increased the risk of CKD only in participants with hypertension (2.09[1.09-4.04]), but not in those without hypertension (1.25[0.73-2.13]). After excluding individuals with eGFR slopes exceeding 10 per year to consider for hyperfiltration of eGFR, the results were consistent.

Conclusions: The eGFR decline over a 3-year observation may predict subsequent CKD only in individuals with hypertension.

Key messages:

- With a relatively short-term evaluation period of three years, eGFR decline can predict subsequent CKD only in hypertensive individuals.
- In middle-aged hypertensive patients, it would be important for the prevention of CKD to pay attention not only to low eGFR but also to the progression of eGFR decline.

Abstract citation ID: ckae144.1293
Living with a chronic disease: tertiary prevention tools in asbestos-exposed patients

Elena Maria Guerreschi

EM Guerreschi[1], L Dragoni[1], AG Sisinni[2], S Fabrizi[2], GB Miceli[2], N Nante[1,3]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Health Surveillance and Preventive Medicine Unit, University Hospital, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: e.guerreschi@student.unisi.it

Background: The main asbestos-related pathology is asbestosis, frequently associated with pleural plaques. The spirometric pattern is mainly restrictive, with reduction in all lung volumes (FEV1, FVC, TLC). Also a reduction in alveolus-capillary diffusion of carbon monoxide (DLCO) may be added, related to the fibrotic process. The aim of the study is to analyze the health surveillance data, correlating the spirometric finding and its variation over time with the clinical and radiological picture.

Methods: The study is conducted on 372 patients with asbestosis from occupational exposure diagnosed in the period 2017-2023, as part of the Tuscany Region's program for former asbestos exposures (DGR 396/2016). The investigation is at the second level of surveillance, which includes chest CT and Respiratory Functionality Testing (RFT). Data are obtained from patients' medical records and processed through a database.

Results: Out of 372 patients with asbestosis, 213 had pleural plaques (57.25%). Out of those, there is a progressive worsening of RFTs in a restrictive direction (TLC <80%, FEV1/FVC >70%) in 71 patients (33.3%), with a mean TLC loss of 8.7 ± 5.9 mL over subsequent follow-ups on a yearly basis. The FEV1/FVC ratio also declines, with a mean reduction of 5 ± 2.4%. Out of those 71 patients, 14 (19.7%) also show a mean reduction in DLCO of 6.7 ± 5 mL/min/mmHg. The negative trend in RFTs correlates with the worsening clinical and radiological picture attributable to the occurrence of plaques on a fibrotic framework.

Conclusions: The health surveillance protocol that we adopted has as objective the ascertainment of pulmonary pleura-parenchymal alterations correlated with occupational exposure, investigating their evolution over time through the analysis of spirometric data, and to optimize the management of the functional disability, with a view to the tertiary prevention of patients with asbestos-related disease.

Key messages:

- The negative trend in asbestosis PFRs correlates with the worsening of the clinical and radiological picture attributable to the appearance of pleural plaques on an interstitial fibrosis.
- Health surveillance is essential in order to optimize the management of functional disability, with a view to tertiary prevention of patients with asbestos-related disease.

Abstract citation ID: ckae144.1294
Disability-adjusted life years 19 former socialist economies in the European region, 1990-2019

Milena Šantrić Milićević

M Šantrić Milićević[1,2], A Stevanović[1,2], J Todorović[1,2], Ž Stamenković[1,2], N Rosic[3], A Anton[4], A Rommel[4]
[1]School of Public Health and Health Management, Faculty of Medicine University of Belgrade, Institute of Social Medicine, Belgrade, Serbia
[2]Laboratory for Strengthening the Capacity and Performance of Health System and Workforce for Health Equity, Belgrade, Serbia
[3]City Institute of Public Health Belgrade, Belgrade, Serbia
[4]Robert Koch Institute, Berlin, Germany
Contact: milena.santric-milicevic@med.bg.ac.rs

Background: Within the Western Balkan Strategic Partnership Project (Work Package 4: Use of Population Health Metrics for Enhanced Surveillance), we conducted a study to describe health progress in 19 former socialist economies (FSEs) in Europe from 1990 to 2019. Our metric of choice was age and sex-standardized rates per 100,000 population of total disability-adjusted life years (ASR-DALY).

Methods: We applied joinpoint regression with extracted ASR-DALY data from the Institute for Health Metrics and Evaluation result tool. The annual per cent change (APC) and average annual per cent change (AAPC) from 1990 to 2019 were analyzed in 19 former socialist economies (FSEs) in Europe, including Albania, Belarus, Bosnia and Herzegovina (BH), Bulgaria, Croatia, Czechia, Estonia, Latvia, Lithuania, Montenegro, North Macedonia, Poland, Moldova, Romania, Russia, Serbia, Slovakia, Slovenia, and Ukraine.

Results: The ASR-DALY decreased in Estonia (APC1994-1997= -5.2%, $p = 0.034$; APC2013-2019= -0.7%, $p = 0.07$), Latvia (APC1994-1997= -6.3%, $p = 0.03$; APC1997-2007= -1%, $p = 0.001$; APC2007-2011= -3.9%, $p = 0.01$), BH (APC1995-1998= -13.3%, $p = 0.041$; APC1998-2019= -0.5%, $p = 0.004$), Bulgaria

(APC1997-2000= -2.5%, p = 0.022), Lithuania (APC2007-2010= -4.9%, p = 0.018), North Macedonia (APC2007-2011= -1.9%, p = 0.023, APC2011-2019= -0.5%, p = 0.005), Czechia (APC2014-2019= -0.6%, p = 0.014), Moldavia (APC1998-2007= -0.6%, p = 0.06), and Ukraine (APC1995-2008= -0.5%, p = 0.035). Slovenia performed the best amongst the FSEs (ASR-DALY2019: 16677.51 for women, 21985.95 for men and 19134.73 for both sexes), Ukraine the worst (ASR-DALY2019: 26154.88 for women, 47983.60 for men and 35852.17 for both sexes).

Conclusions: Except for Ukraine, all FSEs in the European region achieved health improvement. The most common was a three-year decline in ASR-DALY. Health policy changes, investments in health care, and harmonization with EU regulations were among the factors contributing to improved population health in the FSEs.

Key messages:

- Bosnia and Herzegovina is the only FSE in Europe with a continuous 24-year decline in total ASR-DALY.
- Reducing total ASR-DALY significantly in a three-year time frame is possible.

Abstract citation ID: ckae144.1295
Evaluating the feasibility of an Adapted Physical Activity intervention among breast cancer patients

Sabrine Hasnaoui

S Hasnaoui[1]*, A Van Hoye*[1,2]*, M Soudant*[3]*, C Rotonda*[1,4]*, A Carvalho de Freitas*[3]*, A Yacoubou Omorou*[1,3]*, M Poussel*[5,6]

Contact: sabrine.hsn@gmail.com

Adapted physical activity (PA) programs have shown promising results to reduce physical, psychological and social side effects associated with breast cancer (BC), but the extent to which they can be effectively adopted, implemented and maintained is unclear. The aim of this study is to use the RE-AIM (Reach, Effectiveness, Adoption, Implementation and Maintenance) framework to evaluate RIPOSTE (Reconstruction, Image de soi, Posture, Oncologie, Santé, Thérapie, Escrime), an innovative intervention focused on improving the quality of life (QoL) of BC surgery patients through fencing. A convergent mixed-methods pilot study was conducted to evaluate the RE-AIM dimensions of RIPOSTE. 24 participants who have just undergone surgery for invasive BC were randomly allocated either in the "RIPOSTE" group (starting immediately after their inclusion), or the "Delayed RIPOSTE" group (starting at 3 months following their inclusion). They answered to questionnaires at inclusion and at the end of the program on QoL, shoulder functional capacity, fatigue, anxiety-depression and PA. Interviews were conducted with 10 participants, 3 sports physicians and 1 fencing master. RIPOSTE program was able to reach mainly young and dynamic participants, attracted by the originality of fencing and keen to improve their physical condition. Regarding effectiveness, our results suggest a trend to the improvement of health indicators, even without any significant differences between the two groups. The cooperation, exchanges and cohesion within the group greatly facilitated the adoption of the program, whereas interruptions during vacations were the main barriers. Maintenance analyses showed that most participants continued to practice PA after the program. RIPOSTE is an acceptable and effective program for involving BC survivors in PA, that needs to be tested at larger scale to investigate its effectiveness, but has the potential to be transferred and scaled up worldwide.

Key messages:

- These results would help to enrich the literature on how to best intervene to enhance treatment and recovery among patients and facilitate transfer from a research program to a field daily practice.
- By highlighting complexities of RIPOSTE effectiveness and implementation, this study could lead to a more complete program that addresses issues related to improving external and internal validity.

Expanding access to non-communicable disease screening in war-affected communities in Ukraine

Halyna Darahan

H Darahan[1]*, R Rodyna*[1]*, K Karpiuk*[1]*, A Bogdanov*[1]*, B Shcherbak-Verlan*[1]*, N Zaika*[1]*, K Gamazina*[1]*, G Dravniece*[1]
[1]PATH, Kyiv, Ukraine
Contact: hdarahan@path.org

Background: Non-communicable diseases (NCDs) account for 91% of premature deaths in Ukraine. However, NCD screening lags among young people and across the entire population. The ongoing war has exacerbated barriers to NCD screening due to damaged infrastructure, understaffed medical facilities, and health system deterioration.

Intervention/response: To improve screening, diagnosis, and care, in March 2023 the PATH-led, USAID-funded Support TB Control Efforts in Ukraine (STBCEU) project established community level health access points (HAPs) in five conflict-affected communities. STBCEU procured screening tools (tannometers, glucometers, portable ECGs) for common NCDs, printed informational materials, trained 143 specialists, designed a reporting system, and facilitated monitoring visits to 77 HAPs.

Results: By the end of 2023, the project equipped 113 HAPs in the five communities, and 102 of them initiated NCD screening. From January-March 2024, 1,694 people under 40 years old were screened for NCDs. Among 1,488 blood pressure measurements, 143 cases had high readings (9.6 ±1.5%), 90 (62.9%) of which were first-time diagnoses, and 53 (37.1%) treatment monitoring. Glucose levels were measured 809 times, with elevated levels in 44 cases (5.4 ± 1.5%), 30 (68.2%) of which were first-time diagnoses, and 14 (31.8%) treatment monitoring. Additionally, 1,144 mental health consultations were provided.

Conclusions: This initiative represented a first in Ukraine: per national requirements, young people have not historically been screened for NCDs. Expanding NCD screening in war-affected communities has demonstrated substantial early success, with significant detection of high blood pressure and elevated glucose levels among people under 40. This proactive, cost-effective intervention underscores the need for accessible, community-level health interventions in crisis settings and showcases a scalable model for integrating NCD screening into emergency health response frameworks.

Key messages:

- The implementation of community-level NCD screening has shown early success in detecting high blood pressure and elevated glucose levels among people under 40.
- Cost-effective NCD screening underscores the need for accessible, community health interventions, providing a scalable model for integrating NCD screening into emergency health response.

[3]Department of Clinical Psychology, IDIS University of Santiago de Compostela, Santiago de Compostela, Spain
[4]Faculty of Education Sciences, University of Santiago de Compostela, Santiago de Compostela, Spain
Contact: elena_gles@hotmail.com

Background: Evidence shows physical activity (PA) and sedentary behavior (SB) impact health-related outcomes. World Health Organization (WHO) provides PA guidelines for different life stages. A recent study revealed that engaging in SB > 6 hours/day increases all-cause mortality risk. Nevertheless many students spend a significant portion of their daily time on SB and PA levels are insufficient.

Methods: Students were selected by convenience sampling to complete a survey between October-November 2023. A validated PA questionnaire was included including PA Motivations and barriers. PA and SB were classified into 4 levels: Active but sedentary, extremely sedentary, physically active and discreetly active. Data were analyzed using Statistical Package for the Social Sciences (SPSS).

Results: Out of 2,216 surveys 1,648 were women, 568 men and 59.7% were in first university years. In our sample, 12.9% don't do PA. Of those doing PA, 47.1% (n = 1043) don't meet PA recommendations. Regarding SB, 84.7% spend >6 hours/day in SB. When grouped into PA/SB categories 40.5% were extremely sedentary in contrast to 8.8% physically active. Non-university facilities (41.1%) were preferred over university facilities (11.1%). Use of non-university and university facilities correlated with WHO compliance. Main barriers among inactive students were lack of time (48%) and lack of a workout partner (18.6%).

Conclusions: Most students don't meet WHO guidelines. Less than 10% are considered active, while 40.5% are extremely sedentary. University sports facilities are underused even if linked to better compliance. To promote facilities as health-promoting spaces and investigate reasons for their underuse is necessary. Lack of company as a reason for not engaging in PA points out the need to strength university sports communities.

Key messages:

- Although many students exercise, the majority do no meet World Health Organization recommendations.
- We must intensify university programs to promote physical activity and reduce sedentary behavior.

Abstract citation ID: ckae144.1298
Traditional medicine use to manage hypercholesterolemia, hyperglycaemia and hypertension in Ecuador

Marta Puig García

Background: Although the use of traditional medicine (TM) to manage health issues is frequently reported, clinical guidelines often overlook this practice. This study aimed to describe the frequency of TM use to control 3 cardiometabolic risk factors for non-communicable diseases (arterial hypertension, hypercholesterolemia, and hyperglycaemia, collectively referred to as CMRF here); and associated sociodemographic, economic, and clinical characteristics.

Methods: Descriptive cross-sectional study with a representative population of two health districts in Ecuador, one urban in southern Quito and one in a forested rural area with diverse ethnic groups in Esmeraldas. We included 602 individuals with at least one CMRF and calculated the proportion of those who reported regular use of TM (herbal or traditional remedies) to control their CMRF. We used a multivariable logistic regression model to calculate Odds Ratios for TM use according to sociodemographic, economic, and clinical characteristics.

Results: TM was commonly used to control CMRF in both sociocultural contexts (39.4% Esmeraldas, 31.1% Quito), often in combination with conventional medicine (CM). A notable percentage of people (33.9% Esmeraldas, 39.0% Quito) did not take any treatment for their CMRF, and the rest used CM alone. In both settings, education was significantly associated with TM use. While in Quito people with higher education were more likely to use TM (aOR 2.04, 95%CI 1.03-3.90), in Esmeraldas, it was more common among people without formal schooling (aOR 3.76; 95%CI 1.59-8.88) as well as those of younger age (aOR per year 0.97; 95%CI 0.95-0.99) and from Afro-Ecudorian ethnicity (aOR 2.13; 95%CI 1.02-4.45).

Conclusions: Traditional medicine is used by a significant portion of Ecuador's population, highlighting the need for a more accessible and intercultural approach to healthcare.

Key messages:

- The use of traditional medicine to address hypertension, hypercholesterolemia, and hyperglycaemia appears to be widespread in different sociocultural and economic contexts of Ecuador.
- To promote intercultural health, understanding the diverse sociocultural patterns associated with the use of traditional medicine, often combined with conventional medicine, is crucial.

Gut Microbiota and Parkinson's disease - a prospective analysis of the FINRISK 2002 Study

Katri Sääksjärvi

K Sääksjärvi[1], J Tynkkynen[3], V Salomaa[1], A Havulinna[1], P Jousilahti[1], A Kauko[2], J Palmu[2], T Niiranen[2]

[1]Department of Public Health and Welfare, THL, Helsinki, Finland
[2]Department of Internal Medicine, University of Turku, Turku, Finland
[3]Centre for Vascular Surgery and Intervention, Tampere University Hospital, Tampere, Finland
Contact: katri.saaksjarvi@thl.fi

Background: Parkinson's disease (PD) is a neurodegenerative movement disorder with mainly unknown etiology. Constipation is a common symptom, and changes in gut microbiota may play role in PD pathogenesis. Previous studies exploring microbial associations to PD have been mostly cross-sectional, and the role of microorganisms in PD etiology remains unclear. Thus, we examined the association between microbiota features and incident PD in a prospective cohort design.

Methods: In the FINRISK 2002 Study, 7231 participants gave a stool sample that underwent shotgun metagenomic sequencing. Participants with missing stool sample, incomplete covariate data, pregnancy, antibiotic use, and prevalent cases were excluded (final n = 5562). Cox regression models, adjusted for age, sex, education, smoking, coffee consumption, diabetes, cardiovascular events, and constipation, were used to assess associations between incident PD and microbiota features, ie. alpha diversity (the number of different species present in a sample), beta diversity (the differences in microbial composition between individuals), and abundance of 381 core taxa (compositional detection rate of at least 0.1% and a prevalence of 1%). 120 incident cases of PD, identified through register linkage, occurred during a median follow-up of 17.8 years.

Results: In the multivariate models, PD incidence was not associated with the Shannon index, a measure on alpha diversity, (p-value 0.81), or with the ten first principal component axes in beta diversity analysis (p-values ranging between 0.49-0.91). In permutational analysis, PD did not explain differences in the composition of the gut microbiota (R2 <0.001, p-value 0.46)). None of the core species were associated with PD incidence (all FDR-corrected p-values > 0.05).

Conclusions: This prospective study showed no support for an association between gut microbiota features and incident PD.

Key messages:

- Previous findings associating gut microbiota with PD may be due to the cross-sectional design, ie. PD affecting the gut microbiota.
- Suggestions to screen gut bacteria to identify people at high risk of Parkinson's disease are vastly premature as the scientific evidence is inconclusive.

Abstract citation ID: ckae144.1300
Factors associated with type 2 diabetes control in hard-to-reach communities in Esmeraldas, Ecuador

Marta Puig García

M Puig-García[1,2], *C Caicedo-Montaño*[3], *M Márquez-Figueroa*[3], *E Chilet-Rosell*[1,2], *B Lumbreras*[1,2], *LA Parker*[1,2]

[2]CIBER de Epidemiología y Salud Pública, Madrid, Spain
[3]Centre of Community Epidemiology and Tropical Medicine, Esmeraldas, Ecuador
Contact: marta.puig@goumh.umh.es

Background: The rising prevalence of type 2 diabetes mellitus (T2DM) and its detrimental effects on population health make it an urgent public health concern. Maintaining blood glucose control is crucial for avoiding complications; however, there are notable socioeconomic disparities in disease management, especially in low- and middle-income settings. We aimed to examine the factors associated with controlled fasting capillary glucose in a difficult-to-access rural setting of Esmeraldas, Ecuador, and to examine the role of social support in this context.

Methods: Between October 2020 and May 2022, we conducted a cross-sectional study of T2DM adult patients in Esmeraldas' Eloy Alfaro health district. We collected data on socio-demographic and clinical patient characteristics using a questionnaire and measured Fasting Capillary Blood Glucose levels. We estimated the prevalence of controlled glycaemia and used logistic regression to calculate odds ratios (OR) with 95% confidence intervals.

Results: Only 18.1% (95%CI: 14.9-21.8) of the 476 study participants had controlled glucose levels, with a significantly higher percentage in men (28.2%) compared to women (13.8%). Participants reported moderate perceived social support (median=2.33, on a scale of 1 to 4), without significant impact on glycaemic control. Women in urbanised areas were more likely to have controlled glucose levels compared to those in rural areas (aOR=2.34, 95%CI: 1.23-4.44) after adjusting for family support. In contrast, unemployed and older men had non-significant trends towards better odds of achieving controlled fasting glycaemia.

Conclusions: The complex interplay of factors affecting diabetes management and glycaemic control highlights the need for targeted, context and gender-specific public health strategies to address diabetes disparities in vulnerable populations.

Key messages:

- The majority of individuals with T2DM residing in the remote communities of Eloy Alfaro district in Esmeraldas (Ecuador) have uncontrolled glycaemia, showing notable gender-specific disparities.
- Participants reported a moderate level of social support, with family as the most important source. Yet, this perceived support may not effectively overcome contextual barriers in T2DM management.

Abstract citation ID: ckae144.1301
Impact of Multiple Sclerosis on different life dimensions among working women in Sweden

Alejandra Machado

A Machado[1], *FS Teni*[1], *E Friberg*[1]
[1]Division of Insurance Medicine, Karolinska Institutet, Stockholm, Sweden
Contact: alejandra.machado@ki.se

Introduction: Multiple sclerosis (MS), like many other chronic diseases, may impact the whole life situation. MS is more common among women than men, in addition, women tend to report worse health status. We aimed to explore the self-reported impact of MS on different dimensions of life such as work, family, leisure activities and, contact with friends and acquaintances.

Methods: All individuals 20-50 years of age listed in the Swedish MS Registry were invited to answer a survey in 2021. Responses from 2659 working women regarding impact of MS in different dimensions (1, not at all; 2-3, occasionally; 4-5, frequently; 6-7 to a high extend) were explored with descriptive statistics.

Results: Reported impact of MS varied across the different life dimensions. Working women reported that MS had a greater impact on their leisure activities (20.7% - responding to 'to a high extent'), followed by contact with friends and acquaintances (15.8%), work (15.5%) and family (11.7%). This despite the fact that 77.1% had mild levels of disability. Further, the MS diagnosis was reported to have contributed to reduced working time (31.4%), refrained from changing job (28.8%), changed jobs (20.5%) or changed career track (20.4%). When questioned about positive life-changing experiences due to MS diagnosis, a majority of the women stated that it had contributed to learning how to adapt to things one cannot change (59.2%) and being grateful for everyday (51.7%).

Conclusions: An MS diagnosis can significantly impact various aspects of life. While work is notably affected, leisure activities also undergo substantial changes after MS diagnosis. However, acceptance, adaptability and finding meaning, among other, can be important parts of the journey.

Key messages:

- At early stages of MS, the disease tend to affect leisure activities more than other dimensions of life.
- Finding coping mechanisms to handle MS may contribute to compensate the impact of MS.

Abstract citation ID: ckae144.1302
The Association between Social Capital, Food Security, and Type 2 Diabetes Management

Ella Berkovich

E Berkovich[1,2,3], *O Baron-Epel*[1]
[1]Public Health, Haifa University, Haifa, Israel
[2]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
[3]Nutritional Science, Tel-Hai College, Tel Hai College, Israel
Contact: looli1311@gmail.com

Background: Given nutrition's key role in treating diabetes, food insecurity may seriously affect the standard management of the disease. A patient's social environment or community plays an important role in managing the disease. This study explores how food security and social capital are associated with the management of type 2 diabetes.

Methods: A cross-sectional telephone survey of 381 Israelis Jewish and Arab with type 2 diabetes was conducted. Data was collected on food security, social capital, disease management factors, and socioeconomic status. Moreover, medical records provided information about HbA1c, age, and disease diagnosis date for each respondent.

Results: Blood glucose balance (HbA1c $\leq$7mmol/mol) was associated with employment, while unemployed respondents had a better balance. Food security is correlated with health perception - the better the food security, the better the health perception. Food security is related to social and family support, as well as to neighborhood help and connections. The social capital index increases as food security increases. A higher disease management index score, as well as a higher trust index score, indicates a more balanced patient. In light of the fact that food security is associated with social aspects of health, it may act as a mediator between social capital and perceived health.

Conclusions: Social factors directly affect the balance of the disease. Subjective health and gender were associated with food security. Social capital and support are linked to subjective health reporting through food security, so this variable is a mediator. It can be concluded that social factors and food security play a role in subjective health assessment in diabetics. Diabetes management and balancing depend not only on behavioral factors but also on environmental and social factors.

Key messages:

- Food security is a necessary factor in balancing blood glucose levels, as well as a mediator factor between social capital and perceived health among diabetics.
- A balanced diabetes requires social support, such as a supportive social environment and must consider the individual's character.

[3]Lab for Strengthening the Capacity and Performance of Health Systems and Workforce for Health Equity, Belgrade, Serbia

[4]City Institute of Public Health Belgrade, Belgrade, Serbia

Contact: zeljka.stamenkovic@med.bg.ac.rs

Background: Cardiovascular diseases are ranked as the number one cause of death in Serbia, and one-fifth of them present ischemic heart disease (IHD). However, the physicians certifying the cause of death have either not been adequately involved in how to complete a death certificate according to the current International Statistical Classification of Diseases (ICD-10) or due to a high level of administrative tasks sometimes fail to complete the process of death certification. That is why we aimed to investigate the garbage codes (GCs) and the effects of their redistribution on underlying cause of death (CoD) estimates for IHD for 2015 and 2020.

Methods: Data from Belgrade mortality statistics in 2015 and 2020 were used to describe the occurrence and redistribution of garbage codes (GCs), defined as unspecified or impossible causes of death. In order to redistribute GCs we observed the underlying, antecedent, immediate causes and other conditions that contributed to deaths. Redistribution was done by consulting GBD methodology for GC proportional redistribution. The ICD-10 code range for IHD is I20-I25.

Results: In Belgrade, 17% (4022/23663) and 20.9% (5818/27775) of the deaths were coded with a garbage code in 2015 and 2020, respectively. In 2015, 2102 deaths (10.7% of all well-defined CoD) were attributed to IHD, while in 2020, 1806 (8,2% of all well-defined CoD) deaths were attributed to IHD. Finally, we redistributed a total of 452 deaths (GC type 1 203.9, GC type 2 122.1 and GC type 3 126.2 deaths) and 572 deaths (GC type 1 250.1, GC type 2 110.9, GC type 3 210.7 and GC type 4 22) due to IHD in 2015 and 2020, respectively. These calculations indicate a total number of 2554 and 2378 deaths due to IHD in 2015 and 2020, respectively.

Conclusions: A more detailed analysis of local practices, as well as continuing medical education in the field of death certification, could be a step forward in the future process of decreasing the number of GCs.

Key messages:

- Since the huge number of deaths was added to ischemic heart disease in 2015 and 2020, it is crucial to focus on a more reliable disease surveillance system including better coding practices.
- A deep understanding of the garbage codes and their redistribution could significantly shape future decisions on factors contributing to ischemic heart diseases.

Contact: lparker@umh.es

Background: Evidence regarding the likelihood of overdiagnosis in prostate cancer (CaP) screening with PSA are mainly based on clinical trials, which include younger population with fewer comorbidities than those receiving the test in clinical practice. We aimed to assess the likelihood of overdiagnosis and associated variables using real-world data.

Methods: Retrospective cohort of men >40 years with PCa, who had been diagnosed being asymptomatic and after a positive PSA test in the previous 12 months in two hospitals (2004-2022). The probability of overdiagnosis was estimated considering the life expectancy of the Spanish male in the year 2022 and the Charlson Comorbidity Index (lead time 10 years). PSA values and Gleason score were included as independent variables.

Results: Of the 2,331 patients in the cohort, 1,070 (46%) met the inclusion criteria for this analysis. The median follow-up time was 5.7 years (IQR 3.2-8.6). The median age was 71 years (IQR 65-78) and 37% had more than one comorbidity. At diagnosis, the median life expectancy was 12 years (IQR 4-18) and the probability of overdiagnosis was 30.8% (IQR 17.6-52.4). Patients with PSA levels >10 mg/dl tended to be older and with more comorbidities than those with PSA levels 4-10 mg/dl, and thus, with shorter life expectancy. The median probability of overdiagnosis was higher in patients with PSA levels >10 mg/dl (41.4%, IQR 21.5-73.9) than in those with PSA levels 4-10 mg/dl (20.1%, IQR 12.8-30.4), $p < 0.001$. Correspondingly, patients with Gleason score ≥ 8 were more likely to be overdiagnosed (median 42.6%, IQR 23.6-68.6) than those with Gleason score ≤ 6 (median 20.1%, IQR 12.8-30.4) ($p < 0.001$).

Conclusions: In clinical practice, older patients with comorbidities showed high PSA levels and Gleason score ≥ 8, presenting low life expectancy at diagnosis and, therefore, high probability of overdiagnosis. This highlights the importance of considering the patient's comorbidities when ordering a new PSA test.

Key messages:

- A detailed assessment of the prevalence of comorbidities among CaP patients in real-life settings has significant implications for patient management.
- The decision to make an early diagnosis should be based on individual life expectancy, where comorbidity is at least as important as age.

Abstract citation ID: ckae144.1305
Impact of Noncommunicable Diseases on Years of Life Lost in FB&H During the COVID-19 Pandemic

Šeila Cilović Lagarija

Š Cilović Lagarija[1], *S Skočibušić*[1,2], *A Rommel*[3], *A Anton*[3]
[1]Institute of Public Health for FBiH, Sarajevo, Bosnia and Herzegovina
[2]Faculty of Medicine, University of Mostar, Mostar, Bosnia and Herzegovina
[3]Robert Koch Institute, Berlin, Germany
Contact: s.cilovic@zzjzfbih.ba

This study aims to comprehensively investigate the impact of noncommunicable diseases (NCDs) on years of life lost (YLL) within the Federation of Bosnia and Herzegovina (FB&H) across distinct phases: pre-pandemic, pandemic, and post-pandemic periods. Given that NCDs currently represent more than half of the global disease burden, our focus lies in assessing YLL specifically for cerebral infarction (I63-I64) and diabetes mellitus (E10-E14). Conducting a retrospective data analysis, we utilized mortality data sourced from the Institute for Statistics of FB&H to quantify YLL. This assessment involved multiplying age-specific mortality figures by the remaining life expectancy at the corresponding age, utilizing the GBD 2019 life expectancy table. Examining the period between 2019 and 2022, our analysis aimed to elucidate the pandemic's potential influence on NCD burden, through the examination of age-standardized YLL rates based on the world standard population. In 2019, YLL attributable to I63-I64 for both sexes totaled 41,244 in 2019, escalating to 44,790 in 2020, and subsequently decreasing to 39,439 and 32,055 in the pandemic years of 2021 and 2022, respectively. For diabetes mellitus (E10-E14), YLL in 2019 amounted to 23,675, with figures for 2020, 2021, and 2022 standing retrospectively at 24,329, 24,114, 19,125. The increase in 2020 may be attributed, in part, to initial healthcare hesitancy during the pandemic's onset, leading to delayed treatment and heightened mortality rates. Furthermore, patients who died in 2020 from C-19 without being tested may have skewed mortality registration by inflating rates attributed to pre-existing conditions. The declining rates thereafter could be due to a harvesting pandemic effect, in that people who were previously ill died prematurely from C-19. These insights show the pandemic's profound impact on NCD-related mortality, underscoring the urgent need for targeted interventions and healthcare strategies.

Key messages:

- A substantial reduction in years of life lost (YLL) related to certain noncommunicable diseases was observed during the pandemic.
- The pandemic significantly influenced mortality among individuals with noncommunicable diseases, driven partly by healthcare hesitancy and potential misregistration of causes of death.

[3]School of Public Health and Health Management, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[4]City Institute of Public Health, Belgrade, Serbia
Contact: jovana.todorovic@med.bg.ac.rs

Background: Ischemic stroke is a major common cause of death not only in Serbia but worldwide. Mortality statistics commonly include ill-defined, impossible and insufficiently specified causes of death among the underlying causes of death (CoDs). In the activities of the Laboratory for Strengthening the Capacity and Performance of the Health System and Workforce for Health Equity, we examined mortality due to ischemic stroke either as well-defined underlying CoDs or garbage codes (GCs - including the ill-defined, unspecified or impossible CoDs) in Belgrade in 2015 and 2020.

Methods: Anonymous mortality data of the City Institute of Public Health Belgrade were analyzed, and the GCs were redistributed to ischemic stroke as underlying CoDs (ICD-10 codes I63-I63.9), based on the principles of the Global Burden of Disease study, using the three-step approach: 1) exploration and analysis of GCs; 2) modelling of the underlying, antecedent and immediate causes of death; 3) proportionate redistribution.

Results: 17% of the total of all deaths in Belgrade in 2015 and 20.9% in 2020 were GCs. Before the redistribution, the share of ischemic stroke as the well-coded CoDs of total mortality was 7.3% (1443/19641) in 2015 and 4.6% (1022/21957) in 2020. A total of GCs - 309 deaths in 2015 and 322 in 2020 were identified for redistribution to ischemic stroke. Based on the type of GCs, in 2015, a total of 139 cases were redistributed in type 1 GCs, 83 in type 2 GCs and 87 in type 3 GCs. In 2020, 141 cases were redistributed due to type 1 GCs, 62 type 2 GCs and 119 type 3 GCs.

Conclusions: This study underscores the significant proportion of all ischemic deaths in Belgrade that were coded with the GCs. After the redistribution, almost one-fifth of the ischemic strokes, previously known as GCs, were added, emphasizing the crucial role of accurate coding in understanding mortality patterns. Improving the coding of deaths is necessary to have reliable information for health policymaking.

Key messages:

- One-fifth of the ischemic strokes in Belgrade were previously GCs.
- Accurate coding is essential for understanding mortality patterns and developing valid health policies.

Objectives: Dehydration, a risk factor for ischemic cerebrovascular diseases, is common in summer; however, the incidence of ischemic diseases is not necessarily higher in summer. The phenomenon may be influenced by the differences in the susceptibility to vascular dehydration based on the season. Therefore, this study aimed to distinguish types of dehydration in colder and warmer seasons by analyzing serum osmolarity, hematocrit, and daily non-alcohol drink (NAD) intake.

Methods: Participants in the Kobe Orthopedic and Biomedical Epidemiologic (KOBE) Study, consisting of healthy individuals, were categorized into two groups based on the examination month: the warmer and colder seasons. Multivariate analyses were conducted to examine disparities in serum osmolarity, hematocrit, and NAD intake between these two groups.

Results: Participant ratios by age group and the seasons (warmer season/colder season) were as follows: Women under 50 (35/62), 50-60 (77/126), 60-70 (123/170), over 70 (58/52); Men under 50 (14/17), 50-60 (22/36), 60-70 (57/71), over 70 (55/34). The colder season was found to be negatively correlated with serum osmolarity and NAD intake, but positively correlated with hematocrit, even after adjusting for relevant factors. Age was independently associated with serum osmolarity, but not with hematocrit and NAD intake.

Conclusions: This study highlights that vascular dehydration is more likely in the colder season despite lower serum osmolarity than the warmer season. Age-related increases in serum osmolarity without a corresponding rise in water intake may contribute to this. These findings emphasize the importance of addressing dehydration in the colder season, particularly in older adults.

Key messages:

- The colder season showed a negative correlation with serum osmolarity and NAD intake but a positive correlation with hematocrit.
- Raising awareness about the importance of hydration during winter may be essential.

Contact: a.lemlijn@maastrichtuniversity.nl

Background: Persons with a chronic disease, such as chronic gastrointestinal and hepato-pancreatico-biliary (GI-HPB) disease, have a lower work participation (WP) than the healthy population. Instead, they might receive a disability benefit (DB). Positive Health (PH) is a newly developed, holistic view of health and comprises six dimensions: bodily functions, mental well-being, meaningfulness, quality of life, participation, and daily functioning. In this study we aim to determine whether the dimensions of PH relate to WP and DB in persons with GI-HPB.

Methods: GI-HPB patients attending the outpatient clinic of the Maastricht University Medical Center between 2019-2021 received validated questionnaires (Gastrointestinal Symptom Rating Scale, Short Nutritional Assessment Questionnaire, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, Short Form-36, Disease Experience Questionnaire, EuroQol-5D-5L) and items regarding WP and DB. The relation between the six dimensions of PH, and WP and DB, were tested with univariate and multivariate statistics.

Results: 448 patients (Mage = 45 years; 69% female) were included. Univariate analysis revealed that, except for meaningfulness, all dimensions were significantly associated with WP ($p \leq .02$) and DB ($p \leq .005$). In multivariate analyses, lower age ($p = .010$), better general health ($p = .044$) and better physical functioning ($p < .001$) related to WP. Higher age ($p = .002$) and lower physical functioning ($p = .011$) related to DB.

Conclusions: Among GI-HPB patients, physical functioning related to both WP and DB. The chance of working was higher among younger patients and those with better general health while those with a higher age received DB more often. The PH concept was only partially relevant to work status and DB.

Key messages:

- Within the dimensions of Positive health, work participation was associated with a lower age, a better general health and a better physical functioning.
- Within the dimensions of Positive health, disability benefit was associated with higher age and lower physical functioning.

Problem: In 2020, Portugal had the highest cumulative incidence of colorectal cancer (CRC) in the European Union (103 new cases/100,000 inhabitants). The Colorectal Cancer Screening Program (CRCS) is based on fecal occult blood testing (FOBT) as the primary screening method. With the delivery of the stool sample collection device; instruction on its use is provided by the Primary Health Care team. The sample is processed at the Clinical Pathology laboratory of the Hospital Center (HC). In case of a positive result, the general practitioner communicates the result and refers the individual to the Follow-up and Treatment Center.

Description: The general objective of this project was to implement the CRCS in the 19 Family Health Units (FHU) of Loures-Odivelas Health Center Group, between September 2022 and April 2023. The following activities were carried out: 1. Sessions to present the patient pathway, record platform, and stool sample collection device; 2. Application of a checklist of essential points for the start of screening; 3. Preparation and dissemination of monitoring reports to the FHU; 4. Follow-up visits to clarify doubts.

Results: By March 2023, CRCS had been implemented in 15 of the 19 FHU (79%). Between September 2022 and March 2023, 1,430 devices were delivered and 959 FOBT samples were received (67%). Among the devices received with biological samples, it was not possible to issue a result for 5%.

Lessons: The activities carried out allowed for the initiation of CRCS in most FHU. The involvement of professionals in these activities contributes to increased patient adherence and proper collection technique, reducing inconclusive FOBT results. It is necessary to continue this strategy of personalized support for the FHU to consolidate the implementation of CRCS in LO HCG. Ensuring that the

necessary materials are available and that result issuance and referral deadlines are met are important factors for maintaining professional motivation.

Key messages:

- The objective was to implement the Colorectal Cancer Screening Program (CRCS) in 19 Family Health Units (FHU) in Loures-Odivelas. By March 2023, CRCS had been implemented in 15 of 19 FHU (79%).
- It is important to continue these activities in order to put into operation the CRCS in all FHU and to tackle the problem of colorectal cancer.

[3]Academic Knowledge Center Work and Health-SEN, Employee Insurance Agency, Heerlen, Netherlands
Contact: a.lemlijn@maastrichtuniversity.nl

Background: Chronic gastrointestinal and hepato-pancreatico-biliary (GI-HPB) patients experience problems in all life areas. The Positive health (PH) concept, based on six different dimensions of health, may hold the answers for a broader understanding of the patients' well-being.

Aim: To measure the overall health status of GI-HPB patients, according to the PH concept.

Methods: In 2019-2021, patients with GI-HPB attending the outpatient clinic of the Maastricht University Medical Center filled in questionnaires before consultation. The six dimensions of PH (bodily functions, mental well-being, meaningfulness, quality of life, participation, daily functioning) were measured by validated questionnaires (Gastrointestinal Symptom Rating Scale, Short Nutritional Assessment Questionnaire, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, Short Form-36, Disease Experience Questionnaire, EuroQol-5D-5L). Results were compared to control groups and assessed with McDonald's Omega, Zero-order Pearson correlations, and t-tests.

Results: The 235 participating patients scored lower on quality of life, participation, and daily functioning than healthy controls ($p \leq 0.001$) but similar to those with other chronic conditions. Malnutrition (moderate-severe 45.6%) and depressive/anxious symptoms (35%/21.6%) were higher in the GI-HPB group compared to those with other chronic conditions.

Conclusions: Validated questionnaires addressing the six dimensions of PH showed a significant worse health status compared to controls, and malnutrition and depressive symptoms were higher compared to other patient groups.

Key messages:

- GI-HPB patients have a lower quality of life, participate less, and have less daily functioning than healthy controls and higher malnutrition and depression than those with other chronic diseases.
- By using validated questionnaires, an impression of the overall health status of patients can be obtained through the concept of Positive Health.

Social inequalities in cancer incidence, survival and mortality: An umbrella review

Mark Francis

M Francis[1], S Peña[1], T von Wright[1], E Lindell[1], I Bellos[2], V Benetou[2], L Kestilä[1]
[1]THL, Helsinki, Finland
[2]National and Kapodistrian University of Athens, Athens, Greece
Contact: mark.francis@thl.fi

Background: An increasing number of systematic reviews investigating differences in cancer burden by social factors such as race, ethnicity, and socioeconomic status have been published in recent years. Our study aims to evaluate the strength and quality of evidence from systematic reviews investigating associations between social factors and cancer incidence, survival, and mortality to help policy-makers reduce existing social inequalities in the burden of cancer.

Methods: Our study is a pre-registered umbrella review (PROSPERO; CRD42024552884). We systematically searched Medline, Scopus, Web of Science, CINAHL, PsycINFO, the Cochrane Library, the JBI EBP database, and Epistemonikos without date restrictions for published systematic reviews with or without meta-analyses on June 17, 2024. The search identified 15,542 records, which were reduced to 7,421 after deduplication. We are currently screening studies to include systematic reviews of cohort or case-control studies that examined associations between one or more social factors (gender, race/ethnicity, education, occupation, socioeconomic status, place of residence, religion, social capital) and cancer outcomes. Study screening, data extraction, and quality appraisal will be done in duplicate using pre-piloted forms. The strength of evidence of reported associations between social factors and cancer outcomes will be assessed using the Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) criteria. Before data synthesis, we will assess the degree of overlap between primary studies in the eligible reviews by creating citation matrices and calculating corrected covered area indices. Following this, we will narratively summarize associations (for systematic reviews without meta-analyses) and pool the risk estimates for individual social factors and cancer outcomes (for reviews with meta-analyses) using random-effects meta-analysis models. We will have preliminary results ready by November 2024.

Key messages:

- Our umbrella review aims to evaluate the strength and quality of evidence from systematic reviews which have examined social inequalities in cancer incidence, survival, and mortality.
- This high-level evidence synthesis can help policy-makers better plan and target interventions to reduce the existing social inequalities in the burden of cancer.

Abstract citation ID: ckae144.1312
Serum circulating liver enzymes and human diseases

Qi Feng

Q Feng[1]
[1]School of Public Health, Imperial College London, London, UK
Contact: ermadake@gmail.com

Background: This study aimed to comprehensively investigate the observational and Mendelian randomization (MR) associations between liver enzymes (ALP, ALT, AST and GGT) with a wide spectrum of human diseases.

Methods: UK Biobank data was used for observational analysis. Cox proportional hazard models were used to quantify the observational associations between liver enzymes and risks of 1109 diseases, adjusted for covariates. A correction was applied to allow for multiple comparisons. Two-sample MR was performed to replicate the identified observational associations. We assessed the strength, consistency and pleiotropy of these MR associations.

Results: In 438571 participants with a median 12.4 years of follow-up, we found evidence linking liver enzymes and 654 diseases, 254 of which were further assessed in subsequent MR. In MR, 52 associations were replicated (10 for ALP, 14 for ALT, 10 for AST and 18 for GGT). Specifically, ALT was associated with liver conditions, diabetes, abnormal bleeding from the female genital tract, and prostate cancer. AST showed associations with prostate cancer, anxiety, diabetic neuropathy, and stroke. GGT was linked to hepatic and biliary conditions, coronary atherosclerosis, and pneumonia, while ALP displayed positive associations with vitamin D-calcium-parathyroid-bone conditions.

Conclusions: Elevated liver enzymes are risk factors for a wide range of hepatic and extrahepatic diseases, predominantly digestive, circulatory, metabolic/endocrine (including diabetes) diseases. Furthermore, the four liver enzymes demonstrated distinct patterns of disease associations.

Key messages:

- Elevated liver enzymes are risk factors for a wide range of hepatic and extrahepatic diseases.
- The four liver enzymes demonstrated distinct patterns of disease associations.

Abstract citation ID: ckae144.1313
Adult Individuals Applicable to the Family Health Center Knowledge and Awareness About Osteoporosis

Saime Erol

H Özkoç[2], S Erol[1], A Ergün[1]
[1]Public Health Nursing, Marmara University, Faculty of Health Sciences, Department of Nursing, Istanbul, Türkiye
[2]Gaziantep Abdülkadir Yüksel Devlet Hastanesi, Fizik Tedavi ve Nöroloji Servisi, Gaziantep, Türkiye
Contact: serol@marmara.edu.tr

Background: The aim of this study is to determine the knowledge and awareness of adult individuals applying to the Family Health Center (FHC) about osteoporosis.

Methods: A descriptive design study was conducted at a FHC in Turkey/Istanbul between January and May 2022. The sample of the research consisted of 320 adults selected by purposeful sampling method. Ethical approval and necessary permissions were obtained from the the conduct of the study. Data were collected through a socio-demographic characteristics form, a 20-item single-subscale Osteoporosis Knowledge Assessment Questionnaire (OKAQ), and a 27-item Osteoporosis Awareness Scale (OAS). Descriptive statistics, normality tests, analysis of variance, Kruskal-Wallis analysis of variance, t-test, and Mann-Whitney U test were used for data analysis. Statistical significance was accepted at $p < 0.05$.

Results: T The average age of adults is 60.47±13.17 and 55.9% are female and 44.1% are male. 34.7% had completed middle school. Participants' highest correct response rate in the osteoporosis knowledge assessment questionnaire was for the item 'Osteoporosis increases the risk of bone fracture' (81.6%), while the lowest correct response rate was for the item 'Osteoporosis generally causes symptoms (such as pain) before fractures occur' (26.3%). According to the Osteoporosis Awareness Scale, adults' awareness levels were above average. They scored the highest in the preventive behaviors subscale and the lowest in the risk factors subscale. Adults with university-level education scored significantly higher in all subscales of the OAS compared to other education levels ($p < 0.05$). Individuals with knowledge about osteoporosis and those who consumed milk regularly scored significantly higher in all subscales of the OAS ($p < 0.05$).

Conclusions: Although adults' awareness of osteoporosis is above average, their correct knowledge about osteoporosis is inadequate.

Key messages:

- An individual's education level affects osteoporosis knowledge and awareness.
- It is recommended to plan educational initiatives to increase osteoporosis knowledge and awareness.

Abstract citation ID: ckae144.1314
The burden of psoriasis in Belgium, 2021

Rani Claerman

R Claerman[1], B Devleesschauwer[1,2], S Nayani[1], R De Pauw[1,3]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium
[3]Department of Rehabilitation Sciences, Ghent University, Ghent, Belgium
Contact: rani.claerman@sciensano.be

Psoriasis is a common, chronic, inflammatory skin disease with a great impact on healthcare systems. Given the limitations of the currently available burden estimates, estimates of the Belgian national burden of disease study are necessary in order to guide decision-making processes within the health sector. According to the Global Psoriasis Atlas, the prevalence of psoriasis is rising globally. The current study aims to estimate the burden of psoriasis in Belgium using national data. As there is no single comprehensive data source on prevalence of psoriasis in Belgium, a critical appraisal of existing local and national data sources was conducted. We estimated the non-fatal psoriasis burden in terms of years lived with disability (YLD). Estimated prevalence data were combined with disability weights to yield YLDs imposed by psoriasis. Mortality attributable to psoriasis was assumed to be zero, in line with the Global Burden of Disease study (GBD) 2019. We assessed three data sources containing information on existing cases with psoriasis in Belgium. Based on qualitative and quantitative appraisal, a wide-spread network of general practitioners was identified as the best available national data source. In 2021, the prevalence of psoriasis in Belgium was 2.1%, leading to 13084 DALYs (113 DALYs per 100 000). The burden of psoriasis was in line with national disease burden estimates for bipolar disorder, multiple myeloma, and hearing loss. Our prevalence, YLD, and DALY estimates for psoriasis in Belgium were however lower than those of the GBD study. Psoriasis imposes a non-negligible burden on population health in Belgium, despite it not being a cause of death. Along progression in psoriasis management, objective evaluation of psoriasis burden is critical to track the trends at the population level.

Key messages:

- Psoriasis is a common skin disease with a relatively high morbidity burden.
- Information on psoriasis prevalence and burden are crucial for disease management and appropriate health-care planning.

Abstract citation ID: ckae144.1315
Burden of inflammatory bowel disease in Belgium, 2020

Rani Claerman

R Claerman[1], B Devleesschauwer[1,2], S Nayani[1], R De Pauw[1,3]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Translational Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium
[3]Department of Rehabilitation Sciences, Ghent University, Ghent, Belgium
Contact: rani.claerman@sciensano.be

Inflammatory bowel disease (IBD) comprises digestive disorders resulting from non-infectious inflammation of the colon and gastrointestinal tract. With its global prevalence on the rise, IBD poses significant challenges to healthcare systems. There is a need for more accurate disease burden estimates to guide decision-making processes within the health sector. As a part of the Belgian national burden of disease study (BeBOD), this study aims to estimate the burden of IBD in Belgium based on locally available data. We estimated the Belgian IBD burden in 2020 in terms of mortality, prevalence, years of life lost (YLLs) due to premature death, years lived with disability (YLDs), and disability-adjusted life years (DALYs). As there is no single comprehensive data source on prevalence of IBD in Belgium, a critical appraisal of existing local and national data sources was conducted. Prevalence data were combined with disability weights to yield YLDs. YLLs were calculated using the most recent Global Burden of Disease (GBD) 2019 reference life table and the number of deaths caused by non-infective IBD (ICD-10 K50-52). Cause of death data were extracted from Statbel, the Belgian statistical office. The best available data source to estimate the IBD prevalence in Belgium was a widespread network of general practitioners. The prevalence of IBD was 1.5% in 2020. The prevalence-based YLD for IBD was 220 YLDs per 100 000, while the YLL rate was 11.5 per 100 000. We estimated 26 276 DALYs caused by IBD in 2020. Of the total DALYs caused by IBD, 5% were due to YLLs and 95% were due to YLDs. Our burden estimates for IBD in Belgium were however higher than those of the GBD study. IBD imposes a low fatal burden, whereas the burden of morbidity is more prominent. Our findings could be useful for policy makers to justify and prioritize resource allocation. Integrating the current research in BeBOD will allow monitoring the burden of IBD over time.

Key messages:

- Inflammatory bowel disease is characterized by a substantial non-fatal burden due to chronic relapsing and persistent symptoms.
- National inflammatory bowel disease burden estimates are useful to guide decision-making within the health sector.

Tobacco and nicotine products use among adolescents in Serbia – Latent class analysis

Biljana Kilibarda

B Kilibarda[1], *J Gudelj Rakic*[1], *V Jovanovic*[1], *M Vasic*[1], *M Tosic*[1]
[1]Institute of Public Health of Serbia, Belgrade, Serbia
Contact: kilibarda_b@yahoo.com

Background: In parallel with a decline in cigarette smoking in the previous decade, other tobacco and nicotine products (TNPs), that are often used concurrently, have gained popularity among adolescents. The purpose of this study was to identify patterns of tobacco and nicotine product use among Serbian adolescents.

Methods: Data for this study were obtained from Health Behavior in School-aged Children (HBSC), a WHO collaborative cross-national study of adolescent health and well-being, that was conducted in Serbia in 2022 on a sample of 3713 students 11,13 and 15 years old. Descriptive statistics was used as well as latent class analysis to classify students based on their past-month use of cigarettes, e-cigarettes, heated tobacco products, waterpipes, and oral tobacco/nicotine products.

Results: Among students 11,13 and 15 years old, 10.2% smoke cigarettes, 13% use e-cigarettes, 11.1% waterpipes, 3.7% oral tobacco/nicotine products, and 4.5% heated tobacco products with differences by age and sex. We found high percentages of dual use of TNPs among cigarette smokers. Among students who smoke cigarettes, 61.6% also use e-cigarettes, 36.2% smoke waterpipes, 30.2% heated tobacco products, and 24.1% oral tobacco/nicotine products. Latent class analysis identified three classes as optimal solution: (1) dual e-cigarette and cigarette users (6.9%); (2) minimal/non-users (83.2%) and (3) poly tobacco and nicotine products users (9.9%). Statistically significant differences between classes were found in age and sex.

Conclusions: Dual and poly-tobacco and nicotine use is common among Serbian adolescents and presents a challenge for monitoring and public health response. Findings contribute to a better understanding of patterns and heterogeneity of TNPs use among adolescents and might have implications for prevention and cessation interventions for youth.

Key messages:

- Among students 11,13 and 15 years old, tobacco and nicotine products, other than cigarettes is gaining popularity and with the e-cigarettes being the most popular product.
- Dual and poly tobacco and nicotine products use is new challenged that should be taken into account in tobacco and nicotine monitoring, cessation and prevention.

Abstract citation ID: ckae144.1317
Utilization and subjective effectiveness of post-COVID-19 therapies in patients with chronic fatigue

Maike Stolz

M Stolz[1,2], *B Burger*[3], *C Herrmann-Lingen*[4], *JT Stahmeyer*[3], *M de Zwaan*[5], *C Krauth*[1,2]
[1]Institute for Epidemiology, Hannover Medical School, Hannover, Germany
[2]Center for Health Economics Research Hannover, Hannover, Germany
[3]Health Services Research Unit, AOK Niedersachsen, Hannover, Germany
[4]Department of Psychosomatic Medicine, University Medical Center Göttingen, Hannover, Germany
[5]Department of Psychosomatic Medicine, Hannover Medical School, Hannover, Germany
Contact: stolz.maike@mh-hannover.de

Background: A significant proportion of people who have had a SARS-CoV-2 infection suffer from persistent symptoms for more than three months, referred to as post-COVID-19 condition (PCC). Chronic fatigue syndrome (CFS) is common in people with PCC. Little is known about the use of therapeutic measures for people with CFS, and the effect of active exercise in particular is a subject of controversial debate.

Methods: From November 2023 to January 2024, an online survey was conducted among a random sample of statutorily-insured people with PCC (ICD10 U09.9). Patients with CFS were identified using the DSQ-PEM. The utilization of various physical, psychological and alternative medical therapies and their subjective effectiveness on a scale from 1 (significantly worsened) to 5 (significantly improved) were recorded. Mann-Whitney-U-tests were carried out.

Results: Preliminary analyses of 1,699 participants with persisting PCC revealed an indication for CFS in 310 participants. Looking at the active exercises, there is no difference in the utilization of functional training between people with and people without CFS (14.6 % vs. 14.5 %, $p = 1.0$), while rehabilitation sport is utilized significantly more frequently by people with CFS (26.5% vs. 18.7%, $p = 0.003$). While 45-48% of CFS patients benefited from active therapies, 20-30% showed a worsening of their symptoms. On average, people with CFS also showed significantly less improvement from rehabilitation sports (M 3.28 vs. 3.72, $p = 0.002$) and functional training (M 3.16 vs. 3.81, $p = 0.002$) than people without CFS.

Conclusions: People with CFS due to PCC are significantly more likely to utilize therapeutic services than people with PCC without CFS. Active therapies seemed to benefit almost half of CFS patients but led to worsening of symptoms in up to 20-30%. Further studies are needed to provide evidence-based treatment recommendations for this vulnerable population.

Key messages:

- People with PCC and CFS benefit less from active therapies than people with PCC without CFS. Utilization of active therapies worsen symptoms in a relevant minority of 20-30% of CFS patients.
- Further research should focus on evidence-based treatment recommendations for people with PCC and CFS.

Abstract citation ID: ckae144.1318

Advancing mammography uptake among vulnerable groups: a systematic review of intervention strategies

Allegra Ferrari

A Ferrari[1,2], D Jael Herrera[1], W van de Veerdonk[1,3], W D'haenens[3], A Ruiz Alejos[1], L Van Bos[3], S Talboom[3], L Ding[1], M Goossens[4], G Van Hal[1,4]
[1] Social Epidemiology and Health Policy, University of Antwerp, Antwerp, Belgium
[2] Department of Health Sciences, University of Genoa, Genoa, Italy
[3] Thomas More University of Applied Sciences, Antwerp, Belgium
[4] Centre for Cancer Detection, Bruges, Belgium
Contact: allegraferrari@virgilio.it

With over 2 million cases diagnosed annually, breast cancer is a leading cause of cancer-related disability and mortality. Despite global efforts to implement mammography screening programs, uptake rates vary widely across settings due to socioeconomic factors and accessibility challenges. To improve participation, targeted interventions addressing barriers faced by underserved groups are essential for promoting inclusive screening and early detection. As part of the ENTER project, which aims to address disparities in breast cancer screening participation among women with low socioeconomic status (SES) in Flanders, Belgium, we conducted a systematic review and meta-analysis on the effectiveness of interventions to enhance mammography uptake. To explore the differential impact of interventions on mammography uptake among vulnerable groups, including individuals with low SES, underinsured, with immigrant background or part of an ethnic minority, subgroup analyses were performed. 7 databases were searched, resulting in the inclusion of 54 out of 9,366 papers for analysis. 14 types of interventions were identified. The meta-analysis showed significant pooled effects of interventions that increased mammography uptake [OR 1.8 (95%CI 1.6-2.2)], particularly among vulnerable populations [OR 2.2 (95%CI 1.7-2.8)]. The most effective interventions were educational interventions [OR 3.03 (95%CI 2.2-4.9); in vulnerable groups OR 2.7 (95%CI 1.9-3.9)]. As expected, interventions adapted to linguistic needs and culturally sensitive approaches showed a significant effect among vulnerable target groups [OR 2.9 (95%CI 1.1-7.9) and OR 2.5 (95%CI 1.1-5.6), respectively]. Reminders were also highly effective [OR 1.8 (95%CI 1.5-2.1); in vulnerable groups OR 2.5 (95%CI 1.9-3.1)]. This review underscores the critical role of targeted interventions in augmenting screening mammography uptake, particularly among vulnerable populations, where odds of participation can increase by up to 2-3 times.

Key messages:

- Interventions adapted to the linguistic needs of the target population and culturally sensitive approaches, aligned with values and beliefs of a specific community, can greatly enhance screening rates.
- Considering costs, practicality and impact, reminder letters with culturally and linguistically adapted content emerged as the most promising option for implementation in the ENTER project.

[4] Oncology Institute of Vojvodina, Sremska Kamenica, Serbia
[5] Academy of Applied Studies Šabac, Šabac, Serbia
Contact: drsreckovicmaja@gmail.com

Background: Lung cancer (LC) is the top cause of cancer-related deaths globally and in Serbia, often diagnosed in advanced stage of disease with when 5-year survival is 10% to 20%. LC screening with low-dose CT (LDCT) can decrease LC mortality and overall mortality. The first pilot LC screening program in Serbia started in the Institute for Pulmonary Diseases of Vojvodina in September 2020. The main objective of this study was to analyze LC patient characteristics according to their screening status.

Methods: This retrospective study utilized LC hospital registry data from September 2020 to December 2023, including gender, age at diagnosis, settlement area, smoking habits, cancer histological type, TNM classification, disease stage (1-4), and data on participation in LC screening. Group differences were assessed using chi-square and Student's t-tests, with analyses conducted in SPSS v24.0.

Results: During observed period from a total of 4649 LC cases 2948 (63.4%) were males, and 73 (1.6%) were included in LC screening. Average age of all LC patients was 66 years, without differences between groups ($p = 0.778$). Significant differences between groups by gender were find ($p = 0.042$). Non-screened LC patients were significantly common males compared to females (63.6% vs 36.4%), while among screened difference by gender were lower (52.1% vs 47.9%, respectively). Screened compared to non-screened LC patients have significantly lower percentage of SCLC (9.6% vs 19.1%), and higher percentage of NSCLC (90.4% vs 80.9%), ($p = 0.040$). According to LC stage, screened compared to non-screened patients were significantly common diagnosed in stage I of disease (45.8% vs 7.8%), and significantly less common in higher LC stages; stage IIIB (11.1% vs 22.5%), and in stage IV (22.2% vs 45.7%), ($p < 0.001$).

Conclusions: LC screening with LDCT is proven secondary preventive measure with significant influence on decreasing LC mortality by increasing number of LC patients in early stages of disease.

Key messages:

- Lung cancer screening with low-dose CT significantly increases early-stage diagnoses, improving survival chances.
- Population strategies to prevent smoking and screening programs for high-risk groups are needed to reduce lung cancer incidence and mortality rates in Serbia.

Abstract citation ID: ckae144.1320

Dementia in migrants living in Lazio region, Italy: prevalence and population characteristics

Laura Angelici

L Angelici[1], A Acampora[1], S Cascini[1], L Cacciani[1], M Canevelli[2,3], I Cova[4], B Contoli[2], S Pomati[4], G Bellomo[2], A Bargagli[1]
[1] Department of Epidemiology, Lazio RHS, Local Health Authority, Rome1, Rome, Italy
[2] National Center for Disease Prevention and Health Promotion, National Institute of Health, Rome, Italy
[3] Department of Human Neuroscience, 'Sapienza' University, Rome, Italy
[4] Center for Research and Treatment on Cognitive Dysfunctions, 'Luigi Sacco' University Hospital, Milan, Italy
Contact: l.angelici@deplazio.it

Background: Given ongoing demographic and epidemiological transitions, dementia prevalence is expected to rise among both native populations and migrants. Understanding this phenomenon is crucial for healthcare planning. This study, part of the IMMIDEM project (GR-2021-12372081), aims to estimate dementia prevalence in Lazio by migrant status.

Methods: A cross-sectional study was conducted on individuals aged ≥ 50, living in Lazio and receiving assistance from the Regional Health Service as of December 31, 2022. A validated algorithm based on Health Information Systems identified patients with dementia. Migrant status was defined by Country of birth, categorized as native Italians, migrants from Highly Developed Countries (HDCs) and from High Migratory Pressure Countries (HMPCs). Age-standardized prevalence of dementia was estimated overall and by migrant status, and 95% confidence intervals (CI) were calculated. Dementia population characteristics were described and compared according to migrant status using χ2test.

Results: The study included 3,976,160 individuals: 88.9% Italians, 1.7% migrants from HDCs, and 9.4% from HMPCs. Among them, 38,708 had dementia, with a prevalence of 8.48‰ (CI: 8.39-8.57). Dementia prevalence by migrant status was 8.68‰ (CI: 8.58-8.77) in Italians, 6.90‰ (CI: 6.19-7.62) in HDCs migrants, and 5.73‰ (CI:5.37-6.10) in HMPCs migrants. Demographic traits across migrant categories reveal distinct age and gender patterns, with more elderly Italians and a higher male percentage among migrants. From a clinical perspective, Italians showed a higher percentage of circulatory system diseases than migrants (23.5% Italians, 19.2% HDCs, 18.7% HMPCs, $p = 0.001$), along with a greater percentage of anti-dementia drug prescriptions (54.4% Italians, 50.9% HDCs, 47.4% HMPCs, $p < 0.001$).

Conclusions: The study found lower dementia prevalence among migrants compared to native Italians, with reduced access to healthcare services, especially in individuals from HMPCs.

Key messages:

- The dementia prevalence in migrants is lower than in native Italians.
- These findings suggest potential underdiagnosis and undertreatment, urging policymakers and healthcare providers to address these healthcare disparities.

Contact: alexandra.costa@insa.min-saude.pt

Background: The high and increasing burden of Non-Communicable Diseases (NCDs) demands a healthcare shift towards prevention. Personalised preventive interventions (PPIs) that consider biological, sociocultural, environmental, and behavioural characteristics of individuals, are not as widely adopted as other personalised medicine approaches. To identify the main barriers and gaps that are hindering the adoption of PPIs in healthcare systems, we consulted a wide range of European stakeholders, including health professionals, policy makers, citizens and patients, and researchers.

Methods: The consultation process included experts' interviews and an online survey, taking place over 10 months in 2023/2024. Interviews were analysed using qualitative Thematic Analysis. The online survey development was based on the barriers identified by the interviewed experts, complemented with findings from the literature. Respondents scored their level of agreement/disagreement using a 6-point Likert scale. Descriptive statistical analysis was performed.

Results: A total of 26 semi-structured interviews and 270 complete surveys were obtained. Overall, the main barriers highlighted were: 1) Health systems strategies are geared towards curative care and not prevention. 2) Awareness and understanding of the concept of PPIs is low. 3) There is a lack of basic and life-long training for health professionals on PPIs; 4) There is insufficient evidence for PPIs to raise the necessary policymakers' interest. 5) Health literacy of citizens and patients is low. 6) There is insufficient prevention research, evidence of cost-efficiency and regulation procedures for translation into health practice.

Conclusions: Identified barriers are interconnected and the challenges extend beyond prevention to personalized medicine interventions. Collaborative efforts are needed to elevate visibility and engage stakeholders, facilitating integration of PPIs into healthcare systems for widespread adoption.

Key messages:

- This consultation offers valuable insights on challenges that need to be addressed to enable the integration of PPIs into healthcare and reduce the burden of NCDs.
- Investments in disease prevention and PPIs should stand as a global key priority.

[3]Quality of Care and Health Economics, RIVM, Bilthoven, Netherlands
[4]Department of Internal Medicine, University Medical Center Groningen, Groningen, Netherlands
Contact: f.h.ardesch@lumc.nl

Background: There is a concern regarding socioeconomic disparities in prescription of new medications such as SGLT-2is or GLP-1RAs in type 2 diabetes mellitus (T2DM). This study aims to analyze prescription patterns of these medications and assess socioeconomic disparities in their initiation among individuals with T2DM with very high cardiovascular risk.

Methods: Individuals diagnosed with T2DM and very high cardiovascular risk were identified ($N = 10,768$) based on general practitioner' electronic health record data. Socioeconomic status (SES) was based on standardized disposable household income in quintiles. The association between SES and the prescription of SGLT-2is and GLP-1RAs in 2022 was investigated by logistic regression analyses, adjusting for potential confounding factors. SGLT-2is and GLP-1RAs prescription patterns were examined over 2019-2022, stratified for age-groups and sex.

Results: We found a positive association between SES quintile 1 (referent) and quintile 4 in SGLT-2is prescription in all models (OR 1.29 95%CI:1.08-1.54 in the fully adjusted model). For prescriptions of GLP-1RAs, we found no significant differences in SES. Proportionally, men are more frequently prescribed SGLT-2is, while there are no sex disparities in GLP-1RAs prescription. Older individuals consistently receive fewer SGLT-2is and GLP-1RAs prescriptions compared to other age categories.

Conclusions: We observed sex and age disparities but no profound socioeconomic differences in initiation of SGLT-2is and GLP-1RAs in the Netherlands. The latter may be due to guidelines' clear indication of the eligible population (T2DM and very high cardiovascular risk) and GP education. Future development and potential disparities in initiation and maintenance should be monitored.

Key messages:

- We found no disparities in prescribing new Type 2 diabetes medication based on socioeconomic status.
- The adoption of prescribing new medication for Type 2 diabetes patients takes time.

Abstract citation ID: ckae144.1323
Spatial disparities in cancer incidence and mortality, indicating gaps in prevention and/or care

Róza Ádány

R Ádány[1,2,3], A Juhász[1], C Nagy[1], P Pikó[1,4], B Oroszi[1]
[1]Epidemiology and Surveillance Centre, Semmelweis University, Budapest, Hungary
[2]HUN-REN Public Health Research Group, University of Debrecen, Debrecen, Hungary
[3]Department of Preventive Medicine, Semmelweis University, Budapest, Hungary
[4]Department of Public Health and Epidemiology, University of Debrecen, Debrecen, Hungary
Contact: adany.roza@med.unideb.hu

Background: There is a rich literature on the distribution of cancer incidence and mortality in socioeconomically different regions of the world, but none of the studies has compared the spatial distribution of mortality and morbidity to see if they are consistent with each other.

Methods: All malignant neoplasms and separately by cervical, colorectal, breast, pancreatic, lung and oral cancers were studied in the Hungarian population aged 25-64 years for the period 2007-2018 at the municipality level by sex. In each case, the spatial distribution of morbidity and mortality and their clusters were compared with each other and with the level of deprivation using disease mapping, spatial regression, risk analysis and spatial scan statistics.

Results: All-cause cancer morbidity and mortality showed a significant association with deprivation. However, the slope of the increase in mortality with increasing deprivation was much steeper than for morbidity in both sexes. The association between deprivation and morbidity was not consistent across all cancers. No significant association was found for male colorectal cancer (RR: 1.003; 95%CI 0.986-1.019), pancreatic cancer (1.014; 95%CI 0.983-1.045) and female colorectal cancer morbidity (RR: 0.977; 95%CI 0.991-1.029), whereas a negative association was found for breast cancer morbidity (RR: 0.977; 95%CI 0.963-0.991). In contrast, a positive association between deprivation and mortality was found for each type of cancer, although with different RRs. However, disease mapping analyses showed only partial overlap between high-risk morbidity and mortality areas, often independent of deprivation.

Conclusions: Our results highlight not only the diverse relationship between the epidemiological situation and deprivation, but also the disproportionate relationship between cancer morbidity and mortality, thus identifying geographical regions and sub-regions with populations that require special public health attention.

Key messages:
- Comparative spatial analysis of cancer morbidity and mortality at the municipality level is strongly recommended to identify populations in need of targeted cancer prevention and/or care.
- The usefulness of comparative spatial analysis of cancer morbidity and mortality is demonstrated in Hungary, one of the countries with the most unfavourable cancer burden in international comparison.

A review of the risk factors for Autism

Anjum Memon

S McGrevey[1,2], W Farr[1,3,4], I Male[1,3], A Memon[3]
[1]Research & Innovation, Sussex Community NHS Foundation Trust, Haywards Heath, UK
[2]Faculty of Health and Medical Sciences, University of Surrey, Guildford, UK
[3]Department of Primary Care and Public Health, Brighton and Sussex Medical School, Brighton, UK
[4]Department of Education, University of Cambridge, Cambridge, UK
Contact: a.memon@bsms.ac.uk

Background: Autism Spectrum Disorder (or Autism) is a neurodevelopmental and neurological condition, with prevalence of 1 in 100 children globally. This review examines the most common factors associated with Autism.

Methods: We conducted a scoping review of factors associated with an increased risk of developing Autism. These included genetic predisposition, parental age, gender, birth complications and morbidities due to other medical conditions.

Results: Evidence from twin studies shows a 90% genetic predisposition towards Autism - with 102 genes strongly associated with Autism, including SCN1A and SLC6A1. There are also genetic syndromes and chromosomal disorders associated with Autism, including Fragile X syndrome and Tuberous Sclerosis complex (TSC). Several studies have demonstrated an increased risk with advanced parental age (>35 years) (e.g., fathers >50 years are 2.2 times more likely to have a child with Autism than those <30 years). Other factors include infections during pregnancy (e.g. immune dysfunction) and gestational diabetes. Prematurity, such as low birth weight (<1500g) and low gestational age (<32 weeks) are also associated with an increased risk of Autism. With regard to gender, boys are more likely to be diagnosed with Autism - gender ratio of 3:1 and 4:1 has been reported in different populations. Abnormalities in brain development during early prenatal or postnatal periods may increase the risk of Autism. These abnormalities can lead to social, communication, and behavioural challenges characteristic of Autism.

Conclusions: Autism is a complex and heterogeneous condition that likely arises from a combination of factors such as genetic susceptibility and pre- and postnatal factors. An understanding of these factors is important for early detection, intervention, and support for children to improve their quality of life and reduce morbidity.

Key messages:
- Risk factors associated with an increased risk of developing Autism include genetic predisposition, parental age, gender, birth complications and other comorbidities.
- There is need to increase awareness of the risk factors of Autism to improve quality of life.

Abstract citation ID: ckae144.1325
Cancer prevention for homeless people: Qualitative evaluation of the Health Navigator Model

Tobias Schiffler

Contact: tobias.schiffler@meduniwien.ac.at

Background: People experiencing homelessness (PEH) face significant barriers when accessing cancer preventive services. The Health Navigator Model (HNM) seeks to address these challenges by improving access and engagement with cancer preventive care through tailored navigation services. This study aimed to explore PEH's and health navigators' experiences with the HNM.

Methods: This qualitative evaluation involved semi-structured interviews with a total of 61 PEH receiving the HNM intervention and 11 health navigators across four pilot sites in Austria, Greece, Spain, and the UK. Data were analyzed thematically using a cross-national coding framework.

Results: Following overarching themes were identified: (1) State of health and perception of health of PEH; (2) Experiences and understanding of cancer prevention; (3) Perceived effects of the Health Navigation intervention; (4) Navigators' experiences with the implementation of the Health Navigation intervention; and (5) Effects of the Health Navigation intervention from the navigator perspective and sustainability of the intervention. Participants reported a general lack of access to healthcare services and low cancer prevention literacy. The HNM intervention led to increased engagement in cancer prevention activities, such as screenings, facilitated by the personalized support from health navigators. Navigators played a crucial role in bridging the gap between PEH and healthcare systems, though challenges such as mistrust and logistical barriers persisted.

Conclusions: The HNM has shown potential in enhancing cancer preventive care access for PEH by providing personalized guidance and support. The navigators' role was pivotal in overcoming systemic and individual barriers, suggesting the need for integrated services that cater specifically to PEH. Future implementations should consider continuous training for navigators and further integration into local health systems to expand the benefits of the intervention.

Key messages:

- The Health Navigator Model effectively enhanced cancer prevention engagement among people experiencing homelessness and empowered them through tailored and person-centered support.
- Health navigators bridged healthcare gaps for people experiencing homelessness, improving their access to cancer preventive care services in their local settings.

Understanding Knowledge and Perception of Hypertension in Rural Zambia: A Population-Based Study

Yukiko Tateyama

Y Tateyama[1], *Y Honda*[2], *R Zulu*[3]
[1]Department of Preventive Services, Kyoto University, School of Public health, Kyoto, Japan
[2]Department of Social Epidemiology, Kyoto University, School of Public health, Kyoto, Japan
[3]Centre For Primary Care Research, Lusaka, Zambia
Contact: tateyama.yukiko.5e@kyoto-u.ac.jp

Introduction: Hypertension poses a significant challenge in sub-Saharan Africa, with Zambia reporting a 32% prevalence in 2019. However, there is a presumed lack of knowledge among residents due to inadequate preventive education. This study aims to describe the knowledge and perception of hypertension among rural residents in Zambia.

Methods: This cross-sectional study employed rigorous probability sampling. We recruited 690 residents aged 25-64 from the Mumbwa district using a multistage, clustered, household sampling method for surveys and measurements conducted from May to July 2016. Data analysis considered the complex sampling design.

Results: Males accounted for 48.6%, with a mean age of 41.9 (SE 0.6). The prevalence of hypertension was 36.5%, with only 37.1% of those aware of their condition. 98.0% perceived hypertension as common, 71.8% expressed concern, and 62.9% deemed it a more serious health risk than HIV. Stress (85.3%) and dietary habits (excessive oil 51.8%, salt 47.5%, sugar 42.4%, poor diet 31.5%) were recognized as the risks. Perception of smoking and physical inactivity as risk factors was low, at 14.9% and 22.7%, respectively. Regarding hypertension prevention, 73.9% believed it to be preventable, mainly through dietary improvements (69.0%), medication (51.1%), and exercise (36.0%). Perception of smoking cessation and alcohol abstinence was 18.0% and 1.4%, respectively. Only 20.4% had prior hypertension education.

Conclusions: This study reveals residents' concerns about hypertension and their perception of dietary improvements as preventive measures. However, there was a notable gap in perceiving stress as a preventable risk factor, along with limited awareness of smoking and alcohol as risk factors. Comprehensive health education programs in rural Zambia are necessary to address these gaps, emphasizing lifestyle changes such as stress reduction, smoking cessation, and reducing alcohol consumption to enhance hypertension awareness and prevention.

Key messages:

- Participants show a strong awareness of hypertension, perceiving it as a serious health risk and recognizing common factors such as stress and poor dietary habits.
- There is a lack of awareness concerning smoking and physical inactivity as risk factors, emphasizing the necessity for comprehensive education to promote preventive measures.

Contact: gabrynasi@gmail.com

Background: Millions of individuals are affected by gastroesophageal reflux disease (GERD) that causes significant discomfort negatively affecting patients' overall quality of life. For a collaborative approach of continuous improvement in public health we wanted to know the real-world perspectives in the multidisciplinary and multimodal management pathway.

Methods: We aimed to interview a sample of gastroenterologists (GE), primary care physicians (GP), and otolaryngologists (ENT) to investigate the management of the intake and treatment of patients reporting symptoms of GERD. Symptoms were divided into typical and extraesophageal, and their severity and impact on quality of life was explored with the GERD Impact Scale (GSI) and Reflux Symptom Index (RSI).

Results: A total of 6211 patients were analyzed of whom with typical symptoms were 53.5%, while those with extraesophageal symptoms were 46.5%. The latter were more frequently reported by ENT patients (53.6%, $p < 0.0001$). GSI was highest in patients followed by GE (9 points) and GP (9 points) than ENT specialists (8 points), while the RSI was higher in the ENT group (14.3 ± 6.93) than in the groups of GP and GE, respectively (10.36 ± 6.36 and 10.81 ± 7.30, $p < 0.0001$). Chest pain had the greatest negative impact on quality of life ($p < 0.0001$). Of the 3,025 patients who used (proton pump inhibitors) PPIs, non-responders had a lower GSI when treated with a combination of adjunctive drug treatments and bioadhesive compounds, compared with single-component drugs.

Conclusions: The multidisciplinary and multimodal approach to the management pathway of GERD patients reveals variations in patient profiles by physician specialty, directing toward more appropriate and targeted treatments. In addition, the combination of adjunctive drug treatments and bioadhesive compounds appears to be effective in the management of patients refractory to PPIs.

Key messages:

- The presentation of GERD symptoms is different in accordance with the physician's speciality: the patients with GERD referred to a gastroenterologist had more severe disease and poorer quality of life.
- The combination of adjunctive pharmacological treatments and bioadhesive compounds seems to be effective in the management of PPI refractory patients.

Abstract citation ID: ckae144.1328
The Effect of Text messages and Education on Cancer Screening in Women Aged 30-65

Hilal Kutman

H Kutman[1], *H Kadıoğlu*[1]
[1]Public Health Nursing, Marmara University Health Sciences Faculty, Istanbul, Türkiye
Contact: hilalkutman@gmail.com

Background: Despite it is known that cancer screenings reduce cancer-related deaths, screening rates are still inadequate. The aim of this study is to examine the effect of text messaging and training on cancer screening in women aged 30-65.

Methods: This non-randomized controlled trial was conducted with 120 women aged 30-65 between November 2023 and April 2024 in Tekirdağ, Türkiye. Participants were divided into the text message group (TMG) ($n = 60$), the training group (TG) ($n = 60$), and the control group (CG) ($n = 60$). In the text message group, every participant received text messages about cancer and importance of screening procedures, one a day for ten days. The training group was educated for a session that lasted 45 min. Data was collected both before and 3 months after the intervention, using a questionnaire that included two parts (sociodemographic characteristics and stages of change for cancer screening practices). Data was analyzed using the Marginal Homogeneity test.

Results: The rates of those who had a pap smear test, breast self-examination (BSE), mammography, and stool occult blood screening were found to be significantly higher in both the text message group and the training group in the post-test than the pre-test. ($p<.001$). In the text message group, there was an increased rate of 43.4% for pap smear test, 25% for BSE, 17.3% for mammography, and 10% for stool occult blood screening. In the training group, there was an increased rate of 31,7 % for pap smear test, 26,7% for BSE, 13,3% for mammography, and 23,4 % for stool occult blood screening. There was no change in the control group.

Conclusions: The results showed that both text messages and training about cancer screening are effective in increasing the rate of cervix, breast, and colorectal cancer screening.

Key messages:

- Text messaging about cancer screening is as effective as training in increasing the rate of cervix, breast, and colorectal cancer screening.
- Text messaging interventions may be an effective and practical way to increase cancer screening rates in populations most affected by health disparities.

Abstract citation ID: ckae144.1329
Improving breast cancer care post-pandemic from the patient perspective

Charlotte Myers

C Myers[1], *K Bennett*[2], *C Cahir*[2]
[1]Centre for Health Policy and Management, Trinity College Dublin, Dublin, Ireland
[2]Data Science Centre, RCSI, Dublin, Ireland
Contact: myersch@tcd.ie

Background: Since the onset of the pandemic, breast cancer (BC) services have been disrupted in most countries. The purpose of this qualitative study is to explore the unmet needs, patient-priorities, and recommendations for improving BC healthcare post-pandemic for women with BC and to understand how they may vary based on socio-economic status (SES).

Methods: 37 women were invited to take part in follow-up semi-structured qualitative interviews in early 2023. The interviews explored their perspectives of BC care since the easing of COVID-19 government restrictions, including unmet needs, patient-priorities, and recommendations specific to BC care. Thematic analysis was conducted to synthesize each topic narratively with corresponding sub-themes. Additionally, variation by SES was analysed within each sub-theme.

Results: Of the 28 women who participated in interviews, 39% were categorized as high-SES, while 61% were categorized as low-SES. Women expressed unmet needs in their BC care including routine care and mental and physical well-being care, as well as a lack of financial support to access BC care. Patient-priorities included: developing cohesion between different aspects of BC care; communication with and between healthcare professionals; and patient empowerment within BC care. Recommendations moving forward post-pandemic included: improving the transition from active to post-treatment; enhancing support resources; and implementing telemedicine where appropriate. Overall, women of low-SES experienced more severe unmet needs, which resulted in varied patient-priorities and recommendations.

Conclusions: As health systems are recovering from the COVID-19 pandemic, the emphasis should be on restoring access to BC care and improving the quality of BC care, with a particular consideration given to those women from low-SES, to reduce health inequalities post-pandemic.

Key messages:

- The pandemic has impacted BC services considerably and this study has identified a range of unmet needs, patient-centered priorities, and recommendations.
- Particular consideration needs to be given to those women from lower socioeconomic groups, in order to reduce health inequalities, which have been further exacerbated by the pandemic.

Abstract citation ID: ckae144.1330
The Rise in Glucagon-Like Peptide-1 Receptor Agonist Related Calls to United States Poison Centers

Rita Farah

R Farah[1], *AF Kerns*[1], *CT McDonald*[1], *CP Holstege*[1]
[1]Medical Toxicology Division, University of Virginia, Charlottesville, USA
Contact: wwv3zr@uvahealth.org

Background: In 2005, the United States (U.S.) Food and Drug Administration (FDA) approved the first Glucagon-Like Peptide-1 Receptor Agonist (GLP-1RA) as adjunctive therapy to improve glycemic control in type 2 diabetes. In 2021, the FDA approved semaglutide for chronic weight management. We aim to characterize GLP-1RAs related calls to all U.S poison centers (PCs).

Methods: We conducted a retrospective review of the U.S. National Poison Data System (NPDS) between 2005 and 2023 for all GLP-1RA exposures. All 55 PCs covering the entire U.S. population submit, in near real-time, de-identified case data to NPDS after providing poison exposure management to callers from the general public and health care providers.

Results: During the study period, U.S. PCs handled 13,692 GLP-1RAs related calls, of which 12,451 were a GLP-1RA single substance exposures. In 2023, PCs received 4,414 GLP-1RA related calls, compared to 234 in 2014 (a twenty-fold increase over 10 years).

Seventy three percent of exposures involved females (n = 10,017). The main reasons for exposure were therapeutic errors (n = 10,213; 75%), adverse drug reactions (n = 1,222; 9%) and suspected suicide (n = 557; 4%). Gastrointestinal symptoms, such as nausea (n = 2,913; 23%), vomiting (n = 2,515; 20%), and abdominal pain (n = 593; 5%), and neurological symptoms, including central nervous system depression (n = 191; 1.5%), dizziness (n = 563; 5%) and headache (n = 495; 4%) were the most commonly reported clinical effects in single substance exposures. Hypoglycemia was reported in 431 cases (3.5%), Most single substance exposures were managed outside a healthcare facility (n = 8.573; 69%), and hospital admission was reported in 5% of exposures (n = 601).

Conclusions: PCs are well positioned to monitor trends in GLP-1RAs human exposures and associated adverse events and therapeutic errors. Based on available data, PCs can manage specific cases-types without referral to the hospital, preventing unnecessary healthcare utilization.

Key messages:

- Poison centers are well positioned to monitor trends in GLP-1RAs adverse events.
- Poison centers can prevent unnecessary healthcare utilization.

Abstract citation ID: ckae144.1331

Compliance of physical activity among adults with metabolic syndrome with the WHO recommendations

Zdravka Radionova

Z Radionova[1]*, V Birdanova*[2]
[1]Department of Social Medicine and Health Management, Medical University - Pleven, Pleven, Bulgaria
[2]Department of Hygiene, Medical Ecology, Occupational Diseases, Medical University - Pleven, Pleven, Bulgaria
Contact: zradion@yahoo.com

Introduction: Low physical activity is a leading factor in 6% of deaths worldwide. In Bulgaria, it contributes to the deterioration of the health status of the population and determines 4.3% of the global burden of diseases. Over 70% of Bulgarian adults have insufficient physical activity during their free time. The aim of the study is to measure and assess the level of physical activity among adults with metabolic syndrome with the World Health Organization (WHO) Global recommendations.

Methods: A comparative study of the physical activity of a representative sample of 200 individuals with metabolic syndrome aged 54.7±10.5 from Pleven region was made with the WHO Global recommendations on physical activity for people living with chronic conditions. Modified Physical activity Questionnaire (PAQ) for adults was used for assessment of the physical activity. Data were processed with IBM SPSS v. 25.

Results: The weekly frequency of the vigorous-intensity physical activity (VIPA) was 1,61 days with a weekly duration of 215 minutes, which met the WHO recommendations on physical activity for people living with chronic conditions, but 64% of the respondents had none and only 26% had VIPA on 2 and more days a week. More than half of the respondents (55%) had none moderate-intensity aerobic PA. From the remaining, 34% had this type of PA on 3 and more days a week with duration of 225 minutes, which met the WHO recommendations. Walking more than 10 minutes a day on 5 and more days a week had 69% of the respondents (40 minutes/day). Only 12% had none walking. Only 2% stated that the physical inactivity is the most important cause for the rise of many non-communicable diseases.

Conclusions: More than half of the respondents had none vigorous- and moderate-intensity PA but the PA of the remaining met the WHO recommendations. Although physical inactivity is among the risk factors for the rise of many non-communicable diseases, contributing to death, it was not recognised by the respondents.

Key messages:

- Walking is the most important physical activity for the adults with metabolic syndrome.
- Increasing the duration of walking should be encouraged and supported to manage the metabolic syndrome.

[5]College of Pharmacy, University of Sharjah, Sharjah, UAE
[6]Public Health Institute CMHS, United Arab Emirates University, Al-Ain, UAE
Contact: ielbarazi@uaeu.ac.ae

Background: A growing number of COVID-19 survivors are experiencing symptoms post-SARS-CoV-2 infection, known as long COVID. It is a new multisystem condition and understanding its associated factors and its impact on individuals is crucial. This study aims to characterize long COVID in previously hospitalized patients in the UAE, identifying associated factors and assessing its impact on patients' daily lives.

Methods: A multicenter retrospective cohort study was conducted in hospitals in Dubai and Sharjah from January 29, 2020 to October 14, 2021, involving RT-PCR confirmed cases. Clinical, epidemiologic, and long COVID data were collected via hospital records and phone interviews.

Results: Long COVID affected 48.7% of 533 patients, with 46.6% prevalence persisting over a year. A total of 43 symptoms across 11 organ systems were reported. Females had 1.83 times higher odds of long COVID (95% CI [1.22, 2.74], p = 0.003). Each additional initial symptom (AOR = 1.22, 95% CI [1.05, 1.40], p = 0.008), ICU admission (AOR = 1.77, 95% CI [1.06, 2.98], p = 0.030), and $\geq$ 2 comorbidities (AOR = 2.19, 95% CI [1.09, 4.40], p = 0.027) increased the odds of long COVID. Long COVID significantly impacted daily life, with poorer health ratings (AOR = 5.576, 95% CI [3.029, 10.265], $p < .001$), worse health status (AOR = 7.842, 95% CI [4.954, 12.415], $p < .001$), and work limitations due to physical (AOR = 4.808, 95% CI [3.229, 7.158], $p < .001$) and emotional issues (AOR = 3.149, 95% CI [2.01, 4.933], $p < .001$). This impact persisted beyond 12 months post-infection.

Conclusions: Long COVID presents prolonged multisystem involvement and substantial disability among survivors, necessitating further research to understand its lasting effects and intervention development to mitigate its impact

Key messages:

- Long COVID poses a substantial challenge to public health in the UAE, affecting almost half of hospitalized survivors and extending its impact beyond 12 months post-infection.
- Risk factors like gender initial symptoms, ICU stay, and comorbidities increase the risk of long COVID, warranting the need for tailored interventions and support strategies for vulnerable populations.

Abstract citation ID: ckae144.1333
The interplay between healthy lifestyle and body mass index in metabolic syndrome

Tuija Jääskeläinen

T Jääskeläinen[1]*, L Lehtoranta*[1]*, T Palosaari*[1]*, S Männistö*[1]*, NE Kaartinen*[1]*, A Lundqvist*[1]*, J Lahti*[1]
[1]Department of Public Health and Welfare, THL, Helsinki, Finland
Contact: tuija.jaaskelainen@thl.fi

The prevalence of metabolic syndrome (MS) tends to increase as body mass index (BMI) increases. However, the interplay between BMI and overall healthy lifestyle in MS remains unclear. We aimed to examine the association between healthy lifestyle and MS in BMI categories. Data comprised participants aged 30-64 years from the Healthy Finland Survey representing the Finnish adults ($n = 2027$). Information was collected through health examination measurements, blood sampling and questionnaires in 2023. Healthy Lifestyle Score (HLS) was defined as: 1) vegetables and fruits several times/day; 2) adherence to physical activity recommendations; 3) sufficient sleep duration; 4) no current daily smoking; 5) no risky alcohol drinking. Total score ranged 0-5; categorized as 0-2 (unhealthiest), 3, 4-5 (healthiest). MS was defined as exceeding risk limit in ≥ 3 of the following conditions: waist circumference, fasting glucose, triglycerides, blood pressure and HDL-cholesterol. BMI (kg/m2) was categorized as normal weight (<25), overweight, and obesity ($\geq$ 30). Weighted prevalence and 95% confidence intervals (CIs) stratified by sex were calculated considering sampling design and non-response. In both sexes, the prevalence of MS was lowest in those with normal weight and healthiest lifestyle (men 7%; 95% CI 2-11; women 9%; 6-13) and highest in those with obesity and unhealthiest lifestyle (m 86%; 80-92; w 67%; 56-78). In men, the prevalence of MS decreased within each BMI class as HLS scores increased, but the difference between healthiest and unhealthiest lifestyle was greatest in those with normal weight (7% vs. 26%) and lowest in those with obesity (71% vs. 86%). In women, the differences were greatest among those with overweight. Obesity and unhealthy lifestyle together form a major risk factor for MS. Differences in the prevalence of MS according to lifestyle were evident especially in men with normal weight or overweight, but decreased when the obesity threshold was exceeded.

Key messages:

- Obesity is strongly linked to the high prevalence of metabolic syndrome but maintaining a healthy lifestyle is important regardless of body mass index.
- The results indicate the importance of multifaceted prevention influencing lifestyle factors and supporting weight management to enhance the cost-effective prevention of metabolic risk accumulation.

Developing new methods for patient care pathway assessment for breast cancer patients in Hungary

Cecília Surján

C Surján[1]*, G Surján*[2,3]*, Z Horváth*[1,4]*, V Dombrádi*[1]*, É Belicza*[1]
[1]Health Services Management Training Centre, Semmelweis University, Budapest, Hungary
[2]Department of Digital Health Science, Semmelweis University, Budapest, Hungary
[3]Directorate of Prevention and Epidemiology, National Center for Public Health and Pharmacy, Budapest, Hungary
[4]Center of Oncoradiology, Bács-Kiskun County Teaching Hospital, Kecskemét, Hungary
Contact: surjan.cecilia@emk.semmelweis.hu

Issue: The idea of progressive healthcare models is to treat patients preferably in one location as close to their homes as possible. This contradicts the demands of efficiency: to centralise the availability of expensive procedures and highly specialised staff. Healthcare systems need to navigate between these challenges, especially in public health issues such as cancer care.

Description of the problem: Achieving the best possible health outcomes requires evidence-based policies that find balance between the demands of accessibility and efficiency. Therefore, we aimed to set up a methodology to review the healthcare model and assess patient movements across the system. We analysed the roaming paths of breast cancer patients diagnosed in Hungary in 2017. Inter-hospital roaming was represented as a graph: hospitals were the nodes, patient movements from one hospital to another were directed edges. This allowed us to apply network analysis: modularisation, weighted degrees calculation, etc. We then introduced the measure of terminality. A hospital is terminal in a given pathway if it is the last new one, i.e. all hospitals visited later had already been visited before. Terminality is defined as the proportion of terminal events among all pathways that cross a given hospital. The rationale of this is that the last hospital in cancer pathways is usually not the highest level one: after advanced treatments, patients are often referred back to local hospitals.

Results: Testing the method on Hungarian breast cancer patients we observed that results fit our prior expectations. The official ranking of hospitals on the progressivity scale (reflecting the availability of advanced treatments) shows sufficient agreement with terminality. Minor differences may point to situations where the healthcare system does not work fully according to regulations.

Lessons: Our methodology is recommended for system level patient pathway analysis in order to develop evidence-based healthcare policies.

Key messages:

- Graph representation of inter-hospital patient roaming supports evidence-based policy developments for more efficient patient pathways in cancer care, regardless of the healthcare system design.
- The applied new network analysis methodology can help assessing the real life processes of cancer care in a healthcare system through identifying the specifics of inter-hospital patient movements.

[4]Research Department of Behavioural Science and Health, University College London, London, UK
Contact: pennisi.flavia@hsr.it

Background: Pre-existing chronic conditions can influence cancer diagnosis and outcomes. The study aimed to examine variations in diagnostic pathways and outcomes in colorectal cancer (CRC) patients by comorbidity status and socio-demographic characteristics in the provinces of Milan and Lodi, Northern Italy.

Methods: A population-based cohort study using linked administrative health data from the Agency for Health Protection (ATS) of Milan was conducted on individuals aged $\geq$18 years diagnosed with CRC in 2014-2017. We examined pathways to cancer diagnosis, stage at diagnosis and short-term mortality by specific comorbidities and sociodemographic factors.

Results: Among the 5,272 colon cancer and 2,120 rectal cancer patients, 43.9% and 61.5%, respectively, had at least one pre-existing comorbidity, most frequently hypertension (52.7% and 49.9%) and cardiovascular disease (CVD, 23.2% and 18.5%). Cancer diagnostic pathways included screening (4.1% colon and 4.4% rectal cancer patients), EP (22.8% and 12.6%) and inpatient/outpatient admission (73.1% and 82.9%). At multivariable logistic regression, patients with pre-existing cerebrovascular or neurological diseases had significantly higher odds of EP for CRC. In the multinomial logistic regression analysis, the odds of EP were significantly higher for patients aged <50 or ≥ 80 (vs 60-69), belonging to the highest deprivation group and being widowed (vs married). The odds of screen-detected CRC were lower for patients with multimorbidity (2 vs 0 comorbidities: adjusted OR = 0.32, 95% CI 0.14-0.75). 30-day and one-year mortality were higher in colon cancer patients with EP vs inpatient/outpatient (aOR=2.46, 95%CI 1.95-3.09; aOR=2.02, 95%CI 1.74-2.35 respectively). As the number of chronic conditions increased, mortality increased especially at one year. One-year mortality was also higher for rectal cancer patients with 3+ comorbidities (vs no comorbidities).

Key messages:

- Patients with pre-existing chronic conditions had a lower likelihood of screening, higher odds of emergency CRC diagnosis and higher mortality. EPs occur in one in five CRC patients.
- Tailored interventions might be needed to facilitate CRC screening, reducing emergency diagnoses and improving health outcomes for the large number of patients with chronic conditions.

COPD empowerment scale: a scale development and validatıon study

Zahide Aksoy

Z Aksoy[1]*, S Erol*[2]*, Ö Oruç*[3]
[1]Nursing, Istanbul Kent University, Istanbul, Türkiye
[2]Nursing, Marmara University, Istanbul, Türkiye
[3]Medicine, Süreyyapaşa Chest Diseases and Thoracic Surgery Training and Research, Istanbul, Türkiye
Contact: zahide.aksoy@kent.edu.tr

Background: The fact that COPD symptoms seriously affect daily life makes it different from other chronic diseases. The purpose of this study was to develop the COPD Empowerment Scale and test its psychometric properties.

Methods: This study, carried out with a methodological design, was carried out in a Chest Diseases Hospital in Istanbul, Turkey, between June 2023 and March 2024. A scale item pool was created by literature review and semi-structured interviews with COPD patients, and opinions were obtained from 16 experts. The draft scale, consisting of 55 items, was applied to 30 COPD patients as a pilot study. The draft scale was applied to 275 COPD patients and its psychometric properties were tested. The validity of the scale was evaluated by Content Validity Index (CGI) and exploratory and confirmatory factor analysis. Its reliability was evaluated by internal consistency analysis (Cronbach Alpha coefficient), item-total score correlations and test-retest analyses. Statistical significance level was accepted as $p < 0.05$.

Results: The KGI of the scale was found to be 0.97. The draft scale was transformed into a scale with five sub-dimensions and 31 items as a result of exploratory factor analysis. Cronbach's Alpha value of the total scale is 0.896, and its sub-dimensions Cronbach's Alpha values are; knowledge and understanding was found to be 0.731, access to health services was 0.816, self-efficacy was 0.719, symptom management was 0.842, and psycho-social coping was 0.728. Factor loadings of all items were 0.40 and above. As a result of confirmatory factor analysis, $\chi 2$ /df (2.59), RMSEA (0.076), NFI (0.92), NNFI (0.95), SRMR (0.03) and CFI (0.95) measurements are within the desired fit values. In the test-retest reliability study of the scale, the Pearson moment correlation coefficient was found to be ráµ^{a}áµ^{a}=.996 (p<.01).

Conclusions: The COPD empowerment scale was found to be psychometrically valid and reliable.

Key messages:

- The developed scale is a valid and reliable tool to determine the reinforcement needs of COPD patients.
- The scale can be used to evaluate the effectiveness of empowerment initiatives.

[8]Institute of Public Health, Charité - Universitätsmedizin Berlin, Berlin, Germany
Contact: anne.meierkord@charite.de

Background: Long-term health consequences after mild COVID-19 are not well described. Our aim was to estimate their prevalence and describe the time course of signs and symptoms for a period of up to 24 months after confirmed SARS-CoV-2 infection.

Methods: We conducted a cohort study matched for age, sex, and test week among individuals who had attended the public COVID-19 test center at Charité - Universitätsmedizin Berlin, Germany. In early 2022, 576 former COVID-19 patients (>95% non-hospitalised) and 302 uninfected individuals responded to a questionnaire on retrospective monthly symptoms since the test date up to 24 months after.

Results: Symptoms compatible with long COVID were present in 42.9% (247/576) of former COVID-19 patients, compared with 21.2% (64/302) in the uninfected group. In former patients, unadjusted odds ratios (OR) were highest for disturbed taste/smell (OR 9.1 [95% CI: 4.0 - 21.1]), memory difficulties (OR 5.1 [95% CI: 2.9 - 8.9]) and shortness of breath at rest (OR 4.5 [95% CI: 1.9 - 10.6]). Whilst in most former COVID-19 patients, symptoms occurred in one coherent period and resolved after a median of 6.5 months, taste/smell disturbance and neurological/cognitive symptoms showed longer times until recovery and 28.7% (31/108) still reported long COVID-compatible symptoms 18 months after initial COVID-19. Factors associated with long COVID-compatible symptoms included hospitalisation (OR 4.2 [95% CI: 1.7 - 10.8], symptomatic COVID-19 infection (OR 3.4 [95% CI: 1.9 - 6.3], low household income (OR 1.8 [95% CI: 1.2 - 2.7], and female sex (OR 1.7 [95% CI: 1.2 - 2.4]).

Conclusions: Post-infection symptoms in mild COVID-19 mostly persist for about half a year, but sometimes longer. Among uninfected individuals who never experienced COVID-19, 21.2% also reported long COVID-compatible symptoms. The current long COVID definition might require revision to prevent misclassification and over-reporting, and to improve diagnosis and prevalence estimates.

Key messages:

- A more precise definition of long COVID is needed to prevent over-reporting of symptoms compatible with long COVID, and to improve diagnosis, prevalence estimates and research harmonisation.

- Post-infection symptoms after mild COVID-19 are common, mostly persist for about half a year but sometimes longer for more than 20 months.

Loneliness in the elderly and disease development in European welfare regions: a longitudinal study

Julian Perelman

M Paiva Pessoa[1], *F Girão Antunes*[1], *B Coelho*[1], *I Silva*[1], *J Perelman*[2], *S Perelman*[3]
[1]Health Policies and Systems Management, NOVA National School of Public Health, Lisbon, Portugal

[3]University of Liège, Liège, Portugal
Contact: jperelman@ensp.unl.pt

Healthy ageing research has brought a recent focus on the association between loneliness and disease. Regional differences on loneliness prevalence in the elderly across welfare systems, and its association with varying mortality rates, have recently been demonstrated. We hypothesise loneliness affects disease development in the elderly, impacted by socio-economic policies that characterise welfare systems in the EU. We use logistic regression models to assess the association between loneliness (R-UCLA scale) and onset of new chronic disease and disease events, in a European sample of people aged >50 ($n = 40840$), using the SHARE database, during 2013 - 22 (waves 5 to 9). Preliminary results from two subsequent waves (2015-17, $n = 11870$) show a statistically significant effect of persistent loneliness on disease onset (increase in new disease events), when adjusting for sex, age, previous illness, and other socio-economic covariates (AOR 1.22, 95%CI 1.08-1.39, $p < 0.01$). Notably, comparing to the Scandinavian welfare group, only Eastern European countries show higher odds of disease development (AOR 1.52, 95%CI 1.32-1.77, $p < 0.001$), while also having the highest incidence of new disease in our sample. Age and welfare group show the strongest association with the outcome of interest, followed by change in occupation (no longer employed). Our current analyses span a larger period (2013-22), and we are exploring additional mediators of this effect, such as behavioural and social activity-related variables. Additional analyses to control for unrelated disease (low biological plausibility) and a social isolation index, described in the literature, are added. Furthermore, we analyse the longitudinal association between loneliness and healthcare use, such as polypharmacy and consults. With this study, we aim to contribute decision-making in health in all policies, by increasing integration between health and social sectors, while considering different regional and welfare policies.

Key messages:

- Understanding socio-economic and welfare mechanisms which impact health in the elderly allows for better cross-sector policy design, promoting healthier ageing.
- Persistent feelings of loneliness affect disease development in the elderly, which appear to be worsened in some EU welfare groups, independently of socio-economic status.

Contact: domitilla.marconi@gmail.com

Background: Italy counts 1 million people with dementia and 3 million caregivers. An integrated management system provides comprehensive care for people with non-communicable diseases, including dementia, through integrated care pathways (ICPs). Our study identified available dementia ICPs and assessed their compliance with the National Guidance on ICPs for People with Dementia (NGICPD). The project is carried out with the technical and financial support of the Ministry of Health (Chapter 2302).

Methods: We located ICPs by browsing all the websites of regions and Local Health Authorities (LHAs), contacting by email all LHAs, collecting ICPs from a survey carried out by the Dementia Observatory of the Italian National Institute of Health, and communicating with regional contacts. We included the ICPs produced after the NGICPD by the end of 2023. We applied a checklist developed on NGICPD consisting of 3 domains: Reference framework (0-15), Elements of the ICP (0-14), Construction of the ICP (0-14). ICPs were assessed by two researchers; a third solved the conflict points. The concordance was expressed by the intra-class correlation coefficient.

Results: We analysed 39 ICPs (11 regional, 28 LHAs) out of 87 collected. 15/21 regions and 30/110 LHAs developed an ICP. The observed mean total score was 23.5±7.9 for the regional ICPs and 23.1±5 for the LHAs ICPs. We observed low compliance with NGICPD, particularly in domain 3. The development of a health information system was included in 5/11 of regional and 12/28 of ICPs of LHAs; a monitoring system was present in 8/11 of regional and 25/28 LHAs ICPs. Concordance analysis showed an excellent correlation for regional ICPs and good for LHAs ICPs.

Conclusions: Our analysis highlighted low compliance of ICPs with the NGICPD and critical issues in monitoring. Our analysis stresses the need for all regions and LHAs to develop or update ICPs in line with NGICPD and the Italian Guidance on diagnosis and treatment of dementia.

Key messages:

- Developing a pathway of efficient and coordinated care is essential to guarantee the quality of care for people with dementia and their families. All regions and LHAs must develop or update ICPs.
- Monitoring ICP with indicators is crucial to planning cost-effective healthcare services.

Abstract citation ID: ckae144.1340

Bias in Evaluating Trends of Thyroid Cancer Incidence between Rural and Urban Populations

Avi Magid

A Magid[1,2], *S Zolotov*[3], *M Mekel*[2,4]
[1]School of Public Health, Ben-Gurion University of the Negev, Be'er Sheva, Israel
[2]Management, Rambam Health Care Campus, Haifa, Israel
[3]Institute of Endocrinology Diabetes and Metabolism Institute, Rambam Health Care Campus, Haifa, Israel
[4]The Faculty of Medicine, Technion–Israel Institute of Technology, Haifa, Israel
Contact: magid.avi@gmail.com

Background: Diagnosis of thyroid cancer is based on fine needle aspiration cytology of thyroid nodules, based on nodules' sonographic appearance and size. The American Thyroid Association published new guidelines for management of thyroid nodules in 2009 and 2015, where in some cases, only follow-up of thyroid nodules without any other procedure is recommended. This may

lead to a decrease in diagnosed thyroid cancer cases. We studied thyroid cancer trends in Israel between the Arab population who are more likely to be living in rural areas, and the Jewish population who predominantly living in urban areas, and assesses whether these guidelines were reflected in the trends.

Methods: Data on new thyroid cancer cases were retrieved for Jews and Arabs separately from the Israel National Cancer Registry. Trends in age standardized incidence rates between 1996-2019 were evaluated for the two population groups using joinpoint regression model. Population group was included in the regression models to compare the trends between the two groups. We also studied trends in treatment of thyroid cancer at Rambam Health Care Campus.

Results: In both populations, age standardized thyroid cancer incidence rate increased between 1996 and 2013. However, between 2013-2019, Annual Percentage Change continuously increased in Arabs, but decreased in Jews. In the hospital study, we found that the Arab patients were 30% more likely to have surgery for small tumors.

Conclusions: The decrease in thyroid cancer incidence in the Jewish population compared with the Arab population may be related to differences in implementing the 2009 guidelines, which do not recommend fine needle aspiration cytology for very small tumors. We have found evidence that these guidelines were not followed to the same extent among Arab community clinics. This may explain the persisting increasing trend among Arabs, and could be one of the possible explanations for the differences in trends between the two groups.

Key messages:

- Updated Guidelines regarding thyroid cancer diagnosis may be differently implemented by rural and urban populations.
- Trends assessment may be biased due to differences in guidelines implementation.

Abstract citation ID: ckae144.1341
Temporal trends, regional and socio-economic disparities of colorectal cancer burden in Cyprus

Andri Assiotou

A Assiotou[1], *D Lamnisos*[1]
[1]Health Sciences, School of Sciences, European University of Cyprus, Engomi, Nicosia, Cyprus
Contact: aa162401@students.euc.ac.cy

Background: Colorectal cancer (CRC) is one of the main causes of mortality and morbidity worldwide and it is the third most common cancer in Cyprus. Previous studies have documented variations in CRC burden over time, across regions and area-based socio-economic deprivation. The aim of this study was to analyse the burden of CRC over time, across regions and area-based socio-economic deprivation in Cyprus for the time period 2000 to 2015.

Methods: A small area ecological study was performed, with census tracts as units of spatial analysis. The incidence and death date, sex and age of CRC were obtained from the population-based cancer registry of Cyprus. Indirect standardization was used to calculate the sex and age Standardize Incidence Ratios (SIRs) and Standardized Mortality Ratios (SMRs) of CRC while the smoothed estimates of SIRs and SMRs were derived from the Spatiotemporal Bayesian Poisson log-linear model. To investigate temporal trends in the association between area-based socioeconomic deprivation and CRC burden, we have used the national socio-economic index.

Results: The burden of CRC was rising over time. The CRC cumulative incidence increase from 243.7 in the time period 2000-2007 to 347.3 per 100,000 persons in the time period 2008-2015.There was also a more pronounced geographical variation in SIR and SMR in the time period 2008-2015. Four areas out of 369 had smoothed SIR>1.15 while twenty-six areas had smoothed SMR>1.15, with most of those areas located at the east coast of the island and around the capital city. There was a temporal trend in the socio-economic inequalities of CRC burden. The areas in the third and fourth quartile of the socio-economic index had 23% and 45% lower rates of CRC incidence, and 33% and 47% lower rates of CRC mortality in the period 2008-2015.

Conclusions: These findings could shape national prevention policies, such as the national screening program of CRC starting in 2025 and protection strategies for CRC mortality.

Key messages:

- Colorectal cancer screening should be geographically targeted for efficient resource allocation.
- Public health interventions to improve colorectal-specific mortality risk should be geographically targeted.

Abstract citation ID: ckae144.1342
Five-year cancer survival rates in Monastir, Tunisia

Imen Zemni

I Zemni[1], *A Maatouk*[1], *C Bennasrallah*[1], *M Kacem*[1], *W Dhouib*[1], *H Abroug*[1], *M Ben Fredj*[1], *I Bouanene*[1], *A Sriha*[1]
[1]Epidemiology and Preventive Medicine, Monastir University Hospital, Monastir, Tunisia
Contact: imen11zemni@gmail.com

Background: Cancer is a major public health problem worldwide. To the best of our knowledge, there is no Tunisian population-based registry studies investigating cancer survival in Tunisia. The objectives of our study were to estimate the five-year cancer survival rates in the province of Monastir, Tunisia.

Methods: We performed a retrospective cohort study including patients originating from Monastir diagnosed with cancer between 2002 and 2014. Data were collected from the cancer register of the center. Patients were followed until December 2022.

Results: In total, 9318 cancer cases were identified of whom 5741 were included for the survival analysis. The 5-year cancer survival rate, all sites combined, was 46% (95% CI: 45-47.3). Among the 10 most frequent cancer sites in Monastir, cancers having the lowest 5-year survival rates were lung cancer in men (18.2% (95% CI: 15.6-20.7)) and stomach cancer in both sexes (32.1% (95% CI: 23.4-40.7) and 25.3% (95% CI: 16-34.5) in men and women respectively). The cancers with the highest 5-year survival rates among men were skin cancer (other than malignant melanoma) (64% (95% CI: 54.5-73.4)), prostate cancer (59.1% (95% CI:54.7-63.4)) and colon cancer (55.1% (95% CI: 47.7-62.4). In women, cervical cancer (70% (95% CI: 61.8-78.1), skin cancer (other than malignant melanoma) (66.2% (95% CI: 55.1-77.2) and breast cancer (63.8% (95% CI:58.8-67.7)) were those with the highest 5-year survival rates. Patients $\geq$ 65 years had the lowest 5-year survival rates for almost all cancer sites in both genders.

Conclusions: Our study has shown that cancer survival rates in Tunisia remain low compared to developed countries. The widespread implementation of cancer control programs including healthy lifestyle, education, screening and early detection are urgently needed.

Key messages:

- The 5-year cancer survival rate, all sites combined, in Monastir was 46% (95% CI: 45-47.3).
- Cancers with the lowest 5-year survival rates in Monastir were lung cancer in men and stomach cancer in both sexes.

Abstract citation ID: ckae144.1343
Integrated Care in Parkinson's disease: e-training for multidisciplinary team members

Noelia Fernández Salido

G Fornes-Romero[1], N Fernández Salido[1], M Marín Valero[2], M Grande Gordon[2], M López Ortiz[2], M Mattarucco[3], O Zanutto[3], J Garcés Ferrer[1]
[1]Polibienestar Research Institute, University of Valencia, Valencia, Spain
[2]Asociación Parkinson Madrid, Madrid, Spain
[3]Istituto per Servizi di Ricovero ed Assistenza agli Anziani, Treviso, Italy
Contact: Noelia.fernandez@uv.es

Background: Parkinson's is a high prevalence disease worldwide and training in Integrated Care (IC) for professionals in this field is an obvious need. The SUPER training course is focused on integrated care applied to Parkinson's disease (PD) and aimed at social and health professionals. Both the content and the training methodology have been co-designed with people living with PD, relatives/caregivers and professionals from Spain and Italy. The course comprises3 training modules (10 units), alongside self-assessment questions, as well as case studies. Accessible open access via an e-learning platform. It is available in English, Spanish, Italian and French enhancing its applicability and transferability.

Objectives: The SUPER e-training course aims to equip members of multidisciplinary teams with knowledge, skills and competencies in IC applied to PD.

Results: The course was validated with 89 socio-health professionals in Spain and Italy (M age = 37.28; 75.28% women), who completed a questionnaire assessing the usefulness and quality of the training modules and the platform, as well as an overall evaluation of the training in terms of quality and impact. According to the them: the training could improve the quality of care offered to people living with PD; it is expected to heighten interest in IC, while also introducing novel and invaluable elements.

Conclusions: This course is useful to train professionals of different profiles (and European contexts) on IC in PC, increasing their knowledge and skills and improving the provision of care to people living with PD. The SUPER multilingual course is an innovative tool because it has been designed from a bottom-up approach and makes available to any professional a free training that can be taken online at any time.

Key messages:

- SUPER training course equips professionals from a holistic, multidisciplinary and person-centred approach to PD.
- This multilingual tool aids diverse professionals in social & health care.

Abstract citation ID: ckae144.1344
State of oral health in the Portuguese population and associated psychological and social aspects

Helena Krippahl

H Krippahl[1,2], M Neto[1,2], S Namorado[1]
[1]Department of Epidemiology, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
[2]Environmental Health Institute, Faculty of Medicine University of Lisbon, Lisbon, Portugal
Contact: m.helena.krippahl@insa.min-saude.pt

Background: Oral diseases are a global public health challenge and remain among the most prevalent non-communicable diseases. This study aims to characterize the self-assessment of oral health state, degree of edentulism, oral rehabilitation and the quality of life, namely chewing capacity, and the associated psychological and social aspects in the Portuguese Population.

Methods: Data were collected by telefone survey, on the 2nd half of 2018 and 1st half of 2019, using the Portuguese population representative, ECOS panel. Descriptive statistics, as well as prevalence estimates, were obtained with weighting for age, sex, region and sample design, for 95% confidence intervals. The modified F-statistic, a variant of the 2nd order Rao-Scott chi-square adjustment, was used to test the bivariate analyses.

Results: For 53% of the population, the health status of the mouth was perceived as Good or Very Good, for 37% Fair and, in 11% of cases as Bad or Very Bad. It is estimated that around 76% of the population has good oral hygiene habits, approximately 26% have all of their teeth and 8% the total absence of teeth. It is estimated that only around half (49%) underwent rehabilitation using, in the vast majority of cases (78,5%), removable prostheses. It is estimated that 32% of its users have difficulty chewing hard foods and, of these, around 20% have great difficulty or are unable to chew at all. Psychological discomfort due to oral health was higher in the Portuguese population when compared to the European population (17% vs 7 %), psychological limitations due to the appearance of teeth or dentures were equally higher (7% vs 4%), as were social limitations (8,8% vs 4%).

Conclusions: The oral health panorama in Portugal remains bleak, so strengthening the application and deepening of the national oral health promotion program should constitute a priority aspect in the development of public policies in the country

Key messages:

- Integrating oral health into general health promotion strategies and assessing oral health needs to include psychological and social aspects in the Portuguese Population.
- Strengthening the strategies that have been developed in the context of health promotion, prevention and early treatment of oral diseases in Portugal.

Abstract citation ID: ckae144.1345
Sociodemographic Disparities and Prevalence of Type 2 Diabetes Multimorbidities in Serbia

Janko Janković

J Jankovic[1,2], B Djikanovic[1,2], S Ayis[3], J Todorovic[1,2], D Parmar[3], B Marovic[4], M Santric-Milicevic[1,2], V Curcin[3], S Harding[3]

Contact: drjankojankovic@yahoo.com

Introduction: In many countries, including low- and middle-income nations, the prevalence of diabetes is on the rise. Type 2 Diabetes Mellitus (T2DM) is frequently accompanied by the presence of one or more long-term conditions (LTCs), however, their link to patients' socioeconomic traits remains unclear in many LMICs, particularly in the Western Balkans. Thus, our objective was to investigate the risk for the development of T2DM and one or more LTCs in Serbia among different sociodemographic population groups.

Methods: We conducted a secondary analysis of data from the National Health Surveys of 2013 and 2019, focusing on individuals aged 45 and above. Utilizing multinomial logistic regression models, we explored the relative risk ratios (RRRs), along with 95% confidence intervals (CI) and predicted probabilities, to examine the sociodemographic characteristics of participants across various disease groups, distinguishing between those with and without T2DM and one or more LTCs.

Results: The prevalence rates for comorbidities and multimorbidities of T2DM were 8.8% and 29.5%, respectively. In 2019, compared to 2013, there was a rise in the prevalence of T2DM and 1 LTC for 9.4%, and decrease in the prevalence of T2DM and 2 or more LTCs for 6,9%. Most commonly, T2DM was associated with stroke, myocardial infarction, and liver cirrhosis. The highest risk for T2DM and 1 LTC was observed for females in the most disadvantaged fifth quintile of the wealth index (RRR 1.83, 95% CI 1.09-3.07, p = 0.022) compared to those in the most advantaged first quintile.

Conclusions: Socio-economic inequalities contribute to the risk of developing LTCs in Serbia, which must be considered in the early detection and management of diseases and addressed by innovative service models. Similar studies should be conducted in the wider region to explore the feasibility of larger joint research initiatives.

Key messages:

- There are socio-economic disparities in the co-occurrence of Type 2 Diabetes Mellitus and long-term conditions in Serbia, where deprived women of older age are most at risk.
- Innovative approaches in the early identification of populations at risk for multimorbidities can help in disease management and timely prevention of complications.

Abstract citation ID: ckae144.1346
Sarcopenia and associated factors among older adults at high risk of dementia

Daniela de Sousa

D de Sousa[1,2,3]*, AR Costa*[1,2,3]*, M Vicente*[1,2,4]*, VT Cruz*[1,2,5]*, P Padrão*[1,2,4]

[5]Neurology Department, Pedro Hispano Hospital, Matosinhos Local Health Unit, Senhora da Hora, Portugal
Contact: daniela.sousa@ispup.up.pt

Background: Sarcopenia and dementia share pathophysiological pathways and risk factors, including advanced age, physical inactivity, unhealthy diet, smoking and diabetes. Older adults at high risk of dementia may face increased susceptibility to sarcopenia, which can also exacerbate cognitive decline. Thus, this study aims to estimate the frequency of sarcopenia and its associated factors within this vulnerable population.

Methods: This cross-sectional analysis includes data from a subset of older adults ($\geq$65 years of age) enrolled in the MIND-Matosinhos randomized controlled trial, a community-based cognitive decline prevention program. Per the European Working Group on Sarcopenia in Older People, probable sarcopenia is defined as low muscle strength (handgrip strength <16 kg for women and <27 kg for men). Sociodemographic, lifestyle and health-related data were collected via structured questionnaires. To assess factors associated with sarcopenia, odds ratios (OR) and respective confidence intervals (95% CI) were estimated using logistic regression.

Results: A total of 157 participants (58.6% female), with a median age of 73 years (range: 65 to 85 years), were included. The overall prevalence of sarcopenia was 21.7% (n = 34). After adjusting for sex, age and education, inadequate adherence to Mediterranean Diet (MD) (OR = 10.90; 95% CI:1.41-84.52), current smoking status (OR = 5.06; 95% CI:1.06-24.18) and poorer self-perceived health (OR = 2.74; 95% CI:1.03-7.28) were positively associated with sarcopenia. No other statistically significant associations were found.

Conclusions: The observed sarcopenia frequency underscores the need for enhanced screening and management of this condition in community settings and among those at dementia risk. Inadequate adherence to MD, smoking and poor self-perceived health, seem to be associated with sarcopenia in older adults at high risk of dementia. Sarcopenia prevention should involve a holistic approach to promoting a healthy lifestyle.

Key messages:

- Sarcopenia was observed in 21.7% of older adults at high risk of dementia, indicating a significant burden on this vulnerable population.
- Inadequate adherence to the Mediterranean diet, smoking and poor self-perceived health were associated with sarcopenia.

[4]Department of Social Service, Ministry of Public Order, Tripoli, Greece
Contact: mpapadakaki@hmu.gr

Introduction: Chronic illness often brings about existential concerns, including fear of death, which can significantly impact individuals' well-being. The concept of sense of coherence provides a framework for understanding how individuals perceive and cope with stressors, including those associated with chronic illness.

Purpose: This study investigated the correlation between Sense of Coherence, death anxiety, and chronic illness among Greek patients, aiming to understand how these factors interplay.

Methods: An electronic survey was distributed to chronic illness patients in Greece. Sense of Coherence was measured using the Sense of Coherence scale, while death anxiety was assessed using the Collett-Leste Fear of Death scale. Various chronic conditions were considered, and demographic data were collected.

Results: The final sample consisted of 118 participants (female 79.7%; death anxiety score=mean109.2, Sd = 19.2; sense of coherence score=mean55.12, Sd = 13.61). Women and the age group of 58-65 years presented higher death anxiety score followed by the group of 34-41 years. No differences were found between genders in terms of sense of coherence. The highest coherence was manifested in the age group of 50-57 years and the lowest in the age group of 42-49 years. A significant negative correlation was observed between sense of coherence and fear of death (rs(118)= -.299, p < .01). Further correlation tests were performed between axes of coherence, which indicated a stronger negative correlation in two of the three axes of the sense of coherence (Manageability and Meaningfulness) and among all the axes of fear of death, beyond the first, which concerns the loss of one's own life.

Conclusions: The study suggests that individuals with a stronger sense of coherence experience lower death anxiety. Understanding these dynamics is crucial for tailored patient interventions and support strategies.

Key messages:

- Gender and age-specific variations exist in how people approach and experience disease and mortality.
- Understanding patients' coping mechanisms and perceptions of illness is important in disease management.

Abstract citation ID: ckae144.1348
Regional variation in incidence and mortality due to hypertension in Sao Tome and Principe

Background: The analysis of incidence and mortality due to hypertension (HT) provides statistical data for addressing public health programs, particularly in low-income countries where poor health systems impose constraints to address non-communicable diseases (NCDs). This study aims to assess the geographic pattern of incidence and mortality due to HT in Sao Tome and Principe (STP).
Methods: This is a descriptive ecological study. Aggregated data on new cases of and deaths due to HT by gender, age-group and district (2022-2023) were extracted from the Health National Database (STP Ministry of Health). Age-standardized incidence and mortality rates (ASIR and ASMR) and respective 95% confidence interval (95%CI) were obtained. Mortality-to-incidence ratio (MIR) was computed by district (lower values indicate better quality of care). Comparison between districts was done through standardized incidence ratios (SIR) and respective p-value. Analyses were stratified by gender.
Results: ASIR and ASMR per 100,000 were, respectively, 1168.9 (95%CI:1103.3-1237.6) and 76.8 (95%CI:62.0-96.2) among men and 2460.6 (95%CI:2365.0-2559.0) and 99.7 (95%CI:81.4-121.6) among women. Incidence of HT was significantly higher than expected ($p < 0.001$) in Agua Grande, Caue and Lemba with SIR varying from 122.8% (Agua Grande) to 201.1% (Caue) in men and from 125.1% (Lemba) to 224.1% (Caue) in women. Instead, Mé-Zochi presented much lower incidence than expected for both, men (SIR=43.1%; $p<0.001$) and women (SIR=38.4%;$p<0.001$). Large differences between districts were observed in MIR, varying from 0% (Caue and Lobata) to 84% (Mé-Zochi) in men and from 0% (Lobata) to 57% (Mé-Zochi) in women.
Conclusions: According to our findings there is, not only, a high incidence rate of HT, but also regional variation in this rate, deserving particular attention from policy-makers. Regional variation in hypertension incidence could be partially explained by differences in the quality of healthcare services.

Key messages:
- Awareness should be given to the high incidence of hypertension demanding preventive strategies in the field of public health.
- Public health strategies should address the quality of care in regards to the prevention, diagnosis and monitoring of hypertension.

Climate change and health topics in pre-university education in Kosovo: A Content Analysis

Lira Ramadani

L Ramadani[1]*, M Boeckmann*[1]*, G Sioen*[2]
[1]Department of Global Health, University of Bremen, Bremen, Germany
[2]Future Earth Global Secretariat, National Institute for Environmental Studies, Tsukuba, Japan
Contact: lira.ramadani@uni-bremen.de

Background: Climate health literacy (CHL), recommended and recognized as vital for the global response to climate change and impacts on health, lacks comprehensive studies on its integration into primary and secondary school curricula. In Kosovo, where numerous environmental issues already exist and are expected to worsen due to climate change, the resulting health outcomes pose significant challenges. Moreover, the low environmental knowledge among youth further adds to the complexity of addressing these issues. This study addresses this gap by focusing on understanding and enhancing the inclusion of climate change and health topics in pre-university education.
Methods: A content analysis was conducted on: (1) core curricula, (2) subject curricula, and (3) textbooks for pre-university education (grades 0-12) in Kosovo. The outcomes of the content analysis were then juxtaposed with the CHL framework to identify alignment and gaps.
Results: We found that curricula in Grades 0-5, contained one topic on climate change and health topic out of 638 (0.16%) topics documented; however, textbooks did not elucidate this focus. Grades 6-9 had 2 out of 701 (0.28%) and the relevant textbook revealed that various environmental and health topics are covered, but that they lack exploration of the interrelatedness between environmental pollution, climate change, and health. Grades 9-12 had the highest integration with 4 out of 745 (0.54%). Textbook analysis of these grades revealed a more in-depth coverage of climate change and health linkages. In total, seven topics out of a pool of over 2000 topics encompassed learning outcomes related to climate and health in Kosovo's pre-university education.
Conclusions: The current efforts to integrate climate change and health into Kosovo's curriculum fails to meet the recommendations for achieving CHL levels. Localized and context relevant additions are needed to fulfil CHL among students in Kosovo and other countries interested in improving CHL.

Key messages:
- This case serves as a testing ground for a framework assessing climate health literacy within curricula. The results identify gaps and areas of improvement, which inform the implications to attain CHL.
- Results reveal shortcomings in the incorporation of climate change and health topics in schools, underscoring the necessity for tailored strategies to foster CHL among students.

Abstract citation ID: ckae144.1350
Exploring Climate Health Risks and Adaptations among Vulnerable Populations in Israel's Negev Desert

Stav Shapira

S Shapira[1]*, M Negev*[2]*, S Natour*[1]*, M Singer*[2]*, I Porat*[1]*, A Rosenthal*[1]
[1]School of Public Health, Ben-Gurion University of the Negev, Beer Sheva, Israel
[2]School of Public Health, University of Haifa, Haifa, Israel
Contact: stavshap@bgu.ac.il

Background: Climate change represents the paramount challenge to global health, disproportionately impacting particular vulnerable individuals and communities. By identifying and elucidating disparities in health-related climate risks among these groups, we can facilitate the development of appropriate and equitable climate adaptation strategies. This research identified climate-related risks, health perceptions and needs, and behaviors among Jewish and Bedouin populations in the Negev Desert, a region highly susceptible to climate change, located at the intersection of geographical and social marginality.

Methods: Ten focus groups (n = 69) among vulnerable Jewish and Bedouin residents were conducted and systematically analyzed to identify disparities in health-related climate risks and behaviors. Vulnerabilities were defined based on income, age, health status, living environment, and outdoor activities.

Results: The findings highlight both shared and distinct difficulties and barriers vulnerable Jewish and Bedouin Negev residents face in the context of climate-related health risks. Key themes that emerged address: a) the direct and indirect impacts of climate-related events on health and well-being; b) the exacerbation of climate-related health risks by existing vulnerabilities and systemic barriers; c) the pivotal role of community resources in coping strategies; and d) lack of trust in the state and its institutions which underpin climate-related experiences.

Conclusions: The complexity of coping with climate change encompasses individual, community, and national/institutional levels. Vulnerable populations' experiences with climate change are impacted by factors such as poverty, social marginality, violence, and barriers to accessing healthcare and other services, and is not a standalone phenomenon. Therefore, climate change adaptation and mitigation cannot be distinguished from other challenges impacting the health and well-being of populations.

Key messages:

- Climate adaptation efforts must integrate with broader social and health strategies to effectively support vulnerable groups.
- Community resources and trust in institutions are crucial for vulnerable populations facing climate change impacts.

Abstract citation ID: ckae144.1351
Deep learning modeling to assess surface temperature and greenery impact on emergency room access

Fabio Castellana

F Castellana[1], R Zupo[1], F Catino[2], M Ceci[3], F Addabbo[2], S Cervellera[2], A Mincuzzi[2], OV Giannico[2], R Sardone[2]
[1]Department of Interdisciplinary Medicine, University of Bari Aldo Moro, Bari, Italy
[2]Unit of Statistics and Epidemiology, Local Healthcare Authority of Bari, Taranto, Afghanistan
[3]Department of Computer Science, University of Bari Aldo Moro, Bari, Afghanistan
Contact: fabio.castellana@uniba.it

The escalating land surface temperature is a key environmental indicator with potential repercussions on human health. An artificial NN model was built to predict the number of ER accesses as a dependent variable, to establish the predictive power and interactions of land surface temperature and normalized differential vegetation index(NDVI), which is used to measure urban greenery.A map of Taranto was built by vector files on the Apulia region website and processed using R Studio 2023.06.2.The vector file containing the mapping of the city of Taranto was processed to obtain a 200mx200m grid of the entire surface.The Local Health Authority of Taranto provided indications of the residences of ER accesses, and coordinates were merged to gridded vector file to obtain the average of ER accesses and the socio demographic features per single grid unit. NDVI and surface temperature were averaged for July 2023 using images from Landsat 8(30m) and merged to the vector providing an average value of temperature and NDVI index per single quadrant. The dataset was divided into two db according to an 80/20 ratio respectively for the training and test dataset.A NN model was built on dichotomous value (above/below median) for each quadrant (6513 units) with hyperparameter tuning technique using the accuracy to select the best model.A MOC model was built to reduce the probability of NN detection by at least 40% in a randomly selected subject.A MOC model was built considering sociodemographic variables as fixed features and an epsilon of 0 for 175 generations and an ICE curves population initialization strategy. NNET accuracy value was 0.849 and 0.841 in training and testing, suggesting a good fitting of the model.Relative change plots were adopted to show the amount and the direction of generated counterfactuals, to reduce grid unit prediction to be over median.LST decreasing and NDVI score increasing were associated with a reduction of classification probability of grid unit.

Key messages:

- Rising land surface temperature is a critical environmental indicator with potential impacts on human health.
- Artificial neural network models perform well in predicting the number of ER accesses with respect to land surface temperature and NDVI, which is used to measure urban greenery.

Abstract citation ID: ckae144.1352
Eco-anxiety: an additional burden for university students?

Marie-Pierre Tavolacci

M Tavolacci[1,2], J Ladner[2]
[1]Rouen University Hospital, Clinical Investigation Center 1404 Inserm1073, Rouen, France
[2]Rouen University, U1073, Rouen, France
Contact: Marie-Pierre.Tavolacci@chu-rouen.fr

Background: Eco-anxiety encompasses climate change anxiety, including global warming, as well as anxiety about a multiplicity of environmental disasters, which not be directly caused by climate change The objective is to assess eco-anxiety in healthcare and non healthcare students and investigate a relationship with health behaviour, mental health, and environmental opinion.

Methods: A cross-sectional study was conducted among voluntary university students in the Rouen University in Normandy, France. Volunteer healthcare students aged 18 years and older were included. Eco-anxiety was assessed with the Hogg Eco-Anxiety Scale (HEAS-13). Socio-demographics, health behavior, mental health and healthcare data were also collected.

Results: A total of 1,887 students were included with 74.3% of women and a mean age of 21.1 years (SD = 6.8). The HEAS-13 mean was 13.2 (SD = 2.6): affective symptoms 4.1 (SD = 2.7), eco-rumination 3.7 (SD = 2.4), behaviour 1.0 (SD = 1.5), and anxiety about one's personal impact on the planet 4.4 (SD = 2.5). Respectively, 59.6% and 31.4% of students are moderately and very much involved in pro environmental-behaviour. 84.6% of students will consider environmental issues in their career choices. Eco-anxiety was associated with being a woman, being in curricula other than health, accommodation with roommates or in couple, use of cannabis, eating disorders, insomnia, emotional exhaustion, cynicism, depression, quality of life, and visiting a general practitioner for stress.

Conclusions: An high eco-anxiety was associated with impaired mental health and could be an additional burden for university students. Intervention options for those that do experience eco-anxiety and suffering can be as prescribing environmental action, mental health skills, and climate change resolution without imposing the burden of change solely on young people

Key messages:

- A high eco-anxiety is prevalent among university.
- The eco-anxiety impaired mental health that could be an additional burden for university students.

Abstract citation ID: ckae144.1353
Climate change and gastroenteritis projections in Albanian children

Alban Ylli

A Ylli[1], *E Tomini*[1], *G Qirjako*[1], *M Bukli*[2], *G Burazeri*[1]
[1]Institute of Public Health, Tirana University of Medicine, Tirana, Albania
[2]Health and Nutrition, UNICEF Office, Tirana, Albania
Contact: albanylli@yahoo.co.uk

Background: Human health can be affected by climate in direct and indirect ways. Increasing temperatures may affect ecosystems, water safety, and exposure to waterborne diseases. This is the first work in Albania aiming to demonstrate the link between gastroenteritis rate and climate in the country. This research was supported by UNICEF Albania through the WASH Global Thematic Fund, but it doesn't necessarily represent UNICEF's position.

Methods: Epidemiological surveillance reports of the period 2006-2022 were used for the yearly incidence of gastroenteritis in children 0-14 years old. Years 2020 and 2021 were not included because of pandemic confounding potential. Historic data for calculating the average summer temperatures were retrieved from timeanddate.com repository. Pearson coefficient is calculated to quantify the associations and linear regression is applied to project the increased rate in the future.

Results: There was a statistical association between gastroenteritis rate and summer temperatures during the study period (Pearson coefficient=0.78, $p = 0.001$). There was a tendency that in years with hotter summers higher incidence of gastroenteritis was reported by the health system. For each degree (Celsius) increase in the average summer day temperatures, the risk of gastroenteritis in children is expected to increase by 644/100 000 (CI 95%: 317 - 972). An excess rate of 966/100 000 is expected in the case of Intergovernmental Panel on Climate Change medium scenario projection of 1.5o C average temperature increase. That implies more than 4830 additional new cases every year in children 0-14 years old, attributed to climate change in the future in Albania.

Conclusions: The analysis demonstrated excess gastroenteritis risk may be related to higher summer temperatures observed in Albania. The expected gastroenteritis risk increase in a warmer future should be addressed by improvements in sanitation, education of parents and epidemiological intelligence.

Key messages:

- A warmer climate is expected to affect the health by increasing the risk for diarrheic diseases.
- Children will be the most at-risk population category.

Abstract citation ID: ckae144.1354
Urban burden of disease estimation for policy making

Georgia Dyer

G Dyer[1,2,3], *S Khomenko*[1,2,3]
[1]Barcelona Institute for Global Health, Barcelona, Spain
[2]Department of Biomedicine, Universitat Pompeu Fabra, Barcelona, Spain
[3]CIBER Epidemiología y Salud Pública, Madrid, Spain
Contact: georgia.dyer@isglobal.org

Introduction: The Urban Burden of Disease Estimation for Policy Making (UBDPolicy) project aims to estimate the health impacts resulting from urban and transport planning related exposures in nearly 1000 European cities. So far, quantitative burden of disease assessments have estimated premature mortality attributable to the environmental stressors of air pollution, noise, urban heat islands and lack of green space for the year 2015. Regular reporting and trend monitoring of the health impacts associated with urban environments is crucial for assessing the wider impacts of urban and transport planning.

Methods: For almost 1000 European cities, quantitative Health Impact Assessments (HIAs) will be conducted that employ the comparative risk assessment methodology. Baseline exposure levels of air pollution, noise, urban heat islands and green space will be estimated and preventable health impacts modelled using counterfactual exposure scenarios. Analysis will comprise two components: firstly, the 2018 HIA will incorporate multiple environmental exposures for that year, while the second component will monitor trends at three-yearly reporting intervals covering the years of 2015, 2018, 2021 and 2024.

Results: Results are intended to shape evidence-informed urban planning and policies throughout Europe. By ranking cities according to environmental exposures and health impacts, cities are encouraged to address challenges and learn from successful urban design and planning policies in other cities.

Discussion: HIAs serve as an effective tool for identifying the health impacts of current and future urban policies. The provision of burden of disease estimates will provide policy-makers and practitioners robust data for informed decision-making, while estimates over time will allow tracking of changes from implemented policies. To fully harness the potential of cities as key drivers of sustainable and healthy living, robust evidence must be at the forefront of this change.

Key messages:

- A multitude of urban and transport planning pathways contribute toward the health of urban populations.
- Compact city designs often promote health, however there are exceptions.

Is health being considered by funding towards climate adaptation and mitigation?

Ana-Catarina Pinho-Gomes

A Pinho-Gomes[1,2], *L Jamart*[1]
[1]Institute for Global Health, University College London, London, UK
[2]The George Institute for Global Health, Imperial College London, London, UK
Contact: a.pinho-gomes@ucl.ac.uk

Introduction: Funding is essential to build climate resilience in public health and healthcare systems and enable populations to adapt to the increasing impacts on climate change on health across the globe. This study aimed to investigate how health has been considered by the projects supported by the Green Climate Fund (GCF), created by the Paris Agreement to support climate adaptation and mitigation.

Methods: Adaptation, mitigation, and cross-cutting projects funded by the GCF between 2021 and 2023 were included. Information was collected for the percentage of funding allocated to health adaptation by cross-cutting and adaptation projects. For mitigation projects, information was extracted on the extent to which health co-benefits were considered.

Results: The 69 adaptation and cross-cutting projects funded by the GCF in 2021-2023 contributed $226 million towards adaptation, of which $59 (26%) million were for health adaptation. There was an increase in the funding provided by the GCF to adaptation from $1 million in 2021 to $156 million in 2023. Funding for health adaptation increased from $178,000 in 2021 to $42 million in 2023. Of the co-funding provided by beneficiaries, $637 million contributed to adaptation and $165 (26%) million to health adaptation. There was an increase in co-funding for adaptation provided by beneficiaries from $131 million in 2022 to $506 million in 2023, with funding for health adaptation increasing from $23 (18%) million to $142 (28%) million. Among the 48 mitigation and cross-cutting projects, 15 did not mention health, 13 mentioned did not correctly articulate health co-benefits, 11 identified specific health co-benefits, and 9 correctly labelled and measured health co-benefits. The main co-benefits derived from reducing air pollution.

Conclusions: Among the projects funded by the GCF, funding for health adaptation remains a small proportion of the adaptation funding and health co-benefits are rarely considered by mitigation projects.

Key messages:

- The proportion of adaptation funding provided for the health sector remains low.
- Health co-benefits are seldom considered and measured by climate mitigation projects.

[3]CREAGEN, University of Modena and Reggio Emilia, Modena, Italy
[4]School of Public Health, University of California Berkeley, Berkeley, USA
Contact: dr.antoniolorenzon@gmail.com

Background: West Nile Virus (WNV) is a pathogen transmitted by mosquitoes of the Culex genus, affecting both humans and animals such as horses and birds. The prevalence of WNV infection has increased dramatically in recent years in Europe, especially in Italy, and has been related to climate and environmental changes linked to global warming. Our review aims to assess the relation between the spread of WNV in Italy and the different climate change-related factors.

Methods: We conducted a literature search in the PubMed, Web of Science, Embase and Scopus databases, actualised as of 20 February 2024, using as search terms WNV, its vectors and climate change, and limiting our analysis to studies conducted in to avoid an overly heterogeneous setting. We registered the review in PROSPERO (CRD42023430636).

Results: Of the 252 unique records retrieved, we eventually included 25 articles after full-text screening. These studies were published between 2011 and 2023 and evaluated the distribution of WNV or its vectors according to various climatic and environmental factors. Despite rather heterogeneous results, we found a consistently positive association with temperature, especially spring temperature, agricultural land use, demography, and soil moisture, and a negative one with evapotranspiration and wind, while the relationship with other environmental variables and water cycle-related factors was weak, null or conflicting.

Conclusions: Despite some inconsistencies in the results, likely related to differences in study methodologies as well as complex environmental interactions, we found unequivocal evidence that climate change-related factors, such as the lengthening of the warm season, extensive farming, and invasive human activities towards natural environments, favour WNV spread in Italy. Consequently, actions against global warming and preservation of natural environments may counteract the WNV epidemic.

Key messages:

- WNV epidemic seems to be linked to specific climate change-related factors, such as the lengthening of the warm season, extensive farming, and invasive human activities towards natural environments.
- Actions against global warming and preservation of natural environments may counteract WNV spread.

Abstract citation ID: ckae144.1357
Climate change health challenges – a study on heat health-related adaption measures in Germany

Hans-Guido Mücke

HA Grewe[1], *C Kind*[2]
[1]Public Health Care, University of Applied Science, Fulda, Germany
[2]adelphi research GmbH, Berlin, Germany
Contact: hans-guido.muecke@uba.de

Problem: Increasing extreme heat events of summer 2003, 2010 and 2015 induced a rising impact on heat health morbidity and mortality in Germany. A considerable proportion of urban population is affected by thermal discomfort due to the urban heat island burden during summer, particularly vulnerable people at risk. Concerted action to develop appropriate heat health adaptation measures is needed.

Description: As part of the National Adaptation Strategy to Climate Change an expert working group published ‘Recommendations for Action for the Preparation of Heat Action Plans’ for Germany in 2017. A first country-wide project had been conducted between 2019 and 2023 which investigated the status and impact of current or planned Heat Health Action Plans (HHAP), and adaptation measures appropriate to protect and prevent human health. As part of this project an online survey was conducted in May/June 2020 on the awareness and degree of use of the 2017 recommendations and the development and implementation of HHAP.

Results: This survey had been carried out to assess the current state of affairs as well as factors of success and barriers in the development and implementation of HHAP, with a particular focus on municipal environment and health administrations. In total 116 questionnaires had been responded, mainly by participants from the environment sector (53%), and 32% from the public health sector. More than half of the respondents indicated to be aware of the recommendations (very well-known at the federal state level: 90%, at county level known by 43%), which were identified as very helpful by 81%. Respondents from large cities (> 100 000 inhabitants) were main contributors to the study (41 of 81 large cities replied; 34 rural counties responded).

Key messages:

- The 2017 recommendations had been identified and used to start with HHAP.
- Decision makers should develop structures for regulations that anchor HHAP as a nationwide instrument to be established timely.

Abstract citation ID: ckae144.1358
Climate change and its health effects - an optional subject for medical students

Zoltan Abram

Z Abram[1]
[1]Hygiene, UMFST G.E. Palade Targu Mures, Targu Mures, Romania
Contact: abramzoltan@yahoo.com

The Standing Committee of European Doctors urged to include training on the impact of climate change on health for health professionals. Currently, in the curriculum of most medical schools, the health-related impacts of climate change represent a peripheral part. The teaching of health effects of climate change should be made part of the training of health professionals and should be introduced in the curriculum of medical schools. ClimateMed is an Erasmus project that improves the curriculum and expands knowledge about the health effects of climate change at medical universities. The World Café method, based on round table discussions, was applied to assess the needs, summarize the proposals, and develop the necessary strategy. At the same time, a questionnaire was applied to those medical students from UMFST Targu Mureș who chose this subject as an optional subject. Students related the importance of understanding the diseases caused directly or indirectly by climate change, and reported what kind of topics should be included in a new course, in which semester/module and in what format it would be appropriate to teach it. The most frequently reported topics were: excessive heat and heat-related illnesses, extreme weather, vector-borne diseases, food safety, air pollution, and mental health. According to the goals of the project and students' opinions, since 2023 medical students can choose Climate Change and Health Effects as an elective course. Based on the demand for medical universities to include in their curriculum knowledge related to the health effects of climate change, ClimateMed project can facilitate this integration and can promote the increase of teacher motivation and the development of methodological guidelines for university teachers. The project contributes to the preparation of some educational materials and the introduction of an optional subject in the training curriculum of the students of the Faculty of Medicine, UMFST Targu Mureș.

Key messages:

- There must be made efforts to include training on the impact of climate change on health for health professionals, to introduce this subject in the curriculum of medical schools.
- ClimateMed project can facilitate the integration of knowledge about the health effects of climate change into curriculum and can promote the practical use.

Abstract citation ID: ckae144.1359
Heatwaves, Hospitals, and Health System Resilience in England: A Qualitative Assessment (Summer 2019)

Katya Brooks

K Brooks[1], O Landeg[1], S Kovats[2], M Sewell[3], E Oconnell[4]
[1]UKHSA, London, UK
[2]LSHTM, London, UK
[3]NHS England, London, UK
[4]Greater London Authority, London, UK
Contact: Katya.Brooks@ukhsa.gov.uk

Background: Frequent heatwaves challenge healthcare delivery in England, affecting patient safety and staff welfare. This study addresses the observational gap in how healthcare settings adapt to extreme weather.

Methods: We utilised a qualitative approach, conducting semi-structured interviews with fourteen NHS staff across England to explore experiences during the 2019 summer heatwave. Participants included clinical and non-clinical personnel, providing broad insights into operational challenges and adaptive strategies.

Results: The 2019 heatwave significantly disrupted service delivery, with variable staff awareness of the Heatwave Plan for England affecting responses. Key issues included managing infection control versus electric fan usage, impacting patient and staff comfort and safety. These conditions also led to an increase in hospital admissions.

Conclusions: The findings highlight the need for improved workforce training and strategic planning to enhance resilience to heat-related risks. Further research is essential to develop a comprehensive evidence base on the impacts and costs of heatwaves and to assess the effectiveness of adaptation strategies. This will support national health adaptation planning and emergency response.

Key messages:

- Enhanced planning and training are crucial for health system resilience to heatwaves.
- More research is needed to understand heatwave impacts and effective responses.

Abstract citation ID: ckae144.1360
Advancing urban health in Portugal: exploring liveability and its association with mental morbidity

[7]Comprehensive Health Research Center, ENSP, NOVA University, Lisbon, Portugal
Contact: mafalda.uva@insa.min-saude.pt

Background: As cities face challenges posed by urbanisation, it becomes essential to understand how city planning can contribute to protecting public health. In this study, we aimed to assess the liveability of different areas in Lisbon, Portugal, by developing a liveability index at the parish level. Secondly, we aimed to explore its association with hospitalisation due to mental disorders.

Methods: The liveability index was built based on the World Health Organisation's Urban Health Index methodology. We obtained data on liveability related to housing, socio-economic conditions and access to services (e.g. healthcare) from the 2011 census and other open data sources for Lisbon's parishes ($n = 22$). Data on hospital admissions due to mental disorders was sourced at the parish level from the national database for hospital morbidity for the period 2013-2016 and sex-age-standardised. Binomial negative regression was employed to estimate the association between the liveability index tertiles and observed hospital admissions. We used the expected number of hospitalisations as the offset variable and tested for spatial autocorrelation among the regression residuals.

Results: Our analysis showed that living in the most liveable parishes is associated with a significant decrease in the standardised admission ratio due to mental disorders, compared to living in the least liveable areas (Incidence Relative Ratio=0.643; 95% CI: 0.427, 0.967). We did not observe any geographical pattern in the regression residuals (Moran's I= -0.035, $p = 0.427$).

Conclusions: Our findings show disparities in liveability among Lisbon's parishes and identify a protective association between living in higher liveability areas and hospital admissions due to mental disorders. This work should prompt further studies concerning this subject to inform urban planning policies to improve liveability and equally reduce the risk of mental health-related harm within cities.

Key messages:

- A spatial index to assess liveability in urban areas was developed. The association between the liveability of Lisbon's parishes and hospital admissions due to mental disorders was explored.
- We found a significant protective association between higher liveability and hospital admissions due to mental disorders. This work is relevant to inform the implementation of urban planning policies.

Abstract citation ID: ckae144.1361
Association between number of hospitalizations of older adults and heatwaves in Slovenia 1999-2018

Simona Percic

S Percic[1], K Bitenc[1], M Pohar[1], T Cegnar[2], M Krosel[1], VV Hrzenjak[1], A Hojs[1]
[1]NIJZ, Ljubljana, Slovenia
[2]Slovenian Environment Agency, Ljubljana, Slovenia
Contact: simona.percic@nijz.si

Background: Heatwaves frequency, intensity, and duration increase with global climate change. The association between heat and mortality in older adults is well documented, but less is known about associations with hospitalizations. Knowing which diseases contribute to a higher number of hospitalizations during heatwaves is important for planning appropriate public health preventive measures.

Methods: We assessed short-term association between the number of hospitalizations for older adults (75+ years) and heatwaves in the years 1999 to 2018 in Slovenia. We estimated the relative risks (RR) with 95 % confidence interval for the number of hospitalizations for the observed diagnosis (all causes, circulatory, respiratory, endocrine and genitourinary diseases) and gender associated with heatwaves in Slovenia for each year, comparing the number of hospitalizations during heatwaves with reference days.

Results: We could not find an association between heatwaves and hospitalizations for all cause hospitalizations in all observed years. In some years the association was even negative. In cause specific analyses heatwaves were associated with increased hospitalizations for endocrine diseases in 2012 (32%; 95% CI: 1%, 73%), 2013 (23%; 95% CI: 5%, 33%), 2014 (48%; 95% CI: 4%, 110%) and 2015 (42%; 95% CI: 7%, 89%), but not for cardiovascular, respiratory and genitourinary diseases.

Conclusions: Older adults are most susceptible to the effects of extreme heat due to physiological changes that occur with aging, chronic diseases, certain medications, a sedentary lifestyle and social isolation. The results of our study will help in planning appropriate preventive public health measures to better protect older adults during the next heatwaves in Slovenia.

Key messages:

- Heatwaves will become longer, more frequent and more intense in the near future.
- Endocrine diseases are the most important cause for hospitalization during heatwaves. Public health measures shoud adress these most vulnerable groups.

Abstract citation ID: ckae144.1362
Association between the education level and heatwaves mortality in Slovenia, 2015-2022

Simona Percic

S Percic[1], M Pohar[1], K Bitenc[1], A Medved[2], M Krosel[1], VV Hrzenjak[1], A Hojs[1]
[1]NIJZ, Ljubljana, Slovenia
[2]Slovenian Environment Agency, Ljubljana, Slovenia
Contact: simona.percic@nijz.si

Background: So far only a few studies have addressed the heat related mortality risks associated with socioeconomic factors. The study aimed to determine whether low education is associated with more deaths during heat waves, which in turn leads to health inequalities linked to climate change.

Methods: In this time series study, we assessed the association between the level of education in three Slovenian climate regions and mortality during the heatwaves from 2015 to 2022. We estimated the relative risks (RR) with 95 % confidence interval for the number of deaths due to all causes among persons with three different levels of education associated with heatwaves in three Slovenian climate regions independently, comparing the number of deaths during heat waves with the reference days.

Results: Continental and Littoral Climate: We found no statistically significant association in the number of deaths due to all causes during heatwaves according to the three levels of education. When comparing these three levels to each other (Relative Risk Ratio), we found no statistically significant differences between them. Transitional Climate: For the second education level (middle education) we found statistically significant increase in number of deaths due to all causes (12%; 95% CI: 2%, 23%). When comparing the three education levels to each other, we found statistically significant decreased number of deaths in the first education level (low education) compared to second (-13%; 95% CI: -24%, -1%).

Conclusions: When assessing the effects of climate change on health and planning preventive measures, it is necessary to consider both socioeconomic factors and the characteristics of different climate regions in Slovenia. Further studies are needed.

Key messages:

- Heatwaves will contiue to be more intense, longer and more frequent also in Europe.
- Not many studies assessed association between social status and mortality durin heatwaves. WE found statistically significant more deaths in middle class education group. Further studies are needed.

Abstract citation ID: ckae144.1363
Public perceptions of the health impacts of climate change: a survey study in Greece

Demetris Lamnisos

D Lamnisos[1], G Michalopoulos[1], M Andrianaki[1]
[1]Department of Health Sciences, European University Cyprus, Nicosia, Cyprus
Contact: D.Lamnisos@euc.ac.cy

Background: Climate change is the biggest global health threat of the 21st century. Despite the tremendous challenges, many people remain unaware of the human health implications of climate change. People perceptions about the health harms of climate change can increase public support for the action needed to reduce climate change. The aim of this study was to examine the public perception of climate change as a human health issue in Greece.

Methods: A population survey study was conducted from October to December 2023 in the municipalities of Messini and Alexandroupoli, Greece, following proportional quota sampling. A questionnaire was developed and included measures about the socio-demographic background of participants, their understanding of key facts about climate change and their views about climate change thread to human health.

Results: 406 individuals with a mean age 37.7 (sd = 14.8) participated in the study. Participants understood that climate change is happening (93.6%) and 54% of them think climate change is mostly or entirely caused by human activities, whereas 38% think it is caused equally by human activities and natural causes, and about 8% think climate change is mostly or entirely caused by natural causes. A majority of participants reported that climate change has adversely affected the health of people in various way, either a moderate amount or a great deal, including physical or mental harm from forest fires (90%), physical or mental harm from storms and floods (87%), heat-related illnesses (82%), illness due to reduced outdoor air quality (70%) and loss of housing for residents displaced by extreme weather events (70%).

Conclusions: Participants viewed climate change as an important cause of health harm, however they partially understood that climate change is caused by humans. Public health authorities should educate the public and policymakers about the climate change and advocate for policies to address the human health challenges of climate change.

Key messages:

- Public health authorities should educate the public and policymakers about the climate change problem and its impact to human health.
- Providing people with information about the health harms of climate change can increase public support for the actions needed to reduce emissions.

Abstract citation ID: ckae144.1364
A questionnaire to assess ecoanxiety and its sociodemographic determinants among Italian adolescents

Lorenza Nachira

L Nachira[1,2], M Innocenti[1,3], M Di Russo[1,2], G Congedo[1,2], E Campo[1], D Zjalic[1,2], G Lombardi[1,2], A Perilli[1,2], S Bruno[1,2], G Fioravanti[4]
[1]Life Sciences and Public Health Department, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Italian Institute for Planetary Health, Rome, Italy
[3]Associazione Italiana Ansia da Cambiamento Climatico, Florence, Italy
[4]Department of Health Sciences, University of Florence, Florence, Italy
Contact: lorenzanachira@gmail.com

Background: Climate change poses serious challenges to Public Health, including mental health impacts. In Italy, few studies investigated the rise of eco-anxiety, especially among adolescents, who are the main group affected by this feeling. Specific measurement tools for this population are needed to fill this gap. The aim is to adapt the Italian version of the Climate Change Anxiety Scale (CCAS) to adolescents, and pair it with a socioeconomic and demographic questionnaire (SDQ) to assess determinants.

Methods: The Italian CCAS was modified for adolescents through a process involving a literature review, expert discussions, and a pretest. This adapted version (a-CCAS) was tested with individuals aged 14-18 years old, maintaining an ideal ratio of 10 respondents per item. Extant psychometric scales were utilized to assess its validity. The SDQ was developed from results of a systematic review of known associations between socioeconomic and demographic factors and eco-anxiety in youth, and expert discussions, and validated by piloting the SDQ with another sample of adolescents. Internal consistency of the a-CCAS and SDQ was assessed by Cronbach's alpha (Cα).

Results: The a-CCAS kept most of its original content, comprising 13 items and 2 subscales: cognitive and functional impairment. Pilot respondents were 162; Cα coefficient was >0.7 for both subscales. Convergent and concurrent validity showed positive correlations with the extant scales. The SDQ comprised 12 items in 3 domains: family, social and political-environmental determinants. Respondents were 47 and Cα coefficient was >0.7.

Conclusions: The a-CCAS and SDQ are valid tools for assessing baseline eco-anxiety and its determinants in Italian adolescents and can contribute to Public Health efforts to reduce the climate-related mental health burden, by measuring the impact of specific educational interventions about climate change targeted at the young. This questionnaire was created as part of the PRIN P2022JJ3LB project.

Key messages:
- These results contribute to filling an evidence gap on eco-anxiety and its socioeconomic and demographic determinants among Italian adolescents by providing researchers with a valid measurement tool.
- This tool holds promise for assessing the impact of psychologically-informed educational interventions about climate change and adaptive coping strategies on adolescents' eco-anxiety levels.

Abstract citation ID: ckae144.1365
Greening the mind: exploring the link between vertical gardens, urban forests, and mental health

Teresa Urbano

T Urbano[1,2], S Akkawi[2,3], MG Brînzac[2,4], C Savoia[2,6], C Cadeddu[2,5]
[1]Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

[3]Environmental Health Office, Municipality of Strovolos, Strovolos, Cyprus
[4]Department of Public Health, Babeş-Bolyai University Cluj-Napoca, Cluj-Napoca, Romania
[5]School of Health Policy and Management, Erasmus University Rotterdam, Rotterdam, Netherlands
[6]Life Sciences and Public Health, Catholic University of the Sacred Heart, Rome, Italy
Contact: teresaurbano@unimore.it

Background: Mental disorders impose a significant global burden, affecting millions of individuals, contributing to disability, reduced quality of life, and economic costs worldwide. Between 1990 and 2019, the global number of disability-adjusted life-years due to mental disorders increased from 80.8 million to 125.3 million. The economic costs are projected to rise to 6,000 billion euros by 2030. Urbanization has been associated with a worsening of mental disorders over the years due to various factors, such as increased stress, social isolation, reduced access to green spaces, and higher levels of pollution. Decades of research have instead shown that exposure to green space may promote psychological well-being, regulate stress, and endorse social health across the lifespan. In this systematic review, we aim to investigate how proximity to vertical gardens or urban forests, specifically, may affect mental health.

Methods: The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) were followed. The study protocol was registered in PROSPERO (CRD42024517969) with the following PECOS question: Is there an association between vertical gardens or urban forests and mental health?

Results: After performing searches on PubMed, Scopus, and Web of Science, and duplicate removal, we retrieved 556 articles. The main reasons for exclusion after title/abstract screening were mainly wrong outcome (not mental health) and wrong study type (not observational/intervention/cross-sectional studies). The selection of full texts is expected to end shortly and results will be available for November 2024. Preliminary findings support the role of green environmental assets in facilitating physical activity, social contact, and stress reduction.

Conclusions: In summary, mental disorders are exacerbated by urbanization's stressors. Our review will further elucidate the potential benefits of urban green spaces like vertical gardens and urban forests on mental health.

Key messages:
- Urbanization exacerbates the issue of mental disorders global burden.
- Exposure to urban forests and vertical gardens may promote physiological well-being and mental health.

Abstract citation ID: ckae144.1366
Flooding and Mental Health interventions for vulnerable groups

Anusha Rajamani

A Munro[1], L Armstrong[1], A Tran[1], O Landeg[1], C Petrokofsky[1], E O'Connell[1], I Kar-Purkayastha[1], A Rajamani[1], P Coleman[1], A Sousa[1]
[1]UKHSA, London, UK
Contact: Anusha.Rajamani@ukhsa.gov.uk

Issue/Problem: The UK is increasingly vulnerable to flooding due to climate change, which significantly affects mental health. Vulnerable populations are disproportionately impacted, experiencing stress, anxiety, and other severe mental health issues, requiring effective intervention strategies.

Description of the problem: The UK's third Climate Change Risk Assessment (CCRA) highlights flooding as a key challenge, with mental health impacts representing a major health burden. Effective interventions are crucial for these communities.

Results: UKHSA's flooding and mental health guidance is incorporated into flooding and health advice documents for the public and frontline responders. It includes assessment and support strategies for health and social care staff, emergency responders, and local authorities. It focuses on those most at risk and promotes a phased approach to care-from immediate safety and shelter to long-term psychological support. This strategy accommodates the prolonged nature of mental health recovery, requiring adaptable and sustained interventions.

Lessons: Addressing the mental health impacts of flooding demands a comprehensive, multi-phase strategy that adapts to the evolving needs of affected populations. Early intervention and long-term support are vital to mitigate the extensive psychosocial damage.

Key messages:

- Flooding severely affects mental health, necessitating structured, long-term interventions.
- Flexible support strategies that evolve over time are crucial for effective recovery, ensuring that interventions meet the changing needs of those impacted by flooding.

Abstract citation ID: ckae144.1367
Public health effectiveness of cooling centres in adverse hot weather events: a systematic review

Katya Brooks

C Dearman[1], *N Adams*[1], *A Sousa*[1], *N Pearce-Smith*[1], *C Petrokofsky*[1]
[1]UKHSA, London, UK
Contact: Katya.Brooks@ukhsa.gov.uk

Background: The 2022 heatwave in England highlighted the need for effective public health interventions like cooling centres in temperate climates where built-in air conditioning is uncommon.

Aim: To determine the impacts of cooling centres on heat-related health outcomes for users in temperate climates, assessing their effectiveness and identifying barriers to usage.

Methods: This systematic review analysed literature sourced from MEDLINE, Embase, Web of Science, CENTRAL, and Google Scholar from January 2010 to February 2023. Criteria for inclusion focused on studies evaluating health outcomes related to cooling centre use. Screening and quality assessments were independently conducted using the Mixed Methods Appraisal Tool.

Results: The review included six studies: three quantitative, three qualitative. Two were evidence synthesis of prior studies. No studies conclusively measured health and wellbeing outcomes directly after cooling centre use; instead, research emphasised user demographics, barriers, and facilitators. Common barriers included accessibility, operational hours, and public perceptions, which often misalign with user needs. Successful implementations were noted in centres integrated within community facilities like libraries or community centres. One modelling study suggested a number needed to treat to avoid one heat-related death of 1 million. The relevance of this is unclear as it was in a hotter climate with greater prevalence of air conditioning than in England.

Conclusions: While direct health benefits in cooler climates like England are poorly documented, cooling centres play an essential role in comprehensive heat response strategies. They offer potential social benefits and provide a cost-effective alternative to urban redesign. Future studies should aim to directly measure health outcomes and refine operational strategies to maximise benefits.

Key messages:

- Cooling centres are crucial in comprehensive heat response strategies, yet direct evidence in cooler climates like England remains limited.
- Integration with existing community services may significantly enhance cooling centre utilisation and effectiveness.

Abstract citation ID: ckae144.1368
From Pandemic to Heatwave: Digital Strategies for Health Resilience

Maria Daniel Loureiro

M Loureiro[1], *H Vasconcelos*[1], *AL Neves*[2]
[1]Center for Health Technology and Services Research, University of Porto, Porto, Portugal
[2]Institute of Global Health Innovation, Imperial College London, London, UK
Contact: mdl21996@gmail.com

Heatwaves threaten public health in the EU, as evidenced by the high heat-related mortality in the summer of 2022. Despite their frequency, European heat-health action plans (HHAPs) largely exclude digital solutions. The COVID-19 pandemic shifted perceptions and use of digital health tools, demonstrating their effectiveness in responding to health crises and providing insights for heatwave management. This work explores the potential of further including digital health interventions into European HHAPs. The objective is to identify adaptable digital strategies to mitigate heatwave health impacts. We started by analyzing WHO's guidance on the creation of HHAPs, as well as the European Observatory on Health Systems and Policies' assessment of the four main areas supported by digital health tools during the pandemic. Later, we proposed four main areas where digital health solutions could be efficiently integrated. Each area underwent a rapid literature review to identify digital solutions used during COVID-19, followed by a critical analysis for applicability in heat-health action planning. We identified four areas where the implementation of digital tools should be explored: Communication and Information Dissemination (focusing on raising awareness among vulnerable groups, caregivers, and organizations); Modeling and Forecasting (developing precise forecasts for proactive planning); Health services coordination (among services delivering immediate care during heatwaves); Monitoring and Population Surveillance (implementing strategies to identify and mitigate heat-related risks e.g. among vulnerable populations). Results indicate that digital health solutions from COVID-19 can enhance national HHAPs. Tools for pandemic prevention and response are applicable to extreme weather events. The pandemic's increased digital usage resulted from policy changes and infrastructure investment - leveraging these advancements could prepare Europe for extreme heat threats.

Key messages:

- Results indicate that digital health solutions from COVID-19 can enhance national HHAPs. Tools for pandemic prevention and response are applicable to extreme weather events.
- The pandemic's increased digital usage resulted from policy changes and infrastructure investment - leveraging these advancements could prepare Europe for extreme heat threats.

Abstract citation ID: ckae144.1369
Clean-up actions as catalysts for sustainability and physical activity promotion

Matilde Ourique

GB Rosa[1], *M Ourique*[2]
[1]Exercise and Health Laboratory, CIPER, Faculty of Human Kinetics, University of Lisbon, Lisbon, Portugal
[2]Public Health Unit, Santa Maria Local Health Unit, Lisbon, Portugal
Contact: matildourique@gmail.com

Issue: The convergence of global sustainability and health promotion implies integrated policies and actions. Initiatives like the European Green Deal and the UN's Sustainable Development Goals emphasize the urgent need to address climate change while promoting health through behaviours such as physical activity (PA).

Description: We explore the relationship between PA, sustainability, and health outcomes, highlighting the European Green Deal's impact on PA promotion and the 2030 Agenda for Sustainable Development's alignment with health behaviours. In addition, we further discuss the concept of "green exercise" and provide insights about how eco-friendly initiatives (e.g., plogging) may have dual benefits in both individual and environmental domains.

Results: Emerging eco-friendly activities, including plogging, plalking and pliking, directly benefit the environment, while holding the potential to contribute to PA accumulation. Walking while picking up litter (i.e., plalking) can represent up to 4-5 metabolic equivalents (METs), which corresponds to performing a moderate-intensity PA. If other activities - running or cycling - are performed while picking up litter, the number of METs (i.e., >6 METs) involved may correspond to performing a vigorous-intensity PA.

Lessons: The physiological impact of eco-friendly activities, such as litter picking, reveals their potential as moderate to vigorous-intensity PA, favouring compliance with WHO PA recommendations (i.e., 150 min/week). Integrated policies and actions are needed to address global challenges effectively, emphasizing the interconnectedness of PA promotion, sustainability efforts, and health outcomes.

Key messages:

- Engaging in green initiatives fosters PA and supports the United Nations' goals for health and sustainability.
- Plogging and similar eco-activities offer dual benefits: cleaner environments and healthier lifestyles.

Abstract citation ID: ckae144.1370
Finding cool spaces in Frankfurt/Main–a heat protection measure for the population of a major city

Kirsten Duggan

K Duggan[1], A Christ[1], M Maraslioglu[1], A Sauer[2], B Böddinghaus[2]
[1]Climate, Environment and Health, Gesundheitsamt Frankfurt am Main, Frankfurt am Main, Germany
[2]Hygiene and the Environment, Gesundheitsamt Frankfurt am Main, Frankfurt am Main, Germany
Contact: kirsten.duggan@stadt-frankfurt.de

With the European continent heating up faster than ever, cities are facing major challenges protecting their population from the effects of climate change. Heat can have devastating effects on people's physical and mental health with particular significance for the known vulnerable groups - the elderly and young children, people with pre-existing conditions, those who are pregnant and those who cannot protect themselves sufficiently for various reasons plus of course people working outdoors. Following the 2003 heat wave, the city of Frankfurt/Main registered a significant rise in mortality and morbidity, leading the Health Protection Authority to be increasingly concerned with heat-related health problems in the Frankfurt metropolitan area. The city has since developed various systems to protect the population from extreme heat and developed an all-encompassing climate change action plan (CCAP). Part of the CCAP is the provision of cool spaces to provide refuge from the heat for the public and implementation of this project started in the summer of 2022. However, with no legislative basis on which to build such a platform, some creative measures were required to ensure its success. Here, we will not only present the challenges we faced but the solutions we found - and the results of our currently ongoing evaluation of the actual use of our cool spaces to help other cities make their journey to similar measures easier. Starting with a brief overview of the CCAP, we will show the cool spaces' place within the strategy, followed by our original plan of action and what happened when this plan came into contact with the reality of life in a large and diverse city. We will touch on climate injustice and the difficulties in reaching those parts of the population who actually need protection the most. Finally, we present our evaluation strategy and results together with the adjustments we are considering in moving forward with this climate change protection measure.

Key messages:

- (Establishment of) climate change adaptation measures should urgently be enshrined in law.
- Health inequality corresponds to climate inequality and continiously challenges adaptation measures.

Abstract citation ID: ckae144.1371
Contributing to healthier populations by reducing energy poverty via innovative financial models

Belen Costa Ruiz

B Costa Ruiz[1], R Lucas[1], M Ferrando Garcia[1]
[1]Kveloce, Senior Europa S.L, Valencia, Spain
Contact: bcosta@kveloce.com

Issue/problem: Energy poverty is a major challenge affecting 9.3% of the EU population (EUROSTAT 2022). Health problems attributable to energy poverty include respiratory diseases, heart attacks, stroke, and mental disorders. Governments must act quickly and intervene with policies and programmes that reduce energy poverty and promote citizens' health and well-being.

Description of the problem: We propose Social Impact Bonds (SIBs), a new family of instruments that address serious social challenges, to finance interventions targeting energy poverty,improving the health and well-being of households in a context of limited public resources. For this purpose, data from interventions to increase energy efficiency and combat energy poverty implemented during one year in 6 pilot sites in the framework of the EU project WELLBASED are used. First, a compliance check will be carried out, followed by an estimation of the costs, savings, and benefits of the application of SIBs to finance energy poverty reduction interventions with an impact on health.

Results: The results of the analysis will show whether the intervention to reduce energy poverty meets the necessary characteristics for a SIB to be implemented. In addition, the possible key actors that could lead its implementation are identified.

Lessons: If the interventions for the reduction of energy poverty carried out under the WELLBASED project are successful, SIBs could be considered as a valuable alternative to finance interventions that combat energy poverty and increase the well-being of citizens. Key knowledge on how to apply SIBs makers to tackle a serious social issue with important consequences on health will be at disposal of (EU and worldwide) local authorities and policy.

Key messages:

- Energy poverty is a public health issue, requiring urgent support measures.
- SIBs fund interventions via public-private collaboration to fight energy poverty and boost citizen wellbeing.

Abstract citation ID: ckae144.1372
Urban Green Spaces on Maternal Sleep Quality One Year Postpartum Amid COVID-19 Alert Level Changes

Background: Benefits of green spaces (GS) on sleep quality were found, particularly for mothers, which, in turn, contributed to maternal health and offspring development. However, the COVID-19 pandemic imposed restrictions on environmental access, potentially altering the influence of urban GS on sleep quality. This study aims to explore the impact of urban GS on maternal sleep quality one year postpartum during the pandemic.

Methods: Participants were drawn from the Longitudinal Examination across Prenatal and Postpartum Health in Taiwan study, tracking individuals from early pregnancy across five hospitals in Taipei since 2011. We utilized data spanning from 2019 to 2024, with May 2021 (the initial soft lockdown due to community spread) serving as the cutoff point to delineate early and late pandemic stages. Self-reported sleep quality one year postpartum was assessed using the Pittsburgh Sleep Quality Index. Residential GS was evaluated using the Normalized Difference Vegetation Index (NDVI) within various radii (250m to 2000m). Multiple logistic regression was utilized.

Results: From the 311 participants, in the early stage of the pandemic, an increase of 0.1 units in NDVI within a 250m radius during both prenatal and postnatal periods (0-12 months) was associated with improved maternal sleep quality (OR = 1.57; 95% CI = 1.08, 2.32, and OR = 1.58; 95% CI = 1.07, 2.30) after adjustments. The impact diminished as the radius increased. Additionally, no significant association was found during the late stage of the pandemic across any of the studied radii.

Conclusions: The findings suggest a positive correlation between proximity to urban GS and maternal sleep quality during the early stages of the pandemic, with more significant benefits observed at shorter distances, likely due to restricted movement and access. These results underscore the importance of proximity in urban planning and environmental improvement initiatives aimed at enhancing maternal and child health.

Key messages:

- Urban green spaces significantly enhance maternal sleep quality one year postpartum in the early stages of the pandemic, highlighting the importance of proximity for health benefits.
- As the radius of green spaces decreased, their positive impact on maternal sleep quality during the early pandemic intensified, underscoring the need for adaptive urban planning strategies.

Investigation of Global Climate Change Awareness Levels Among Faculty of Medicine Students

Ali Ozer

S Gündoğdu[1], M Sülü[1], G Boz[2], A Baran[1], A Özer[1]
[1]Public Health, Inonu University Faculty of Medicine, Malatya, Türkiye
[2]Public Health, Ordu Provincial Directorate of Health, Ordu, Türkiye
Contact: aliozer91@hotmail.com

Background: According to the WHO, climate change is the biggest threat to global health in the 21st century. Thus, it is important to understand medicine faculty students'-who are future doctors-awareness of climate change and its effects on human health. The aim of this study is to determine the level of awareness of Inonu University Faculty of Medicine students about global climate change.

Methods: This descriptive cross-sectional study was conducted between February and March 2024. The target population consisted of 1692 students studying in a medical university. The sample size was calculated as 260 students based on a percentage of awareness of global climate change of 32.3%, and 283 respondents were included in the study. A questionnaire was used that included questions about the respondents' sociodemographic characteristics and global climate change awareness. In addition, they answered the items of the Awareness Scale of University Students About Global Climate Change (GCCAS). The dependent variable was total GCCAS scores, and the independent variables included age, concern about climate change, and knowledge status. A Student's t-test was used in the statistical analysis.

Results: Of the students, 50.2% were female, 51.6% were older than 22 years of age, 82% were worried about the negative effects of climate change, 79.5% said they received no education about climate change during their medical education. The mean total GCCAS score in the study group was 71.74 +/-13.81. Women, students who were concerned about climate change, and those who had knowledge about climate change had significantly higher mean GCCAS scores ($p < 0.05$).

Conclusions: More than 75% of study group said that they had received no education about climate change. However, the percentage of students who were aware of and concerned about climate change and who had information about climate change was even higher.

Key messages:

- Due to the potential for medical students to encounter the health effects of climate change, these issues should be included in education programs to increase their awareness of this important issue.
- Medical students need to take conscious and informative steps regarding climate change to help protect the health of future generations.

Abstract citation ID: ckae144.1374
Climate Change, Air Pollution, African Dust Impacts on Public Health and Sustainability in Europe

Ioannis Adamopoulos

I Adamopoulos[1], N Syrou[2]
[1]Environmental Hygiene and Public Health Inspections, Hellenic Republic, Region of Attica, Athens, Greece
[2]Department of Physical Education and Sport Science, University of Thessaly, Trikala, Greece
Contact: adamopoul@gmail.com

Climate change poses a significant threat to environmental sustainability and public health, leading to extreme weather events, rising sea levels, and biodiversity loss. Research on air pollution from African dust adversely associated with climate change highlights its significant role in trapping heat in the atmosphere and causing heat-related illnesses, cardiovascular disorders, and respiratory ailments. Smog, dust, acid rain, and ozone depletion also negatively impact ecosystems. The methods of the study also include the dynamics of climate change-induced air pollution. The implications for public health and environmental sustainability through GWR modeling and MODIS-NDVI analysis of controlling air pollution are crucial for reducing the climate crisis, safeguarding public health, and maintaining ecosystem sustainability. Results from particulate matter (PM 2.5-10), which consists of tiny particles with varying diameters, can enter the respiratory system through inhalation. This can lead to a diameter of less than 10 μm (PM 2.5-10). According to the relevant legislation, the limit value refers to the daily average value and must not exceed 50 μg/m3. While ozone in the stratosphere serves a protective function against ultraviolet radiation, excessive levels at ground level can be harmful and have been recorded in atmospheric samples ranging from 146.6 μg/m3 up to 702.3 μg/m3. impacting the respiratory and cardiovascular systems. Policy leaders, businesses, and individuals need to be proactive in reducing air pollution, adopting clean energy technology, and implementing stricter pollution rules. Stricter pollution rules, environmentally friendly transportation choices, and the adoption of clean energy technology. The sustainability of the ecosystem and public health are significantly impacted by climate change linked to air pollution. To solve these global problems and move toward a healthier, cleaner future for future generations, we must act now on climate justice.

Key messages:

- Examine the impact of African dust air pollution on public health and its significant impacts from climate change, provide solutions to mitigate its effects on environmental sustainability in Europe.
- Public health workers, Policymakers and stakeholders must prioritize reducing emissions and enforcing strict air quality laws to mitigate the negative impact of African dust on European populations.

Abstract citation ID: ckae144.1375
Ensuring sustainable impact of the national report on climate change and health in Germany 2023

Martin Mlinarić

M Mlinarić[1], K Kelleher[1], H Niemann[1], A Taylor[1], T Ziese[1]
[1]Office for Climate Change and Health, Robert Koch Institute, Berlin, Germany
Contact: mlinaricm@rki.de

Issue/problem: The Robert Koch Institute recently coordinated a status report on climate change and health for Germany, detailing the current and future impact of climate change on health through 14 chapters.

Description of the problem: A central aim was to ensure the report's long-term impact and public health value. Essential areas of focus have therefore been stakeholder-specific communication and establishing a network of experts for continued scientific exchange.

Results: The publication of the report as peer-reviewed articles has served to reach the scientific community. Another target group are public health practitioners and decision makers at subnational levels, who can contribute towards climate change mitigation and adaptation measures relevant to health, as recommended in the report. This latter group was reached through various methods and formats of science communication, including conferences aimed at the public health sector, through target-group oriented podcasts, social media engagement and digital town hall discussions. Following publication, the experts involved in writing, reviewing and using the report were invited to establish a network in order to support long-term scientific exchange and collaborations and in turn ensure the report's sustainable impact and value.

Lessons: Through follow-up evaluations, the reception of the report and the further communication needs of this target group were analysed. A major lesson was to include the insights of public health practitioners more systematically and at an earlier stage in any future reports. As for the establishment of a network, a survey amongst the authors and other experts showed what this group considers the goals of this network: creating synergies and connections with existing initiatives and providing a platform for further exchange, especially amongst researchers addressing similar questions, such as the efficacy of mitigation and adaptation measures, from different angles.

Key messages:

- Local public health practitioners are important stakeholders for climate change and health for ensuring public health impact.
- The expertise in the network will support continued scientific exchange on climate change and health and thus ensure the national report's sustainability.

Abstract citation ID: ckae144.1376
Building bridges in Climate Pact activities and Climate Action - example from Serbia

Marija Jevtic

M Jevtic[1,2], C Cattoir[3], V Matkovic[4]
[1]University of Novi Sad, Faculty of Medicine, IPHV, Novi Sad, Serbia
[2]Environmental Health and Occupational Health, Université Libre de Bruxelles, School of Public Health, Brussels, Belgium
[3]Climate Pact, Brussels, Belgium
[4]Lungs Europe, Brussels, Belgium
Contact: marija.jevtic@uns.ac.rs

The European Climate Pact is a movement of citizens united around a common cause, each taking steps in their own worlds to build a more sustainable Europe. Launched by the European Commission, the Pact is part of the European Green Deal and is helping the EU to meet its goal to become climate-neutral by 2050. This work presents examples of activities of the EU Climate pact ambassador in different directions (international and national/local level), with an unique goal, to increase awareness of importance of action, change of mindset, and exchange positive experiences. Climate Action is presented:

- through educational activities in EUGLOH project (European Global Health Universities Alliance) - by organizing Course Climate Action for Health and presenting to students at international level different Climate actions activities.
- engagement of citizens through Rotary Climate Action in RD 2483 and wither in Rotary international community - as citizens activities - Rotary Climate Action with the aim to increase awareness of climate change and health consequences.
- as mentorship activities with PhD students in the field (climate change and air pollution impact on respiratory diseases) - as a research activities.
- as an example of cooperation with media in Serbia - increasing of awareness among journalists.

There are a lot of possibilities to work in the long-term in the community, using glocal principles and trying to find a way to change the behaviour of citizens towards acceptance of climate neutrality as an important goal.

Key messages:

- Climate Action is citizens action.
- Climate action is a way to change the behaviour of citizens towards acceptance of climate neutrality as an important goal.

Abstract citation ID: ckae144.1377
Urban transformation interventions for the promotion of active home-school mobility: overview

Rosella Saulle

R Saulle[1,2], A Perilli[1], L Biscaglia[3], T Kalem[4,2], A Masini[4,2], Z Mitrova[1,2], F Faggiano[4,2]
[1]Department of Epidemiology, Lazio Regional Health Service - ASL Rome 1, Rome, Italy
[2]NIEBP, Italian Network of Evidence Based Prevention, Italy
[3]Lazio Region, Health Promotion and Prevention Area, Rome, Italy
[4]University of Eastern Piedmont, Department of Sustainable Development and Ecological Transition, Vercelli, Italy
Contact: r.saulle@deplazio.it

Background: Active home-school mobility can contribute to a series of benefits, both for the health of children and adolescents (higher levels of physical activity, better cardio-metabolic profile, better school performance), and for the health of the general population and of environment (reduction of air pollution and greenhouse gas emissions). An overview of systematic reviews (RS) was conducted in order to evaluate mainly the effectiveness of interventions promoting active home-school mobility on physical activity, overweight/obesity, well-being and reduction of road accidents in children and adolescents.

Methods: The bibliographic search was carried out on the following databases: Cochrane Database of Systematic Reviews, MEDLINE, Embase and CINAHL, without any limits. Endnote software was used for the systematic reviews (SRs) selection. Data relating to the main characteristics and results of the SRs were extracted. The assessment of the methodological quality of the SRs was carried out using the "Health Evidence^{TM} Quality Assessment Tool".

Results: On the basis of the relevance and adherence to the research PICO, n. 12 systematic literature reviews evaluating effects of interventions of interest in the study population.

The strategies took multiple levels into consideration, i.e. they aimed at organizing the home-school journey to encourage active mobility, as well as training and information aimed at the population under study for the promotion of physical activity.

Conclusions: Combined interventions appear more effective in promoting active home-school mobility with a better impact on increasing physical activity levels. Further high quality studies are necessary to investigate the impact of these interventions also on the reduction of incidence of overweight/obesity and in terms of school performance.

Key messages:

- Policy makers should promote programs to increase active home-school transport.
- Further high quality studies are necessary to investigate the impact of these interventions also on the reduction of incidence of overweight/obesity and in terms of school performance.

Guidance on health promoting and climate-friendly hospitals and health services

Nadine Zillmann

B Metzler[1], *A Ronge-Toloraya*[1], *J Eder*[1], *N Zillmann*[1]
[1]Competence Center Health Promotion in Hospitals and Health Care, Austrian National Public Health Institute, Vienna, Austria
Contact: Nadine.Zillmann@goeg.at

The negative impacts of climate change on health and the healthcare system are becoming increasingly evident. The healthcare sector, which accounts for nearly seven percent of Austria's CO2 emissions, contributes to the exacerbation of climate change on one hand, but is also affected by its consequences on the other. To meet these challenges, it is necessary for healthcare facilities to both adopt climate-protective measures and adapt to the changed conditions. A project launched in 2023, supported by the Austrian Health Promotion Agenda and in cooperation with the Austrian Network of Health Promoting Hospitals and Health Services, has shown that there is a need for support in implementing climate protection measures in healthcare facilities. In response, the WHO Collaborating Centre for Health Promotion in Hospitals and Healthcare, located at the Competence Centre for Health Promotion and Healthcare at the Austrian National Public Health Institute, will work on the development of standards based on international models to support healthcare facilities in the introduction of climate-friendly practices until 2026. The methodology of the project includes the analysis of existing quality criteria and instruments, as well as a modified Delphi process with two rounds of online questionnaires directed at an international panel of experts. After each round, exchange meetings with a smaller group from the panel take place to achieve consensus. Based on the research findings and the Delphi consultations, a draft of standards and an implementation manual will be created. These drafts will be piloted in various healthcare facilities in Austria and other countries to assess their practicability and effectiveness. Following the pilot tests, the standards and the manual will be revised to integrate the practical insights gained. At the time of the conference, the initial results of the Delphi process will be presented, providing insights for the further development of the standards.

Key messages:

- Integrating climate-friendly practices into all aspects of healthcare can reduce its environmental impact, improve health outcomes, and contribute to the broader sustainable development goals.
- Climate-friendly approaches yield significant health, economic, and social co-benefits.

Introduction: Climate change (CC) has been identified as the greatest global health threat of our time. To foster the resilience of our health system and promote sustainable health, it is essential to rely on aware and trained actors. We evaluated the level of awareness, perception, and commitment of health students in France about CC and sustainable development (SD) issues. We also assessed their expectations in terms of initial training on these subjects.

Methods: We conducted an observational, cross-sectional, multicentre study targeting students enrolled in Medicine, Pharmacy, Odontology, Maieutics, Nursing, Physiotherapy, and Medical Electroradiology in the southwest region of France. The questionnaire used was designed to identify the Knowledge, Behaviors, Practices, and expectations on SD and CC during their studies. It was distributed in a format to be completed online in April 2022.

Results: A total of 529/7000 (7.5%) health students participated in our survey. Our results show that students have little perception of the impact of the health system on CC. However, they are already committed to reducing energy (97%) and water consumption (94.5%) and sorting their waste (87.8%) in their daily lives. Among students, 73.6% envision themselves as future actors in sustainable healthcare. Although they expect a strong commitment from their training institution, 92% of them think that students are the most active on these issues. Regarding their training, 83% of them think that it should integrate CC and SD issues, while 58.7% say that they have never dealt with this topic at this stage of their studies.

Conclusions: In France, the initial training of future health professionals must be rapidly adapted and must enable them to acquire the knowledge and skills necessary to understand the health impacts of CC on the one hand and to reduce the impact of the health sector on the climate on the other to build climate resilient and environmentally sustainable health systems.

Key messages:

- French health students appear to be committed to the fight against climate change.
- Initial training of future health professionals needs to be adapted to give them the knowledge and skills to understand the challenges of climate change with health and the health system.

Abstract citation ID: ckae144.1380
The role of Public Health during an emergency: the 2023 flood in the Emilia-Romagna Region

Marco Monti

M Monti[1,2], *M Fabbri*[1], *G Silvestrini*[1], *M Golfera*[1], *R Angelini*[1]
[1]Public Health Department, AUSL Romagna, Ravenna, Italy
[2]Postgraduate School of Public Health, University of Modena and Reggio Emilia, Modena, Italy
Contact: marco.monti@auslromagna.it

Issue: Major meteorological events like floods are a primary issue for public health. In May 2023, the Emilia-Romagna Region (Italy) was hit by a major rainfall: more than 4.5 billion m3 of rainwater, more than 30 rivers overflowed, 36.000 displaced people, 17 casualties. Public health is called upon to mitigate health consequences with an epidemiological approach in the pre-disaster phase to better address the population; through rapid need assessment during the response phase; and through health surveillance and tracking systems in the post-disaster phase.

Description of the problem: A continuous epidemiological approach throughout the emergency was applied. Rescue: coordination for rescue and sheltering of displaced people (especially from flooded healthcare structures); veterinarian intervention for livestock assistance; carcass removal. Assistance: hygienic controls in shelters; distribution of a handbook with instructions for flooded residents and volunteers to prevent potential injuries and infectious disease outbreaks; immunization campaigns, primarily against tetanus and HAV. Health surveillance: monitoring of ER accesses and hospitalizations, notification of communicable diseases, syndromic surveillance. Post-emergency management: VBDs monitoring and preventive treatment, waste management, bathing water surveillance.

Results: A rapid need assessment was critical for the coordinated effort with other intervention forces, like the Civil Protection. A prompt risk communication ensured simple and clear information, mitigating the risks of exposure to floodwater. More than 10.000 vaccine doses were administered. The syndromic surveillance proved valuable in monitoring post-flood health trends.

Lessons: Several measures were implemented thanks to healthcare workers and volunteers. Nonetheless, a better and faster reaction is possible if disaster management protocols are already available. This experience must increase future preparedness of PH services.

Key messages:

- Public health intervention is crucial in all phases of an emergency, to take care of the affected population and to prevent further health issues.
- The public health response needs to be well-timed, long-lasting, and supported by a clear and well-defined risk communication to population and health workforce alike.

Abstract citation ID: ckae144.1381
Extreme Heat and Specific-Cause Mortality during Summer 2018 in Mainland Portugal

Inês Subtil

I Subtil[1,2], *SP Silva*[2], *A Leite*[2,3]
[1]USP Loures-Odivelas, Loures, Portugal
[2]Department of Epidemiology, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
[3]Public Health Research Center, NOVA National School of Public Health, Lisbon, Portugal
Contact: ines.subtil@ulslod.min-saude.pt

Climate change has led to increased frequency and duration of extreme heat periods, impacting human health and mortality. During the 2003 heatwave, it was estimated that there were between 25,000 and 70,000 excess deaths in Western Europe. Specific-cause mortality analysis was conducted in Portugal that year and has not been assessed since. The goal of this study is to estimate the impact of an extreme heat period in 2018 on specific-cause mortality in mainland Portugal. An ecological study was conducted comparing observed and expected deaths, from August 2 to 9, 2018, in Portugal. Two comparison periods were chosen: from July 19 to 26, 2018 (C1) and the average deaths from August 2 to 9 in 2017 and 2019 (C2). Excesses, ratios, and respective 95% confidence intervals were calculated in R. Analyses were stratified by sex, age group, and district. Consistent excess deaths were observed between comparators, showing a greater impact in circulatory diseases (C1: 283, 95% CI: 210; 356 and C2: 239, 95% CI: 164; 314) and respiratory diseases (C1: 98, 95% CI: 55; 141 and C2: 95, 95% CI: 52; 138). Regarding death ratios, with C1, the highest death ratios were observed for exposure to excessive natural heat (50.00, 95% CI: 37.11; 65.92) and ischemic stroke (4.00, 95% CI: 2.07; 6.99). With C2, the highest death ratios were observed for exposure to excessive natural heat (50.00, 95% CI 37.11; 65.92) and atherosclerosis (2.71, 95% CI 1.63; 4.24). The excesses and ratios of deaths were higher in more urbanized districts, females, and age groups above 75 years. The results suggest that the extreme heat in 2018 had an impact on mortality. Elevated death ratios and excesses were observed for various causes of death with considerable statistical magnitude and significance. These findings align with other national and international studies. Public health action is increasingly critical to mitigate the observed rise in mortality during periods of extreme heat.

Key messages:

- Specific-cause mortality analysis during extreme heat suggests a greater impact in circulatory and respiratory diseases, in residents of urbanized districts, females, and individuals of 75+ years.
- Understanding these specific causes can better inform public health actions and planning, thereby mitigating the adverse effects of extreme heat.

[6]Urban Planning Sector, Municipality of Modena, Modena, Italy
[7]Epidemiology Unit, AUSL-IRCCS di Reggio Emilia, Reggio Emilia, Italy
[8]Architecture Department, University of Ferrara, Ferrara, Italy
Contact: montimarco7@gmail.com

Background: As dealing with the complexity of urban living conditions becomes more and more evident and urgent, it is fundamental to promote cross-sectoral interventions that allow cities to become more inclusive and supportive of health. The Emilia-Romagna region, Italy, has promoted a participatory initiative to structurally integrate health into urban planning tools, identifying a framework of tailored urban indicators linked to locally perceived population health issues.

Methods: Through internal discussion and systematic literature research, a set of urban planners, epidemiologists, and public health experts from regional offices, local health services, universities, and environmental protection agencies identified the urban and health dimensions most suitable for embedding population health into city planning. The result was summarised in a preliminary working paper, which included a matrix of associations between urban features and health dimensions framed according to the DPSEEA framework. Its applicability was then tested in a participatory process (March-May 2024) involving urban planners and public health departments of 7 different sized municipalities.

Results: A group of epidemiologists identified local-level computable indicators for the health dimensions already included in the matrix or added at request. Each municipality focused on specific topics based on local priorities: 3 groups assessing their already-approved urban plans and looking for computable urban indicators; the others integrating their under-construction plans with local health indicators.

Conclusions: The need for professional contamination and cross-sectoral interventions is significant. Epidemiological support is pivotal in integrating different professional languages and reading health data. The outputs of this experience will contribute to a technical document outlining how to incorporate health promotion into urban planning tools and practice while actively considering the local context.

Key messages:

- Although the development of a common vocabulary can be difficult, multidisciplinary collaboration is essential in promoting a model for integrating health promotion into urban planning.
- Local municipalities' involvement in the experimentation can improve the model's applicability by taking into account territorial specificities.

Interaction of polychlorinated biphenyls exposure, lifestyle and genetic risk in dyslipidemia

Yuxin Yao

Y Yao[1,2], *J Ma*[1,2], *W Chen*[1,2]
[1]Department of Occupational and Environmental Health, Huazhong University of Science and Technology, Tongji Medical College, Wuhan, China
[2]Key Laboratory of Environment and Health, School of Public Health, Tongji Medical College, Wuhan, China
Contact: yao131434@sina.com

Background: Polychlorinated biphenyls (PCBs) are endocrine-disrupting chemicals that have been associated with various adverse health conditions. However, the interaction effects between PCBs, lifestyle, and/or genetic susceptibility on dyslipidemias are still unknown.

Methods: Six serum PCBs including PCB-28, 101, 118, 138, 153, and 180 were determined in 3,845 participants from the Wuhan-Zhuhai cohort. Dyslipidemias, including hyper-total cholesterol (HyperTC), hyper-triglyceride (HyperTG), hyper-low density lipoprotein cholesterol (HyperLDL-C), and hypo-high density lipoprotein cholesterol (HypoHDL-C) were classified based on serum lipids levels, which were examined by an automatic biochemical analyzer. Besides, we constructed lipid-specific polygenic risk scores (PRS) and healthy lifestyle scores, and used Logistic regression models to explore the relationships of serum PCBs, lifestyle, and PRS with dyslipidemias.

Results: We observed that all six PCB congeners were positively associated with the prevalence of dyslipidemias to varying degrees. In particular, dose-response manners were observed between ΣPCB levels and odds ratios (ORs) of HyperTC, HyperTG, and HyperLDL-C, respectively. Besides, we found that PRSs and unhealthy lifestyles were both positively associated with dyslipidemias. For the combined effect of ΣPCB, lifestyle, and PRS, participants with high ΣPCB, unfavorable lifestyle, and high genetic risk had the highest odds of HyperTC (2.285; 1.533, 3.417), HyperTG (7.944; 5.169, 12.329), and HyperLDL-C (3.523; 2.311, 5.394) when compared with those with low ΣPCB, healthy lifestyle, and low genetic risk.

Conclusions: Our study provided evidence that PCB exposure potentially increases the prevalence of dyslipidemias, which may be exacerbated by genetic susceptibility and unhealthy lifestyles.

Key messages:

- Our results highlighted the importance of reducing PCB exposure, adopting healthy lifestyles for the prevention of dyslipidemia.
- Our work might facilitate the emergence of reducing or regulating PCB pollution to control blood lipids and the resultant dyslipidemia epidemic.

Determinants in disaster preparedness of nurses in the Azores

Andreia Silva da Costa

A Costa[1,2,3], *E Gatinho*[1,4], *P Nogueira*[1,2,3], *R Mexia*[2], *M Arriaga*[2,3], *A Henriques*[1,2,3]
[1]CIDNUR, ESEL, Lisbon, Portugal
[2]ISAMB, FM/UL, Lisbon, Portugal
[3]TERRA, Laboratório, Lisbon, Portugal
[4]Hospital do Divino Espírito Santo, São Miguel, Ponta Delgada, Portugal
Contact: andreiajsilvadacosta@gmail.com

Background: Disasters are situations of complexity and unpredictability, increasingly frequent and more destructive. They require rapid and effective action from different teams from different contexts, with preparation and qualifications for an adequate response to victims, recovering the environment, and restoring living conditions, and nurses play a significant role in these events. Understanding the level of preparedness of nurses for disasters is fundamental for defining the competency framework in the disaster management cycle.

Objectives: To analyze the preparation of nurses in the Azores for a catastrophe.

Methods: A cross-sectional study was performed with 160 nurses from the Azores. The questionnaire validated for the Portuguese population "Disaster Preparedness Evaluation Tool (DPET ®): Preparation of nurses in the face of a catastrophe" was applied. It was approved by the Ethics Committee.

Results: More than half of respondents (n = 137, 71%) indicated that they were not fully prepared to respond to disasters, while 29% (n = 46) acknowledged that they felt adequately prepared. Of the 160 respondents, only 20% (n = 30) participated in the development of emergency plans and only 14% (n = 22) participated in the creation of emergency plans that contribute to improvements at the local level. Training through simulation training was cited as important in disaster preparedness (n = 129, 78%).

Discussion: The present study identified little involvement of RAA nurses in preparing emergency plans and less than half feel poorly prepared in responding to a catastrophe. This finding is consistent with studies by Baker, Alamri, & Aboshaiqah (2019) and Emaliyawati et al. (2021).

Conclusions: This study was conducted in a region prone to natural disasters. It is vital to invest in the training of these professionals throughout the disaster cycle so that they can contribute to reducing the impact that the catastrophe will have on the individual/family and community.

Key messages:

- Strengthening capabilities through regular disaster training based on effective information.
- Low participation in the development of emergency plans that contribute to improvements at the local level.

Background: As the fifth-largest CO2 emitter globally, the healthcare industry must act to mitigate its environmental impact. This includes de-implementing low-value care and adopting eco-friendly innovative treatment alternatives. Our study aims to explore existing research on the environmental effects of these actions and the outcome measures utilized.

Methods: We conducted a rapid scoping review following a pre-published protocol, searching Ovid MEDLINE® and Scopus (Elsevier) from January 2015 to June 19, 2023. Initially, dual abstract and full-text screening was performed, followed by a single review. Data extraction was cross-checked by a second reviewer. Findings were narratively described using summary statistics.

Results: We analyzed 182 articles, primarily life cycle assessments and modeling studies (92 out of 182), with only one study being a randomized controlled trial. The research covered various healthcare practices, including consultation methods/telemedicine (32%), surgical and medical device usage (26%), medication (25%), surgical procedures (19%), as well as diagnostic tests, screening, and imaging (13%). The main sustainability strategies mentioned were 'Rethink' (99%) and 'Reduce' (81%), with 'Reuse' (32%), 'Recycle' (19%), and 'Refuse' (10%) being less utilized. Environmental outcomes reported included global warming (88%), resource consumption (27%), and chemical hazards (23%). Most studies were conducted in Europe (48%), followed by the USA (37%), with 75% published after 2020.

Conclusions: The environmental impact of healthcare is a pivotal area for public health action and fortunately, it is also emerging as a significant research field. Utilizing methodological approaches less common in evidence-based healthcare research underscores the necessity for innovative interdisciplinary collaboration and capacity building. The most pressing research gap lies in the impact of de-implementation strategies ("refuse") targeting low-value care practices.

Key messages:

- Measuring the environmental impact of healthcare demands the development of novel cross-disciplinary research methods and collaborations.
- De-implementing low-value care represents a future win-win scenario for patients, the financial viability of healthcare systems, and global environmental sustainability.

Why greenhouse agricultural workers do not use pesticide protection methods? A case study

Aysegul Ilgaz

A Ilgaz[1], IH Karabiyik[2]
[1]Department of Public Health Nursing, Akdeniz University, Antalya, Türkiye
[2]Department of Public Health Nursing, Afyonkarahisar Health Sciences University, Afyonkarahisar, Türkiye
Contact: aozer2012@gmail.com

Background: Exposure to pesticides in individuals working in greenhouse agriculture is an important public health problem that threatens their health more than individuals working in other agricultural jobs for the same period of time, causing an increase in mortality and morbidity rates. Applying protection methods plays an important role in reducing/preventing exposure-related health risks. It is aimed to explore the reasons why greenhouse agricultural workers do not use pesticide protection methods.

Methods: This case study was adopted the descriptive qualitative approach between February-March 2024. Individual in-depth face-to-face interviews were conducted with semi-structured interviews, resulting in 20 participants. The inclusion criteria for participants include being a greenhouse agricultural worker (at least 1 year), being 18 years of age or older, using pesticides, not using any personal protective equipment, and not engaging in protective behavior. Braun and Clark's (2021) reflexive thematic analysis methodology was used to analyze the data.

Results: In this study generated three main themes and fourteen subthemes. The main themes identified were a) personal attitudes/characteristics b) negative features of the physical environment, c) negative features of personal protective equipment.

Conclusions: The reasons why greenhouse agricultural workers do not use pesticide protection methods are individual attitudes/characteristics such as laziness and not to care about, negative characteristics of the environment such as temperature, humidity and wetness, and negative characteristics of personal protective equipment such as being heavy and inflexibility. Health institutions and health professionals serving in regions where agricultural workers should develop interventional studies, intervention programs and strategies to protect and improve the health of these individuals.

Key messages:

- Greenhouse agriculture workers do not use any of the pesticide protection methods due to individual attitudes/characteristics, negative characteristics of environment and personal protective equipment.
- Health professionals can ensure that greenhouse agricultural workers use pesticide protection methods by increasing their awareness of health risks and planning interventional studies.

Abstract citation ID: ckae144.1387
Air Pollutants and Ovarian Reserve: A Systematic Review of the Evidence

Rodolfo Sardone

R Zupo[1], F Castellana[1], T Nawrot[2], L Lampignano[3], I Bortone[3], OV Giannico[3], A Gruszecka Kosowska[4], R Sardone[3]
[1]Department of Interdisciplinary Medicine, University of Bari Aldo Moro, Bari, Italy

[3]Unit of Statistics and Epidemiology, Local Health Authority of Taranto, Taranto,
[4]Department of Environmental Protection, AGH University of Krakow, Cracow, Poland
Contact: rodolfo.sardone@asl.taranto.it

Background: Growing evidence points to an association between ambient air pollution and decreased human reproductive potential. The aim of this study was to systematically review the association between air pollutants and female ovarian reserve.

Methods: The literature was searched in six electronic databases through August 2023. Screening of the 75 articles retrieved for inclusion criteria resulted in the selection of 12 human observational studies that evaluated the effect of environmental pollutants on markers of female ovarian reserve. The study protocol was registered on PROSPERO (registration code CRD42023474218).

Results: The study design of selected studies was found to be cross-sectional (2 of 10), retrospective cohort (7 of 10), prospective cohort (2 of 10), and case-control (1 of 10). The study population was equally distributed between Asians (60%) and Americans (50%) with an Italian minority (10%). The main findings showed a higher body of evidence for the environmental pollutants PM2.5, PM10, and NO2, while a low body of evidence for PM1, O3, SO2, and a very low body of evidence for benzene, formaldehyde, and benzo(a)pyrene, yet consistently showing significant inverse association data. The overall methodological quality of the selected studies was rated moderated across the 14 domains of the NIH toolkit.

Conclusions: Increased exposure to air pollutants seems to be associated with reduced female ovarian reserve with evidence being strongest for pollutants such as PM2.5, PM10, and NO2. More evidence is needed to draw conclusions about causality.

Key messages:

- Increased exposure to air pollutants seems to be associated with reduced female ovarian reserve with evidence being strongest for pollutants such as PM2.5, PM10, and NO2.
- Global environmental policy programs are urgently needed to reduce the risks associated with reduced fertility such as reduced birth rates or the use of assisted reproductive technologies.

Abstract citation ID: ckae144.1388
Long-term effects of arsenic on glucose-insulin homeostasis: A gene-environment interaction study

Zhang Yongfang

Z Yongfang[1]
[1]Huazhong University of Science and Technology, Wuhan, China
Contact: 799651298@qq.com

Background: Arsenic exposure and genetic factors are associated with an increased risk of type 2 diabetes, yet study of environment-gene interaction on glucose-insulin homeostasis remains scarce. We aimed to investigate the associations and interactions of urinary total arsenic (UTAs) and genetic susceptibility with glucose-insulin homeostasis through a longitudinal epidemiological study.

Methods: A total of 6136 observations (3063 participants) from the baseline, 3-year follow-up, and 6-year follow-up of the Wuhan-Zhuhai cohort were included in this study. In each study period, we repeatedly measured UTAs, fasting plasma glucose (FPG), fasting plasma insulin (FPI), and homeostasis model-assessed insulin resistance (HOMA-IR) and β-cell function (HOMA-β). Polygenic risk scores (PRSs) specific for all traits were constructed by corresponding genome-wide association summary statistics. Linear mixed models were used to assess associations and interactions of UTAs and PRSs with four indicators of glucose-insulin homeostasis.

Results: After adjustment for all covariates, the βs (95% CIs) for the annual growth rates of FPG, FPI, and HOMA-IR were 0.020 (0.008, 0.032), 0.007 (0.002, 0.013), and 0.011 (0.004, 0.017), respectively, associated with each ln-unit increase in UTAs. Compared to subjects with the first-quartile PRS and low UTAs, participants with the fourth-quartile PRS and high UTAs had a 0.029 (0.012, 0.047) or 0.032 (0.012, 0.051) ln-unit increase in the annual growth rate of FPI or HOMA-IR, respectively. UTAs and PRS had significant interactions on the longitudinal progressive increases of FPI and HOMA-IR (P interaction < 0.05).

Conclusions: Arsenic exposure and genetic variants are significantly synergistic risk factors for dysregulation and progressive deterioration of glucose-insulin homeostasis. Our findings emphasize the importance of reducing arsenic exposure to maintain normal glucose-insulin metabolism, especially for those at higher genetic risk.

Key messages:

- Arsenic exposure was associated with annual increased rates of FPG, FPI, and HOMA-IR.
- Arsenic exposure and trait-specific PRSs are synergistic risk factors for glucose-insulin homeostasis impairment.

Contact: b.sezer@maastrichtuniversity.nl

Background: Low socioeconomic position (SEP) is a risk factor for type 2 diabetes mellitus (T2DM). An underlying mechanism behind socioeconomic health inequalities can be stigma, particularly classism. Studying the influence of class stigma in the context of (pre) diabetes and socioeconomic inequalities may shed light on the societal factors influencing diabetes.

Methods: Data from 1947 participants aged 49-88 who participated in the second phase of The Maastricht Study starting between November 2020 and April 2023 were used. SEP (education, income, occupation) and 6-item classism scale were measured through self-reported questionnaires. (Pre)diabetes was measured through an oral glucose tolerance test. We conducted multinomial logistic regression analyses to investigate the associations between SEP, classism, and diabetes status.

Results: 20.9% ($N = 406$) of the study sample had T2DM (Mage=69.8(±6.8) years; 31.3% women). People with low SEP had more often T2DM (e.g., income OR = 2.13, 95%CI:1.54-2.82) and reported perceived classism (e.g., education OR = 2.07, 95%CI:1.33-3.21) than people with high SEP. Classism was not statistically significantly associated with T2DM (OR = 0.78, 95%CI:0.48-1.29).

Conclusions: Social health inequalities are apparent in T2DM; however, our results suggest that class stigma might not be a major factor in underlying processes. Further research can investigate the role of chronic stress and intersection of multiple stigmas.

Key messages:

- The underlying factors behind socioeconomic health disparities are complex. Social and psychological environment in low SEP should be investigated carefully.
- Although low SEP is strongly associated with T2DM and perceived classism, class stigma might not be a major target in explaining socioeconomic pathways in diabetes.

Abstract citation ID: ckae144.1390
Benefits of hypothetical air pollution reduction interventions on NCDs in Belgium

Ingrid Pelgrims

I Pelgrims[1,2], B Devleesschauwer[3,4], J Van der Heyden[3], E De Clercq[1]
[1]Chemical and Physical Health Risks, Sciensano, Brussels, Belgium
[2]Applied Mathematics, Computer Science and Statistics, Ghent University, Ghent, Belgium
[3]Epidemiology and Public Health, Sciensano, Brussels, Belgium
[4]Translational Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium
Contact: ingrid.pelgrims@sciensano.be

Background: The adverse health impact of air pollution on non-communicable diseases (NCDs) is well documented, yet methodological tools for assessing the potential health benefits of interventions are lacking. This study uses a parametric g-computation approach to evaluate the impact of hypothetical interventions targeting long-term air pollution exposure on reducing NCDs prevalence in Belgium, using data from three national Health Interview Surveys (BHIS 2008-2013-2018).

Methods: BHIS data ($n = 27{,}536$) were linked to environmental data at participants' residential addresses. A g-computation approach was used to calculate the potential impact fractions of air quality interventions on several NCDs. Regression models were adjusted for socio-economic, environmental and lifestyle factors. The scenarios involved reducing individual long-term air pollution exposure to WHO air quality guideline levels, followed by investigating dose-response functions through various percentage reductions in air pollution exposure.

Results: Significant associations were found between air pollution and asthma, stroke, and multimorbidity. Adhering to WHO air quality guidelines would substantially reduce stroke risk in Belgium by 0.87% (95% CI:0.38; 1.35) for PM2.5 and 0.32% (95% CI:-0.05; 0.70) for NO2, preventing 63% and 22% of cases, respectively. For asthma, risk reduction was 1.43% (95% CI:-0.53; 3.4) for PM2.5 and 0.83% (95% CI: 0.01; 1.63) for NO2, preventing 27% and 16% of cases, respectively. For multimorbidity, risk reduction was 3.20 % (95% CI: -1.75; 8.16) for PM2.5 and 0.43% (95% CI:-2.03; 2.90) for NO2, preventing 7% and 0.4% of cases, respectively. Results revealed a clear dose-response association between air pollution reduction and the prevalence of stroke, asthma, and multimorbidity in Belgium.

Conclusions: This study demonstrates that air pollution reduction interventions could effectively decrease the prevalence of asthma, stroke, and multimorbidity in Belgium.

Key messages:

- Air pollution reduction interventions could effectively decrease the prevalence of asthma, stroke, and multimorbidity in Belgium.
- The g-computation approach to assess PIF of interventions represents a straightforward approach for drawing causal inferences from observational data.

Abstract citation ID: ckae144.1391
Does perceived neighbourhood social cohesion moderate the effects of demographic changes on health?

Odile Sauzet

O Sauzet[1,2], M Schäffer[1,2]
[1]Bielefeld School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Department of Business Administration and Economics, Bielefeld University, Bielefeld, Germany
Contact: odile.sauzet@uni-bielefeld.de

Small-area characteristics changes over time may be associated with health. Various theories have been proposed to explain small-area effects on health, including those concerning social capital. The effect of small-area demographic changes on health are very little researched and hardly anything is known about their relationship with social cohesion. We use longitudinal data from the German Socio-Economic Panel linked to demographic measures at county level. We explore the association between 5-year changes in the proportion of over 65 and of 18-24 years-old and physical and mental health and the moderating effect of perceived neighbourhood social cohesion (SC) using random intercept models. Control variables include education, income, and relevant baseline measures. Included are all participants with a 6-year continuous exposure to their county of residence. The main outcomes are the physical and mental health components (PCS, MCS) of the SF-12. We included 21,239 persons up to 6 times in 399 counties. 5-year changes in the over 65, of 18-24 and measure of SC are associated to MCS and PCS. Significant interactions between the changes in over 65 and social cohesion are seen for MCS only in rural areas and some interactions are significant for PCS. For MCS there are no interactions between social cohesion and the changes in 18-24. Important interaction effects for PCS: for those exposed to a small decrease in 18-24, an increase in one unit of SC is associated with an increase of 1.71 (95% CI[1.38, 2.03]) PCS units. For those exposed to a large decrease this effect is lower by 0.88 PCS units. Exposition to some demographic changes have the effect to reduce the positive effects of perceived social cohesion on health. Thus, demographic changes appear to be health stressors. The evidence shown by this work need to be further developed by considering smaller scales but the evidence opens up a new range of possible intervention targets to reduce health inequalities.

Key messages:

- County level demographic changes are associated with physical and mental health and certain exposition to changes reduce the positive effects of perceived neighbourhood social cohesion.
- Social cohesion can be an intervention target to reduce small-area health inequalities, population changes can annulate positive effects. This must be accounted for in public health interventions.

Abstract citation ID: ckae144.1392
Long-term exposure to PM2.5 and mortality among Japanese community-dwelling adults

Takehiro Michikawa

T Michikawa[1,2], Y Nishiwaki[1], H Nitta[3], IPHS Ibaraki Prefectural Environmental Health Study Group[2]
[1]Department of Environmental and Occupational Health, Toho University, School of Medicine, Tokyo, Japan
[2]Department of Public Health Medicine, University of Tsukuba, Tsukuba, Japan
[3]National Institute for Environmental Studies, Tsukuba, Japan
Contact: takehiro.michikawa@med.toho-u.ac.jp

Background: Long-term exposure to PM2.5 (particulate matter with a diameter of 2.5 μm or smaller) is a risk factor for mortality and cardiovascular disease including stroke. However, there was limited evidence for the association between PM2.5 exposure and stroke in Asia where the major cardiovascular disease is stroke. Additionally, the causal association between PM2.5 and respiratory disease is still unresolved. The aim of this study was to investigate the association between long-term exposure to PM2.5 and all-cause, cardiovascular, and respiratory disease mortality in a Japanese community-based prospective cohort.

Methods: This study included 46,974 participants (19,707 men; 27,267 women) from the second cohort of the Ibaraki Prefectural Health Study. The participants were followed up from baseline survey (in 2009) to 31 December 2019. We confirmed underlying causes by death certificates. Using the PM2.5 concentrations estimated by the inverse distance weighting methods based on ambient air monitoring data, administrative area level concentrations were

assigned to each participant. The hazard ratios (HRs) and 95% confidence intervals (CIs) of mortality using a Cox proportional hazard model were presented.

Results: We identified 2,789 all-cause deaths during the 470,178 person-years of follow-up. PM2.5 exposure had no significant association with all-cause and cause-specific mortality. The multivariable-adjusted HRs per 1 μg/m3 increase in the PM2.5 concentration were 0.94 (95% CI = 0.80-1.12) for coronary heart disease, 0.92 (95% CI = 0.81-1.04) for stroke and 1.09 (95% CI = 0.97-1.23) for non-malignant respiratory disease.

Conclusions: We observed little evidence of increased risk of all-cause and cause-specific mortality by long-term exposure to PM2.5 whose concentrations ranged from 8.3 to 13.1 μg/m3. A somewhat increased trend for non-malignant respiratory disease mortality may not be negligible.

Key messages:

- We found little evidence of increased risk of all-cause and cause-specific mortality by long-term exposure to PM2.5.
- Somewhat increased tendency for non-malignant respiratory disease mortality associated with PM2.5 exposure was observed.

Abstract citation ID: ckae144.1393
Association of Built Environment with Well-Being: An Experience Sampling Method

Yu-Ru Chen

Y Chen[1]*, A Nakagomi*[1]*, M Hanazato*[1]*, N Abe*[1]*, K Ide*[1]*, K Kondo*[1,2]
[1]Center for Preventive Medical Sciences, Chiba University, Chiba, Japan
[2]Social Insurance and Welfare, Institute for Health Economics and Policy, Tokyo, Japan
Contact: yuruchen9411@gmail.com

Background: Well-being (WB) is important because it extends beyond physical health, as defined by the World Health Organization (WHO). From a temporal perspective, WB encompasses two aspects: long-term WB (LWB), such as overall life satisfaction, and momentary WB (MWB), such as immediate mood. While research has demonstrated a positive association between built environments such as urban land, grassland areas, and LWB, there is limited research exploring the association between the characteristics of built environments and MWB.

Methods: We applied the Experience Sampling Method (ESM) to collect data on the location, detailed environmental characteristics, and the MWB and LWB of adult participants living in Kashiwa City, Japan. Structural equation modeling was used to calculate the correlation coefficients between different built environments and both MWB and LWB.

Results: Nine hundred reports from 273 valid participants were obtained. In terms of types of locations, it was shown that cafes/restaurants/bars (coefficients = 0.85), culture/sport/education facilities (0.45), and public spaces (0.62) have a positive association with MWB. Additionally, environments perceived as natural (0.43), relaxing, and clean (2.31) have a positive association with MWB. Conversely, being on the move (-0.88) and vibrant environments (-0.58) have a negative association with MWB. Moreover, higher LWB levels were associated with higher MWB (0.64).

Conclusions: This study used the ESM to measure MWB and confirmed an association with various built environments. These findings provide guidance for city planning and policies that focus on enhancing urban well-being. This study highlights the benefits of places such as parks and cafes that promote happiness and the need for well-designed transportation and roads. These elements are important for developing urban areas that not only meet residents' physical requirements but also support their emotional and psychological well-being.

Key messages:

- Our findings show that public spaces, cafes, and cultural facilities are significantly associated with MWB, highlighting their role in urban planning as places that promote happiness.
- 'Being on the move' is associated with lower MWB, indicating the need for well-designed transportation and road environments.

Abstract citation ID: ckae144.1394
How characteristics of place affect multimorbidity: a systematic scoping review

Chunyu Zheng

C Zheng[1]*, C MacRae*[2]*, L Rowley-Abel*[2]*, S Arakelyan*[2]*, E Abubakar*[3]*, C Dibben*[1]*, B Guthrie*[2]*, A Marshall*[3]*, J Pearce*[1]
[1]School of GeoSciences, University of Edinburgh, Edinburgh, UK
[2]Usher Institute, University of Edinburgh, Edinburgh, UK
[3]School of Social and Political Sciences, University of Edinburgh, Edinburgh, UK
Contact: C.Zheng@ed.ac.uk

Background: Multimorbidity has become a global public health challenge. Increasing work has identified different individual- and household-level determinants of multimorbidity; however, our understanding of how characteristics of place affect multimorbidity remains limited. This scoping review aims to identify the place-based risk factors of multimorbidity and to synthesis evidence (longitudinal in particular) on how place-based risk factors affect multimorbidity.

Methods: Following PRISMA-ScR guidelines, a predefined search strategy (https://osf.io/bf84m) was run across 7 major databases in 2023, with a double screening and data extraction process. English-language peer-reviewed studies exploring the relationship between place-based characteristics (from neighbourhood to region) and multimorbidity among the general population aged over 18 years old were included from 2010 to 2023.

Results: Out of 7761 records, 129 underwent full-text review, resulting in 76 included studies (15 longitudinal). We identified 12 types of place-based risk factors of multimorbidity, with area-level deprivation/SES, pollution, and urban/rurality most frequently examined. Fairly consistent findings suggested that people in more deprived, polluted, or urbanised areas were more likely to be multimorbid, which may further vary by multimorbidity definitions/measurements. Other place-based risk factors, such as social cohesion and greenspace availability, were linked to different single health conditions, but their associations with multimorbidity were underexplored. Finally, we proposed a potential theoretical framework that links place and multimorbidity through multiple pathways based on the synthesised evidence.

Conclusions: There remains only a partial understanding of how 'place' affects multimorbidity. Future studies should employ more precise measures for both place-based risk factors and multimorbidity and use longitudinal designs and analytical approaches for more causal insights.

Key messages:

- This is the first scoping review that proposed a theoretical framework that demonstrates the links between place and multimorbidity.
- This study will greatly benefit local policymaking and public health intervention initiation.

Abstract citation ID: ckae144.1395
Built environmental characteristics, physical activity in neighbourhoods of Accra, Ghana

Emmanuel Effah

ES Effah[1], A Nai[1], H Bardos[1]
[1]Department of Public Health and Epidemiology, University of Debrecen, Debrecen, Hungary
Contact: sintim.effah@med.unideb.hu

There is increasing evidence that characteristics of the built environment can influence residents' lifestyles, physical activity thereby influencing the development of obesity and non-communicable diseases even in low- and middle-income countries. The aim of this study is to describe the characteristics of the built and the social environment of neighbourhoods of Accra, Ghana, and to explore association between neighbourhood characteristics and the physical activity of the residents. A cross-sectional study was conducted in Accra, 12 neighbourhoods were randomly selected based on high and low values of residential density and socioeconomic status. Sociodemographic, household and neighbourhood information were collected with an adapted questionnaire of NEWS (Neighbourhood Environment Walkability Scale) for Africa. Physical activity was assessed by WHO Global Physical Activity Questionnaire and social cohesion by the Perceived Neighbourhood Social Cohesion Questionnaire. Differences between variables by neighbourhood types were analysed using Chi square test and Kruskal Wallis test. Generalized linear model was performed to determine the association between neighbourhood characteristics and residents' physical activity. The built environmental characteristics of different neighbourhood types and the physical activity of the residents showed significant differences. The associations indicated that individuals living in high residential density neighbourhoods had increased levels of engaging in physical activities. Land use mix, street connectivity, safety, aesthetics and social cohesion of neighbourhoods showed correlation with physical activity of residents. The built environment and social characteristics of neighbourhoods can influence the lifestyle and physical activity of residents in Accra, Ghana.

Key messages:

- High residential density neighbourhoods correlated with higher level of physical activity.
- Land use, street connectivity, safety and aesthetic of neighbourhoods and social cohesion showed correlation with physical activity.

Abstract citation ID: ckae144.1396
Antibiotic resistant Pseudomonas aeruginosa in dental unit waterline: a case study in Milan (Italy)

Michela Consonni

M Tesauro[1], M Consonni[1], G Lodi[1], R Mattina[1], A Bergna[2], G Zehender[2], A Lai[2]
[1]Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy
[2]Biomedical and Clinical Sciences, University of Milan, Milan, Italy
Contact: michela.consonni@unimi.it

P.aeruginosa (Pa) is one of the most serious cause of healthcare-associated bacteremia, well-known for its antibiotic resistance (AR). Pa has often been found in dental unit water representing a great risk in public health. Aims are to evaluate the presence of Pa in dental unit (DU) water and its phenotypic and genotypic properties. Pa isolates derive from a monitoring of DU water in an Italian hospital (Milan). Samples were collected on Monday and on Friday, before the beginning and after the end of activities. Resistant PA strains were characterized by phenotypic method using E-test for 6 different classes of antibiotics, and by genotypic method with Whole-genome sequencing (WGS). Resistance genes were annotated with ResFinder v. 4.5 and Sequence Type (ST) was determined using the PA MLST database. 70/272 strains were identified as Pa and 21 of them were AR to one or more antibiotics. They were detected in 10/44 (22.7%) DUs and 2/4 (50%) control sinks (1-2000UFC/100mL). WGS was obtained for 18 strains. 17 belonged to serogroup O11 and ST667 was prevalent (8/18) followed by ST395 (4/18). At the ground floor ST395 was the most prevalent, followed by ST667 and 260, while, at the first floor, ST309 and 667 were in the two controls and ST667, 3245 and 260 in the other DUs. Resistant genes blaPAO, aph(3')-IIb, catB7 conferring resistance to β-lactams, aminoglycosides and amphenicol, respectively, were observed in all isolates. Only ST3245 strain did not show resistance to Fosfomycin. Genotypic and phenotypic analyses present some discrepancies with the presence of AR genes and no antibiotic resistance detection (4/18) or resistance to other different classes of antibiotics (6/18). The MLST analyses showed a high diversity, with the presence of strains sharing different antibiotic resistance mechanisms in DU water. Detection and analyses by WGS can help to track dissemination of genetic resistance determinants and potential emergence of high-risk clones.

Key messages:

- Phenotypic and genotypic analyses in DU water are needed to evaluate risk for human health, in addition to routine microbial monitoring.
- WGS can help to track dissemination of genetic resistance determinants and potential emergence of high-risk clones.

Abstract citation ID: ckae144.1397
Exploring knowledge, attitudes and practices towards sustainable food aid programmes across Europe

Matina Kouvari

Contact: m.kouvari@prolepsis.gr

Background: Food insecurity has increased following the COVID-19 pandemic and the Ukraine conflict. In some EU high-income countries, more than 70% of food aid users experience food insecurity, highlighting the need for food aid programmes to provide good quality and sustainable services and maximise the social inclusion of food aid users. The aim of this study was to identify areas that can promote sustainability in food aid programmes.

Methods: Knowledge, attitudes and practices towards sustainable food aid were assessed via a quantitative questionnaire. Socio-demographic data were also collected. The survey was translated and disseminated online across 5 EU countries (Austria, Cyprus, Greece, Poland, Portugal), targeting staff and volunteers involved in food aid programmes (20 per country, total $N = 100$). Descriptive statistics were used for data analysis.

Results: Most participants were female (68%), 18-49 years old (87%) and occupied in a NGO (89%) as employee (55%). The mean total knowledge score was 11.8 out of 19 (SD 3.2) with low knowledge (% of correct answers) on household food waste (18%) and environmental impact of cooking appliances (29%). In all countries (except Austria) more than 70% of participants agreed that they can apply sustainability through their work; however, more than 50% agreed that sustainability is not always feasible in food aid programmes. Food loss/waste, access to local food and the economic crisis were the main parameters reported to impact sustainability in food aid

($\geq$70% of N). The most frequently applied practices were storing food according to expiration date, monitoring quantities in food distribution, considering beneficiaries' needs and reading food labels. The least frequently applied practices were composting food leftovers and using energy-efficient methods to distribute food.
Conclusions: Sustainability is considered important; however, more effort is needed to promote and embed sustainability parameters in food aid programmes.

Key messages:

- Sustainability is considered important in food aid programmes; however, more effort is needed to promote and embed sustainability parameters in practice.
- Identifying sustainability areas in food aid programmes can lead to successful educational and training initiatives.

Abstract citation ID: ckae144.1398
Greenspace and mental health research – the question of scale

Hannah-Lea Schmid

H Schmid[1,2], *J Freymüller*[1], *B Senkler*[1,5], *S Lopez Lumbi*[1], *C Hornberg*[1,2], *S Zerbe*[3,6], *T McCall*[1,4]
[1]Sustainable Environmental Health Sciences, Medical School OWL, Bielefeld University, Bielefeld, Germany

[5]Berlin School of Public Health, Charité Universitätsmedizin Berlin, Berlin, Germany
[6]Geography Department, Hildesheim University, Hildesheim, Germany
Contact: hannah-lea.schmid@uni-bielefeld.de

Background: Greenspaces have been proven to promote mental health and wellbeing. Research is conducted in diverse fields with various methods. However, studies and theoretical concepts frequently fail to address or define the scale of the environment in question. Furthermore, the different types of greenspace at the same scale are often inconsistently or inaccurately defined. Such limitations may impede the comparability of results and interdisciplinary understanding. The aims were therefore: 1. To provide a quantitative overview of the combinations of greenspace and mental health measures used at the ecological scales; 2. To embed the results in the existing theoretical background.
Methods: A systematic search and a scoping review were conducted, applying an PEO framework. The data was charted with an extraction table and analysed with regard to the ecological scales which are: landscapes, ecosystems/land-use types, and species/natural elements.
Preliminary Results: Generally, distinct greenspace measures are used at different scales, while the mental health measures do not show such a clear pattern. The "landscape" scale is most often assessed via GIS approaches. The scales "ecosystems" and "species" are mostly investigated via interventions. Overall, the "ecosystems" scale is the most frequent in both research and theory. Qualitative mental health measures often focus on ecosystems. However, the qualitative theoretical concepts are based on landscapes, e.g. Therapeutic Landscapes. Species and natural elements are rarely directly addressed by both studies and theories.
Conclusions: We propose increased attention to the types and scales of green and nature at both the theoretical and the practical research level. Established ecological scales can provide a common basis for interdisciplinary research and improve the comparability of studies. This can elucidate the potential differences in the impact of the diverse forms and dimensions of nature on human health.

Key messages:

- The methods employed to assess the relation between greenspace and mental health vary according to the ecological scale. Ecosystems are the main focus in research and theory, species the least.
- The type and scale of nature should be considered in environmental health research and theory. Established ecological scales can provide a basis for interdisciplinary comparability and understanding.

How social and commercial determinants influence exclusive breastfeeding in the Philippines

Zeyuan Wang

Z Wang[1,2], *E Di Ruggiero*[1], *L Lau*[3], *M L'Abbe*[4]

[2]University of Toronto Scarborough, Scarborough, Canada
[3]International Care Ministries, Manila, Philippines
[4]Nutritional Sciences, Faculty of Medicine, Toronto, Canada
Contact: zey.wang@mail.utoronto.ca

Background: The World Health Organization recommends exclusive breastfeeding (EBF) for the first six months after delivery. However, the EBF rate in the Philippines is only 29%. Existing literature suggests that the influence of infant formula marketing (IFM), communication channels, and traditional health beliefs are possible contributors to low EBF rates, but rare studies have been conducted in low-resource settings.
Methods: : To bridge the gap, 15 barangays in Palawan were selected; 97 interviews were conducted with lactating mothers (LM), health workers (HW), traditional healers, infant formula sellers, and community leaders (CL) to represent different perspectives. The results were coded and analyzed inductively.
Results: LM received EBF information through multiple resources. Poverty, lacking breast milk (BM), EBF education, and health benefits (HB) to infants are top contributors to EBF while maternal employment and no BM are top barriers to EBF. Elders, traditional health beliefs (THB), and the influence of COVID-19 can influence EBF in both directions. LM emphasized more on poverty and elders to EBF while HW and CL emphasized the role of EBF education and HB. Urban LM tend to have more regular EBF education, use pumps when going out, and are more influenced by IFM. LM in remote areas tend to have more THB, have more BM substitutes, and share BM. Social classes, locations, Indigeneity, migration, and poverty are intersectioned to influence EBF.
Conclusions: Multiple social and commercial determinants influenced EBF. LM is facing more challenges to EBF under globalization and capitalism. Remote LM are less benefited from new technologies and policies to promote EBF. Different stakeholders have echo chambers to perceive the determinants of EBF. To improve health equity and EBF, the situations of marginalized people in remote areas should be more considered in policy making. Community building should also be considered differently to assist in EBF.

Key messages:

- The project focuses on social and commercial determinants of exclusive breastfeeding with people in extreme poverty.
- The project includes plenty of Indigenous breastfeeding behavior that are underreported.

Abstract citation ID: ckae144.1400
Thermal indices for evaluating the impact of thermal conditions on human health: a systematic review

Georgios Nikolopoulos

K Pantavou[1], A Fillon[2], L Li[2], Z Maniadis[2,3], G Nikolopoulos[1]
[1]Medical School, University of Cyprus, Nicosia, Cyprus
[2]Department of Economics, University of Cyprus, Nicosia, Cyprus
[3]Department of Economics, University of Southampton, Southampton, UK
Contact: nikolopoulos.georgios@ucy.ac.cy

Background: Thermal indices assess individuals' perception of their ambient thermal surroundings (thermal comfort and heat/cold stress) considering several meteorological factors, such as temperature, humidity, wind, and radiation. As climate change progresses, there is an increased demand for accurately monitoring the association between thermal environment and human health. This study summarizes the available evidence on the association between thermal indices and health outcomes.

Methods: We conducted a systematic search in PubMed, Scopus, and Web of Science until December 31st, 2023, to identify all relevant studies examining the association between thermal indices and health outcomes in outdoor environments.

Results: A total of 5,034 electronic records were screened. Of these, 310 were considered eligible, examining 1,143 associations. Seventeen indices were identified, with 32 (10.3%) articles using more than one index. The most commonly employed index was Apparent Temperature (articles: $n = 141$, 38.2%; associations: $n = 634$, 55.5%). The specific-cause health outcomes examined spanned 18 categories of the International Classification of Diseases. Most associations ($n = 304$, 26.6%) pertained to mortality/morbidity related to diseases of the circulatory system, followed by all-cause morbidity/mortality ($n = 288$, 25.2%). The 48.6% ($n = 556$) of the associations suggested an increased risk of adverse health outcomes when indices increased while 32.5% ($n = 372$) of the associations were non-significant. The 14.2% ($n = 162$) of the associations suggested an increased risk of adverse outcomes when indices decreased while 16% ($n = 183$) of the associations were non-significant.

Conclusions: The relevant literature revealed associations between thermal indices and health outcomes. Therefore, thermal indices, considering several meteorological variables, could be a useful tool for public health planning. However, there is diversity in their methodologies and reporting.

Key messages:
- Summarizing the published evidence regarding thermal indices is expected to attract the interest of public health professionals and policy makers, and enhance their use.
- Implementing integrated methods to monitor the association between thermal conditions and health, including using thermal indices, could be valuable for developing and evaluating policies.

Abstract citation ID: ckae144.1401
Estimation of Environmental Burden of Disease related to Arsenic exposure in European Populations

Carla Martins

R Benchrih[2], J Buekers[3], C Demoury[2], C Martins[1], A Purece[3], ST Thomsen[4], N Waegeneers[2], E De Clercq[2], B Devleesschauwer[2]

[2]Sciensano, Brussels, Belgium
[3]Flemish Institute for Technological Research, Mol, Belgium
[4]Technical University of Denmark, Lyngby, Denmark
Contact: carla.martins@ensp.unl.pt

Background: Arsenic (As) exposure poses significant health risks to exposed populations, with exposure occurring predominantly via diet for the general population as recently referred by the European Food Safety Authority. This study assesses the environmental burden of disease (EBD) for three cancer types related to arsenic, across Europe.

Methods: A literature review was conducted to 1) identify the dose-response function (DRF) to assess the cancer risk in European populations, and 2) define EBD approaches applicable to the available data. Country-specific data (Belgium, Denmark, Portugal) for EBD calculation (exposure, socioeconomic status, health outcomes) were gathered. Disability-Adjusted Life Years (DALY) estimations were performed by calculating attributable cases (AC).

Results: Two main references are used for DRF: the United States Food and Drug Administration DRF for assessing bladder and lung cancer risks, and the United States Environmental Protection Agency DRF for skin cancer. Preliminary results for Belgium indicate that inorganic arsenic dietary exposure ranges from 0.084 [0.080 - 0.088] to 0.102 [0.097 - 0.107] µg/kg body weight per day, varying with education level. Stratified estimates suggest that individuals with higher educational attainment (ISCED levels 5 & 6) have a marginally higher average daily intake of arsenic compared to those with lower educational attainment (ISCED levels 0, 1 & 2). DALY attributable to inorganic arsenic exposure follow the same trend as exposure levels, i.e. individuals with a higher education level bear a higher burden of disease than individuals of the low education stratum. This concerns the three studied cancers.

Conclusions: This study quantifies DALY related to inorganic arsenic from dietary exposure for different European countries. Our findings will contribute to better target public health policies and interventions for arsenic risk mitigation.

Key messages:
- Exposure to inorganic arsenic is confirmed in European countries.
- EBD studies guide action priorities to tackle chemical risk factors.

Abstract citation ID: ckae144.1402
Flatbreads in Kazakh, Kyrgyz, and Uighur Groups and its Role in Sustainable Food System

Zeyuan Wang

Z Wang[1,2], A Sultan[3], S Feruza[4], A Asanaliev[5], G Maimaiti[6]

[4]Foreign Philology and Translation Studies, M.Kh.Dulaty Taraz Regional University, Taraz, Kazakhstan
[5]Department of Plant Science and Plant Protect, Kyrgyz National Agrarian University, Bishkek, Kyrgyzstan
[6]Xinjiang Nomal University, Ürümqi, China
Contact: zey.wang@mail.utoronto.ca

Background: Flatbreads are various types of comparably thin bread and are widespread in a large region. People embed flatbreads with special cultural meanings and adapted local ingredients for baking flatbreads. More attention has been focused on flatbreads in recent years. However, how the cross-border Kazakh, Kyrgyz, and Uighur groups use flatbreads is understudied.

Methods: To understand how the cross-border Kazakh, Kyrgyz, and Uighur groups use flatbreads, the current paper reviews existing English, Mandarin, and some Russian literature to summarize how the Kazakh, Kyrgyz, and Uighur groups use flatbreads.

Results: The results show that these three ethnic groups prepare and use flatbreads in multiple aspects. The Kazakh, Kyrgyz, and Uighur people use 23, 9, and 17 types of flatbreads respectively. The flatbreads used by the Kazakh and Kyrgyz people have more overlapping than those of the Uighur people while the relevant studies of Kyrgyz people are more understudied. This resemblance may be because of the closer nomadic lifestyle and the similar influences of Russia and the USSR. The ingredients of flatbreads are aligned with the local ecosystems and have been evolving consistently in the past centuries because of the changes in technology, politics, lifestyles, health perceptions, acculturation, and globalization.

Conclusions: Because of the eco-friendly features of flatbreads and the widespread use of these foods, flatbreads have a high potential to support a regional strategy for sustainable food system transformation and planetary health along the Silk Road countries. To achieve this goal, more studies should be conducted to contribute missing information about ingredients, cooking methods, features, and regional differences in using flatbreads; more nutritious and bio-diverse recipes of flatbreads and the most eco-friendly cooking energy resources for baking flatbread should be identified; new meanings should be given to flatbreads to promote the use.

Key messages:

- The first study to summarize how Kazakh, Uighur, and Kyrgyz peoples use flatbread.
- Justify a potential to use flatbread for sustainable food system transformation.

Abstract citation ID: ckae144.1403
The Impact of Poor Air Quality on Hospitalisation of Multi-morbid Patients: A Systematic Review

Nehal Hassan

N Hassan[1], L Mohamed[1], A Ahmed[1], C Baxter[1], S Wilson[1], C Tolley[1], A Namdeo[3], R Slight[1,2], SP Slight[1,2]
[1]School of Pharmacy, Newcastle University, Newcastle Upon Tyne, UK
[2]Cardio-thoracic, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, UK
[3]Geography and Environmental Sciences, Northumbria University, Newcastle Upon Tyne, UK
Contact: nehal.hassan@newcastle.ac.uk

Background: Exposure to poor air quality worsen existing health conditions, particularly amongst vulnerable patients, leading to increased healthcare utilization. We conducted a systematic review to explore the impact of exposure to poor quality on healthcare requirements in multi-morbid patients.

Methods: We searched six major databases (Medline via Ovid, Embase via Ovid, Web of Science, CINAHL, Global Health, and Scopus) using search terms grouped into sets relating to 'air pollution,' 'multimorbidity,' "association" and 'hospitalisation.' We were interested in the impact of common air pollutants (PM2.5, PM10, SO2, NO2, O3, and CO) and articles were screened independently by two researchers. The review was registered with The International Prospective Register of Systematic Reviews (CRD42022369757) and followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.

Results: A total of nineteen studies were included. All six air pollutants increased hospitalisation amongst multi-morbid patients, especially those with diabetes and cardiovascular comorbidity. Females and the elderly (>65 years old) were the most vulnerable to the effects of air pollution, with an increase in hospitalisations of 9.23% and 6.35% when exposed to PM2.5 and PM10, respectively. Patients >65 years had a higher likelihood of hospitalisation for ischemic and haemorrhagic stroke when exposed to PM2.5 or PM10 at warm season. Patients (≥70 years) who had cardiovascular and pulmonary comorbidity were 3.9% more likely to be hospitalised for a cardiopulmonary event with a rise in NO2 levels. We found an intersectional effect (referred to as "the CADC effect" - Climatic changes, Air pollutant, Demographics, Chronic conditions) that influenced the likelihood of hospitalisation.

Conclusions: Future research is required to further understand this CADC effect in other high-risk population.

Key messages:

- Females, elderly, those with cardiovascular, and pulmonary comorbidity are at the highest risk of hospitalisation with poor air quality.
- The CADC effect explains the intersectional effect between hospitalisation in multimorbid patients, patients demographics and chronic conditions, and air pollution and temperature effects.

Up to now, studies on environmental, climatic, socio-economic factors, and non-pharmacological interventions (NPI) show diverse associations, often contrasting, with COVID-19 spread or severity. Most studies used large-scale, aggregated data, with limited adjustment for individual factors, and most of them focused on viral spread rather than severe outcomes. Moreover, evidence simultaneously evaluating variables belonging to different exposure domains is scarce, and none analysing their collective impact on an individual level. Our population-based retrospective cohort study aimed to assess the comprehensive role played by exposure variables belonging to four different domains, environmental, climatic, socio-economic, and non-pharmacological interventions (NPI), on individual COVID-19-related risk of hospitalization and death, analysing data from all patients (n.68472) tested positive to a SARS-CoV-2 swab in Modena Province (Northern Italy) between February 2020 and August 2021. Using adjusted Cox proportional hazard models, we estimated the risk of severe COVID-19 outcomes, investigating dose-response relationships through restricted cubic spline modelling for hazard ratios. Several significant associations emerged: long-term exposure to air pollutants (NO2, PM10, PM2.5) was linked to hospitalization risk in a complex way and showed an increased risk for death; while humidity was inversely associated; temperature showed a U-shaped risk; wind speed showed a linear association with both outcomes. Precipitation increased hospitalization risk but decreased mortality. Socio-economic and NPI indices showed clear linear associations, respectively negative and positive, with both outcomes. Our findings offer insights for evidence-based policy decisions, improving precision healthcare practices, and safeguarding public health in future pandemics. Refinement of pandemic response plans by healthcare authorities could benefit significantly.

Key messages:

- Evaluating simultaneously four exposure domains on COVID-19 outcomes informs public health policy for future pandemic management.
- The comprehension of risk factors associated with severe outcomes, such as hospitalization and mortality, is pivotal for planning responses to similar health emergencies in the future.

[4]Department of Health Sciences, University of Florence, Florence, Italy
Contact: gaiasuryalombardi@gmail.com

Background: The climate crisis greatly affects mental health, often leading to climate change anxiety. In Italy, there is a lack of research and school programs to help manage climate anxiety and other climate-related psychological consequences. The aim of the CAMBIO CLIMA project is to evaluate the levels of eco-anxiety and pro-environmental behaviours (PEBS) in a sample of Italian middle and high school students, before and after a tailored intervention on the climate crisis.

Methods: The intervention involves one hundred middle and high school classes from three Italian regions. The students will complete a set of surveys, including psychometric scales and questions on socio-demographic factors and climate change awareness. The students will then participate in a two-hour online workshop. A video will be shown at the beginning to raise awareness about climate change. The instructor will ask the students which solutions could be found to solve specific problems caused by climate change. The instructor will then propose and explain a list of PEBS that students can implement to fight against climate change. Finally, students will be invited to put into action these behaviours. A week after the intervention, students will be asked to take part in a post-intervention survey, completing the same set of questionnaires they completed at enrolment.

Results: Currently, the research team is in the preparatory stage, establishing contacts with schools and organizing materials for the online workshop. The intervention is scheduled for the upcoming school year.

Conclusions: The intervention, focused on enhancing the sense of self-efficacy, is expected to increase the resilience of adolescents, making them less vulnerable to the impact, both direct and indirect, of climate change on mental health. The project is funded by PRIN: PROGETTI DI RICERCA DI RILEVANTE INTERESSE NAZIONALE - Bando 2022 (Prot. 2022N22J5F).

Key messages:
- Climate change has a disproportionate impact on young people.
- It is essential to plan adequate school programs that stimulate the sense of awareness and encourage PEBS simultaneously.

Abstract citation ID: ckae144.1406
Oxidative stress and cytotoxicity of co-formulants of glyphosate-based herbicides in HMWB cells

Khadija Makame

K Makame[1,2], S Masese[1], B Ádám[3], K Nagy[1]
[1]Public Health and Epidemiology, University of Debrecen, Debrecen, Hungary
[2]Doctoral School of Health Sciences, University of Debrecen, Debrecen, Hungary
[3]Institute of Public Health, College of Medicine and Health Sciences, Al Ain, UAE
Contact: khadija.makame@med.unideb.hu

Background: Glyphosate-based herbicides (GBHs) are widely used worldwide because of their effectiveness and low cost. However, there is a growing concern regarding the potential health risks associated with glyphosate exposure. Glyphosate is always marketed in formulations containing ingredients other than the active substance. These co-formulants may have toxic effects on humans and animals. Although several studies have assessed the health risks related to glyphosate, the toxicological effects of the co-formulants must be analysed in more detail to ensure the health and safety of pesticide users and the general population. This study aimed to characterize and compare the cytotoxic effects of co-formulants with those of the active substance and GBH formulations.

Methods: Human mononuclear white blood (HMWB) cells were exposed to varying concentrations (0.1 μM, 1μM, 10 μM, 100 μM, 1 mM, 10 mM) of glyphosate, three GBHs (Fozat 480, Roundup, and Glyfos), and two co-formulants for 4- and 20-hours. Cytotoxicity was assessed using the CCK-8 assay, and oxidative stress levels in HMWB cells were evaluated using the superoxide dismutase (SOD) assay. Cell viability and SOD activity were analysed using a spectrophotometer at 460 nm absorbance.

Results: Glyphosate alone did not significantly affect the cell viability. However, notable cytotoxic effects were observed in response to GBHs and adjuvants at concentrations as low as 100 μM. Furthermore, the Oxidative stress levels in cells treated with GBHs or adjuvants were significantly higher than those treated with glyphosate alone.

Conclusions: These findings suggest that the cytotoxic effects of GBHs are likely attributed to the adjuvants present in the formulations, which promote oxidative stress. Further studies are necessary to evaluate the health risks associated with using glyphosate-based herbicides, and co-formulants should be considered when assessing their safety.

Key messages:
- The safety of GBHs cannot be solely attributed to glyphosate itself but also to the other components in the formulation.
- Toxicity evaluation should take into account not only glyphosate but also the co-formulants present in these herbicides when assessing their safety.

There are still uncertainties around the effects, beneficial and adverse, of water fluoride exposure on bone density and strength. We selected bone mineral density (BMD) for investigation as it is recognized as the major non-invasive indicator of bone strength, representing its clinical assessment standard. The aim of this systematic review and meta-analysis was to characterize for the first time the relation between fluoride exposure and BMD through a dose-response approach, using a one-stage dose-response meta-analysis based on a cubic spline random-effects model. Out of 1201 potentially relevant literature records retrieved, after removing duplicates, title/abstract screening, and full-text evaluation, 16 studies were eligible for this review, 12 of which were also suitable for the dose-response meta-analysis. We observed an almost linear association between fluoride and BMD, yielding a mean difference of 2.60 (95% CI 0.17 to 0.40) at 4 mg/L of fluoride exposure. This pattern was also confirmed for hip BMD (MD = 2.83; 95% CI 0.11 to 0.40 at 4 mg/L). However, sex-specific analyses showed different patterns of association. In males, the relation between fluoride exposure and BMD was almost linear until 0.75 mg/L (MD = 0.24; 95% CI -0.22to 0.37), after which it plateaued. Females showed a slight increased BMD at 1 mg/L (MD = 0.05; 95% CI -0.02 to 0.16) but decreasing values above 2.5 mg/L (MD=-0.22; 95% CI -2.72 to 2.38 at 4 mg/L), with an indication of an inverted U-shaped association. This pattern was clearer when we restricted our analysis to hip BMD (MD=-0.56; 95% CI -2.98 to 1.85 at 4 mg/L). Sensitivity analyses examining both bone-specific BMD and conducting risk of bias assessments are currently underway. Moreover, imprecision of the estimates, especially in stratified analyses, and potential for residual confounding, underscore the need for further prospective studies, to more adequately assess the relation between fluoride exposure and bone density and strength.

Key messages:

- At fluoride exposure below 1 mg/L, we observed a linear correlation between fluoride exposure and increase bone density in the overall pooled dose-response analysis of eligible studies.
- Sex-specific patterns: males show positive response until certain exposure threshold; while females demonstrate an increase only at low doses of exposure and a downward trend at higher exposures.

Abstract citation ID: ckae144.1408
The effect of outdoor air pollution on Alzheimer's disease: a systematic review

Sarah Wilson

S Wilson[1], *G Dhillon*[1], *N Hassan*[1], *R McArdle*[2], *L Su*[3,4], *S Slight*[1]

Air pollution is one of the largest global environmental risks to public health. Over recent years, neuroimaging techniques have started to uncover the detrimental impact air pollution has had on brain health, including the development of Alzheimer's Diseases (AD). We systematically reviewed the literature to evaluate the effects of long-term exposure (months to years) to outdoor air pollutants on the development of AD-like neurology. This review was registered on PROSPERO (CRD42023482979) and followed PRISMA guidelines. Four large databases (MEDLINE, Embase, Scopus, and CINAHL) were searched in November 2023 using terms associated with air pollution, neuroimaging, and AD. Only peer-reviewed primary research articles using neuroimaging data to examine AD-like pathology after long-term exposure to air pollutants (Particulate Matter (PM2.5, PM10), SO2, NO2, O3, and/or CO) were included. Titles, abstracts and full-texts were screened, and included articles were quality assessed using the Newcastle Ottawa Scale. A narrative synthesis was conducted to analyse the studies. Our search yielded 397 results, of which eight articles met our inclusion criteria. Articles focused on changes to white matter (n = 5), cortical thickness (n = 6), and grey matter (n = 2). Exposure to PM2.5 was commonly associated with white matter reductions, and PM10 and NO2 exposure was associated with reduced cortical thickness. The effect of exposure to different outdoor pollution on grey matter was inconclusive, with both increases and decreases in grey matter volume observed. This review highlighted how PM2.5, PM10 and NO2 exposure was associated with neurological changes commonly seen in AD. These findings can be used by policymakers and researchers to identify specific pollutants that need greater restrictions and regulations to improve population health.

Key messages:

- PM2.5, PM10 and NO2 exposure are associated with neurological changes commonly seen in AD.
- Greater restrictions and regulations are needed on specific pollutants to improve population health.

The management of the Post-Consumer Tyres (PCTs) is still a hot topic. In 2021, the 27 EU Member States plus Norway, Switzerland, and the UK discarded 4,200 Ktons of PCTs. The main application of the rubber granules obtained from their recycling is represented by infill material in synthetic turf playgrounds. These widespread installations have become fundamental tools for the promotion of physical activity, especially among children. However, this material is in the spotlight for the presence in its composition of hazardous substances and for the small size of granules, which the European Commission classified as "microplastics". This review aims to clarify the scientific knowledge, focusing on the assessment of the bio-accessibility/availability of hazardous chemicals and the risk assessment for users. Eligible articles reporting original data were identified in CAB Direct, Embase, PubMed, Scopus, and Web of Science. The included articles (preliminary results) variously demonstrated the presence of PAHs, metals, volatile organic compounds, and phthalates in artificial biofluids (n = 9 articles). The risk assessment for these toxicants and the potential cancer risk induction (n = 19), revealed a risk for users from absent or negligible to potential, according to the exposure scenario considered and the relative assumptions, the contaminants, the exposure route, the age of the pitch, and characteristics of the rubber granules such as origin, concentration of the different toxicants, and particle size. The assessment of the potential hazard due to the exposure to artificial sports surfaces is anything but simple. Indeed, the crumb rubber compositions may vary in different settings and over time and can be variously influenced by the climate and environmental conditions, making it difficult to quantify the possible health effects, as well as the specific mixture, the quantities, and sources responsible for them (Funded by LIFE20 GIE FR 282 - RE-PLAN CITY LIFE).

Key messages:

- The bioccessibility of PAHs, metals, volatile organic compounds, and phthalates included in the infill material composition was variously demonstrated in literature.
- The assessment of the potential risks due to the exposure to synthetic turf, revealed a risk from negligible to potential, according to the exposure scenario considered and the relative assumptions.

Abstract citation ID: ckae144.1410
Self-reported health effects from wildfire smoke: A cross-sectional study in New York State

Corinna Noel

CA Noel[1], *E Barrera*[1], *A Hayden*[1], *G Meredith*[1]
[1]Department of Public and Ecosystem Health, Cornell University, Ithaca, USA
Contact: can64@cornell.edu

Background: Wildfires and exposure to wildfire smoke (WFS) are forecasted to increase, in part driven by climate change. As witnessed in 2023, regions in Europe and North America are facing

more sustained periods of poor air quality due to WFS. Growing evidence suggests average daily WFS correlates with morbidity and mortality, but the impact of prolonged WFS exposure remains understudied, especially in areas where WFS is a newer occurrence. We examine associations between consecutive days of WFS experienced and self-reported health symptoms in the northeastern United States.

Methods: This retrospective cross-sectional study explored New York State (NYS) residents' experience with WFS in summer 2023 via an online survey. Participants reported the longest period of consecutive WFS days and symptoms experienced. Log-binomial regression models estimated prevalence ratios (PR) and 95% confidence intervals (CI).

Results: 553 NYS residents were included, representing a healthy, primarily female and White population, ranging from 18 to 86 years. 549 (99.3%) reported experiencing WFS, with the longest period of consecutive WFS days varying ($\leq$3 days: $n = 152$; 4 to 6 days: $n = 255$; $\geq$7 days: $n = 146$). 490 (88.6%) reported $\geq$1 health symptom, with itchy/watery eyes, sore throat, and headache as the most frequent. Compared to $\leq$ 3 consecutive WFS days, symptom prevalence was 9.1% higher for those reporting 4 to 6 days (PR [95% CI]:1.09 [1.00, 1.19]) and 16.7% higher for $\geq$7 days (1.17 [1.07, 1.27]). The trend of increased symptom prevalence with longer WFS periods persisted and was pronounced for specific symptoms. Control for potential confounders did not appreciably change estimates.

Conclusions: Our findings suggest longer sustained WFS exposure associates with higher symptom prevalence, which may be precursors to more serious health conditions. As global populations face more WFS with climate change, public health professionals should prioritize strategies to mitigate prolonged exposure.

Key messages:

- In a convenience sample of 553 primarily healthy New York State residents, 99.3% reported experiencing wildfire smoke and 88.6% reported at least 1 symptom of poor health during summer 2023.
- Associations between consecutive days of wildfire smoke experienced and prevalence of any and specific symptoms tended to vary in a dose-response manner.

Abstract citation ID: ckae144.1411
Sanitary Surveillance Program for pools in Matosinhos, Portugal

Rachel Barbabela

R Barbabela[1], MA Maia[1], AS Jesus[1], C Abreu Gomes[1], JG Silva[1], M Balazeiro[1], F Sousa[1], G Duarte[1], A Fernandes[1], D Queiroz Almeida[1], D Penedos Oliveira[1], V Pinheiro[1], N Rodrigues[1]
[1]Public Health Unit, Matosinhos Local Health Unit, Matosinhos, Portugal
Contact: rachel.barbabela@gmail.com

The use of pools for sports, recreational, and therapeutic activities has increased over time. It is important to ensure and control the quality of the water and surrounding areas, as well as the hygienic-sanitary conditions of these spaces. The '2018 Pool Sanitary Surveillance Program' of the Portuguese Northern Regional Health Administration proposes the surveillance of water quality, teaching accessories, and surfaces. The aim of this investigation is to conduct microbiological analysis of the teaching accessories and surfaces in public pools in the municipality of Matosinhos and assess if this program has improved the results for water quality, teaching accessories, and surfaces from 2018 to 2023. The environmental health team of our Public Health Unit performed swabs of the teaching accessories and surfaces of all seven public pools in Matosinhos for microbiological analysis. The swabs were performed in 2018 (21), 2019 (48) and 2023 (42). During each visit, three random points were selected for analysis. In 2019, 31 rugs (64,6%) were analysed, but in 2023 only 10 (23,8%) were rugs. It was found that rugs had the highest contamination by P. aeruginosa (94,4%), fungi (60,8%), and the only sample with coagulase-positive Staphylococci. There was a decrease in samples from twelve to six with P. aeruginosa and an increase from 22 (46.8%) to 29 (69.0%) with fungi from 2019 to 2023. Bacterial colonies grew in 20 samples (95.2%) in 2018, 44 (91,6%) in 2019, and 42 (100%) in 2023. All water samples collected for the evaluation of microbiological parameters outlined obtained compliant results. Fungal and P. aeruginosa detection indicate a potential risk to the health of pool users. A quality report with corrective measures was produce for each pool in each visit. Surveillance of pool water, teaching materials and surrounding surfaces, is crucial to ensure water quality and safety. By doing so, we may lower the risk of disease transmission and protect the population's health.

Key messages:

- To ensure the safety of pool users is a public health challenge. It would be relevant to have legislation that addresses this issue.
- To survey pools and its surroundings and accessories must be a continuous task, allied with literacy to management and users.

[4]Comprehensive Health Research Center, NOVA University Lisbon, Lisbon, Portugal
Contact: gomes.lr@gmail.com

Background: Mercury (Hg), a global pollutant, poses risks to both human and environmental health. The management and recycling of electrical and electronic waste (e-waste) is recognized as having the potential to promote workers' exposure to this pollutant. Human biomonitoring (HBM) is a tool that can be used to evaluate exposure and monitor the health of workers. The objective of this study was to characterize exposure of workers from an e-waste recycling company and to analyze the relevance that HBM holds in the detailed characterization of exposure.

Methods: A cross-sectional observational study was conducted using data collected within the framework of the European Human Biomonitoring Initiative (HBM4EU). Data from environmental monitoring (settled dust) and biological monitoring (urine and hair) of 30 workers potentially exposed to Hg were analyzed in comparison with 12 unexposed workers from other occupational settings (controls).

Results: Exposed workers did not exhibit significantly higher concentrations of Hg in urine when compared to control workers. We found a significantly positive correlation between the concentration of Hg in urine ($\rho = 0.688$; $p \leq 0.001$) and hair ($\rho = 0.470$; $p \leq 0.01$) and the consumption of fish and shellfish.

Conclusions: Diet appears to be the most significant source of Hg in this context. These results suggest the importance of information and dietary habits to prevent mercury exposure. HBM stands out as an essential tool for identifying the most relevant exposure sources and risk management measures for workers and the general population.

Key messages:

- Diet appears to be the most significant Hg source in workers from a Portuguese e-waste company.
- HBM stands out as essential for identifying the most relevant exposure sources and risk management.

Abstract citation ID: ckae144.1413
Attitude of Romanian students and their families concerning waste management

Ileana Prejbeanu

I Prejbeanu[1,2], *ME Dina*[4], *DF Prejbeanu*[3]
[1]Environmental Health Department, University of Medicine and Pharmacy, Craiova, Romania
[2]Radiation Hygiene Department, Public Health Authority, Craiova, Romania

[4]Oncology Institute, Bucharest, Romania
Contact: ileana.prejbeanu@gmail.com

Waste recovery, recycling included, is an important step in waste management, preceding final disposal. In 2018, according to Eurostat, the recycling rate of municipal waste was 47% in the European Union and only 11.1% in Romania. Thus governmental institutions have implemented new measures in order to reduce environmental pollution by ineffective waste management. In 2022, 535 students aged 22-24.5 years, males and females, studying in Craiova (one of the six largest academic cities of Romania), were asked to answer an 18-item questionnaire regarding their and their families' attitude towards waste recycling. Most of the students (60.7%) were residents in the university city, while the others - in smaller cities or in villages of the region. Only 38.3% of the subjects ($N = 205$) declare their families recycle waste; the most common excuse for no-recycling (37.8%) is the lack of recycle bins in the house proximity. Only 20 families (3.7%), all of them living in Craiova, take the fried oil to collecting points in supermarkets; most of the others eliminate it in the sewerage system, especially those from outside the city ($p < 0.01$). Seventy-five students (14%) are not able to mention any recent measure taken by the government in order to reduce plastics environmental pollution; the others discuss about the increased number of recycle bins around the city (53.2%), recycling of single-use plastics (34.5%) or use of biodegradable bags (25.2%). No-recycling (42%), using daily his/her own car (18.7%, $p < 0.01$ males vs. females), using too much plastics (11.2%) are the most frequent self-reported students' disregards for the environment. Most of the subjects consider environmental health of essential importance (88.7%) and would like to participate in environment protection actions (92.5%). Romanian students seem to have a positive attitude and like to be involved in the environment protection, without a significant influence regarding the gender and the residence place.

Key messages:
- Education and information are essential tools to make people ecologically aware.
- Recycling is one of the best ways to have a positive impact on both natural and community environment.

Abstract citation ID: ckae144.1414
School canteens healthier for children and the planet in the Valencian Region

Ana Boned-Ombuena

H Muelas[1], *J Quiles*[2], *A Boned-Ombuena*[2], *P Vicent*[3], *P Hernández*[3], *P Taut*[4], *R Sánchez-González*[4], *E Navarro*[5], *A García*[6], *M Garcia-Sierra*[1]

Contact: anaboned@hotmail.com

Issue: SchoolFood4Change (SF4C), an EU Horizon 2020 project in 12 EU countries, aims at making school meals healthier for children and the planet through innovative and sustainable food procurement, promotion of planetary health diets and cooking, and a Whole School Food Approach. In the Valencian Region two subsequent market dialogues (MDs) were organised to explore a new school food procurement and feeding model.

Description: In our context, most children have lunch at school daily. SF4C sees schools as catalysts for a systemic change. Two intersectoral MDs were conducted with the participation of public authorities, food procurers, cooks and schools. The first one MD1, 23 attendees, used a gamification dynamic through building blocks. MD2, 58 participants, used a World Cafe methodology to analyse nutritional, environmental, educational, social and economic determinants.

Results: MD1 highlighted the need to increase food education in the curricula, value regional products and cuisine, improve culinary training and reduce food waste. It suggested establishing percentages of local and organic products in tenders and improving communication between the public administration and the educational community. MD2 emphasised the objective of promoting the Mediterranean diet and sustainability in canteens. To that end, participants identified the importance of establishing requirements in public tenders, annual planning of procurement, optimising logistics and integrating the canteen into the educational project. This would enhance predictability, economic sustainability, and social support for a new innovative model.

Lessons: Structured interaction between stakeholders was essential to devise innovative and sustainable solutions. The creation and dynamization of intersectoral working groups is an effective public health strategy to build networks for the co-creation of viable alternatives to achieve a healthier and more environmentally sustainable school feeding.

Key messages:
- Structured interaction in intersectoral working groups is an effective public health strategy for the co-creation of viable alternatives to make school feeding healthier for children and the planet.
- Tailored innovative and sustainable solutions entail a framework for structured discussions, specific context analysis, negotiations between stakeholders and locally adaptation of good practices.

[2]School of Specialization in Hygiene, Department 'GF Ingrassia', University of Catania, Catania, Italy
[3]Nephrology, Department of Clinical and Experimental Medicine, University of Catania, Catania, Italy
Contact: mfiore@unict.it

Background: Hemodialysis (HD) may contribute to microplastics (MPs) burden in dialysis patients. The aim of the study was to estimate any differences in exposure to MPs between cases (on dialysis patients) and controls (not on dialysis patients), investigating any sex differences.

Methods: We organized a case-control study. Both cases and controls were recruited at the Policlinic "G. Rodolico-San Marco" Hospital Nephrology Unit. Preparation and determination of MPs smaller than 10 µm in blood samples were carried out using a patented method (Italian Patent n. 102018000003337-07 March 2018, European Patent n.3788344 20 July 2022) and SEM-EDX electron microscopy analysis, respectively.

Results: A convenience sample was recruited including 15 dialysis (60.0% women) and 10 not on dialysis patients (60.0% women) with a median (IQR) age of 77.0 (59.0-83.0) in dialysis patients and 65.5 (49.3-79.0) in those not on dialysis. No significant differences were found between cases and controls on the consumption of bottled water (100% vs 80%, $p = 0.07$), bagged foods (93.3% vs 70%, $p = 0.12$) unlike the use of drugs (100% vs 70%, $p = 0.02$). Women in general declared a greater use of drugs than men (F 93.3%, M 80.0%, $p = 0.32$). Dialysis patients had higher MPs levels than non-dialysis patients [9132(4896-15847) vs 3554(1661-7340), p-value=0.06]. In particular, female dialysis patients had values comparable to males [9132 (4665-17205) p/d vs men: 10438 (3672-16699) p/d] while non-dialysis female patients had higher levels than males [3274 (1681- 7814) p/g vs 1661 (1661-3354) p/g]. No difference was detected about the diameter of the MPs (IQR) [dialysis patients 4.28 (3.72-4.66) μm vs non-dialysis patients [4.67 (4.15-5.08) μm].

Conclusions: Future studies must focus on studying the relationship between exposure to MPs and their levels in dialysis patients as well as investigating the differences between men and women and the possible consequences of dialysis as a further source of exposure.

Key messages:

- On dialysis patients, both men and women, had higher MPs exposition compared to not on dialyzed ones.
- Not on dialysis women had higher MPs levels than not on dialysis men.

Abstract citation ID: ckae144.1416
Long-term ozone exposure and asthma: a systematic review and meta-analysis

Hamid Y Hassen

HY Hassen[1], P Charalampous[2], A Luyten[3], C Martins[4], S Breitner-Busch[5,6], B Devleesschauwer[7,8], JA Haagsma[2], J Buekers[1]

[6]Helmholtz Zentrum Muenchen - German Research Center for Environmental Health, Neuherberg, Germany
[7]Sciensano, Brussels, Belgium
[8]Ghent University, Merelbeke, Belgium
Contact: hamid.hassen@vito.be

Background: Ambient air pollution, particularly surface ozone, is a significant global health concern, with 9 out of 10 people exposed to levels exceeding WHO guidelines. This exposure is linked to approximately 7 million premature deaths annually, a number expected to double by 2050. While the effects of short-term exposure to ozone on exacerbation of asthma symptoms and mortality are well-documented, the impact of long-term exposure remains unclear.

Aim: This systematic literature review aims to quantify the association between long-term exposure to ozone and asthma incidence and prevalence and derive an exposure-response relationship.

Methods: International electronic databases, including PubMed, Embase, Cochrane Central Register of Controlled Trials, and Web of Science, were searched, supplemented by grey literature sources such as Google Scholar and WHO - Global Index Medicus from conception to July 31, 2023. Observational epidemiological cohort, case-control, or cross-sectional studies reporting quantitative associations between exposure and outcome were included. Meta-analysis will synthesize effect size estimates using a Meta-Regression - Bayesian, Ensemble, Regularized, Trimmed (MR-BRT) model.

Results: A total of 5,947 titles were initially identified from databases, and following the removal of duplicates, 3,235 titles and abstracts were screened, resulting in 84 articles deemed eligible for full-text review. The full-text screening identified 29 studies comprising 38 articles. A comprehensive overview of the included studies will be provided. We will describe the study settings, design, and measurement methods used by the identified studies. Furthermore, results of the MR-BRT model will be summarized, and exposure-response functions will be discussed. Funding: This work is part of the BEST-COST project which is funded by the European Union's Horizon Europe programme under Grant Agreement No.101095408.

Key messages:

- This research fills the gap in understanding the association between long-term exposure to ambient ozone and asthma incidence and prevalence.
- Developing exposure-response functions would enable estimation of the disease burden associated with long-term ozone exposure.

Abstract citation ID: ckae144.1417
Distribution of the Culex pipiens mosquito in mainland Portugal: a geospatial modelling study

Júlia Martinho

J Martinho[1,2,3], H Osório[3], F Amaro[3], M Silva[3], L Zé-Zé[3], MJ Alves[3], B Nunes[2], P Soares[3]
[1]Lezíria Public Health Unit, Lezíria Local Health Unit, Santarém, Portugal
[2]National School of Public Health, NOVA University Lisbon, Lisbon, Portugal
[3]CEVDI, National Institute of Health Dr. Ricardo Jorge, Águas de Moura, Portugal
Contact: juliamartinho94@gmail.com

Background: The mosquito Culex pipiens is a vector for several pathogens, such as the West Nile virus. As the most abundant mosquito in Portugal, understanding its spatial distribution can support vector-borne diseases control and robust public health planning, given the mainland's favourable climate for this vector. Information on its spatial distribution at a national level is limited, especially its association with climate variables. Thus we aimed to predict the suitability of Culex pipiens distribution in mainland Portugal, considering climate factors.

Methods: We used presence records for adult and larvae of Culex pipiens mosquitoes sampled across mainland Portugal from January 2017 to October 2023, as part of the Portuguese Vector Surveillance Network program (REVIVE). Between May-October, in random locations and throughout the year in point-of-entry sites, adult mosquito collection used CDC light traps and BG-Sentinel traps, and larvae collection used dippers in breeding sites. Sampling bias was corrected by filtering presence sites, retaining one record per each cell grid of 1 km2. Climatic data (including temperature, precipitation and elevation) were used as predictors in a maximum entropy (MaxEnt) model of the Culex pipiens geographical distribution.

Results: From the dataset of 6859 records, 1416 unique sites were obtained after filtering. Suitable habitats seem to be mainly distributed on the coast, particularly in Minho, Porto and Lisbon metropolitan areas, and Tagus Valley, with precipitation as the most important predictor.

Conclusions: Most West Nile Virus case reports come from the south of Portugal, but the potential distribution of Culex pipiens covers the whole mainland territory, with seemingly higher distribution on the north coast. However, bias due to convenience sampling could be present. West Nile vector surveillance should be a priority across all regions to accurately assess transmission risk and implement effective control measures.

Key messages:

- The suitability of Culex pipiens distribution covers the entire mainland of Portugal, with higher presence in the north.
- The distribution of Culex pipiens in the country points towards a need for developing region-specific strategies regarding West Nile Virus prevention and control.

Abstract citation ID: ckae144.1418
The burden of lung cancer attributable to ambient PM2.5 exposure: a systematic literature review

Mariana Corda

M Corda[1,2]*, M Clemente*[3]*, J Oliveira*[1]*, J Morgado*[3]*, H Redondo*[4]*, P Charalampous*[5,6]*, JA Haagsma*[6]*, S Pires*[4]*, C Martins*[2,3]*, R Assunção*[1]

[6]Department of Public Health, Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands
Contact: mcorda@egasmoniz.edu.pt

Background: Lung cancer is recognized as one of the most common causes of cancer morbidity and mortality worldwide and is the second cause of death with highest years of life lost in highly developed regions. Ambient exposure to particulate matter (PM2.5) is the leading global environmental risk factor. Long-term exposure to PM2.5 is associated with several health outcomes, including lung cancer, ischemic heart disease, and chronic obstructive pulmonary disease.

Aim: To review and estimate the impact attributable to PM2.5 exposure due to lung cancer.

Methods: A systematic review and a meta-analysis were conducted to determine whether long-term exposure to PM2.5 increases the risk of lung cancer and to derive exposure-response relationships between PM2.5 and lung cancer. The literature search was performed in databases (i.e., Pubmed/Scopus) and studies published from January 1, 2010 onwards were considered. Studies describing the association between long-term exposure to the pollutant under research and the incidence, prevalence, and mortality of lung cancer, considering a relative measure of association were included, with no restriction in geographical area.

Results: In the literature review, 2215 articles were considered for the first step of data synthesis, all articles were screened, considering the screening of titles (first step), abstracts (second step) and full-text (third step) considering the inclusion criteria. In a second step the data was extracted from the included articles ($n = 129$) and considering the variables related to the characteristics of the study and the study population, exposure, and outcome measurement, and details of risk of bias assessment.

Conclusions: These findings provide data to synthesize effect size estimates using a Meta-Regression - Bayesian, Ensemble, Regularized, Trimmed (MR-BRT) model, important to provide evidence data on the impact of air pollution on human health, which is crucial for decision-making.

Key messages:

- Long-term exposure to PM2.5 increases lung cancer risk so the estimating of the impact of the exposure is an urgent need to provide evidence-based data for air quality improvement.
- Meta-analysis aims to establish a relation between PM2.5 exposure and the burden of lung cancer.

Contact: tommaso.filippini@unimore.it

Background: A few studies have suggested that exposure to lighting during night hours, i.e. light at night (LAN), may increase the risk of dementia. In this study, we aimed to evaluate the association between exposure to outdoor artificial LAN and risk of conversion to dementia in an Italian cohort of subjects with mild cognitive impairment (MCI).

Methods: We recruited subjects with a diagnosis of MCI at the Cognitive Neurology Clinic of Modena Hospital in the period 2008-2014, and we followed these subjects up to 2021 for conversion to dementia. We collected their residential history and we assessed LAN exposure at subjects' residences using satellite imagery data available from the Visible Infrared Imaging Radiometer Suite (VIIRS) for the period 2014-2022. Using a Cox-proportional hazards model adjusted for relevant confounders, we computed the hazard ratio (HR) of dementia with 95% confidence interval (CI) according to increasing LAN exposure through linear, categorical, and non-linear restricted-cubic spline models.

Results: Out of 53 recruited subjects, 34 converted to dementia of any type including 26 Alzheimer's dementia. In linear regression analysis, LAN exposure was positively associated with dementia conversion (HR 1.03, 95% CI 1.00-1.06 for 1-unit increase). Using as reference the lowest tertile, subjects at both intermediate and highest tertiles of LAN exposure showed increased risk of dementia conversion (HRs 2.26, 95% CI 0.88-5.85, and 2.89, 95% CI 1.10-7.58). In spline regression analysis, the risk linearly increased up to a LAN exposure of 30 nW/cm2/sr, above which a plateau seemed to be reached. Results were almost confirmed when limited to conversion to Alzheimer's dementia, except for an almost linear relation.

Conclusions: Our findings suggest that exposure to outdoor artificial LAN may increase conversion from MCI to any type of dementia, especially above 30 nW/cm2/sr, while such relation appears to be almost linear for Alzheimer's dementia.

Key messages:

- Light at night exposure above 30 nW/cm2/sr was associated with risk of conversion to dementia.
- Light at night showed almost linear association with risk of conversion to Alzheimer's dementia.

Abstract citation ID: ckae144.1420
Fluoride exposure and risk of fractures: a systematic review and dose-response meta-analysis

Inga Iamandii

I Iamandii[1]*, R Mazzoli*[1]*, L De Pasquale*[2]*, M Vinceti*[1,3]*, T Filippini*[1,4]
[1]CREAGEN, University of Modena and Reggio Emilia, Modena, Italy
[2]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

Contact: i.iamandii@unimore.it

Introduction: Fluoride (F) is a widespread natural element, whose exposure occurs mostly through drinking water, fluoridated foods and use of toothpastes. At high levels, it may adversely affect human health by altering thyroid and cognitive function in children, and inducing dental and skeletal fluorosis. Since bone health significantly impacts quality of life, we performed a systematic review and meta-analysis to evaluate the effect of F exposure on risk of bone fractures.

Methods: We conducted a literature search in online databases and selected studies that were carried out in humans and reported risk estimates with 95% confidence intervals for bone fractures according to F exposure. We eventually performed a meta-analysis using a random effects model, comparing the highest versus the lowest exposure, and one-stage dose-response model, to explore the shape of the association.

Results: Of the 1052 potentially eligible articles, 28 were included in the quantitative analyses. Most studies were conducted in adults (n = 26) and in Western countries (North America=16, Europe=11) and assessed fluoride exposure in drinking water, urine, serum, toenail or diet. The preliminary dose-response curve showed a positive non-linear relation between F exposure through drinking water and bone fracture risk, regardless of site, starting at 1.5 mg/L. Sex-stratified analyses, based on a lower number of studies, showed similar trends, with an indication of higher susceptibility in males compared with females.

Conclusions: Overall, risk of bone fractures appears to non-linearly increase along with exposure to fluoride in drinking water, regardless of bone site and sex, at levels of exposure above the WHO standard and similar to those that have associated to altered thyroid and cognitive function. Under a public health perspective, fluoride in drinking water should be kept below 1.5 mg/L to prevent bone fractures.

Key messages:

- Our analysis revealed a positive non-linear association between fluoride in drinking water and bone fracture risk.
- Public Health actions should be oriented in keeping fluoride in drinking water below 1.5 mg/L to prevent bone fractures.

Background: The aim of our study was to determine the amount of mercury in Chamomile. In certain parts of Slovakia, such as Middle Spiš region in Eastern Slovakia, there has been reports of higher concentration of mercury in the soil. Heavy metals, including mercury, can enter human organism by ingestion. In case of using Chamomile infusions orally there is a risk of administration of mercury into the organism through digestive system.

Methods: We monitored mercury presence in Chamomile (Matricaria chamomilla) (n = 20) and the soil. We determined the mercury concentration by using the flameless atomic absorption spectrometer - Advanced Mercury Analyzer (AMA-254).

Results: Chamomile: The lowest concentration was in the roots (0.513 mg.kg^{-1}). The second lowest was in the flower stem samples (1.105 mg.kg^{-1}). The concentration of mercury was higher in the leaves (2.205 mg.kg^{-1}). The highest was measured in the flower (2.541 mg.kg^{-1}). Soil: The mercury content in soil in the entire territory of Slovakia is higher compared to the soil in the world. During our measurements, the concentration of mercury in the soil samples in the territory of Middle Spiš ranged from 100 to 500 mg.kg-1.

Conclusions: We have to take into account that the quality and contents of the soil are important for the crops, as it will entail their contents. With the knowledge of exceeded norms of mercury content in Slovak soils, it is crucial to monitor the mercury concentration in plants that are harvested there.

Key messages:

- In the examined samples of Chamomile we found mercury, with its highest concentration in flowers and lowest in roots.
- In the regions with significant mercury contamination it is crucial to monitor mercury content in harvested plants and to be cautious in regards of their consumption.

Health burden and economic costs of vector-borne diseases in Italy: the AUSL Romagna case

Marco Monti

M Monti[1,2], *M Golfera*[1], *P Angelini*[3], *M Soracase*[3], *R Angelini*[1]
[1]Public Health Department, AUSL Romagna, Ravenna, Italy
[2]Postgraduate School of Public Health, University of Modena and Reggio Emilia, Modena, Italy
[3]Public Health Service, Emilia-Romagna Region, Bologna, Italy
Contact: marco.monti@auslromagna.it

Introduction: Vector-borne diseases (VBDs) are a serious threat for global health, representing around 17% of communicable diseases and more than 700.000 deaths every year. In Europe, and especially in Italy, this is a subject of growing concern, due to the increase of VBDs outbreaks that need vector control plans.

Objectives: Evaluate the 2013-2022 trend of VBD outbreaks within the AUSL Romagna area (provinces of Ravenna, Rimini, and Forlì-Cesena, in Emilia-Romagna Region, Italy) and the economic impact caused by hospitalizations and local prevention/disinfestation treatments.

Methods: We used aggregated and anonymized data from 3 informative systems: communicable disease system (SMI) for VBD prevalence; hospital discharge records (SDO) for hospitalizations, with a contribution of the VBD-related Diagnosis Related Groups (DRG); municipality records regarding the cost of dedicated interventions for vector prevention and disinfestation, communicated to the Emilia-Romagna Region.

Results: For the area of interest, 479 cases of VBDs were notified from 2013 to 2022, with a slight increasing trend over the years. Through hospital SDOs, 252 cases were identified with a diagnosis of VBD, plus 283 with a VBD-related DRG, with a total expenditure of €9.587.777. The distribution was not uniform between the provinces, Ravenna having the highest expense. The municipality records highlighted expenses for €95.443 for prevention and control interventions against mosquitoes, with a very variable trend over the period considered. Forlì had the highest expense.

Conclusions: VBDs show a highly variable trend and distribution during time, also in relatively small, sub-regional areas. The Emilia-Romagna regional plan against arboviruses, annually updated, can contribute to reduce this specific health and economic burden, lowering transmission among the population and resulting hospital pressure, thanks to prevention and timely interventions.

Key messages:

- The use of information systems enables monitoring of the impact of arboviruses, as well as the related cost for hospital care and local treatments.
- Putting in place an effective and updated plan against arboviruses, like the Emilia-Romagna Region one, helps managing VBDs and mitigating economic costs.

Abstract citation ID: ckae144.1423
Monitoring of mosquito breeding sites in the municipality of Cascais, Portugal

Carlos Quelhas

R Costa e Silva[1], J Duarte da Silva[1], R Nunes[1], C Quelhas[1], M Lopes[1], M Fernandes[1]
[1]Cascais Public Health Unit, Western Lisbon Local Health Unit, Cascais, Portugal
Contact: carlos.quelhas@ulslo.min-saude.pt

Culex pipiens is the primary West Nile Virus vector in Portugal. Additionally, in 2017, Aedes albopictus, vector of various arboviruses, was detected in Northern Portugal. To mitigate viral transmission risks, effective surveillance is crucial, including monitoring egg, larva, and pupa stages. Located on the west of Lisbon, Cascais implemented a surveillance based on monitoring invasive species at Points of Entry and, complementarily, on detecting and intervening in breeding sites. Active searches for new breeding sites and monitoring those that were already identified are conducted weekly during the peak mosquito season (May to October) and biweekly during the colder season (November to April), following the methodology outlined below: • Upon detection, samples of immature stages are collected for submission to the National Institute of Health (INSA); • Corrective measures are requested to the managing entities of the locations where the sites are found; • Date of action, location, collection point, date of report, and status (pending or intervened) are recorded on a database; • Locations with pending status undergo continuous monitoring.

In 2023, 16 artificial breeding sites were identified. These findings resulted from 23 actions conducted across 8 locations. 35 samples of immatures were collected, followed by their submission and notification to the respective managing entities. Recurrent detections were noted in 9 breeding sites. The managing entities implemented measures at 13 of the identified sites, leaving 3 with pending intervention. The identification of breeding sites demands continuous monitoring efforts and requires an effective coordination between the Public Health services and the management entities. Based on the achieved outcomes, it is evident that the implementation of corrective measures has been successful, making a significant contribution to reducing mosquito density.

Key messages:

- Effective surveillance and intervention strategies are crucial in mitigating West Nile Virus and arbovirus transmission risks in Portugal.
- Continuous monitoring and coordination between public health services and management entities are key for maintaining effective vector control measures.

Abstract citation ID: ckae144.1424
Microbial source tracking to address of bacterial contamination in recreational waters

Sarah Esenther

S Esenther[1,2], M Pascucilla[2,3]
[1]Institute at Brown for Environment and Society, Brown University, Providence, Rhode Island, USA
[2]East Shore District Health Department, Branford, Connecticut, USA
[3]Yale School of Public Health, Yale University, New Haven, Connecticut, USA
Contact: sesenther@gmail.com

Background: Beach closures in the USA are determined by fecal indicator bacteria thresholds, which are insufficient to identify causes of contamination. We use microbial source tracking (MST) to identify the species source of bacteria entering chronically impaired waters. We find canine bacteria is the primary source of high E.coli levels and demonstrate the power of MST for direction of remediation efforts.

Methods: This environmental sampling study was performed in Short Beach, Branford, Connecticut, USA. Water samples were collected from outfalls under wet and dry precipitation conditions by 10 Citizen Scientist volunteers. The highest E.coli samples were analyzed for avian, human, and canine markers using MST.

Results: E.coli from 103 samples was tested from April-October 2023. Pearson's r between average site E.coli and same day precipitation was 0.71 (p-value = 0.006). Among the high E.coli samples, 19 (76%) were low/non detectable, 5 (20%) were moderate, and 1 (4%) were high for human tracers; 10 (50%) were low/non detectable and 10 (50%) were moderate for avian tracers, and 3 (15%) were low/non detectable, 11 (55%) were moderate, and 6 (30%) were high for canine tracers.

Conclusions: Precipitation is a driver of elevated bacteria levels. Canine bacteria is likely the primary source of elevated bacterial levels in beach waters, while avian contributors are of moderate concern and human contributors are of low concern. As a result, an education campaign and watertight waste receptacles, rather than costly sewer line replacements, are being deployed to improve beach quality.

Key messages:

- Use of microbial source tracking found canine bacteria is the likely driver of elevated E.coli levels in local beaches, initiating a community education campaign rather than costly sewer replacements.
- Microbial source tracking technology offers a powerful public health tool for identifying causes of bacterial contamination in chronically impaired recreational waters.

Abstract citation ID: ckae144.1425
Spatially varying associations between community-level predictors and COVID-19 outcomes in NYC

Rachel Thompson

RL Thompson[1,2], GD Johnson[1,2], R Gordon[3], T Nakaya[4]
[1]Department of Environmental and Geospatial Health, City University of New York School of Public Health, New York, USA
[2]Center for Systems and Community Design, City University of New York School of Public Health, New York, USA
[3]Department of Epidemiology and Biostatistics, City University of New York School of Public Health, New York, USA
[4]Graduate School of Environmental Studies, Tohoku University, Sendai City, Japan
Contact: rachel.thompson@sph.cuny.edu

Background: The cumulative impacts of COVID-19 on hospitalization and mortality were not uniformly distributed across New York City (NYC). To better understand potential drivers of this observed geospatial disparity, we explored the associations between community-level sociodemographic characteristics and cumulative COVID-19 hospitalizations and mortality using geographically weighted Poisson regression (GWPR).

Methods: Cumulative COVID-19 hospitalization and mortality rates in 177 NYC modified ZIP code tabulation areas as of Dec 2022 were taken from the NYC Department of Health and Mental Hygiene, and sociodemographic predictors were taken from the 2018 American Community Survey. GWPR was applied using both non-multiscale (single bandwidth) and multiscale (flexible bandwidth) models to assess which predictors were significant and which associations varied spatially (allowing them to potentially act as both risk and protective factors, depending on the location).

Results: Multiscale GWPR models outperformed non-multiscale models in rendering residual spatial autocorrelation insignificant. Although multiscale GWPR allowed flexible bandwidths for each predictor, most yielded global bandwidths, suggesting geographically consistent effects. For mortality, the percent of residents without health insurance acted solely as a risk factor. Similarly, for hospitalizations, the percent of residents with a disability acted solely as a risk factor. The percent of residents with a bachelors degree or higher acted solely as a protective factor against both outcomes.

Conclusions: Even when associations were allowed to vary spatially in GWPR models, we still found geographically consistent associations between many sociodemographic predictors and cumulative COVID-19 outcomes in NYC. Consistent risk factors, such as prevalence of disability, or protective factors, such as prevalence of higher education, highlight potential areas for city-wide policies to reduce the burden of future epidemics.

Key messages:

- For cumulative COVID-19 outcomes across NYC communities, geographically consistent risk factors include disability prevalence for hospitalization and lack of health insurance for mortality.
- Increasing prevalence of higher education acted as a geographically consistent protective factor against both hospitalization and mortality due to COVID-19.

Abstract citation ID: ckae144.1426
Development of an air quality communication strategy with underserved groups

Nehal Hassan

C Tolley[1], *S Wilson*[1], *N Hassan*[1], *AJ de Nazelle*[2], *R Slight*[3], *S Slight*[1]
[1]School of Pharmacy, Newcastle University, Newcastle upon Tyne, UK
[2]Centre of Environmental Policy, Imperial College London, London, UK
[3]Cardiothoracic Services, Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK
Contact: nehal.hassan@newcastle.ac.uk

Air quality is the greatest environmental health threat. Effective communication can support individuals to take actions to protect themselves, however, we know some groups are less likely to engage with exposure reducing behaviours than others. We aimed to explore what information individuals want to receive about raised air pollution levels, when, where and how they would like to receive it. In this qualitative study individuals participated in either semi-structured interviews (n = 6) or focus groups (n = 8) in North East England between Oct23-Feb24. We used purposive sampling underpinned by extensive community-based engagement to ensure inclusion of those who were underserved and/ or at risk of digital exclusion. The Capability Opportunity Motivation-Behaviour model was used to help guide discussions and the data thematically analysed using an inductive approach. Fifty individuals participated, many of whom were of non-white ethnicity (n = 23, 46%), spoke English as an additional language (n = 12, 24%), and had lower educational attainment levels (i.e., no-qualifications n = 7, 14%). Participants discussed four aspects that they deemed important to include in air quality communication: (1) the risk and harms of air pollution should be stated, and be tailored because "what's a dangerous level for one person isn't a dangerous level for another"(P41) (2) Participants felt detail about the pollutants should be included such as: "what is causing the air pollution?"(P15) to "avoid the exposure to this source"(P21). (3) Messages should also include actionable recommendations about how to protect oneself and, (4) various ways to communicate these messages (text-message-based approaches being the most popular) were suggested. Our findings indicated using a combined communication strategy including text messages and community-based approaches. This work can inform the development of inclusive future air quality information communication

Key messages:

- Effective communication can support individuals to take actions to protect themselves from air pollution.
- A combined communication strategy including text messages and community-based approaches were suggested as being effective communication strategies.

Abstract citation ID: ckae144.1427
Reducing the climate impact of food choices with comparable nutritional quality: a randomised trial

Lucía Aguirre Sánchez

L Aguirre-Sánchez[1,2], *S Maione*[3], *S Maeder*[4], *E Infanger*[5], *LS Suggs*[1,2]
[1]Università della Svizzera Italiana, Lugano, Switzerland
[2]Swiss School of Public Health, SSPH+, Zurich, Switzerland
[3]University of Applied Sciences and Arts of Southern Switzerland, Manno, Switzerland
[4]Integrale Planung GmbH, Zurich, Switzerland
[5]Externas GmbH, Zurich, Switzerland
Contact: aguirrel@usi.ch

Background: Diets largely contribute to the global disease burden, and a third of global warming emissions. We assessed the climate footprint reduction effect of framing the climate impact of diets as a collective action problem (social dilemma), compared or in combination with a reflective intervention (information) and a choice architecture intervention (nudge). Interactions with lifestyle factors were examined.

Methods: A randomised 2X2X2 between-subjects online experiment was conducted among university students $\geq$18 years, enrolled at a Swiss university, and not following a medically prescribed diet. The outcome was the mean climate footprint of food choices (in kg CO2-eq), based on a Life Cycle Assessment. Meals varied in climate footprints while adhering to the Swiss dietary guidelines.

Results: This analysis focused on the subset of meat eaters (n = 1691). Median age was 24 years, and 59.85% (n = 1012) were female. Seven intervention groups resulted in significantly lower climate footprints compared to the control. The social dilemma plus a nudge menu was the most effective behavioural intervention leading to 20.20% footprint reduction (b = -1.20 kg CO2-eq) compared to the control group (Mcontrol=5.94, SDcontrol=2.76; Mdilemma+nudge=4.74, SDdilemma+nudge=2.09 t(436) = -5.10, $p < 0.001$). Lifestyle factors linked to a higher climate footprint of food choices included adhering to a low-calorie diet (b = 1.21 kg CO2-eq, $p < 0.05$), or a muscle gain diet (b = 2.12 kg CO2-eq $p < 0.05$) and practising physical activities (PA) while adhering to a muscle-gain diet (Aerobic/Cardio: 3.82 kg CO2-eq, $p < 0.05$; Muscle-strengthening: 2.24 kg CO2-eq, $p < 0.05$).

Conclusions: The combination of reflective collective action communication and menu nudges is an effective strategy to mitigate the climate footprint of food choices in education institutions. Adherence to a muscle-gain diet was identified as a critical but manageable lifestyle factor linked to a higher climate footprint.

Key messages:

- The dilemma plus a nudge was the most effective to reduce the climate footprint of food choices.
- This combined intervention can manage the high climate footprints linked to lifestyle factors.

Abstract citation ID: ckae144.1428
Adapting the Place Standard Tool for Border Regions: The Euregional Approach

Brigitte Van Der Zanden

B Van Der Zanden[1,2,3], *O Mekel*[4], *M Struß*[1]
[1]euPrevent, Heerlen, Netherlands
[2]AWPG Mosa, South Limburg Public Health Service, Heerlen, Netherlands
[3]CAPHRI, Maastricht University, Maastricht, Netherlands
[4]Healthy Living Environments, Landeszentrum Gesundheit Nordrhein-Westfalen, Bochum, Germany
Contact: vanderzanden@euprevent.eu

The Place Standard Tool (PST) is a well-established tool that helps policymakers and communities discuss which aspects of a place - like buildings and transportation or the the way people are involved in decision making concerning their surroundings - need attention in order to improve public health. Even though the PST is widely used in many countries, it primarily focuses on a national level, overlooking the fact that 35% of EU citizens live in border regions. Many people living in these areas cross national borders for work, school, or social activities, so their everyday lives span more than one country. Using this tool to develop policies may ignore the real needs of border residents or even exclude their views, which can have a significant impact on their lives. To address this, the euPrevent Active Citizenship Participation (ACP) project adjusted the tool for a cross-border setting in the Euregio Meuse-Rhine (EMR). In this project, the German version of the StadtRaumMonitor, which is based on the PST, was modified to include questions that reach beyond national borders. This adaptation encourages people to respond to questions not just from a national perspective, but also to reflect on their experiences in neighboring countries. It was further translated into the four languages: French, German, Dutch and English, and made available online across the entire border region, which is home to nearly 4 million people. Moreover, the Euregional PST was effectively tested with local and cross-border citizen panels, and it's set to become a key element in creating a sustainable framework for citizen participation within the EMR. And although this Euregional PST was initially developed for the border regions of the EMR, the modifications are such that the tool can be applied in no matter which European border region. Thereby, the Euregional PST offers a way to create policies that truly reflect the diverse needs and realities of border citizens, all over Europe.

Key messages:

- The Cross-border Place Standard Tool EMR is easy to apply for a broad spectrum of stakeholders in border regions and applicable to all border regions in Europe.
- The tool helps preventing policy issues by considering the entire context of people living in border areas.

Abstract citation ID: ckae144.1429
Cancer mortality attributable to air pollution in Slovakia

Jarmila Pekarcikova

J Pekarcikova[1]
[1]Department of Public Health, Trnava University, Trnava, Slovakia
Contact: jarmilapekarcikova@gmail.com

Introduction: Air pollution is considered one of the most significant global environmental health risks. According to the Global Burden of Disease estimates, fine particulate matter, a key component of ambient air pollution, was the fifth leading risk factor for mortality worldwide in 2015, contributing to 4.2 million deaths (7.6% of total global deaths). In 2019, ambient air pollution was responsible for 4.5 million deaths. This rise is attributed to the growing levels of air pollution and the increasing incidence of NCDs associated with air pollution.

Aim: This contribution aims to clarify the possible association between environmental air pollution and cancer in Slovakia in the years 2015-2019 overall and by gender and age.

Methodology: This ecological study focuses on the population of Slovakia from 2015 to 2019. The data used are from the Global Burden of Disease study (IHME, 2019), the Statistical Office of the Slovak Republic and the Slovak Hydrometeorological Institute.

Results: In 2019, mortality from NCDs related to environmental pollution accounted for 6.6% of total mortality in Slovakia, which is lower than the global average of 8.3%. Cancer mortality attributable to ambient particulate matter pollution (APMP) was lower in 2019 (2.97 per 100,000, CI 95% 4.43-1.76) than in 2015. Higher cancer mortality rates attributable to APMP, were observed mainly in men (7.18 per 100,950, CI % 10.67-4.31 in 2015) and especially in the 80-84 age group (59.49 per 100,000; CI 95 % 94.60-32.20) in 2015 and in men aged 75-79 (510.76 per 510.76 per 100,000) in 2019.

Conclusions: While Slovakia has experienced a long-term decline in cancer mortality, bucking the global trend, challenges persist due to the country's relatively poorer outcomes associated with environmental pollution. Addressing environmental pollution remains a critical aspect of ongoing efforts to enhance population health through targeted strategies and policies.

Key messages:

- The significant impact of environmental pollution on cancer mortality underscores the urgent need for targeted interventions and policies to improve public health outcomes in Slovakia.
- Cancer mortality attributable to air pollution differs by gender.

Abstract citation ID: ckae144.1430
Assessing inequalities and inequities in Health Impact Assessment: a systematic review

Sara Properzi

S Properzi[1]*, AA Coa*[2]*, C Fiorilla*[3]*, R Pasetto*[4,5]
[1]Department of Medicine and Surgery, University of Perugia, Perugia, Italy
[2]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy
[3]Department of Public Health, Federico II University, Naples, Italy
[4]Department of Environment and Health, ISS, Rome, Italy
[5]WHO CC for Environmental Health, ISS, Rome, Italy
Contact: saraproperzi90@gmail.com

Background: Health Impact Assessment (HIA) procedures can include the assessment inequalities and inequities associated with the distribution of environmental health risks and benefits, attenuating the exacerbation of health disparities in this domain. However, prevailing approaches to tackle inequalities in accessing ecosystem services exhibit limitations. We explored how this kind of assessment in HIA procedures is documented within the international literature.

Methods: Following PRISMA Guidelines, we conducted a systematic review of scientific literature by searching in MEDLINE/PubMed, Scopus, and Embase databases up to 8 March 2024. Moreover, a grey literature analysis was conducted, examining the World Health Organization's Institutional Repository for Information Sharing (IRIS) to identify guidance considering equity in HIA.

Results: Eight out of 158 documents identified on IRIS, using 'health impact assessment' as a filter, underscore the importance of integrating the equity domain into the HIA; of these, only 1 employs methodologies to actively consider it. Of the 806 literature studies analyzed, only 14 included used methods to evaluate inequalities and equity in HIA in various contexts, ranging from urban planning, such as green or redeveloped areas, and transport planning, to mining. Preliminary results show that in most studies, data were collected through surveys, focus group discussions, and peculiar "walks" with local experts. The predominant approaches in extant literature entail the use of socioeconomic status and health determinants as metrics for assessing equity and inequalities within HIA.

Conclusions: Our findings highlight a critical gap in integrating equity into HIA practices, with limited attention and methodological diversity observed across the analysed documents and studies.
Strategies for probing and mitigating inequalities can be strengthen by engaging different stakeholders and the residing population.

Key messages:

- There are few and highly heterogeneous methods for assessing inequality in HIA.
- An effective and standardized strategy to asses inequality in HIA could involve stakeholders and the resident population.

Abstract citation ID: ckae144.1431
Exposome, oxidative stress and inflammation in multiple sclerosis: the EXPOSITION study protocol

Maria Cristina Monti

MC Monti[1,4], R De Giuseppe[1,4], G Bertoli[2,4], E Tavazzi[3], A Kalmpourtzidou[1,4], MA Alemayohu[1,4], B Maccarini[1,4], E Oddone[2,4], C Montomoli[1], H Cena[1,4]
[1]Department of Public Health, University of Pavia, Pavia, Italy
[2]IBFM, CNR, Segrate, Italy
[3]Multiple Sclerosis Research Center, IRCCS Mondino Foundation, Pavia, Italy
[4]National Biodiversity Future Center, NextGenerationEU, Palermo, Italy
Contact: cristina.monti@unipv.it

Background: The functional exposome approach examines the relationship between biological effects (internal exposome) and the sum of environmental exposures (external exposome). Multiple sclerosis (MS) is characterized by selective demyelination and acute inflammation; miRNAs and microbiota are emerging in the pathogenesis as inflammation and oxidative stress biomarkers. The EXPOSITION study protocol has been designed to study such biomarkers variation in response to the external exposome (air pollution, urbanization, lifestyles) in people with MS (pwMS).

Methods: EXPOSITION is a cross-sectional observational study collecting a sample of 200 pwMS residing in Lombardy, Northern Italy. Sample size is based on the prediction of differential expression of candidate miRNAs through bioinformatic analyses. All participants will be investigated for social, demographic and clinical data as well as general and specific external exposome factors. The internal exposome factors will be collected for each participant from blood and stool samples, as well as from nasal swabs. Exposome clustering and correlation statistical techniques will be applied and variation of miRNA and microbiota will be tested in association with the variation of the external exposome in urban and extra-urban environments.

Results and conclusions: The expected results will help pwMS and researchers understanding which biomarkers and which components of the external exposome are associated to oxidative stress and inflammation, to improve precision medicine and contrast disease progression. The relationship between urban exposome and biodiversity is an important dimension in the study of environmental impact on human health. This study may provide preliminary data to assess which nature-based solutions are suitable for enhancing the biodiversity of urban areas.

Key messages:

- The functional exposome approach could be used to link environmental risk factors and disease biomarkers using the right methology.
- EXPOSITION will quantify the variation of miRNA and microbiota in association with the variation of external exposome, in urban and extra-urban environments.

BMI Trajectories and the Influence of Missing Data

Laura Gray

LA Gray[1,2]
[1]Division of Population Health, University of Sheffield, Sheffield, UK
[2]Healthy Lifespan Institute, University of Sheffield, Sheffield, UK
Contact: laura.gray@sheffield.ac.uk

Introduction: Body Mass Index (BMI) trajectories have been estimated in various ways. These estimates are important to understand how BMI develops over time and for use in cost-effectiveness analysis. However, missing data is often stated as a limitation in studies that analyse BMI over time and there is little research into how missing data can influence these BMI trajectories. The aim of this study is to determine how much influence missing data can have when estimating BMI trajectories and to explore the effects this has on subsequent analysis.

Methods: This study uses data from the English Longitudinal Study of Aging. First, a growth mixture model is used to estimate distinct BMI trajectories in adults over the age of 50. Next, methods that assume data is missing at random (MAR) are used: complete case analysis and multiple imputation. Finally, Diggle Kenward and Roy methods that assume data is missing not at random (MNAR) are implemented. Estimated trajectories from each method are then used to predict the risk of developing type 2 diabetes (T2DM) using discrete-time survival analysis.

Results: Four distinct trajectories are identified using each of the methods to account for missing data: stable overweight, elevated BMI, increasing BMI, and decreasing BMI. However, the likelihoods of individuals following the different trajectories differs between the different methods.

Results show that the influence of BMI trajectory on T2DM is reduced after accounting for missing data. More work is needed to understand which methods for missing data are most appropriate and give the most reliable results.

Conclusions: Missing data can significantly influence estimations of BMI trajectories. When using BMI trajectories to inform cost-effectiveness analysis or policymaking, missing data should be considered. More research is needed to examine the extent to which accounting for missing data might influence the cost-effectiveness of policies, e.g. weight management interventions.

Key messages:

- Missing data is important when modelling BMI trajectories.
- More research is needed to examine the extent to which accounting for missing data might influence the cost-effectiveness of policies, e.g. weight management interventions.

[5]UWZH, University of Zurich and Balgrist University Hospital, Zurich, Switzerland
[6]Multimedia an E-Learning Services, University of Zurich, Zurich, Switzerland
Contact: felix.gille@uzh.ch

Background: Qualitative research and mixed methods are core competencies for epidemiologists. In response to the shortage of guidance on graduate course development, we wrote a course development to guide faculty and students designing similar courses in epidemiology curricula. We combine established educational theory with faculty and student experiences from a recent introductory course for epidemiology and biostatistics doctoral students at the University of Zurich and Swiss Federal Institute of Technology, Zurich.

Objectives: We propose a 1-ECTS, six session long, student-centred course with inverse in-person classroom teaching and practice exercises with faculty input. The overarching course objective is to introduce students to qualitative research and mixed methods. The proposed course covers learning outcomes in comprehension, knowledge, application, analysis, synthesis and evaluation.

Results: Following an introductory session, the students engage in face-to-face interviews, focus group interviews, observational methods, analysis and how qualitative and quantitative methods are integrated in mixed methods. Furthermore, the course covers interviewer safety, research ethics, quality in qualitative research and a practice session focused on the use of interview hardware, including video and audio recorders. The student-led teaching characteristic of the course allows for an immersive and reflective teaching-learning environment.

Conclusions: After implementation of the course and learning from faculty and student perspectives, we propose these additional foci: a student project to apply learned knowledge to a case study; integration in mixed-methods; and providing faculty a larger space to cover theory and field anecdotes. Based on: Gille, et al. A guide for a student-led doctoral-level qualitative methods short course in epidemiology: faculty and student perspectives, International Journal of Epidemiology, Volume 53, Issue 2, April 2024.

Key messages:

- Qualitative research methods and mixed methods are core competencies for epidemiologists.
- Students appreciate a student-centred course design with inverse classroom teaching and practice exercises.

Abstract citation ID: ckae144.1434

Occupational exposure to nickel or hexavalent chromium and the risk of lung cancer (SYNERGY)

Thomas Behrens

T Behrens[1], C Ge[2], R Vermeulen[2], B Kendzia[1], A Olsson[3], H Kromhout[2], S Peters[2], J Siemiatycki[4], K Straif[5,6], T Brüning[1]

[5]ISGlobal, Barcelona, Spain
[6]Boston College, Chestnut Hill, USA
Contact: thomas.behrens@dguv.de

Background: Hexavalent chromium (Cr(VI)) and nickel (Ni) are known occupational carcinogens, with frequent exposures, for example, in welding-related activities. However, limited evidence exists on the exposure-response relationship of Cr(VI) or Ni with lung-cancer risk. We estimated lung-cancer risks based on quantitative indices of occupational exposure to each metal, and their interaction with smoking habits.

Methods: Fourteen case-control studies from Europe and Canada (16,901 cases, 20,965 control subjects) were pooled. A measurement-based job-exposure matrix was used to estimate year- and region-specific exposure levels for Cr(VI) and Ni, which were linked to the study subjects' occupational histories. Odds ratios (OR) and 95% confidence intervals (CI) were calculated, adjusting for study, age group, smoking, and exposure to other occupational lung carcinogens.

Results: The OR for the highest quartile (>99.5 µg/m3-years) of cumulative exposure to Cr(VI) in men was 1.32 (95% CI 1.19-1.47) and for nickel (highest quartile >78.1 µg/m3-years) OR = 1.29 (95% CI 1.15-1.45). Corresponding effect estimates in women were slightly lower. The joint effects of Cr(VI) and nickel with smoking were generally greater than additive.

Conclusions: We observed positive exposure-response relationships in the low-dose range of Cr(VI) and Ni exposures, based on a large study population including detailed information on smoking habits and a measurement-based job-exposure matrix. Although, we cannot rule out a combined classical measurement and Berkson error structure that may have caused bias in our risk estimates, our results provide empirical evidence to further specify preventive measures at the workplace in order to protect workers from hazardous substances.

Key messages:

- Relatively low cumulative levels of occupational exposure to Cr(VI) and Ni were associated with increased ORs for lung cancer, particularly in men.
- Important empirical insights for the prevention of cancer at the workplace can be drawn from the results.

Abstract citation ID: ckae144.1435

Association between body mass index and mental health status among community-dwelling older adults

Ya-Huei Nian

YH Nien[1], CF Hsiao[1], YZ Wu[1], HL Hsieh[1], CH Tseng[1], YC Chou[1]
[1]Department of Education and Research, Taipei City Hospital, Taipei, Taiwan
Contact: A3487@tpech.gov.tw

Background: Maintaining a better physical and mental health status is an important issue for older adults in their later life. Although obesity has been suggested to reduce the risk of mood disorders in older adults, the findings are controversial. Thus, we aimed to investigate the association between body mass index (BMI) and mental health status among older adults in Taipei City and to elucidate risk factors contributing to mood disorders.

Methods: The elderly health examination database was obtained from the Department of Health, Taipei City government, from 2005 to 2016. A total of 80,121 older adults underwent at least two publicly funded health examinations, with 398,416 visits. We used the Brief Symptom Rating Scale (BSRS-5) questionnaire to estimated relative risks among potential risk factors with the generalized estimating equations (GEE) model to measure the mental health status of older adults. Mood disorders were defined as a score of ≥ 6 on BSRS-5. BMI, age, education level, gender, living alone, income status, number of chronic diseases, smoking, drinking, and exercise were included as covariates.

Results: Older adults who are overweight or obese have a lower risk for mood disorders (adjusted odds ratio [OR] = 0.82; 95% confidence interval [CI] = 0.79 - 0.85), while those underweight have a higher risk (OR = 1.31; 95% CI = 1.21 - 1.41). Other results show that being male (OR = 0.66; 95% CI = 0.63 - 0.69), higher education (OR = 0.72; 95% CI = 0.69 - 0.75), and have exercise habits (OR = 0.73; 95% CI = 0.70 - 0.76) were all positively correlated with better emotional status. However, low income (OR = 1.24, 95% CI = 1.14 - 1.35) and having more chronic diseases (OR = 1.99, 95% CI = 1.87 - 2.11) were all correlated with poor mental status among older adults.

Conclusions: Keeping an appropriate weight or even being overweight might be beneficial for older adults. In addition, encouraging older adults to maintain exercise habits can also help improve mood disorders.

Key messages:

- Keeping an appropriate weight or even being overweight might be beneficial for older adults.
- Encouraging the elderly to maintain exercise habits can also help improve mood disorders.

Neighbourhood immigrant density and COVID-19 infection and hospitalization among healthcare workers

Chioma Nwaru

C Nwaru[1,2], *C Bonander*[2], *H Li*[2], *A Santosa*[2], *J Löve*[2], *F Nyberg*[2]
[1]Population Health Sciences Institute, Newcastle University, Newcastle Upon Tyne, UK
[2]School of Public Health & Community Medicine, University of Gothenburg, Gothenburg, Sweden
Contact: chioma.nwaru@newcastle.ac.uk

Background: Studies have shown inequalities in COVID-19 infection among healthcare workers (HCWs), with occupational exposure failing to fully explain the inequalities. Little is known about the role of other social determinants of health, such as neighborhood immigrant density. We examined if living in immigrant-dominated neighborhoods was associated with increased risk of COVID-19 infection and hospitalization among HCWs in Sweden, and if so, whether such exposure amplified the risk of COVID-19 among immigrant HCWs. Addressing this question would contribute to a better understanding of factors driving COVID-19 disparities among HCWs.

Methods: Data were from HCWs aged 20 to 62 years (N = 86187) resident in one of 14 Swedish municipalities (three of which are Sweden's largest metropolitan cities) on 1 January 2020. Residential neighborhoods were categorised into Swedish-dominated, mixed, and immigrant-dominated. The study outcomes were the first occurrence of COVID-19 infection and hospitalization registered until 30 September 2022. Multilevel mixed-effects survival regression was used for the association analyses, with control for confounders (age, sex, income, comorbidities etc).

Results: After adjusting for confounders, living in immigrant-dominated neighborhoods was only associated with an increased risk of COVID-19 infection in the first pandemic wave (HR 1.17, 95%CI 1.07 - 1.29), but living in these areas was associated with an elevated risk of COVID-19 hospitalization throughout the entire period. Immigrant HCWs, regardless of where they lived, had around 2-fold higher risk of being hospitalised for COVID-19 than non-immigrant HCWs living in Swedish-dominated neighborhoods.

Conclusions: Neighborhood immigrant density was associated with COVID-19 hospitalization among HCWs in Sweden. However, immigrant HCWs had a high risk of the outcome regardless of where they lived. More research is needed to identify the root causes of the excess risk among immigrant HCWs.

Key messages:

- HCWs living in immigrant-dominated neighborhoods had an elevated risk of COVID-19 hospitalization.
- This study sheds additional light on the drivers of COVID-19 inequalities among Swedish HCWs.

The trends of arterial hypertension and ischemic heart disease in Lithuanian population (1983-2023)

Ričardas Radišauskas

R Radisauskas[1], *D Luksiene*[1], *D Kranciukaite-Butylkiniene*[1], *L Sileikiene*[1], *A Tamosiunas*[1]
[1]Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: ricardas.radisauskas@lsmu.lt

Background: During the past two decades, in Lithuania, the morbidity and mortality from circulatory system diseases such as ischemic heart disease (IHD) have been increasing. The increasing incidence of IHD can be linked to the IHD prevention program implemented in Lithuania, which was launched in 2005. This study aimed to determine and evaluate the prevalence of IHD, their risk factors, and trends among middle-aged (45-64 years) urban males and females in Lithuania over the last 40 years.

Methods: During our study, the changes in the prevalence of arterial hypertension (AH) and IHD, among Kaunas city inhabitants aged 45-64 years in six population-based cohorts (1982-1983 (n = 1660), 1986-1987 (n = 1152), 1992-1993 (n = 824), 2001-2002 (n = 978), 2006-2008 (n = 4604) and 2023 (n = 554)) were analyzed. AH was defined when the arterial blood pressure was ≥140/90 mmHg or a person had taken antihypertensive drugs during 2 weeks. IHD was defined when a person had a previous myocardial infarction (MI) and/or ischemic changes on electrocardiogram (ECG) were assessed by Minnesota codes. The prevalence of AH and IHD changes were evaluated using regression analysis.

Results: During 1983-2023, the prevalence of AH among males aged 45-64 significantly increased from 58.7% (1982-1983) to 72.7% (2023) (p = 0.04), but among females aged 45-64 the prevalence of AH tended to decrease from 63.0% (1982-1983) to 50.9% (2023) (p = 0.18). The prevalence of IHD among males aged 45-64 was without significant changes and was from 14.4% (1982-1983) to 13.6% (2023) (p = 0.7), but among females aged 45-64 the prevalence of IHD significantly decreased from 21.7% (1982-1983) to 16.6% (2023) (p = 0.04).

Conclusions: From 1983 to 2023, among Lithuanian middle-aged urban males, the prevalence of AH significantly increased, but the prevalence of IHD was stable, meanwhile, among Lithuanian middle-aged urban females the prevalence of AH tended to decrease, but the prevalence of IHD significantly decreased.

Key messages:

- From 1983 to 2023, among Lithuanian middle-aged urban males, the prevalence of AH significantly increased, meanwhile among females - tended to decrease.
- Over 40 years, the prevalence of IHD among Lithuanian males was without significant changes, but among females - significant decreased.

Regional deprivation and suicide mortality in Germany

Matthias Belau

M Belau[1]
[1]Insitute of Medical Biometry and Epidemiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany
Contact: m.belau@uke.de

Background: Regional deprivation has been shown to be an important determinant of suicide risk. However, little is known about regional differences in suicide mortality in Germany.

Methods: Data from cause of death statistics (2015 to 2021) were analyzed. Regression analysis for data with negative binomial distribution was used to examine the association between the German Index of Multiple Deprivation 2015, covering 401 districts and district-free cities in Germany, and suicide mortality.

Results: The adjusted rate ratio for suicide in the most deprived deprivation area compared to the least deprived area was 1.18 (95% CI [1.72, 2.00]). A sensitivity analysis shows similar rate ratios for men (1.99 (95% CI [1.80, 2.18])) and women (1.69 (95% CI [1.49, 1.92])), but a higher rate ratio for rural areas (2.29 (95% CI [2.04, 2.57])) compared with urban areas (1.51 (95% CI [1.36, 1.68])).

Conclusions: The findings suggest that regional deprivation is associated with suicide mortality, and call for a more targeted approach to suicide prevention in deprived regions.

Key messages:

- Study reveals higher suicide rates in deprived regions in Germany.
- Study calls for tailored prevention strategies to address this disparity.

Abstract citation ID: ckae144.1439
Deprivation and stroke incidence, treatment and mortality in Germany

Matthias Belau

M Belau[1], *H Becher*[2], *M Riefflin*[1], *D Bartig*[3], *L Schwettmann*[4], *CJ Schwarzbach*[5], *A Grau*[5]

[5]Department of Neurology, Hospital of the City Ludwigshafen, Ludwigshafen, Germany
Contact: m.belau@uke.de

Background: Previous research suggests that regional deprivation significantly influences the risk of stroke. However, little is known about regional differences in stroke incidence and mortality within Germany.

Methods: We utilized data from the Diagnosis Related Groups statistics (2016-2019) and the German Federal Register of Physicians (2019). We used negative binomial regression analysis to investigate the relationship between the German Index of Multiple Deprivation 2015, covering 401 districts and district-free cities in Germany, and stroke incidence, treatment, and mortality.

Results: The adjusted rate ratios of stroke incidence and mortality with the highest deprivation level compared with the least deprived area were 1.16 (95% CI [1.14, 1.17]) and 1.19 (95% CI [1.14, 1.23]), respectively. Furthermore, this study showed that the density of physicians was higher in district-free cities than in districts.

Conclusions: The findings document a relationship between regional deprivation and stroke incidence and mortality, and call for a more targeted approach to stroke prevention in deprived regions.

Key messages:

- Regional deprivation in Germany linked to increased stroke incidence and mortality rates.
- Policy action needed for effective prevention measures.

[3]Department of Computing, Federal Center for Technological Education of Minas Gerais, Belo Horizonte, Brazil
Contact: romulo.paes@fiocruz.br

To alleviate the effects of socioeconomic inequalities and of the fall in economic activity on vulnerable populations during the COVID-19 pandemic, many countries have implemented or expanded income distribution programs. Brazil, amid the political and economic 2020 crisis, exacerbated by the pandemic, established Emergency Aid (EA). This longitudinal ecological study aimed to analyze whether the availability of EA contributed to the reduction of morbidity and mortality due to COVID-19 in the Brazilian 5,570 municipalities, from March 2020 to December 2021. The theoretical model considered as control covariates socioeconomic, sociodemographic and morbidity characteristics and access to health services, including COVID-19 testing availability and vaccination. Classical variable selection methods were applied considering the theoretical model, culminating in the adjustment of Bayesian hierarchical models with the inclusion of spatial and temporal effects. First dose COVID-19 vaccine coverage and EA had a protective effect against hospitalization (RR = 0.982 and RR = 0.986) and mortality (RR = 0.978 and RR = 0.976) due to COVID-19 in Brazil, when controlled by socioeconomic variables, access to health services and spatial-temporal effects. The results highlight the important role of income transfer in morbidity and mortality due to the disease, however, the way in which EA was implemented in Brazil presented a series of problems, the main ones being discontinued payment of aid, reduction in values throughout the duration of the benefit, in addition to the use of public resources to pay people who did not meet the eligibility criteria. Such problems might not have happened if the federal government had maintained the registration structure of Bolsa Familia Program (BFP), which did not happen. Furthermore, vaccination was started late for several reasons, that is, its role in reducing morbidity and mortality could have been even greater if started as soon as it become available.

Key messages:

- Even with planning and execution problems, income transfer and specific vaccination were important in reducing COVID-19 morbidity and mortality in Brazil during the COVID-19 pandemic.
- Income transfer during the COVID-19 pandemic in Brazil was not done in the best way possible, due to discontinued payment, reduction in values and payment to not eligible people.

Measured obesity and overweight in adults: the Italian Health Examination Survey 2023-CUORE Project

Luigi Palmieri

B Marcozzi[1], *C Lo Noce*[1], *S Vannucchi*[1], *A Di Lonardo*[1], *C Damiano*[1], *D Galeone*[2], *P Bellisario*[2], *L Palmieri*[1], *C Donfrancesco*[1]
[1]ISS, Rome, Italy
[2]Italian Ministry of Health, Rome, Italy
Contact: luigi.palmieri@iss.it

Background: The WHO recommends to halt the rise of obesity by 2025, considering 2010 as baseline. This analysis aims to assess if Italy can meet the WHO target in the general adult population using data measured in the periodic health examination surveys (HESs) conducted within the CUORE Project.

Methods: In the HES started in 2023, mean level of BMI and prevalence of obesity (BMI > =30 kg/m2) and overweight (25 < =BMI< 30 kg/m2) were assessed in representative random samples of resident population, aged 35-74 years, stratified by age and sex (727 men and 706 women), from 7 (of 20) Italian Regions, in Northern, Central and Southern Italy. Weight and height were measured using standardized methods. Insufficient physical activity was defined as less than 150 minutes of moderate-intensity activity per week, or equivalent. The survey is funded by the Italian Ministry of Health-CCM.

Results: Prevalence of obesity was 23% (95% C.I. 16-29%) in men and 25% (19-31%) in women; prevalence of overweight was 47% (39-54%) in men and 30% (24-37%) in women. Mean level of BMI was 27.5 kg/m2 (27.2-27.8 kg/m2) in men and 26.9 kg/m2 (26.4-27.3 kg/m2) in women. Obesity resulted tendencially higher in persons with insufficient physical activity (27%, with 95% C.I. 17-36% in men; 28%, 19-37% in women) than among those without (19%, 11-27% in men; 21%, 12-30% in women), and in persons with primary or secondary school education (29%, 17-40% in men; 32%, 20-44% in women) than in those with higher educational level (20%, 12-27% in men; 21%, 14-28% in women).

Conclusions: Going in the direction of WHO target, preliminary data collected within 2023 showed a prevalence of obesity not statistically different in comparison to HES data of 15 and 5 years ago, both in men and women, however, 70% of men and 55% of women are in the overweight/obesity condition. Preventive actions at national and community level should be still massively implemented.

Key messages:

- Prevalence of obesity and overweight resulted still at epidemic level in the Italian adult general population.
- In the Italian adult population stable obesity prevalence trend was observed in comparison to 15 and 5 years ago.

Background: The post-COVID condition involves a range of persistent or new symptoms affecting various organs, including an increased risk of cardiovascular issues. As there are limited data on cardiovascular events in post-acute COVID-19 patients, we aimed to estimate their incidence and assess its association with patient and infection characteristics in Portugal.

Methods: We conducted a registry-based retrospective cohort study from seven hospitals across Portugal, including individuals hospitalised due to COVID-19 between March 2020 and March 2021. Our outcome of interest was cardiovascular events in the post-acute phase of COVID-19, occurring at least 30 days after the positive SARS-CoV-2 test. The variables of interest considered were the severity of the episode, existing cardiovascular risk and vaccination status before the SARS-CoV-2 test. Person-years and incidence rates were estimated. A Cox proportional hazard regression model was employed to assess risk factors.

Results: We included 1,803 patients in the analysis, of which 143 (7.9%) experienced at least one cardiovascular event following COVID-19 hospitalisation. The overall incidence rate of having at least one cardiovascular event was 34.65 per 1,000 person-years (95% confidence interval (CI): 29.20; 40.82). We found a higher risk of cardiovascular events for individuals with pre-existing cardiovascular risk (adjusted hazard ratio (aHR): 3.76, 95% CI: 1.53; 9.24) and lower risk for individuals with at least one vaccine dose before the SARS-CoV-2 test (partial - aHR: 0.44, 95%CI: 0.30; 0.64, complete - aHR: 0.46, 95%CI: 0.2; 0.80). We did not find a significant difference between the severity of the COVID-19 episode and the risk of having cardiovascular events post-COVID-19.

Conclusions: Our results indicate the presence of cardiovascular complications post-COVID-19, emphasising the need for healthcare systems to initiate screening and preventive strategies for individuals deemed at elevated risk.

Key messages:

- COVID-19 vaccination decreases the risk of cardiovascular events post-COVID-19.
- Healthcare systems should start screening and preventive strategies for individuals with pre-existing risk of cardiovascular events.

Integrated sentinel surveillance of influenza, SARS-CoV-2, RSV and respiratory viruses in Serbia

Dragana Dimitrijevic

D Dimitrijevic[1], V Jovanovic[1], M Milinkovic[1], J Protic[2], E Grego[1], S Maris[3]
[1]Institute of Public Health of Serbia, Belgrade, Serbia
[2]Institute of Virology, Vaccines and Sera 'Torlak', Belgrade, Serbia
[3]City Public Health Institute of Belgrade, Belgrade, Serbia
Contact: dragana.dimitrijevic@yahoo.com

Introduction: Integrated sentinel SARI surveillance of influenza, SARS -CoV-2 and RSV has been established in Serbia since 2021-2022 influenza season. Nine sentinel hospitals in 3 cities participated in the SARI surveillance system. The aim of this study is to provide a review of integrated sentinel surveillance of SARI in Serbia in 2023-2024 influenza season, from October 2023 to April 2024.

Methods: On a weekly basis, both epidemiological and virological data were collected. Surveillance is be conducted year-round. Specimens were tested for influenza, SARS-CoV-2,RSV and other respiratory viruses. Respiratory disease wards, intensive care units (ICUs) and pediatric wards were all represented. Real time polymerase chain reaction (RT-PCR) was used.

Results: From October 2023 to April 2024, a total of 1571 SARI cases were reported with 100% recorded age. Of these, 35% were 0-4 years old, 16% were 5-14, 6% were 15-29, 14% were 30-64, 18% were 65-79 and 11% were 80+. Among these cases, 1002 (64%) respiratory specimens were collected. The number of positive samples for influenza was 294 (29%). The positivity rate was 10% for SARS-CoV-2 and 19 % for RSV. The highest proportion of laboratory-confirmed influenza cases was 67% in week 04/2023. Then above 50% in week 05/2023 and 06/2023. Type A viruses was predominated, accounting for 97% of all influenza SARI detections. Activity was dominated by A(H3) with 42% positivity rate. Also, collected swabs were tested for rhinoviruses, positivity rate was 26%, for adenoviruses, 12%, for human metapneumovirus, 7% and for parainfluenza 3 viruses, 4%.

Conclusions: Sustaining and intensified effective integrated surveillance for influenza, SARS-CoV-2,RSV and other respiratory viruses in Serbia is the priority especially in the frame of International Health Regulations. In this way, we improve national capacity for preparedness and emergency response to national and cross-border public health threats.

Key messages:

- Building and maintaining integrated respiratory surveillance that can rapidly integrate the surveillance of a new viruses is crucial.
- Establishing well structured surveillance of severe acute respiratory infections, strengthening and expanding respiratory viral surveillance is one the base pillars preparation for future pandemics.

Do poor psychosocial resources mediate health inequalities in type 2 diabetes? The Maastricht Study

Bengisu Sezer

B Sezer[1,2], J Albers[1,2], R Meisters[1,2], MT Schram[3,4,5], S Koehler[5,6,7], C Stehouwer[3], A Koster[1,2], H Bosma[1,2]

Contact: b.sezer@maastrichtuniversity.nl

Low socioeconomic position (SEP) has been identified as a risk factor for type 2 diabetes mellitus (T2DM). A potential pathway of this association is psychosocial resources. Disadvantageous environmental conditions result in low control beliefs through adverse resources and inferiority beliefs through social comparison for people with a low SEP. We examined two poor psychosocial resources, low control beliefs and inferiority beliefs, to explain socioeconomic inequalities in T2DM. We analysed mediating roles of low control beliefs and inferiority beliefs by using counterfactual mediation analysis. 8293 participants aged 40-75 living in Limburg, the Netherlands participated in The Maastricht Study starting from September 2010 to October 2020 and were followed up to 10 years with annual questionnaires with a median follow-up time of 7.18 years. SEP (education, income, occupation), control and inferiority beliefs, and (pre)diabetes by oral glucose tolerance test were measured at baseline. Incident T2DM was self-reported per annum. 3.2% (N = 203) of the participants without T2DM at baseline reported incident T2DM. People with low SEP had more often prevalent and incident T2DM (e.g., low education:HR=2.13, 95%CI:1.53-2.97). Lower control beliefs and higher inferiority beliefs were more common among people with low SEP than people with high SEP. Moreover, lower control beliefs and higher inferiority beliefs were risk factors for T2DM (e.g., low control beliefs: HR = 1.50, 95%CI:1.08-2.09). The relationship between SEP and T2DM was partially mediated by control beliefs (7.98-13.56%) and inferiority beliefs (2.16-4.53%). Poor psychosocial resources are important in socioeconomic inequalities in diabetes. Researchers and practitioners should consider the psychosocial profile of people with lower SEP might differ from those with higher SEP and this might interfere with the development, treatment, and prevention of T2DM. We should aim to work with such beliefs, instead of against it.

Key messages:

- Socioeconomic health inequalities in diabetes has many underlying mechanism including psychosocial pathways.
- Interventions and research should consider the different environment of low SEP and psychosocial profiles of people. We should aim to work with it, instead of against it.

Abstract citation ID: ckae144.1445
Did the COVID-19 Pandemic Affect Suicide Rates Differently in Urban and Rural South Korea?

Yerin Choi

S Kweon[1,2,3]*, M Baek*[2]*, Y Choi*[2]
[1]Department of Preventive Medicine, Chonnam National University Medical School, Hwasun-gun, South Korea
[2]Gwangju Institute for Public Health and Equity, Gwangju, South Korea
[3]Gwangju-Jeonnam Regional Cancer Center, Chonnam National University Hwasun Hospital, Hwasun-gun, South Korea
Contact: yerin2132@icloud.com

Background: The influence of the COVID-19 pandemic on suicide rates remains a subject of debate. Despite increases in suicidal ideation and attempts reported during the pandemic, several recent meta-analyses have not demonstrated corresponding rises in suicide rates. Given the potential for substantial regional and demographic variability in the psychological consequences of COVID-19-related restrictions, this study explores differential suicide rates in urban versus rural contexts within South Korea subsequent to the pandemic outbreak.

Methods: This investigation employed age-standardized suicide rates from two periods, 2015-2019 and 2020-2022, across 234 administrative divisions (152 urban, 82 rural). A difference-in-differences approach was utilized to evaluate the pandemic's impact on suicide rates, segmented by urban and rural classifications. A linear regression model was developed to examine the interaction between location (urban/rural) and time period, controlled for annual variations, perceived stress, and health status within each locale.

Results: Analysis revealed higher suicide rates in rural areas compared to urban counterparts ($\beta = 1.247$, $p = 0.003$), although no significant changes were observed during the pandemic period itself (β=-0.425, $p = 0.682$). Furthermore, the interaction between urban/rural status and the pandemic period did not reach statistical significance ($p = 0.367$).

Conclusions: The findings indicate no significant contribution of the COVID-19 pandemic to increased suicide rates, irrespective of the urban or rural setting. Further research is warranted to dissect the impact of more direct socioeconomic factors on this dynamic.

Key messages:

- There in no evidence of increased suicide rates during the COVID-19 pandemic in South Korea.
- The impact of the COVID-19 pandemic on suicide rates did not significantly different between urban and rural areas.

Abstract citation ID: ckae144.1446
Sexual harassment among higher education students: a worldwide review

Rodeline Telfils

R Telfils[1]*, J Ladner*[1,2]*, MP Tavolacci*[1,3]
[1]UMR 1073 ADEN, University Rouen Normandie, Rouen, France
[2]Department of Epidemiology, CHU Rouen, Rouen, France
[3]CIC-CRB 1404, CHU Rouen, Rouen, France
Contact: rodeline.telfils@univ-rouen.fr

Introduction: Sexual harassment is an uprising problem in higher education systems worldwide with major impacts on students. The aim of this study was to describe and meta-analyze quantitative data on sexual harassment prevalence among higher education students.

Methods: We searched in seven databases and included studies published in English and French from 2000 until 2023 if they measured sexual harassment prevalence on students attending higher education, and they were quantitative cross-sectional studies. Prevalence estimates disaggregated by gender identity, and world region were meta-analyzed using a random-effects model and reported following PRISMA guidance.

Results: We identified 53 articles, from 6 different regions of the world, with highly variable sample sizes, ranging from 164 to 779,170. 45% of the samples were from the United States. 32% of studies used convenience or purposive sampling and 39% random sampling. The meta-analyzed prevalence of sexual harassment was globally 36.9% (95% CI [30.6, 43.6], 43.7% for women, 16.8% for men, 33.4% for non-binary. In additional, variations in prevalence were observed across the different world regions. In particular, the Eastern Mediterranean region presented the highest prevalence estimates for sexual harassment among women, reaching 67.5%, while the Americas region presented the highest prevalence estimates for sexual harassment among men, at 18.8%.

Discussions: Higher education institutions, especially in low- and middle-income countries, should commit to the conduct of surveys to monitor the prevalence of sexual harassment, and policymakers should allocate specific funds and resources to support the implementation of sexual harassment prevention and intervention initiatives in higher education, prioritizing the safety and well-being of students.

Key messages:

- High prevalence of sexual harassment in higher education underscores urgent need for proactive measures to ensure student safety and well-being.
- Policymakers should allocate specific funds and resources to support the implementation of SH prevention and intervention initiatives in higher education.

Introduction: The study of crisis events provides important lessons to prepare for upcoming events. The Great Recession's impact on perinatal health in Europe can provide relevant insights into the healthcare and social protection systems' response to protecting the health of the most vulnerable groups.

Objectives: To assess time trends and international disparities in perinatal mortality rates (PMR) and infant mortality rates (IMR), following the Great Recession, and their association with socioeconomic indicators in Portugal, Greece, Italy and Spain.

Methods: Associations were assessed through generalised linear models for all four countries. A Poisson joinpoint regression model was applied to explore PMR and IMR trend changes between 2000 and 2018. Country disparities were analysed using mixed-effects multilevel models.

Results: IMR and PMR have decreased overall in the four selected countries between 2000 and 2018. Still, whereas in Spain, Italy and Portugal the decreasing pace was attenuated after 2009, in Greece a positive trend was found after the 2008 crisis. IMR and PMR were significantly associated with socioeconomic indicators in all four countries. National disparities in the evolution of IMR and PMR were significantly associated with most socioeconomic indicators between 2000 and 2018.

Conclusions: Our results confirm the impact of the Great Recession on PMR and IMR trends in all four countries, taking recurring associations between macroeconomic cycles, variations in mortality trends, macroeconomic volatility and stagnation of IMR and PMR into account. The association with socioeconomic indicators stresses the need to strengthen social protection and healthcare systems to better protect the population's health from the earliest days.

Key messages:

- Mortality patterns refer to the internal variability of the crisis' effect and to persistent spatial regional inequalities appealing to the need for attention in policymaking.
- The relevance of considering the political economy of global health finance and macroeconomic volatility as a major influence on the association of mortality rates with socioeconomic indicators.

Gender Differences in Years of Life Lost resulting from the 2015 Gorkha Earthquake in Nepal

Margo Tonnelier

M Tonnelier[1]*, M Bhandari*[1]*, D Delforge*[1]*, M Moitinho de Almeida*[1]*, J van Loenhout*[1,2]*, B Devleesschauwer*[2,3]*, J Haagsma*[4]*, N Speybroeck*[1]*, P Charalampous*[1,4]

Contact: margo.tonnelier@uclouvain.be

Background: Nepal has a history of regular natural hazards, including significant earthquakes and floods. Previous studies have shown that females, particularly younger females, are more likely to die due to disasters compared to males. This study aimed to explore gender differences in mortality - measured in Years of Life Lost (YLL) - caused by the 2015 Gorkha earthquake across 41 districts of Nepal.

Methods: Mortality counts were derived from the Nepal Police Report. YLL was estimated by multiplying mortality counts (stratified by age, gender, and district) by age-conditional life expectancy from the 2019 Global Burden of Disease reference life table. Both absolute numbers and rates of YLL per 100,000 population were calculated. YLL per deaths, stratified by age-gender-and-location, were estimated and compared. Male-to-female YLL rate ratios were estimated as well, and compared across districts.

Results: The 2015 Gorkha earthquake resulted in 8,950 deaths (females: 56.1% versus males: 43.9%), accounting for 526,617 YLL. Males had a slightly higher number of YLL per death (59.2) compared to females (58.5); this is mainly due to the different number of deaths between males and females. YLL per deaths ranged from 65.4 (Rautahat district) to 0 (in several districts) among males and, from 65.3 (Rautahat district) to 0 (in several districts) among females. The YLL rate per 100,000 population was higher for females (3,158 per 100,000) than for males (2,575 per 100,000). Approximately 40% of the districts had male-to-female YLL rate ratios of less than one, which can be partly explained by the gender distribution of the population at rik of dying due to earthquake.

Conclusions: The study found relatively higher YLL per death for males and higher YLL rates for females. This underscores the necessity to further investigate the factors that contribute to fatalities from earthquakes, especially in lower middle income countries such as Nepal.

Key messages:

- Gender disparities in mortality following the 2015 Gorkha earthquake in Nepal were addressed using Years of Life Lost (YLLs); males had higher YLL per death, while females had higher YLL rates.
- Exploring the factors that contribute to earthquake-related fatalities should be a priority for disaster mitigation strategies.

Abstract citation ID: ckae144.1449
Using Social Network Analysis during COVID-19 contact tracing in Libya, 2020

Jebril Gebril

J Gebril[1,2]*, K Danis*[2]*, T Emahbes*[1]*, H Aqeehal*[1]*, A Alarbi*[1]*, H Ahlab*[1]
[1]Epidemiology Office, National Center For Disease Control Libya, Tripoli, Libya
[2]MediPIET, ECDC, Stockholme, Sweden
Contact: jebgebril1@gmail.com

Background: Social network analysis (SNA) may provide valuable insights into individual-level transmission dynamics, allowing for targeted contact tracing interventions. We used SNA to understand the variability in SARS-CoV-2 transmission at the case level during the first wave in Libya.

Methods: We analyzed the spread of COVID-19 in Libya from March to August 2020 using contact tracing data from 287 confirmed cases. We created a network to visualize the transmission patterns, representing each case as a node and connections as links. We focused on direct contacts identified through contact tracing and calculated network measures such as out-degree centrality, in-degree centrality, and betweenness centrality. Gephi software was used for data visualization and understanding the network structure.

Results: Of the 287 COVID-19 cases, 264 (92%) had nodes with zero outdegrees, indicating that they did not contribute to infection transmission. The remaining 23 (8%) had non-zero out-degree measures and transmitter infection to other cases, 10 (4%) of whom were super-spreaders (outdegree$\geq$5) causing 70% of the transmission. Six (2%) had no epidemiological contact, indicated by zero in-degree centrality measures; 63% had zero betweenness centrality measures, suggesting they did not act as intermediaries connecting separate transmission chains within the network. The network contained nine clusters of connected nodes, with the largest having 91 (24%) cases; the mean path length between cases was 1.846, and the network diameter was 4.

Conclusions: The study revealed distinct clusters of connected cases, along with the presence of super-spreaders. This network structure underscores the critical role of early identification and isolation of individuals with high transmission potential to effectively contain outbreaks. This revised conclusion directly references the findings of nine clusters and super-spreaders, demonstrating how these results support the importance of early intervention.

Key messages:

- Social network analysis identifies clusters and super-spreaders in COVID-19 transmission, emphasizing the need for targeted interventions.
- Connected clusters and super-spreaders highlight the importance of contact tracing and early isolation for effective control of COVID-19 outbreaks.

Background: As colorectal cancer (CRC) survivorship increases, so does the challenge of managing cancer-related fatigue, a prevalent condition that severely impacts survivors' ability to work and overall quality of life. This study delves into the relationship between lifestyle behaviors, assessed using the HEALTHY lifestyle score, and its influence on fatigue among CRC patients.

Methods: Data was derived from MIRANDA, a multicenter cohort study that enrolls adult CRC patients during a 3-week in-patient rehab within a year after primary CRC treatment. Up to date, n = 438 participants provided information on lifestyle factors at the rehabilitation start (baseline) and then every three months for the first year. The predictors were the HEALTHY lifestyle score and its components (diet, alcohol consumption, physical activity, BMI, and smoking status) calculated at three time points: before surgery, after surgery, and 12 months following rehabilitation. The outcome was fatigue, assessed using the Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F-FS) scale.

Results: Participants with a higher HEALTHY lifestyle score after CRC surgery had statistically significantly lower fatigue levels. The components that contributed most to this finding were smoking and physical activity. Participants who engaged in exercise post-surgery or did not smoke before their cancer diagnosis experienced lower fatigue levels during rehabilitation.

Conclusions: Lifestyle modifications, such as increasing physical activity and smoking cessation, are crucial in preventing or reducing fatigue among CRC patients. Tailored public health initiatives that advocate for these lifestyle adjustments and their incorporation into CRC rehabilitation protocols could significantly advance survivor care, ultimately leading to better health outcomes.

Key messages:

- The HEALTHY score is associated with fatigue of CRC patients during rehabilitation, highlighting the crucial role of lifestyle changes after CRC treatment.
- Smoking cessation and physical activity programs may be the most effective measures for decreasing the fatigue burden of these patients.

Abstract citation ID: ckae144.1451
Defining neighborhood walkability for children in the ELFE cohort study

Devin Parker

D Parker[1]*, E Chazelas*[1]*, M Melchior*[1]
[1]Epidemiology, Sorbonne, Paris, France
Contact: devin.parker@inserm.fr

Background: Although walkability is known to be associated with obesity in adults, there is a paucity of data evaluating the association of walkability and health outcomes in children. In particular, little is known regarding the possible association with children's mental health.

Methods: We used data from the Etude Longitudinale Française depuis l'Enfance (ELFE) cohort study. Participating mothers gave birth in 2011 in a representative sample of 320 maternity hospitals in mainland France. This pilot study is limited to participants in Paris and children at 5.5 years old. Walkability is defined by three parameters: population density (defined by census data), street connectivity (defined by intersection density), and land-use mix (entropy index). To approximate walkable areas, 500-meter street-network buffer zones were created around each participants address using a geographic information system. Children's mental health was assessed using parent-reported Strengths and Difficulties Questionnaire at age 5.5 years.

Results: There was a total of 280 children in this pilot study. On measures of land-use mix, we found a mean of 0.79 (SD: 0.12), representing high accessibility. Residential and intersection density were highly correlated ($p < 0.01$). The walkability index demonstrated high variability among participants (mean: 10.6; SD: 10.44; range: -1.67 - 30.59).

Conclusions: Developing a walkability index is a multifactorial measure to describe a children's neighborhood environment. Future work includes determining the association with children's mental health disorders, while accounting for individual and neighborhood variables. This ecological model can inform social epidemiology and contextual disparities in children's health.

Key messages:

- Little is known about neighborhood walkability and the association with children's mental health.
- Using objective measures to calculate neighborhood composition and help elucidate this relationship.

[5]Epidemiology Unit, Regional Agency for Public Health of Tuscany, Florence, Italy
Contact: guglielmo.bonaccorsi@unifi.it

The Mediterranean basin hosts endemic areas for leishmaniasis, mainly attributable to the presence of sand flies. Leishmaniasis has gained importance in Europe due to climate change, globalisation and migration. For at least the last 10 years in Tuscany, Italy, there has been an important discrepancy between official notifications of visceral and cutaneous leishmaniasis cases in humans and the number of hospital admissions, highlighting an important underestimation, despite mandatory notification. Moreover, official reports have increased alarmingly in the last three years. Human leishmaniasis does not always require hospitalisation: it often presents cutaneous manifestations, whereas in the immunocompetent individual it may not occur at all. For this reason, it is reasonable to assume that the number of cases is higher than the number of hospitalisations. The project aims to investigate the underreporting of human leishmaniasis cases from 2014 to 2023 by analysing laboratory diagnoses (considering any laboratory test that, according to the Italian Ministry of Health guidelines, is useful to identify a 'confirmed case', thus serological tests; parasitological tests; culture tests; PCR). To estimate the extent of underreporting, the capture-recapture method will be used, taking into account laboratory data, official reports and hospital data. Subsequently, a comparison will be made with the incidence, in the same territory, of veterinary cases, particularly in dogs, using data obtained from the Lazio-Tuscany Zooprophylactic Institute, to compare the trend of human and canine cases over time. Analyses are in progress and the results will be presented at the conference. Poor surveillance leads to ineffective prevention policies. The impact of the project is to strengthen the leishmaniasis surveillance system in Tuscany in order to reinforce prevention systems and face emergencies.

Key messages:

- Due to climate change, globalization, and migration, there has been an increase in diagnoses of vector-borne diseases, including Leishmaniasis.
- Leishmaniasis surveillance need to be strengthened in order to enhance prevention systems and address emergencies.

Abstract citation ID: ckae144.1453
Mediterranean diet score linked to cognitive functioning in women: evidence from the Czech Republic

Eliska Hrezova

E Hrezova[1], D Stefler[2], H Pikhart[1,2]
[1]Faculty of Science, Masaryk University, Brno, Czechia
[2]Institute of Epidemiology and Public Health, University College London, London, UK
Contact: eliska.hrezova@recetox.muni.cz

Background: Evidence suggests that adherence to the Mediterranean diet (MED) may be beneficial in preventing cognitive decline, although findings are inconsistent. We aimed to explore this association in the Czech population of older adults.

Methods: A total of 6,028 males and females from the Czech arm of the Health Alcohol and Psychosocial factors in Eastern Europe (HAPIEE) study were included in the analysis. Dietary data were collected using a food frequency questionnaire, and MED was calculated based on nine food groups. The MED score ranged from 0 to 16 points and was categorized into three groups: 0-7, 8-10, and 11-16 points. Cognitive function was measured using four tests assessing verbal memory and learning, verbal fluency, and attention, mental speed and concentration, from which single z-scores were computed. The composite score of cognitive function was computed as the mean of z-scores. The cross-sectional associations between MED and composite score of cognitive function were analyzed using multivariate linear regression.

Results: Females with a dietary score of 8-10 points (Beta=0.05, 95% CI: -0.002; 0.097), and those with a score of 11-16 points (Beta=0.08, 95% CI: 0.016; 0.140) had a higher composite cognitive score than women in lowest adherence group. Looking at specific domains, women in the highest adherence group had significantly better immediate verbal memory (Beta=0.12, 95% CI: 0.031; 0.205) and delayed recall (Beta=0.12, 95% CI: 0.027; 0.212), respectively, than those in the lowest adherence group. There were no associations in males.

Conclusions: Higher adherence to the MED was associated with better cognitive functioning in verbal memory and composite cognitive score in Czech females. The results suggest that the Mediterranean diet may help to improve cognitive functioning in older women. #NGEU

Key messages:

- Findings suggest that Mediterranean diet may be beneficial in cognitive functioning in older women.
- Higher adherence to the Mediterranean diet is connected to better cognitive function particularly in verbal memory domain.

Abstract citation ID: ckae144.1454
Metabolically healthy obesity and cardiovascular outcomes

Yasuharu Tabara

Y Tabara[1]
[1]Shizuoka Graduate University of Public Health, Shizuoka, Japan
Contact: tabara@s-sph.ac.jp

Obesity increases cardiovascular risk through a deterioration of the metabolic profile. However, obesity is not always accompanied by a worsening metabolic profile. This longitudinal study aimed to determine whether obesity with a normal metabolic profile, i.e. metabolically healthy obesity, increases the risk of cardiovascular disease. We analyzed a health insurance data of Shizuoka prefecture resident. This data includes data from annual health check-ups performed for insured persons. This study analyzed data from 168,699 individuals aged <65 years. Obesity was defined as ≥ 25 kg/m2 body mass index. Metabolically healthy was defined as ≤ 1 metabolic risk factors (high blood pressure, low high-density lipoprotein cholesterol, high low-density lipoprotein cholesterol, or high hemoglobin A1c). Incidence rate of cardiovascular diseases (stroke and myocardial infarction), and all-cause mortality identified from the insurance data were compared between clinical profile-matched metabolically healthy obesity and non-obesity groups ($n = 8,644$ each). Clinical parameters, namely systolic blood pressure (standard mean difference = 0.03), HDL cholesterol (0.01), LDL cholesterol (0.01), and hemoglobin A1c (0.01) did not differ among the metabolically healthy obesity and non-obesity groups. The incident rate of stroke (obesity: 9.2 per 10,000 person-years; non-obesity: 10.5; log-rank test P = 0.595), myocardial infarction (obesity: 3.7; non-obesity: 3.1; P = 0.613), and all-cause mortality (obesity: 26.6; nonobesity: 23.2; P = 0.304) also did not differ significantly among the groups even when abdominal obesity was considered in the analysis, though the population with metabolically healthy obesity reported negligibly worse metabolic profiles than the population with nonobese at the 5.6-year follow-up. Obesity, when accompanied by a healthy metabolic profile, did not increase the risk of cardiovascular outcomes and all-cause mortality.

Key messages:

- Metabolically healthy obesity did not increase cardiovascular disease risks.
- Metabolically healthy obesity was associated with worse metabolic profiles after a few years later.

Abstract citation ID: ckae144.1455
Asbestos is still paid for dearly

Elena Maria Guerreschi

EM Guerreschi[1], L Dragoni[1], AG Sisinni[2], S Fabrizi[2], GB Miceli[2], N Nante[1,3]
[1]Post Graduate School of Public Health, University of Siena, Siena, Italy
[2]Health Surveillance and Preventive Medicine Unit, University Hospital, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: e.guerreschi@student.unisi.it

Background: In Italy, asbestos is a current and important problem in terms of health effects due to the long latency of diseases related to its exposure. The aim of the study is to analyze the case history of malignant pleural mesothelioma (MPM) in the University Hospital of Siena in the period 2019-2023, comparing the type of exposure (occupational/non-occupational), the mean conventional latencies (MCL) of diagnosis, the histotype and the most exposed categories.

Methods: The study was conducted from January to April 2024, on 69 patients (79.7% male and 20.3% female) with a diagnosis of pleural mesothelioma between 2019 and 2023. 48 patients lived in Tuscany and 21 outside the region. The data were collected by consulting the medical surveillance records and radiological images through the VuePacs platform, then organized in a filtered database.

Results: Of 69 patients, exposure was occupational in 54 cases and non-occupational in the remaining 15. In patients with occupational exposure, the MCL was 55.9 years and the mean age at diagnosis was 73.66 years; in the other group, the MCL was 47.3 years and the mean age at diagnosis was 66.8. The study revealed the prevalence of epithelioid histotype in 76.81% of cases, biphasic in 15.94% of cases and sarcomatoid in 7.25%. The most at-risk categories were: metalworking (10 cases), construction (8), electricity/gas production (6) and shipyards (4). The study also identified two cases of atypical occupational exposure.

Conclusions: The shorter average latency in cases with non-occupational exposure is in accordance with the current scientific literature, as well as the prevalence of epithelioid histotype. Are hereby confirmed the primary role of health surveillance in the in-depth investigation of occupational anamnesis and of the environmental sites' survey as prevention tool, especially in those cases of MPM whose evaluation, deviating from the exposure standards, could lead to the assignment of a misdiagnosed exposure.

Key messages:

- The effects of asbestos exposure are a current and important problem in our country, even after its disposal, due to the long latency of disease onset.
- In-Department investigation of occupational anamnesis and survey of environmental sites as prevention tool play an essential role in MPM evaluation, especially in those cases of atypical exposure.

Abstract citation ID: ckae144.1456
Past-year mental health issues: discrepant survey & administrative data

Matej Vinko

M Vinko[1], L Zaletel Kragelj[2], A Kukec[2]
[1]NIJZ, Ljubljana, Slovenia
[2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia
Contact: matej.vinko@nijz.si

Introduction: Accurately measuring mental health disorder prevalence is crucial for public health planning. Administrative and survey data are common methods, but often yield differing results. This study compares case identification of mental health issues across these data sources in Slovenia.

Methods: We linked the 2019 European Health Interview Survey (EHIS) with three Slovenian health administrative databases: the National Hospital Health Care Statistics Database, Outpatient Prescription Drugs Database, and Absence From Work Database. Case identification utilized self-report of any mental health issue in the past 12 months and healthcare utilization records in 12 months preceding participation in EHIS. Multinomial logistic regression was used to examine the association between socio-demographic factors and case identification across data sources.

Results: Significant differences were found in 12 month prevalence of any mental health issue estimates between data sources. Only 45.9% of self-reported cases were identified in administrative data, and 36.6% of administrative cases self-reported mental health issues (Kappa = 0.302). Socio-demographics, including age, gender, education, and employment status, were significantly associated with the likelihood of identification in specific data sources.

Discussion: Our findings underscore the importance of data source and assessment tool selection on mental health prevalence estimates. Variations in identification across population subgroups could reflect differences in healthcare access and self-disclosure biases. Linking data sources and considering their inherent limitations is crucial for accurate burden estimation.

Key messages:

- Data source and assessment methods significantly impact how we identify individuals with mental health issues in the past year.
- Combining data sources and understanding their limitations is essential for improving mental health burden estimation.

Abstract citation ID: ckae144.1457
Breast implant illness in women with implant-based reconstruction after breast cancer

Annemiek Lieffering

[6]Plastic, Reconstructive and Hand Surgery, Ziekenhuis Groep Twente ZGT, Almelo, Netherlands
[7]Plastic and Reconstructive Surgery, Erasmus MC Cancer Institute, Rotterdam, Netherlands
Contact: a.lieffering@nivel.nl

Background: This study investigated the association between silicone breast implants and health symptoms (Breast Implant Illness (BII)) in women with implant-based breast reconstruction after breast cancer. While there is increasing evidence of an association with BII in cosmetic breast augmentation cases, for women with implant-based breast reconstruction this is unknown.

Methods: Retrospective cohort study of 254 women who underwent implant-based reconstruction after breast cancer and a control group of 487 women who underwent breast-conserving therapy or simple mastectomy. We linked Dutch Breast Implant Registry data (2015-2019) and general practice electronic health records data (2014-2022) to study the occurrence of thirteen BII-related health symptoms in general practice and the number of consultations for these symptoms one year before to three years after breast surgery.

Results: Over the three years following implantation, no significant differences in symptom occurrence were observed compared to both the year before implantation and the control group. Women with breast implants did not have more consultations compared to the control group during follow-up. However, there was an increased likelihood of multiple consultations in the first and second years post-implantation compared to before implantation ($\geq$3 consultations first year OR = 2.10, p = 0.005; second year OR = 1.70, p = 0.048; $\geq$5 consultations first year OR = 2.57, p = 0.02).

Conclusions: This study found no evidence for BII in women with implant-based reconstruction after breast cancer. Despite certain limitations in examining BII in this specific patient group, these findings add valuable information to the decision-making process of breast cancer patients considering reconstructive options.

Key messages:

- This is the first study on BII that focused solely on women with breast implants for reconstruction after breast cancer.
- No evidence of BII was found in this patient group.

Abstract citation ID: ckae144.1458

Educational inequalities in cervical cancer mortality in the Baltic Sea region in 2008–2015

Oskar Nõmm

O Nõmm[1,2], K Innos[1], M Leinsalu[1]

[1]Department of Epidemiology & Biostatistics, The National Institute for Health Development, Tallinn, Estonia

[2]Institute of Family Medicine & Public Health, University of Tartu, Tartu, Estonia

Contact: oskar.nomm@tai.ee

Background: Reducing inequalities in cervical cancer mortality is a public health priority. This study aims to assess the absolute and relative educational inequalities in cervical cancer mortality in the Baltic countries and Finland in 2008-2015.

Methods: Data for Estonia, Latvia and Lithuania were obtained from longitudinal mortality follow-up studies of population censuses in 2000/2001 and 2011, and data for Finland from the longitudinal register-based population data file of Statistics Finland. Cervical cancer deaths (ICD-10 code C53) were linked from national mortality registries. Educational level was census- or registry-based. Absolute and relative educational inequalities in cervical cancer mortality were assessed in 2008-2015 for women aged 30-49 and 50-64, using age-standardized mortality rates (ASMRs) per 100 000 person-years and mortality rate ratios (RRs) with 95% confidence interval (CI).

Results: This study included 1724 cervical cancer deaths and about 22 million person-years. Absolute and relative educational inequalities in cervical cancer mortality were considerably larger in the Baltic countries compared to Finland. Among 30-49-year-olds, ASMRs for high educated ranged from 0.6 (95% CI: 0.4-1.0) in Finland to 3.6 (95% CI: 2.5-5.0) in Lithuania, and for low educated from 2.2 (95% CI: 1.2-3.7) in Finland to 24.6 (95% CI: 18.2-32.4) in Lithuania. RRs for low educated compared to high educated ranged from 3.51 (95% CI: 1.57-7.68) in Finland to 9.11 (95% CI: 4.28-19.32) in Estonia. Among 50-64-year-olds, ASMRs for high educated ranged from 1.3 (95% CI: 0.8-2.0) in Finland to 9.8 (95% CI: 7.2-13.1) in Estonia and for low educated from 2.9 (95% CI: 1.9-4.1) in Finland to 43.9 (95% CI: 34.4-55.1) in Lithuania. RRs for low educated compared to high educated ranged from 2.18 (95% CI: 1.20-4.05) in Finland to 6.32 (95% CI: 4.30-9.36) in Lithuania.

Conclusions: Equitable prevention is a key to reducing cervical cancer mortality in the Baltic countries.

Key messages:

- Lower-educated women largely drive high cervical cancer mortality in the Baltic countries.
- Equity-focused prevention is crucial for reducing cervical cancer mortality in the Baltic countries.

[4]Department of Sociology, University of North Carolina at Chapel Hill, North Carolina, USA

Contact: nazihah.noor@unifr.ch

Background: Health behaviors in adolescence could have a life-long effect on cardiometabolic health and differ by parental socioeconomic conditions. Adopting a life course perspective and a causal inference framework, we aimed to quantify the differential effect of adolescent unhealthy behaviors on adult cardiometabolic conditions by parental financial situation.

Methods: Using the National Longitudinal Study of Adolescent to Adult Health in the United States (n = 3,772), we estimated conditional causal effect by parental financial situation through inverse probability-weighted marginal structural models. Exposures were adolescent health behaviors (dietary habits, cigarette smoking, alcohol consumption and physical activity) and the effect modifier was parental financial situation (difficulty paying bills vs. no difficulty), both measured at ages 12-19 (1994-1995). Outcomes were cardiometabolic conditions (hypertension, stroke, cardiac failure, diabetes, chronic kidney disease), measured at ages 33 - 43 (2016-2018) using biomarkers and self-reports.

Results: There were 1,206 participants with cardiometabolic conditions after 20 years of follow-up. Alcohol consumption among adolescents with parental financial difficulty led to 325 more cardiometabolic cases (95% confidence interval: 2 - 647) compared to alcohol consumption by their peers without financial difficulty. This differential effect is driven more by cardiovascular conditions (hypertension, stroke, or cardiac failure) than by metabolic conditions (diabetes or chronic kidney disease). There were no differential effects of dietary habits, cigarette smoking and physical inactivity on the occurrence of adult cardiometabolic conditions.

Conclusions: Public health initiatives targeting alcohol consumption during adolescence could mitigate socioeconomic inequalities in adult cardiometabolic conditions.

Key messages:

- Socioeconomically disadvantaged adolescents are more susceptible to the long-term detrimental health effects of alcohol consumption.
- These susceptible groups may need targeted interventions to mitigate the cardiometabolic effect of alcohol consumption.

Abstract citation ID: ckae144.1460
Risk Scores for Five Early Life Domains and Odds of Obesity and Hypertension Comorbidity

Contact: S.J.Stannard@soton.ac.uk

Background: For outcomes such as obesity and hypertension, determinants are likely to be complex and multidimensional. Therefore, to design realistic interventions, epidemiological research should incorporate information from multiple risk exposure domains to assess the effect on health. In this paper we explore risk scores for five early life domains and odds of obesity and hypertension comorbidity.

Methods: We used data from 17,196 participants in the 1970 British Cohort Study. The outcome was obesity (BMI of $\geq$ 30) and hypertension (blood pressure$>$140/90mm Hg or self-reported doctor's diagnosis) comorbidity at age 46. Early life domains included: 'prenatal, antenatal, neonatal and birth', 'developmental attributes and behaviour', 'child education and academic ability', 'socioeconomic factors' and 'parental and family environment'. Stepwise backward elimination selected variables for inclusion for each domain. Predicted risk scores of obesity and hypertension for each cohort member within each domain were calculated. Logistic regression investigated the association between domain-specific risk scores and odds of obesity-hypertension, controlling for demographic factors and other domains.

Results: In unadjusted models, higher domain-specific risk scores were associated with increased odds of obesity-hypertension comorbidity. In adjusted analyses, higher domain-specific risk scores remained associated with increased odds of obesity-hypertension comorbidity, with the strongest associations to the parental and family environment domain (OR1.11 95%CI 1.05-1.18) and the socioeconomic factors domain (OR1.11 95%CI 1.05-1.17).

Conclusions: Appropriate modelling choices of combined effects of early-life risk factors need to be explored and tested. Targeted prevention interventions aimed at population groups with shared early-life characteristics could have an impact on cardiovascular risk in adulthood.

Key messages:

- Targeted prevention interventions aimed at population groups with shared early-life characteristics could have an impact on obesity-hypertension prevalence.
- Appropriate modelling choices of combined effects of early-life risk factors need to be explored and tested.

Contact: m.kozela@uj.edu.pl

In older people health condition contributes to the feeling of being alone (loneliness). We aimed to assess which chronic health conditions are the strongest determinants of loneliness in older urban residents. Participants of the Polish part of the HAPIEE Study (Health Alcohol and Psychosocial Factors in Eastern Europe) examined in 2019-20 were included to the analysis. Trained nurses interviewed respondents in their homes. Loneliness was assessed using 3-item UCLA scale (range: 3-9, cuf-off$\geq$ 6 points). Socioeconomic data, self-rated health (SRH) and the history of 18 diseases diagnosed by the doctor was assessed using standardized questionnaire. Multivariable logistic regression was used; odds ratios and 95% confidence intervals are presented (OR (95%CI)). There were 461 participants (48% males) of mean age 72 years (SD = 6.3). In 34 participants (7%) UCLA score was 6 or more. The majority (63%) of respondents were married or cohabiting. Nearly 90% declared having children. After adjustment for marital status and having children, poor distance vision 3.84 (1.31-6.12), hearing problems 2.20 (1.07-4.53), acute back pain syndrome 2.21 (1.06-4.59) and cancer 2.36 (1.03-5.41) were determinants of loneliness. Further adjustment for age weakened the association with distance vision 2.74 (1.26-5.94) and waved the relationship with hearing problems 2.06 (0.99-4.29). The estimates for remaining health conditions remained almost unchanged. The strongest predictor of loneliness was SRH. After adjustment for age, marital status, having children and objective burden of chronic diseases, compared to good SRH, participants with moderate and poor SRH were more likely to report loneliness by over 3 and 6 times: 3.41 (1.29-9.05) and 6.60 (2.16-20.18), respectively. The perception of poor health and diagnosis of cancer strongly determined loneliness in older people, but other important predictors of loneliness were conditions that objectively hinder maintaining social contacts.

Key messages:

- In older people health condition is related to the feeling of being alone, and the strongest objective health determinant of loneliness was diagnosis of cancer.
- Independently of objective burden of chronic diseases, self-rated health was a significant predictor of loneliness in older urban residents.

[6]School of Public Health, Nazarbayev University, Astana, Kazakhstan
Contact: zhanlazim@gmail.com

Background: The factors contributing to the fatal outcome of COVID-19 in pregnant women remain not entirely clear. We compared the prevalence rates of comorbidities and laboratory test results in pregnant survivors and non-survivors.

Methods: This retrospective study relied on clinical and laboratory data obtained from medical records of pregnant women with COVID-19 admitted to three hospitals of the Republic of Kazakhstan from 16.07.2021 to 31.01.2022. Overall, we obtained data on 157 pregnant women with COVID-19, of whom 95.9 % survived and 4.1 % died in the hospitals.

Results: Arterial hypertension was present in 50% of non-survivors vs. 7.9% of survivors ($P = 0.001$), diabetes mellitus was diagnosed in 16.7% of non-survivors vs. 2.3% of survivors ($P = 0.044$), and the rate of hyperglycemia was 40% and 7.2%, respectively ($P = 0.009$). Heart rhythm disturbance was present in 50% of non-survivors vs. 6.4% of survivors ($P < 0.001$), and already at the time of admission to the hospital, the non-survivors had significantly higher heart and respiratory rates. Laboratory tests showed that non-survivors had higher erythrocytes sedimentation rate, C-reactive protein, leukocyte count, and D-dimer levels ($P = 0.001$, $P < 0.001$, $P = 0.038$, $P = 0.014$, respectively). The creatinine level was within the normal range in both study groups, but it was relatively higher in the deceased pregnant women (71.3; IQR: 66-251.75) vs. 52; IQR: 43-63; $P = 0.001$). Finally, a higher proportion of those who died presented with abnormal chest CT as compared with the survivors (33.3% vs. 4.2%, $P < 0.001$).

Conclusions: The deceased had a higher rate of comorbidities. Given the vulnerability of pregnant women to COVID-19, it is essential to plan a prospective study to provide insights into the factors that contribute to severe COVID-19 outcomes in pregnant women.

Key messages:

- Determining risk factors for fatal COVID-19 is crucial for effective medical care of pregnant women.
- Identifying potential risk factors of fatal COVID-19 among pregnant women could help inform public health policies and clinical guidelines.

Abstract citation ID: ckae144.1463
Narrowing socioeconomic inequalities in coronary heart disease: insight from Mendelian randomization

Xuan Xu

X Xu[1], *J Fu*[1], *F Wu*[2], *W Xu*[1]
[1]Department of Epidemiology, Fudan University School of Public Health, Shanghai, China
[2]Intelligent Medicine Institute, Fudan University, Shanghai, China
Contact: xuanxu22@m.fudan.edu.cn

Background: Socioeconomic inequalities in coronary heart disease (CHD) represent a pressing global public health concern. However, which dimensions of socioeconomic status (SES) affect CHD and the potential modifiable mediators remain elusive.

Methods: We performed two-sample Mendelian randomization (MR) analyses based on summary data from large-scale genome-wide association studies in populations of European ancestry. Specifically, by applying bidirectional univariable MR (UVMR) and multivariable MR (MVMR), we investigated the causal relationships of education, occupation, income, Townsend deprivation index (TDI) with CHD and the independent effects of these SES indicators. We further employed a two-step MR to comprehensively profile the mediating effects of 23 behavioral, 3 psychological and 5 biological factors in the relationships.

Results: An independent causal association was observed between genetically predicated education and CHD, with a 30% lower risk of CHD (OR: 0.70; 95% CI: 0.53-0.93) for each 4.2-year of schooling. Each one-s.d. higher household income was causally, but not independently, associated with a 39% lower risk of CHD (OR: 0.61; 95% CI: 0.49-0.77). No significant causal association was suggested for occupation and TDI with CHD, and no reverse causal effect was observed for CHD on the SES indicators. Of 31 candidate mediators, nine factors mediated the effect of education on CHD significantly, with an individual mediation proportion of 33.5% for smoking, 29.2% for sedentary behaviour, 14.4% for blood lipids, 13.4% for BMI, 11.7% for systolic blood pressure, 9.5% for diastolic blood pressure, 7.8% for well-being spectrum, 6.4% for depression and 2.8% for blood glucose.

Conclusions: This study highlights that education was the primary SES indicator affecting CHD with considerable mediation by a number of modifiable risk factors. These findings inform policies to mitigate disparities of CHD risk attributable to socioeconomic inequalities.

Key messages:

- Education can be prioritized over other common SES indicators as an essential strategy to reduce the burden of CHD.
- Interventions for narrowing socioeconomic inequalities in CHD could focus on more easily modifiable mediating factors.

Abstract citation ID: ckae144.1464
Excess all-cause mortality in 21 countries during 2022: COVID-19 impact by C-MOR project

Christiana Demetriou

CT Pallari[1], *S Achilleos*[1], *A Quattrocchi*[1], *CM Bennett*[2], *G Ambrosio*[3], *A Polemitis*[4], *A Charalambous*[5], *CA Demetriou*[1]

[5]University of Nicosia Medical School, Nicosia, Cyprus
Contact: demetriou.chri@unic.ac.cy

National published COVID-19 mortality estimates do not fully encompass the extent of the pandemic's impact on mortality. To address this challenge, calculating excess all-cause mortality at the national level is important. Our focus was on understanding total weekly excess mortality for 2022, by analysing mortality data across 2020-2022, from 21 countries participating in the international consortium (C-MOR), which provided data for examination. Excess mortality was calculated by comparing the weekly 2022 age-standardized mortality rates per 100,000 population against a baseline mortality, estimated using historical data from 2015-2019. Excess cumulative mortality for 2022 was found in all 21 countries. The excess mortality for the total population varied between 8.6 and 116.2, with the minimum excess belonging to Peru and the maximum to Georgia. Australia, Austria, Cyprus, Denmark, Estonia, Georgia, Greece, Israel, and Norway showed a higher excess in 2022 than in 2020, while Australia, Austria, Cyprus, Denmark, Israel, Italy, Norway, Spain, and Sweden also showed a higher excess in 2022 than in 2021. Mauritius showed a significant excess mortality for the first time in 2022. For all countries, but Australia, the % of COVID-19 deaths out of all deaths decreased in 2022 compared to 2021. Contrary to the 'harvesting effect', which would expect a decline in mortality rates post-pandemic, our results underscore a sustained excess mortality throughout 2022. The 2022 excess deaths are mainly non-COVID-related, stemming from broader pandemic impacts on healthcare systems and other factors. Conversely, in Australia, international boarders reopened in 2022, resulting in the first community-wide transmission and a substantial rise in excess deaths. Our study reveals nuanced excess mortality dynamics post-vaccination, providing crucial insights for policymakers and stressing the necessity of continued vigilance and adaptive strategies against COVID-19's diverse impacts.

Key messages:

- All countries investigated experienced continued all-cause excess mortality during 2022, compared to pre-pandemic years. For most, excess mortality in 2022 was higher than in 2021 and 2020.
- For all countries, except Australia, the contribution of COVID-19 deaths to the mortality estimates in 2022 is decreased, highlighting the impact of indirect pandemic related effects on mortality.

Abstract citation ID: ckae144.1465
Are answers affected by data collection on paper or online? The case of Belgian adolescents

Katia Castetbon

K Castetbon[1], *A Momo Damo*[1], *C Mertens*[1], *E Holmberg*[1], *W Assakali*[1], *M Eggen*[1]
[1]School of Public Health, Université Libre de Bruxelles, Brussels, Belgium
Contact: Katia.Castetbon@ulb.be

Background: In the early 2000s, the prevalence estimations were compared in relation with the mode of data collection, i.e. paper or online. Following the widely spread routine use of connected devices, especially in adolescents, such a monitoring is of interest. Within the 2022 “Health Behaviour in school-aged children” survey in French-speaking primary and secondary schools of Belgium, those participating could choose between paper and online collection. Our objective was to compare a large set of indicators between the two modes after adjusting for the students’ characteristics.
Methods: After a two-stage random selection of schools and classes, 11,751 10-to-20-year-old adolescents completed the questionnaire either on paper or online. Descriptive analysis and comparisons were conducted using chi2 and multiple logistic regressions adjusted for the students’ sociodemographic characteristics that may vary according to the questionnaire mode.
Results: Overall, 54.9% of the questionnaires were completed online. The choice of the collection mode provided to the schools’ headteachers was associated with the adolescents’ characteristics. Those who completed the questionnaire online were more likely to be in secondary schools, in Wallonia, and of a more favourable socioeconomic profile. After adjustments, no difference in the indicators regarding health, well-being, substance use, or sleep duration was observed. Conversely, a difference was observed for screen time (internet $\geq$2h/weekday: 70.4% on paper vs. 72.3% online; adjusted P-value: 0.02), some food groups (daily vegetables: 51.2% vs. 58.0%; P-value$<$0.001) and body weight status (overweight including obesity: 16.7% vs. 14.0%; P-value$<$0.001).
Conclusions: In some circumstances such as data collection in the school setting, mixed modes are still necessary due to operational issues. While most indicators did not show a difference between online and paper collection, potential implications for others need to be further understood.
Key messages:

- Collecting data through online or paper questionnaires does not lead to major differences in prevalence estimates.
- With the rise of online surveys, further assessment is required to understand the potential declaration biases.

Abstract citation ID: ckae144.1466
Investigation of a Norovirus GII.4Sydney[P16] outbreak in a care facility in Portugal, 2022

Matilde Ourique

M Ourique[1], *C Minetti*[2], *V Manageiro*[2], *A Vicente*[1], *C Roque*[3], *A Coelho*[3], *M Oleastro*[3], *D Martins Correia*[1], *R de Sousa*[3], *N Rodrigues*[1]

[2]ECDC fellowship Programme, Public Health Microbiology Path EUPHEM, ECDC, Solna, Sweden
[3]National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
Contact: matildourique@gmail.com

Background: On the 29th of April 2022 the local Public Health unit was notified of 12 cases of acute gastroenteritis in residents of a long-term care facility (LTCF). A joint epidemiological investigation team was established and initiated an outbreak investigation to characterize the outbreak and implement infection control measures.
Methods: Epidemiological questionnaires were administered to staff (n = 44) and residents (n = 60). Case definition was LTCF residents or staff members with at least one of the following symptoms: diarrhoea, vomiting, nausea, between April 25th and May 14th, 2022. Stool or vomit samples were collected for 11 individuals. To assess environmental contamination fifteen food samples from previous meals and six surface samples from toilet faucets, wash tubs, and cutting boards were collected. Spatial distribution of cases within the LTCF was performed to guide infection control implementation.
Results: A total of 43 people met the case definition. Attack rates in residents and staff were 37% (23/63) and 42% (20/48), respectively. Of the total tested specimens, six (6/8) from residents and two (2/3) from staff were positive for the Norovirus (NoV) GII.4 Sydney [P16] variant by genotyping. Two (2/6) samples from surface swabs from the toilet faucet in the resident’s living room were also positive for NoV GII. Food samples were negative for major bacterial agents implicated in gastrointestinal outbreaks. Cases were distributed throughout the LTCF wards with no clear clustering. Four residents required hospital admission.
Conclusions: Results suggest person-to-person as well as environmental transmission of NoV. Identification of behavioural and spatial patterns of residents and staff and subsequent enactment of infection control strategies mitigated the outbreak. These findings reinforce the need for public health to maintain continuous technical support to LTCF on the implementation of infection control best practices.
Key messages:

- Outbreak investigation in LTCF confirms Norovirus transmission, emphasizing the importance of infection control measures in long-term care facilities.
- Study reveals Norovirus outbreak in LTCF, underscores the role of person-to-person and environmental transmission, highlighting the need for robust infection control protocols.

Musculoskeletal disorders and risk factors in the modern era: results from the Specchio cohort

Stephanie Schrempft

A Bouhet[1], *H Baysson*[1], *A Uppal*[1], *J Lamour*[1], *M-E Zaballa*[1], *S Stringhini*[1,3], *M Nehme*[1,2], *I Guessous*[2,3]
[1]Unit of Population Epidemiology, Geneva University Hospitals, Geneva, Switzerland
[2]Division of Primary Care Medicine, Geneva University Hospitals, Geneva, Switzerland
[3]Department of Health and Community Medicine, Geneva University Hospitals, Geneva, Switzerland
Contact: stephanie.schrempft@hug.ch

Background: Musculoskeletal disorders (MSDs) represent a major challenge for occupational and public health, but data are scarce in Switzerland or concentrated on a few sectors of activities. The aim of this study is to provide results on the prevalence and risk and protective factors of MSDs in the general working-age population of the Geneva canton, Switzerland.
Methods: A cross-sectional analysis was conducted as part of Specchio population-based cohort study. Prevalence and associations between MSDs and sociodemographic variables, individual behaviour (smoking, physical activity, sleep), health conditions (BMI, chronic diseases), physical and psychological risks at work were examined using regression models. The impact of teleworking was also evaluated.
Results: 2’733 participants took part in the survey, of which 38% were men, and mean age was 50. Overall prevalence of MSDs was 74% among men and 84% among women. 80% of the individuals experience back pain and 56% shoulder pain. Among individuals who experienced MSDs, 55.2% consulted a healthcare professional.

The risk factors for MSDs were female sex (OR = 1.95; 95% IC = 1.55-2.28), body mass index (obese) (2.2; 1.51-3.32), lower education (1.77; 0.84-4.37), smoking (1.65; 1.19-2.35), exposure to physical risks (3.54; 2.78-4.51), stress at work (effort-reward imbalance) (3.23; 2.45-4.29) and a poor work-life balance (2.36; 1.88-2.97). The prevalence of MSDs remained high among workers who telework (78% versus 84% in working population).

Conclusions: This study, carried out in a large population-based cohort, confirmed several risk factors for MSDs. These results will contribute to the implementation of prevention strategies, especially as teleworking has gained in importance in recent years, which may have aggravated workers' isolation and stress, sedentariness, and poor body posture. Main message: These data confirm the weight of musculoskeletal disorders and will help implementation of prevention health strategies.

Key messages:

- The relationship between psychosocial risks at work and the occurrence of Musculoskeletal Disorders (MSDs) persists even following adjustment for exposure to physical risks and individual risk factors.
- The prevalence of musculoskeletal (MSDs) disorders remained high among workers who telework.

Abstract citation ID: ckae144.1468
Waiting for hip fracture surgery: Analysis of individual heterogeneity and discriminatory accuracy

Johan Öberg

J Öberg[1,2], K Khalaf[1,2], R Perez[1], J Merlo[1,3]
[1]Unit for Social Epidemiology, Lund University, Malmö, Sweden
[2]Department of Healthcare Management, Region Skåne, Malmö, Sweden
[3]Centre for Primary Health Care Research, Region Skåne, Malmö, Sweden
Contact: johan.oberg@med.lu.se

Background: Evaluation of healthcare inequality could be improved by considering (i) the intersection of socioeconomic axes of inequality, (ii) the existence of individual heterogeneity and (iii) criteria to quantify group differences and how those differences translate into recommendations for universal or targeted interventions. In this study we illustrate how to achieve these improvements.

Methods: We applied analysis of individual heterogeneity and discriminatory accuracy (AIHDA) to analyze data from the Swedish patient registry for the quality indicator hip fracture (HF) surgery within the same day. We analyzed 57,340 patients residing in Sweden during 2011-2014 and belonging to 36 socioeconomic strata defined by age, sex, income, and country of birth and the 21 Swedish regions. We calculated prevalences and 95% confidence intervals as well as the absolute number of cases. The benchmark was set to 80%. To quantify group differences, we evaluated the discriminatory accuracy (DA) using the area under the ROC curve (AUC).

Results: 68% (39,073/57,340) of the patients were operated in time. The prevalence across the 36 sociodemographic strata ranged from 51% (43-58%) to 81% (67-91%). However, the DA was low (AUC= 0.562) indicating very small group differences. About half of the operated HP (n = 20,287) occurs in 18/36 strata with the lowest prevalences of operations in time. The regions' prevalences ranged from 37% (36-38%) to 88% (88-89%) with a rather high DA (AUC= 0.736) indicating larger differences. About half of the operated HP (n = 19,677) occurs in 12/21 regions with the lowest prevalence of operations in time.

Conclusions: The 80% benchmark was only achieved in one socioeconomic stratum and the group differences were very small. 6/21 regions achieved the benchmark and the group differences were large. Interventions aiming to reach the benchmark in the entire population should proportionately target regions and be universal and tailored to sociodemographic strata.

Key messages:

- The AIHDA-framework improves evaluations of healthcare inequalities.
- Both differences between group averages and the groups' DA need be considered when planning healthcare interventions.

Abstract citation ID: ckae144.1469
A novel developed DGS can be used to identify gene loci that may be associated with osteoporosis

Sui-Lung Su

S-L Su[1]
[1]School of Public Health, National Defense Medical Center, Taipei, Taiwan
Contact: a131419@gmail.com

Purpose: Previous meta-analyses only examined the association between single gene polymorphisms and osteoporosis; there is no compilation of all gene loci that correlate with osteoporosis in the literature. In this study, we develop a new literature-based approach, a decisive gene strategy (DGS), to examine the sufficiency of the cumulative sample size for each gene locus and to assess whether a definite conclusion of the association between the gene locus and osteoporosis can be drawn.

Methods: The DGS was used to search PubMed, Embase, and Cochrane databases for all meta-analyses that correlated gene polymorphisms with osteoporosis. Trial sequential analysis was employed to examine the sufficiency of the cumulative sample size. Finally, we assessed the importance of gene loci in osteoporosis based on whether there were enough sample sizes and the heterogeneity of the literature with the I2 value.

Results: After excluding 169 irrelevant publications, 39 meta-analysis papers were obtained. Among Caucasians, in 17 gene loci, there were eight gene loci (e.g., vitamin D Receptor ApaI rs7975232) with sufficient cumulative sample size to confirm that they were unrelated to the disease. Among Asians, in 15 gene loci, four gene loci that had sufficient sample sizes were risk factors: VDR FokI rs2228570 (odds ratio (OR) = 1.44, 95% confidence interval (CI) = 1.22-1.70), TGF β1 rs1800470 (OR = 1.35, 95% CI = 1.10-1.65), IGF1 rs2288377 (OR = 1.44, 95% CI = 1.28-1.62), and IGF1 rs35767 (OR = 1.20, 95% CI = 1.06-1.36), respectively, whereas one gene locus, ESR2 RsaI rs1256049 (OR = 0.69, 95% CI = 0.59-0.81), was a protective factor.

Conclusions: The DGS successfully identified five gene loci in osteoporosis that will apply to other diseases to find causal genes, which may apply disease-related genes in clinical practice, and to provide appropriate disease prevention policies.

Key messages:

- The DGS that will apply to other diseases to find causal genes.
- The DGS, which may apply disease-related genes in clinical practice, and to provide appropriate disease prevention policies.

Background: International comparisons provide essential benchmarks for evaluating perinatal health policies, but these rely on the availability of routine national birth data. This study aimed to describe population birth data sources in Europe by their ability to provide core perinatal health indicators.

Methods: The Euro-Peristat Network collected routine national data on a recommended set of core indicators from 2015 to 2021 using a federated protocol based on a common data model with 17 data items. Data providers filled in an on-line questionnaire to describe the sources used in each country. We classified countries by the number of data items they provided (all 16, 15-14, <14).

Results: 28 out of the 31 countries that provided data responded to the survey. Routine data sources included birth certificates (14 countries), electronic medical records (EMR) from delivery hospitalizations (14 countries), direct entry by health providers (9 countries), EMR from other care providers (6 countries) and Hospital Discharge Summaries (7 countries). Completeness of population coverage was at least 98%, with 15 countries reporting 100%. These databases most often included mothers giving birth on the national territory, regardless of nationality or place of residence (19 countries). In 20 countries, routine sources were linked, including linkage between birth and death certificates (15 countries). Countries providing all 16 items (N = 8) were more likely to use EMRs from delivery hospitalizations, 88%, compared to 50% and 13% in countries with 15-14 items (N = 13) and <14 items (N = 8). Linkage was also more common in these countries, 100%, versus 75% and 50% respectively. Other data source characteristics did not differ by the ability to provide data for the common data model.

Conclusions: There is high diversity in the data sources used to construct perinatal health indicators in Europe. Countries using EMR with linkage to other sources had the best data availability.

Key messages:

- There is high diversity in the data sources used to construct perinatal health indicators in Europe.
- Countries using Electronic Medical Records with linkage to other sources had the best data availability.

As the global population ages, dementia poses a significant health challenge, ranking seventh among leading causes of death worldwide. Considering the high societal and financial burden of dementia, our study aims to provide estimates of prevalence and incidence for any dementia and Alzheimer's dementia (AD) in the Campania Region (South Italy). It is Population-based study, using routinely collected healthcare data of individuals living in the Campania Region (South Italy) from 2015 to 2020. We included individuals aged ≥65 years who had at least one administrative record for dementia and/or AD. Prevalence rates adjusted for age and sex used 2020 European population as reference. To estimate incidence, we tested three possible algorithms, which differed for the duration of the time interval between study baseline (Jan 1, 2015) and index date (first record for dementia and/or AD in administrative databases). We employed a clinical database for the validation of our algorithms towards neuropsychological test results. Among individuals, 80,392 had dementia, of which 35,748 had AD. The age- and sex-standardized prevalence rates per 1,000 individuals for any dementia and AD were 77.64 (95%CI=77.57; 77.68) and 34.05 (95%CI=34.01; 34.09), respectively. There were 82.10 incident cases of any dementia per 100,000 per year (0.79 sensitivity and 0.62 specificity), and 59.89 incident cases of AD per 100,000 per year (0.80 sensitivity and 0.59 specificity). The capture-recapture method showed low number of undetected cases (1.7% for any dementia and 3.0% for AD). Our algorithms showed acceptable performance with AUC ranging from 0.59 to 0.72, and double likelihood ratio of correctly identifying individuals above and below MMSE standard cut-offs (24 and 26). Our algorithm, integrating administrative and clinical data, holds potential for assessing dementia's epidemiological burden, identifying risk factors, planning healthcare access, and developing prevention strategies.

Key messages:

- Providing comprehensive estimates of dementia burden aids public health planning and resource allocation.
- Integrated administrative and clinical data provide robust tools for epidemiological analysis and preventive strategies.

[3]Department of Biomedical Imaging, Medical University of Vienna, Vienna, Austria
Contact: richard.felsinger@meduniwien.ac.at

Background: Life expectancy and healthy life years diverge considerably in Austria, and quality of life (QoL) varies widely among older people. Identifying the factors most relevant to QoL in older people is crucial. We aimed to investigate the association between health behaviour, including lifestyle and preventive behaviour, and QoL in this population.

Methods: Cross-sectional data from the Austrian Health Interview Survey (2019) were used, including 3,995 individuals aged 65 years and older. We performed latent class analysis (LCA) to identify patterns of health behaviours. Variables were selected based on the WHO framework of Active Ageing including factors related to lifestyle (physical exercise, fruit/vegetable intake, BMI, oral health, smoking, alcohol use) and the health care system (satisfaction, unmet needs, participation in screening, health checks and vaccination). Domain scores of the WHOQOL-BREF were used for QoL assessment. Class differences were assessed by survey regressions.

Results: In the LCA, four different behavioural classes emerged among the older-aged Austrian population, including (class 1) 'best preventive behaviour and very good lifestyle' (17.7%), (class 2) 'worst lifestyle and worst preventive behaviour, high unmet healthcare needs and unsatisfied with the system' (16.5%), (class 3) 'very good preventive behaviour and best lifestyle, but worst vaccination probability' (24.8%) and (class 4) 'poor preventive behaviour, good lifestyle, but no physical activity' (41.0%). The classes with unhealthy lifestyles (classes 2 and 4) had worse QoL in all domains compared to the classes with healthy lifestyles (classes 1 and 3). The four classes differ on demographic, socio-economic and health characteristics.

Conclusions: To improve the QoL of the older population, policies and interventions need to be tailored to the specific characteristics and needs of each behavioural class.

Key messages:

- This study explores the relationship between health behaviour and QoL in older Austrians.
- Findings support the development of differentiated interventions targeting different types of behaviour.

[5]Institute and Polyclinic for Occupational and Social Medicine, Medical Faculty, TU Dresden, Dresden, Germany
Contact: bauer.juliane@baua.bund.de

Background: In order to implement targeted type 2 diabetes (T2D) prevention measures for the workplace, it is important to identify high-risk occupations. Most previous studies examine the association between T2D and occupation cross-sectionally, but longitudinal studies are missing. This study aims to investigate the 10-year incidence of T2D in the working population of a German cohort and identify occupations with an increased risk.

Methods: Data from the population-based Gutenberg Health Study (GHS) were used to examine occupation at baseline (2007-2012) and T2D incidence at the 10-year follow-up. Occupational phases were coded into categories according to the KldB 2010. T2D was defined as either a physician-diagnosed T2D, HbA1c-level $\geq$6.5% or use of antidiabetic drugs. Age- and sex-standardised incidence and 95% confidence intervals (CI) were calculated for occupational groups based on the age- and sex-distribution of the German population. Standardised incidence ratios (SIR) and 95% CI were calculated using the incidence in the total GHS working population as the reference.

Results: Of 8130 workers at baseline, 45.2% were female, the mean age was 48.4 years and 4.5% had prevalent T2D. 388 cases occurred between baseline and the 10-year follow-up within the subgroup of persons without prevalent T2D at baseline and with follow-up data ($n = 5954$). The standardised incidence was 6.9%. "Food production and processing" (20.7%), "cleaners" (16.5%) and "drivers and mobile plant operators" (14.8%) had the highest standardised incidences. Compared to the total working population, we observed a threefold increased SIR for employees in "food production and processing" (3.0, 95% CI 1.8-4.7) and a two times higher SIR for "cleaners" (2.2, 95% CI 1.0-4.7) and "drivers and mobile plant operators" (2.2, 95% CI 1.3-3.3).

Conclusions: We identified occupations with an increased risk of T2D. Preventive measures and etiological research on work-related risks should focus on these occupations.

Key messages:

- The highest standardised incidence was observed in the occupational groups "food production and processing", "cleaners" and "drivers and mobile plant operators".
- Targeted prevention measures for type 2 diabetes in the workplace should focus on these occupational groups with increased incidence.

Abstract citation ID: ckae144.1474
Factors associated with drowning in Portugal, 2019-2023

Pedro Marques Mendes

P Marques Mendes[1,2], T Alves[2], V Gaio[2], C Aniceto[2], F Horta Correia[1], C Matias Dias[2]
[1]Public Health Unit, Local Health Unit of Algarve, Faro, Portugal
[2]Department of Epidemiology, National Institute of Health Dr. Ricardo Jorge, Lisbon, Portugal
Contact: pmmendes@arsalgarve.min-saude.pt

Worldwide, mortality from drowning amounted to 236.000 individuals in 2019, corresponding to 8% of the total global mortality, making drowning the third leading cause of death from unintentional injuries and a universal public health problem. Portugal has a coastal zone of 950 km long, with 658 bathing waters and, in 2023, 157 people died due to drowning. This work aims to determine the factors associated with drownings that occurred in Portugal, between 2019 and 2023. This epidemiological descriptive-analytical study used the National Maritime Authority database, regarding the users of the portuguese coastal zone who suffered maritime incidents between 2019 and 2023. SPSS was used for statistical analysis and the results of the Poisson regression models are presented as adjusted prevalence ratios (APR) with 95% confidence intervals, according to individual (sex, age group and nationality), temporal (period of the week and day) and environmental (maritime department and beach surveillance status) variables. The total sample was 406 drownings and 15 860 other maritime incidents. Overall, the frequency of drownings in Portugal was higher in men (APR=1.393, 95%CI=1.130-1.717, p=.002), in the >55y age group (APR=1.780, 95%CI=1.005-3.152, p=.048), in foreigners (APR= 1.293, 95%CI=1.037-1.612, p=.022), on weekends (APR=1.299, 95%CI=1.063-1.586, p=.010), in the afternoon (APR=1.584, 95%CI=1.127-2.226, p=.008) and on unsupervised beaches (APR=2.436, 95%CI=1.958-3.029, p<.001) in comparison with users who suffered other maritime incidents. Individual, temporal and environmental factors are associated with a higher frequency of drownings in Portugal. Despite the limitation of the study that only includes users suffering maritime incidents and not all users of the portuguese coastal zone, our results allow a preliminary characterization of the drowning profile in Portugal and can contribute to the design of preventive strategies and policies to address this public health problem.

Key messages:

- This study shows that there are individual, temporal and environmental factors strongly associated with a higher frequency of drownings in Portugal.
- Portugal has a large coastal zone and the characterization of a drowning profile is the first step for the development of prevention strategies in order to oppose drowning morbidity and mortality.

Abstract citation ID: ckae144.1475
Socioeconomic deprivation and tuberculosis in Germany: a longitudinal spatial analysis (2001–2022)

Jan Oppenberg

J Oppenberg[1], S Rohleder[1], O Sauzet[1], K Bozorgmehr[1,2]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Section Health Equity Studies & Migration, Heidelberg University Hospital, Heidelberg, Germany
Contact: jan.oppenberg@uni-bielefeld.de

Background: Socioeconomic conditions may affect tuberculosis (TB) dynamics. We analyzed the relation between area-level socioeconomic deprivation and TB incidence in Germany between 2001-2022.

Methods: Using nationally representative data at the level of 400 German districts, we fitted generalized linear mixed models to assess the effect of socioeconomic deprivation on TB incidence controlling for age, sex, share of non-nationals population, share of refugees, geographic effects, location and time. We estimated crude and adjusted risk ratios (RR) and corresponding 95% Confidence Intervals (95%-CI) for socioeconomic deprivation quintiles (Q1-Q5), ranging from least (Q1) to most deprived (Q5) districts.

Results: Preliminary findings show that crude TB incidence risk was 7% higher (RR = 1.07, 95%-CI=1.04-1.09) in least (Q1) compared to most deprived areas (Q5). Districts with medium-low (Q2), medium (Q3), and medium-high (Q4) socioeconomic deprivation showed 1% higher (1.01, 0.98-1.03), 4% lower (0.96, 0.94-0.99) and 3% lower (0.97 0.94-1.00) risk, respectively, compared to the most deprived districts (Q5). Fully adjusted incidence risk was 6% lower for Q1 compared to Q5 (0.94, 0.86-1.02), while districts classified in quintiles Q2-Q4 showed 8% (0.92, 0.86-0.99), 6% (0.94, 0.88-1.01) and 3% (0.97, 0.92-1.02) lower risk compared to Q5, respectively.

Conclusions: The adjusted effect of area-level socioeconomic deprivation on the risk of TB incidence has been low in Germany. Not considering the assumed confounders leads to over-estimation of the association between area-level SES and TB. Future studies should explore further area-level or individual factors in order to better understand the spatial variation of TB incidence in Germany.

Key messages:

- Area-level socioeconomic deprivation has a low effect on the risk of TB incidence across German districts.
- Further research is needed in order to better understand the spatial variation of TB incidence in Germany.

Abstract citation ID: ckae144.1476
Measles cluster in Northern Portugal: enhancing surveillance strengths

Ana Mendes

A Mendes[1]*, M Vieira*[1]*, J Vidal-Castro*[1]*, L Duarte*[1]*, R Areias*[1]*, G Cruz-Alves*[1]
[1]Epidemiological Surveillance Functional Area, Public Health Department of Northern Region Health Administration, Porto, Portugal
Contact: ana.carvalho@arsnorte.min-saude.pt

Although measles was declared eliminated in Portugal in 2015, outbreaks persist, despite high vaccination coverage. The last outbreak in the northern region was in 2017. Portugal has a Surveillance System implemented for mandatory communicable diseases (SINAVE) integrating clinical, epidemiological and laboratory data. In 2021, WHO expressed concern about the low sensitivity of measles surveillance and urged Portugal to strengthen its surveillance practices. Our study aims to describe a measles cluster in northern Portugal during the first trimester of 2024. Data from measles cases from the first trimester of 2024 were collected from SINAVE. Contact tracing and Public Health (PH) intervention data was sent by Local Public Health Authorities through a survey designed for that purpose. A total of 70 suspected cases were reported and investigated: 6 cases were laboratory confirmed and 64 were discarded. The confirmed cases had a mean age of 28 years (all adults), with 50% female. The mean notification time was 0,3 days. The index case was imported (Mauritania) and unvaccinated, leading to 2 secondary cases. Five cases had 2 doses of a measles vaccine, with 1 case being a health professional. Additionally, 1 case was imported from France. For 2 cases the source of infection could not be unequivocally identified and no travel history during incubation period. A total of 851 contacts of confirmed cases were identified. Although sustainable transmission is not evident in our region, measles is being introduced through migration and tourism. Despite clinical awareness, strengthening early case detection is essential to enforce effective control measures. PH teams have been working tirelessly to trace clusters origins, gathering large number of contacts and adapting strategies for sustained control. In a globalized world, ensuring surveillance sensitivity is paramount. Integrating other data sources in surveillance routine is crucial for upholding Measles-Free Status compliance.

Key messages:

- Measles must take centre stage on our agenda.
- Reinforcing surveillance, integrating additional data sources, is crucial for heightened sensitivity and prompt response.

Abstract citation ID: ckae144.1477
SINAVE's quality: completeness for Meningococcal Disease – Northern Portugal, 2020-2022

Rita Areias

A Rodrigues[1]*, F Mouta*[1]*, M Vieira*[1]*, J Vidal-Castro*[1]*, A Mendes*[1]*, G Cruz-Alves*[1]
[1]Epidemiological Surveillance Functional Area, Public Health Department of Northern Region Health Administration, Porto, Portugal
Contact: raazevedo@arsnorte.min-saude.pt

Due to Meningococcal's Disease (MD) severity and impact in public health, in Portugal it is mandatory to notify the suspicious cases to implement effective control measures. MD cases are notified in the National Surveillance System (SINAVE), which triggers epidemiological investigation, risk assessment and community intervention. The quality of SINAVE is defined by various attributes, being their evaluation crucial to improve and guarantee quality standards. Our goal is to evaluate the external and internal completeness of SINAVE for MD in northern Portugal from 2020 to 2022. We have conducted a cross-sectional study, using MD cases from 2020 to 2022. External Completeness was estimated using a two-source capture-recapture method, with data from SINAVE and Diagnostic-Related Group (DRG) cases. Hospital readmissions', duplicates and cases from other regions were excluded. Internal completeness of SINAVE was accessed for each case and for each non-mandatory variable. For external completeness (EC) analysis, 21 of the 23 DRG cases were eligible for matching. Out of 31 SINAVE confirmed cases, 20 were eligible for matching. EC of SINAVE was 66,7%. For internal completeness (IC) analysis, we excluded 7 cases that did not meet the criteria for inclusion. The mean IC was 73,5% (min 38,5%, max 85,7%) when analysing by case. When assessing each of the 30 non-mandatory variables of the reports, 7 (23,3%) had an IC of 100% and 13 (43,3%) had an IC of 0%, the mean value was 49,7%. SINAVE assessment, as a routine, is crucial to identify the need for improvement. Completeness is fundamental to ensure an effective public health response. Our results confirm under-reporting and incomplete report of MD. There is a need to strengthen the improvement of data quality of SINAVE. Future studies may be important to estimate true incidence of MD and compare the results for other diseases in order to improve public health actions.

Key messages:

- Meningococcal disease requires timely public health intervention.
- valuation of the surveillance system is crucial, with completeness playing an important role for data quality and prompt response.

Abstract citation ID: ckae144.1478
Molecular surveillance of A. baumannii in intensive care units: exploration of transmission chains

Mariateresa Ceparano

M Ceparano[1], *V Capitani*[1], *S Rondòn*[1], *G Migliara*[2], *V Baccolini*[1], *C Marzuillo*[1], *P Villari*[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Department of Life Sciences, Health and Health Professions, Link Campus University, Rome, Italy
Contact: mariateresa.ceparano@uniroma1.it

Background: Multidrug-resistant Acinetobacter baumannii (MDR-Ab) is one of the main causes of healthcare associated infections (HAIs). During the SARS-CoV-2 pandemic there was an increase in MDR-Ab infections, especially in intensive care units (ICUs). This study aimed to assess the potential spread or emergence of specific clusters of MDR-Ab across four different ICUs at the Umberto I teaching hospital of Rome.

Methods: From January 2020 to January 2022 microbiological surveillance was conducted in four ICUs: two dedicated to COVID-19 patients (ICU-1C, ICU-2C) and two to non-COVID-19 patients (ICU-1R, ICU-2R). The genetic relatedness between A. baumannii isolates was assessed using pulsed-field gel electrophoresis (PFGE). Illumina whole genome sequencing was conducted on 26 representative isolates.

Results: In total, 178 A. baumannii isolates were obtained from 129 COVID-19 patients and 49 non-COVID-19 patients. The isolates were classified into 17 PFGE pulsotypes, being two major (A, B) and five intermediate (C, D, E, H, Q). Clone A was present in all ICUs, while Clone B was present only in ICU-1C and ICU-2R. Overall, 117 isolates belonged to clone A and exhibited a MDR phenotype; all of them were placed within the international clonal lineage II. All isolates showed carbapenems resistance primarily attributed to the presence of the blaOXA-23 gene, while aminoglycosides resistance observed in almost all isolates was attributed to the presence of the armA gene. Small outbreaks involving intermediate pulsotypes were detected between ICU-1R and ICU-2R, ICU-1C and ICU-2R, ICU-1C and ICU-2C, ICU-1C and ICU-1R.

Conclusions: The observed outbreaks could be attributed to a decline in attention to normal care practices for the prevention of HAIs during the COVID-19 pandemic, favouring the spread of MDR-Ab. Therefore, it is recommended the strengthen of control measures and the implementation of long-term strategies targeting MDR microorganisms in the ICUs.

Key messages:

- Acinetobacter baumannii was frequently found infecting patients across four different ICUs at the Umberto I teaching hospital of Rome.
- Acinetobacter baumanni outbreaks and multidrug resistance were observed. Therefore, the implementation of long-term strategies targeting MDR microorganisms in the ICUs is highly recommended.

Abstract citation ID: ckae144.1479
Factors associated with actinic keratoses in people with albinism in the Albivoire program

Fousseyni Diadouba Coulibaly

FD Coulibaly[1], *MH Dassi Tchoupa Revegue*[1], *KLWG Amani*[2,3], *E Lauressergues*[1], *S Lenaud*[2,3], *B Garette*[1], *C Przybylsky*[1], *K Kouamé*[2,3]
[1]Département Scientifique, Fondation Pierre Fabre, Lavaur, France
[2]Département de Dermatologie, Centre Hospitalier Universitaire de Treichville, Abidjan, Cote d'Ivoire
[3]Secours Médico-Social Ivoirien, Abidjan, Cote d'Ivoire
Contact: fousseyni.coulibaly@fondationpierrefabre.org

Background: People with albinism (PWA) face health inequalities partly due to barriers in accessing health care, consequently delaying the diagnosis of skin precancerous and cancerous lesions. Actinic keratoses (AK), are common precancerous lesions, indicating a high risk of skin cancer. Given the scarcity of research on skin cancer prevention among PWA in Africa, this study aimed to determine the prevalence and factors associated with AK in PWA followed in the Albivoire program.

Methods: This cross-sectional analytical study was conducted within the ongoing Albivoire program in Ivory Cost. Initiated in Ivory Coast in 2021, Albivoire is the largest comprehensive preventive and care initiative with and for PWA, offering medical consultation campaigns in dermatology, ophthalmology, and psychology. Dermatological records of consenting patients were analyzed. The prevalence (95%CI) of AK was estimated, and the associated factors assessed using logistic model.

Results: To date, a total of 1978 PWA received care across four regions (Abidjan, Bouaké, Korhogo and Man). Available data from 475 PWA were analyzed, among whom 247 (52%) were women. The median age was 14 years (interquartile range [IQR]: 7-25). Of these, 181 individuals (38.1%, 95% CI [33.7 - 42.6]) presented with actinic keratoses (AK). The median age of PWA with AK was 22 years (vs 11 years for without AK ($p < 0.001$). Among PWA with AK, 87.8% were daily exposed to sun (vs 12.2% for those exposed occasionally, $p = 0.026$). In the multivariate analysis, factors significantly associated with AK included age 22 years or older (vs age < 22 years, aOR=4.83, $p < 0.001$), the presence of ephelides (vs absence; aOR=2.08, $p = 0.003$) and presence of xerosis (vs absence aOR=4.88, $p < 0.001$).

Conclusions: This study highlights the high prevalence of AK in PWA in Ivory Cost, and identifies specific modifiable associated factors which should be targeted in global health strategies to prevent skin cancer among this vulnerable population.

Key messages:

- Prevalence of skin precancerous lesions (actinic keratoses) in people with albinism in Ivory Cost is high (38%) and associated with modifiable risk factors.
- Tailored public health interventions needed to prevent skin cancers in vulnerable populations, targeting lesions like xerosis, ephelides, and actinic keratoses through skin protection.

Contact: murrell@liverpool.ac.uk

Background: The financial crisis in 2008 has led to governments across Europe introducing austerity measures. England has experienced significant financial cuts to local authority (LA) services. Environmental and regulatory (ER) services provide key functions in public protection such as, Food Safety (FS) and Animal and Public Health Infectious Disease Control (APH), services which are key infectious disease resilience. Here we investigate inequalities in local funding cuts to ER services by socioeconomic deprivation, LA type, and urbanicity, and impact on key ER service indicators.

Methods: This ecological study uses longitudinal modelling techniques to analyse trends in ER expenditure since the introduction of austerity and the inequalities present. We use Generalised Estimating Equations to estimate the annual percent change of ER service expenditure, and FS and APH expenditure between 2009/10 and 2020/21 in relation to deprivation, LA type and population density. Quasi-Poisson regression is used to assess impact of cuts on ER service indicators.

Results: Areas of higher deprivation had the largest reduction in expenditure, with ER and FS and APH cuts of 2% and of 23% respectively, compared to a 1% and 8% reduction in the least deprived areas. The share of ER expenditure spent on FS and APH decreased by 13% in the most deprived authorities compared to 6% in the least deprived areas. London boroughs had the greatest reductions in FS and APH expenditure, decreasing by 10%. Both ER and FS and APH expenditure decreased with increasing population density. Preliminary analysis shows inequalities in food business hygiene ratings in addition to other key ER service indicators since the introduction of these cuts.

Conclusions: The unequal distribution of cuts shows the need for increased and equitable investment into these services to enable resilience to infectious disease threats, and to prevent widening of health inequalities.

Key messages:

- This work provides strong evidence of inequalities in local funding cuts to ER services and highlights where investment should be focused, in order to protect environmental and public health.
- This work introduces the impact of local funding cuts on a vital public health service and lays the foundation for future work into the unequal impact of cuts to these services on health outcomes.

Comparing statistical forecasting methods for modelling respiratory virus healthcare demand

Rhys Earl

R Earl[1,2], M Baguelin[1], E Van Leeuwen[2], J Lopez-Bernal[2], N Ferguson[1]
[1]Infectious Disease Epidemiology, Imperial College London, London, UK
[2]UKHSA, London, UK
Contact: r.earl22@imperial.ac.uk

Background: Emergency departments in the United Kingdom are under sustained pressure with rising demand for healthcare, gradually decreasing the functionality of the NHS. Forecasts can aid management in the allocation of appropriate healthcare supplies and staffing needs in advance of an expected surge, as well as allow stakeholders to assess most likely outcomes and potential worst-case scenarios. This is especially valuable during the seasonal waves of respiratory infections. Respiratory viruses are usually concentrated in a 6-8 week seasonal surge during the winter period, creating large pressure on the health system. Current forecast models' performance depreciates significantly after 1 week. This analysis will forecast 6 weeks of respiratory health admissions, comparing traditional and newly emerging forecasting methods.

Methods: Using 20 years of English hospital admissions data, we evaluated both within season training models (2-20 weeks) and longer term seasonal models (1-10 years), to forecast 6 weeks of hospital admissions. Respiratory admissions were defined according to ARI/ILI ICD10 codes assigned in hospital, stratified by age and region. Models were iteratively constructed, trained and probabilistic forecasts were evaluated across the respiratory season of September to April using Weighted Interval Score. Averages of each model across iterations were generated for comparison.

Results: For non-seasonal models, shorter model training lengths created better forecast models for 6 weeks. For seasonal models, optimal training length varied across model complexity. Simple models performed best at forecasting 1 week, however performance deteriorated the most as the forecast window increased. Overall, the Prophet model performed best on average at forecasting 6 weeks across all scenarios.

Conclusions: Applying our framework for optimal model selection in forecasting analysis will help to inform better practice for future health demand modelling.

Key messages:

- This analysis will inform better practice for future health demand forecasting 6 weeks in advance, allowing for preparation of resources for seasonal surges in healthcare demand.
- This analysis suggests using models with modest levels of increased complexity over simpler models could significantly improve forecast performance in the short-medium term.

Abstract citation ID: ckae144.1482
Tobacco smoking during COVID-19 pandemic among social media users in Russia

Artyom Gil

AU Gil[1], AP Novikov[2], AK Demin[3], L D'Souza[4]
[1]Country Office, WHO, Astana, Kazakhstan

[3]Institute for Leadership and Health Management, Sechenov University, Moscow, Russia
[4]Health and Development, United Nations Development Program, New York, USA
Contact: gil.artyom@gmail.com

Background: The COVID-19 pandemic has forced countries to take various restrictive measures, including "lockdowns", which may have affected tobacco smoking. The study explored associations between an increase in smoking, sociodemographic, and related to pandemic factors during pandemic among social media users in Russia.

Methods: Between June-September 2020, 1518 users of the most popular in Russia social media networks participated in online survey investigating changes in alcohol, tobacco, and substance use during pandemic. Binary logistic regression was used to identify factors associated with an increase in tobacco smoking. The analysis was adjusted for sex, level of education, perception of the severity of public life restrictions, negative work/financial consequences of the pandemic, stress, changes in the frequency of drinking, heavy episodic drinking (6 or more standard drinks at a time), and the volume of alcohol consumed on a typical occasion.

Results: 46.8% of the surveyed population were current smokers. 17.0% of them reduced, 37.9% increased, and 45.1% didn't change their smoking during the pandemic. Relative to those whose smoking reduced or didn't change, those who increased their smoking were more likely to be: 18-29 years old (OR = 1.906; 95% CI = 1.109-3.277), residents of medium to big cities (up to 1 mln inhabitants) (1.519; 1.017-2.270), had their income reduced (1.508; 1.024-2.222), faced severe restrictions in everyday life as a result of measures taken to contain SARS-CoV-2 (2.398; 1.440-3.758). After introducing alcohol consumption variables to the model, only two factors were associated with an increase in smoking: severe restrictions in everyday life (2.147; 1.227-3.993) and increased frequency of heavy episodic drinking during pandemic (2.338; 1.167-4.685).

Conclusions: Increase in tobacco smoking during pandemic was associated with severe restrictions in everyday life and increased frequency of heavy episodic drinking among social media users in Russia.

Key messages:

- More than a third of social media users increased tobacco smoking during pandemic, which was associated with severe restrictions in everyday life and increased frequency of heavy episodic drinking.
- During pandemics and similar public health crises, it is advisable to expand remote counseling services for alcohol and tobacco cessation, which can be delivered through social media.

[4]Surgery, Medical and Social Sciences, University of Alcala, Alcalá de Henares, Spain
Contact: hanish.kodali@sph.cuny.edu

Background: Racial/ethnic inequities in mortality risk are pervasive in the United States even after controlling for socioeconomic status indicators such as educational attainment. Although the mechanisms underlying these inequities remain unclear, telomere length (TL) has emerged as a potential mediator. We aimed to investigate the joint association of race/ethnicity and education with all-cause mortality risk, and the contribution of TL to this relationship.

Methods: We used data from the U.S. National Health and Nutrition Examination Survey, 1999 to 2002, and 2019 Linked Mortality File (n = 6,526 non-institutionalized adults aged 25 years or older, including 2,166 deaths), a retrospective cohort study with a follow-up period to December 31, 2019. Cox proportional hazards regression and causal mediation analysis were used to address these aims. We reported hazard ratios (HR) and 95 % confidence intervals (CI). Furthermore, for the mediation analysis, we reported the total, direct, and indirect effects measured as HR and 95 % CI.

Results: After adjusting for age and sex, among White individuals, those with less than a high school education had a 2.26 times higher (95% CI: 1.93, 2.65) rate of all-cause mortality compared to those with some college or higher education. When compared with White adults with at least a college degree, Black adults with at least a college degree had a 1.38 higher rate of dying (95% CI: 1.04, 1.84). There was no significant joint association of race/ethnicity and education on all-cause mortality in Mexican Americans. In the mediation analysis, TL did not significantly contribute to the joint association of race/ethnicity and education with all-cause mortality risk.

Discussion: These findings underscore the need for a better understanding of the joint relationship of race/ethnicity and education on mortality risk inequities and their potential mechanisms to improve population health ultimately.

Key messages:

- Lower educational attainment was associated with higher mortality rates among White individuals, disparities persisted among the Black population, despite higher education levels.
- Our analysis did not find a significant mediation effect of telomere length on the joint effect of race/ethnicity and education-mortality relationship.

Mammography screening among women attending primary healthcare centers in Monastir, Tunisia

Cyrine Ben Nasrallah

C Ben Nasrallah[1,2], *M Kacem*[1,2], *W Dhouib*[1,2], *A Maatouk*[1,2], *A Gara*[1], *I Zemni*[1,2], *H Abroug*[1,2], *M Ben Fredj*[1,2], *I Bouanène*[1], *A Belguith Sriha*[1,2]
[1]Department of Epidemiology and Preventive Medicine, Fattouma Bourguiba University Hospital, Monastir, Tunisia
[2]LTIM - LR12ES06, University of Monastir, Monastir, Tunisia
Contact: cyrine.bennasrallah@gmail.com

Background: Breast cancer is the leading cancer among women worldwide. Early detection through mammography screening improves prognosis and enhances survival rate for this disease. The aim of this study was to identify the factors associated with mammography screening utilization among women attending primary healthcare centers.

Methods: A cross-sectional study was conducted in four primary healthcare centers in Monastir governorate in October 2023 using a pre-tested questionnaire. Women aged over 45 years-old were included as they were the target group in the breast cancer screening strategy. Univariate then multivariate analyses were performed in order to identify the factors associated with mammography screening utilization. Data was analyzed by SPSS 21.0.

Results: A total of 192 women were included in the study with a mean age of 56.7±8.8 years-old. Among them, 79.7 % (n = 153) were married and 51.6% (n = 98) had three children and less. A total of 55.3 % (n = 94) had a primary education level. Regarding participants' practices of breast cancer screening, 35% of our participants have had mammogram. Univariate analysis showed that the knowledge about breast cancer symptoms (p = 0.015), practicing Breast self-examination (BSE) (p = 0.002), being aware about mammography (p = 0.001) and the recommended age of the screening at 45 years-old (p = 0.001) were significantly associated with adherence to breast cancer screening. Multivariate analysis revealed that practicing BSE (ORa=2.60 [95%CI: 1.22-5.55] and knowing the recommended age of mammography screening (ORa=2.28 [95%CI: 1.17-4.45] were significant ($P < 0.05$) predictors of mammography screening utilization.

Conclusions: Mammography screening rate is low. This study had provided some informations about factors influencing mammography screening. Policymakers and public health practitioners should consider the identified factors when developing intervention programs to improve breast cancer screening.

Key messages:

- There is a need to conduct education sessions in schools to raise awareness about breast cancer screening at an early age.
- Social media can be a tool for health education on mammography screening.

Abstract citation ID: ckae144.1485
Memory impairment after one year of the acute episode of Covid-19 infection

Imen Zemni

I Zemni[1], *M Kacem*[1], *C Bennasrallah*[1], *W Dhouib*[1], *M Ben Fredj*[1], *H Abroug*[1], *N Ben Rached*[2], *A Mhalla*[2], *I Bouanene*[1], *A Sriha*[1]
[1]Epidemiology and Preventive Medicine, Monastir University Hospital, Monastir, Tunisia
[2]Psychiatry, Monastir University Hospital, Monastir, Tunisia
Contact: imen11zemni@gmail.com

Introduction: Memory impairment is one of the most frequently reported sequelae of COVID-19 infection. The aim of our study was to estimate the risk of memory disorders one year after the acute episode of COVID-19 infection in the Tunisian population of Monastir.

Methods: This is a cohort study conducted in Monastir University Hospital. The study included two groups: Exposed subjects were randomly selected among those with a positive diagnosis of COVID-19 between September 2021 and January 2022. The non exposed group was selectd among subjects with a negative COVID-19 diagnosis during the same period and who had no COVID infection during the following year. The Mac Nair scale was used to assess memory impairment after one year of follow up.

Results: Our study included 140 subjects diagnosed with Covid-19 and 139 subjects who had never been in contact with this virus. The incidence rate of memory impairment at one year post-Covid-19 infection was 17.9% (IC95% [11.5 - 24.2%]), whereas in the non exposed group it was 9.4% (IC95% [4.45% -14.5%]). Multivariate analysis revealed that the group exposed to Covid-19 had a significantly higher Mac-Nair Total score after one year of the acute episode of infection compared with the non exposed group (exp $\beta = 1.25$, IC95% [1.10; 1.42]). The other main predictors of memory impairment in the study population were age (exp $\beta = 1.006$, IC95% [1.001; 1.01]), diabetes (exp $\beta = 1.67$, IC95% [1.44; 1.95]), history of anxiety and depression ((exp $\beta = 1.71$, IC95% [1.35; 2.17]) and obesity (exp $\beta = 1.25$, IC95% [1.10; 1.42]), whereas vaccination with two or more doses prior to COVID-19 infection (exp $\beta = 0.84$, IC95% [0.74; 0.96]) and male gender (exp $\beta = 0.65$, IC95% [0.57; 0.73]) were found to be protective against these disorders.

Conclusions: Our study allowed us to estimate the risk of long-term memory disorders following Covid-19 infection. This could help better guide preventive measures to reduce the incidence of these disorders.

Key messages:

- The incidence rate of memory impairment at one year post-Covid-19 infection was 17.9%.
- The main other predictors of memory impairment were age, female gender, diabetes, history of anxiety and depression and obesity whereas vaccination prior to COVID-19 infection was a protective factor.

Contact: zribi.mariem.fmt@gmail.com

Introduction: Tunisia is undergoing rapid nutritional transition, with increasing rates of abdominal obesity. Coupled with rising diabetes prevalence, it poses significant challenges to public health. This study aimed to estimate the morbi-mortality prevalence and trends of diabetes among Tunisian adults, particularly examining its association with abdominal obesity.

Methods: We conducted a secondary data analysis on adults aged 35 to 70 from three national surveys in Tunisia, in 1996 (n = 3513), 2005 (n = 7700), and 2016 (n = 6007) respectively. Mortality data was sourced from the Tunisian National Information System on Causes of Death in 2020. The underlying cause of death was determined using the IRIS software, following WHO guidelines for tabulating mortality statistics. Diabetes was defined according to the American Association of Diabetes criteria. Abdominal obesity was defined as a waist-to-height ratio ≥ 0.6. We performed chi-squared test for trend analysis.

Results: A total of 17220 participants were analyzed. We found a significant upwards trend in diabetes prevalence ($p < 10\text{-}3$): it increased from 13.1%[11.9-14.3] in 1996 to 15.1% [12.5-17.4] in 2005, then to 20.5%[18.9-22.1] in 2016. Linear trend test concluded to significant increase in diabetes prevalence estimated at 56.6% in two decades. Diabetes was significantly associated with abdominal obesity (Odds ratio (OR)=2.17[2.11-2.21]). Diabetes was the leading cause of death among Tunisian adults in 2020 (n = 22715). The proportional mortality due to diabetes was estimated at 6.2% (n = 1407) (6.4% for men and 6% for women). The age group with the highest proportional mortality due to diabetes was 65-70 years old (44.6%).

Conclusions: Our findings highlight the burden of diabetes on public health in Tunisia and its association with abdominal obesity. Hence the urgency to strengthen comprehensive preventive and control measures to alleviate its repercussions among the Tunisian population.

Key messages:

- The prevalence of diabetes increased significantly amongTunisian adults in the past two decades.
- Immediate implementation of targeted interventions and policy measures is imperative to effectively address this issue.

Changes in overweight and overweight-related health behavior in higher education students in Finland

Suvi Parikka

S Parikka[1], J Ikonen[1], V Pohjola[1], K Sarttila[1], A Lundqvist[1]
[1]Department of Public Health and Welfare, THL, Helsinki, Finland
Contact: suvi.parikka@thl.fi

Introduction: Covid-19 pandemic may have had negative effects on overweight and overweight-related health behavior in young adults. The aim was to examine the changes in overweight, physical activity, sedentary behavior and daytime tiredness in higher education students during and after the pandemic.

Methods: Two cross-sectional student representative surveys (aged 18-34 y) were conducted in 2021 (n = 6258, response rate 53 %) and 2024 (n = 3638, response rate 31 %). Overweight (BMI $\geq$25 kg/m2) was based on self-reported height and weight. Physical activity was dichotomized into those meeting physical activity recommendations and others. Sedentary behavior was dichotomized into sitting in front of TV, computer or smart device over three hours a day during leisure time and others. Daytime tiredness was dichotomized into those feeling tired 6-7 days a week and others.

Results: The preliminary results indicate that overweight in women increased from 34 % to 39 % whereas no increase was observed among men (47 % vs. 46 %) between 2021 and 2024. Meeting the physical activity recommendation increased from 46 % to 55 %, the change being similar for both sexes. Sitting over three hours in leisure time in front of TV, computer or smart device decreased from 54 % to 50 %. In men, the prevalence of sitting decreased (62% vs. 57 %) whereas in women no statistically significant change was observed (47% vs 45 %). No statistically significant change was observed in feeling tired almost every day (26 % vs 24 %).

Conclusions: Among higher education students, an increase in prevalence of overweight in women was observed for three years period. Favourable changes were observed in physical activity in both men and women, and sedentary behavior in men. Surveillance of the long-term health consequences of the pandemic in young adults is important for planning and targeting preventive activities.

Key messages:

- Overweight increased among female higher education students after COVID-19 pandemic.
- Factors supporting favourable changes in health behaviour of young adults after pandemic should be examined in longitudinal setting.

Abstract citation ID: ckae144.1488
Risk factors for COVID-19 infection among the German older adult population

Ana Magdalena Ordonez Cruickshank

A Ordonez Cruickshank[1,4], *B Gaertner*[1,3], *H Neuhauser*[1,3], *A Zanuzdana*[2], *C Poethko-Muellller*[1], *E Nowossadeck*[1], *J Fuchs*[1]
[1]Epidemiology and Health Monitoring, Robert Koch-Institut, Berlin, Germany
[2]Infectious Disease Epidemiology, Robert Koch-Institut, Berlin, Germany
[3]German Centre for Cardiovascular Research, Berlin, Germany
[4]Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität, Berlin, Germany
Contact: Ordonez-CruickshankA@rki.de

Background: There are scarce analyses on COVID-19 infection risk factors for the older adult population. This study aims to examine COVID-19 infection risk factors in the older adult general population.

Methods: The data for this analysis came from the population-representative Study on Health of Older People in Germany (Gesundheit65+) conducted by the Robert Koch Institute from 10/2021 to 08/2022. We considered information on COVID-19 infection status (self-reported infection confirmed by PRC test at least once vs. never), socio-demographic factors, health risk factors, and different face-to-face interactions. The analysis was restricted to 2,976 individuals aged 65+ years with complete infection status information. We assessed weighted prevalences and used univariable and multivariable logistic regressions to evaluate infection risk factors.

Results: The overall prevalence of infection was 7.2% (95% confidence interval, 6.0-8.7). Infection prevalences were significantly higher (compared to their respective reference group) among participants living in assisted living facilities (24.7% vs. 6.7%), individuals who got help to perform basic activities of daily living (10.8% vs. 6.8%), COVID-19 unvaccinated individuals (25.2% vs. 6.9%), individuals who did not meet family or friends in the last month (12.7% vs. 6.7%), and participants who did not smoke (7.8% vs. 2.6%). No other variable was significantly related to COVID-19 infection. In multivariable analysis, variables independently associated with higher odds ratio (OR) of COVID-19 infection were: living in an assisted living facility OR 3.6 (1.8-7.2), not being vaccinated against COVID-19 OR 4.6 (1.5-14.1), and not smoking OR 1.6 (1.1-2.6).

Conclusions: The preliminary results of this study align with the prevalence of COVID-19 infection found in concomitant studies. A noteworthy element of our study is the vaccine's protective effect. The pandemic had a particularly detrimental effect on residents of assisted living facilities

Key messages:

- Improvement in quality of care and infection preventive measures in nursing homes is necessary.
- Pandemic preparedness must consider the need for help in the daily life of the older population.

Abstract citation ID: ckae144.1489
Neonatal screening for hearing loss and its associated factors: A pediatric hospital experience

Carlos Emilio Castillo Ceballos

MC Ceballos Vela[1], *LD Ruiz Hernandez*[1], *R Diaz Macedo*[1], *B Colonna Aguirre*[1], *P Martinez Breton*[1], *JC Viñas Dozal*[1], *CE Castillo Ceballos*[1], *JE Villegas-Dominguez*[1]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
Contact: zs18007657@estudiantes.uv.mx

Introduction: Hearing impairment affects 0.6% of children worldwide, with 60% of cases being preventable. Identifying risk factors for hearing impairment would facilitate early detection and better patient prognosis.

Objectives: To identify factors associated with abnormalities in auditory screening in a pediatric hospital.

Methods: A cross-sectional study was conducted on patients assessed in the early hearing detection program at the Pediatric Tower of the High Specialty Hospital of Veracruz, Mexico, between June 2022 and 2023. Screening was performed using otoacoustic emissions initially. Those with abnormalities underwent two retests, and those positive in all three evaluations underwent confirmatory testing. Newborn screening was conducted at discharge for healthy neonates and after reaching a weight of over 1.8 kg and more than 34 gestational weeks for preterm infants. For term and low-birth-weight babies, screening occurred when they reached 2 kg, considering positive results in any of the three tests indicative of altered screening and probable hearing impairment.

Results: A total of 2731 patients were fully evaluated, with 1416 (51.8%) being male, and a median Apgar score of 9 at 5 minutes. The incidence of hearing impairment was 0.7%, comprising 19 patients. Evaluation of sex, 5-minute Apgar score, weight, gestational age, congenital malformations, history of neonatal asphyxia, hyperbilirubinemia, sepsis, TORCH infections, family history of hearing impairment, maternal exposure to ototoxic drugs, substances, COVID-19, gestational diabetes, or maternal hypertension obtaining values of $p > 0.05$ in each of them.

Conclusions: The prevalence of hearing loss is similar to that reported in the literature. In our population, auditory screening abnormalities are not associated with classic perinatal factors, indicating the complexity of contributors to neonatal hearing impairment.

Key messages:

- The neonatal screening program plays a fundamental role in identifying patients with hearing loss even without any clinical factor that arouses suspicion of hearing loss.
- Early diagnosis will favor timely care for patients with hearing loss, favoring their development with adequate care to improve their quality of life.

Abstract citation ID: ckae144.1490
Epidemiology of ESKAPEE Complex at Veracruz Children's Hospital during 2023

Carlos Emilio Castillo Ceballos

MC Ceballos Vela[1], *CE Castillo Ceballos*[1], *JA Marín Vargas*[1], *JE Villegas-Dominguez*[1], *GJ Carranza Promotor*[1], *M Perez Villanueva*[1], *YR Sosa Gonzalez*[1], *E Bravo Sarmiento*[2], *DE Alba Aburto*[2]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
[2]Microbiologia, Hospital Regional De Alta Especialidad de Veracruz, Veracruz, Mexico
Contact: zs18007657@estudiantes.uv.mx

Introduction: The ESKAPEE complex comprises bacterial species known for their propensity to develop multiple mechanisms of resistance against antibiotics. The elevated rates of mortality and morbidity associated with these microorganisms, along with the challenges posed by their treatment, have transformed them into a significant concern in global public health. However, in Mexico, the prevalence of the ESKAPEE complex in pediatric patients within tertiary care hospitals remains understudied compared to adults.

Materials and methods: A cross-sectional, retrospective, and descriptive study was conducted, encompassing 179 bacteria belonging to the ESKAPEE complex. These bacteria were isolated from pediatric patients between January and December 2023 at Veracruz Children's Hospital. Laboratory samples were processed using the

VITEK 2.0 system, and descriptive statistical analyses were performed using SPSS v22 software.

Results: A total of 179 antibiograms were analyzed, with 55.1% corresponding to male patients. The most prevalent age group among pediatric patients was school children (5 to 11 years old), comprising 20.2% of the sample. Blood culture was the most frequently sampled site, representing 35.4% of cases. Klebsiella pneumoniae emerged as the most common bacterium, accounting for 22.5% of isolates. The Pediatric Emergency Department was the primary area from which samples were obtained, constituting 18.5% of the total.

Conclusions: Klebsiella pneumoniae was the most frequently isolated bacteria inside de hospital in 2023, especially among school-aged patients, followed by E. coli, which coincides with reports in the literature from various countries around the world.

Key messages:

- Establishing a national surveillance network within public health institutions is imperative, where ESKAPEE complex microorganisms are reported.
- Knowing the epidemiological profile of the ESKAPEE complex will favor the diagnosis and intentional search for infections with greater etiological certainty.

Abstract citation ID: ckae144.1491
Resistance Profiles of the ESKAPEE Complex at Veracruz' s Children Hospital, 2023

Carlos Emilio Castillo Ceballos

M Ceballos Vela[1], *JA Marín Vargas*[1], *CE Castillo Ceballos*[1], *JE Villegas-Dominguez*[1], *YR Sosa Gonzalez*[1], *E Bravo Sarmiento*[2], *DE Alba Aburto*[2]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
[2]Microbiología, Hospital Regional De Alta Especialidad de Veracruz, Veracruz, Mexico
Contact: zs18007657@estudiantes.uv.mx

Introduction: ESPAKEE complex bacteria are well known as a Multidrug Resistance Organisms that cause difficult mange infections. Management of these infections should be based on the monitoring of resistance profiles to provide appropriate therapy to reduce hospitalization costs and patient improvement.

Materials and methods: A cross-sectional, retrospective, descriptive study analyzed 179 ESKAPEE bacteria isolated from pediatric patients (0-18 years) between January 1 and December 31, 2023. Laboratory tests utilized VITEK 2.0 technology, reporting Minimal Inhibitory Concentration (MIC) and classifying them as resistant or non-resistant. Descriptive statistics were generated using SPSS v22.

Results: The study included 179 antibiograms. Among Enterobacter species, E. aerogenes (3) and E. cloacae (17) showed 100% resistance to cefalotin. S. aureus (22) exhibited the highest resistance to Oxacillin (36.4%). Klebsiella pneumoniae (40) demonstrated 97.5% resistance to Ampicillin, followed by resistance to first-generation cephalosporins: cefalotin 62.5%, and third-generation cephalosporins: ceftriaxone and ceftazidime both at 60%. Acinetobacter baumannii (9) showed 100% resistance to Fosfomycin. Pseudomonas aeruginosa (30) displayed 100% resistance to Ceftriaxone, Cefotaxime, and Cefuroxime. Enterococcus faecium (2) exhibited 100% resistance to ciprofloxacin, erythromycin, ampicillin, and levofloxacin, while Enterococcus faecalis (16) showed 50% resistance to tetracycline. E. coli (39) exhibited the highest resistance to Ampicillin (87.2%), while in first-generation cephalosporins: cefalotin 66.7%, third generation: cefotaxime 66.7%, ceftazidime 64.1%, and ceftriaxone 66.7%.

Conclusions: The ESKAPEE complex species isolated in the hospital displayed diverse resistance profiles against various antibiotic families.

Key messages:

- Monitoring ESKAPEE bacteria's resistance profiles enables physicians to select appropriate antibiotics at optimal dosages and timings.
- Physician should know the rate of resistance of the antibiotics that they use for treatment of ESKAPEE bacteria.

Contact: angelo.giosue.mezzoiuso@ki.se

Background: The use of Assisted Reproductive Technology (ART), such as in vitro fertilization (IVF) and intracytoplasmic sperm injection (ICSI), is rising in Europe. These treatments involve high doses of hormones to increase oocyte collection. While most safety studies in women have focused on cancer risks, the association with cardio-renal diseases remains under-explored. This study examines whether the use of ART is linked to coronary ischemic disease (CHD), stroke, brain hemorrhage, other cerebrovascular diseases, chronic kidney disease, and aortic aneurysm/dissection, while also exploring the association between infertility and these conditions.

Methods: A nationwide cohort study was conducted using Swedish national registries, following all nulliparous women who gave birth between 1982 and 2002 until the end of 2017. Descriptive statistics and inverse probability weighted Kaplan-Meier curves to adjust for body mass index, maternal age, country of origin, smoking, and year of delivery, were used to compare 1) women who conceived with or without ART, 2) women who used IVF or ICSI respectively to women with known infertility that conceived without ART, and 3) women with and without known infertility.

Results: Compared to all other women, women undergoing ART were at elevated risk for CHD, stroke, and other cerebrovascular diseases, but after adjustment for underlying risk factors, including infertility, no substantial differences were seen. As a group, women with known infertility were at elevated risk of CHD and stroke, also after adjustment for known background factors.

Conclusions: Data suggest that the use of ART does not increase the long-term risk of cardio-renal diseases. Nonetheless, infertility itself is associated with a higher risk of CHD and stroke.

Key messages:

- Infertility, more so than the use of ART, is linked to elevated risks of CHD and stroke.
- Preventive measures for these conditions should be considered for women with infertility.

Health symptoms in individuals with and without post-covid in the Dutch general population

Jenny Gerbecks

J Gerbecks[1], *CJ Yzermans*[1], *M Duckers*[1], *C Baliatsas*[1]
[1]NIVEL, Utrecht, Netherlands
Contact: j.gerbecks@nivel.nl

Background: Health symptoms, often non-specific in nature such as headache and sleep problems, are more prevalent in the aftermath of disasters. Relatively little research focused on non-specific symptoms in the context of the COVID-19 pandemic, including those with post-covid conditions. The aim of this study was to assess the symptomatic profile of people with post-covid conditions, and to assess differences in health symptoms between non-infected individuals, infected individuals, and individuals with post-covid.

Methods: A nation-wide cross-sectional health survey performed in 2022 was combined with routine primary care electronic health records (EHRs). Prevalence of individual symptoms was analyzed, as well as symptom scores for number, duration, and severity of symptoms. The total survey sample consisted of 315,586 individuals. The EHR sample consisted of 29,797 individuals with matched survey data. Both samples were divided into three groups: non-infected, infected, and post-covid.

Results: Survey participants with post-covid experienced significantly (CI 99%) more (incidence risk ratio (IRR) 1.55), longer lasting (IRR 1.87), and more severe self-reported symptoms (IRR 1.95) compared to non-infected individuals. For infected compared to non-infected survey participants, there were hardly differences in symptom scores. The most distinct differences in individual symptoms were observed for loss of smell or taste, fatigue, and respiratory problems. Based on EHR data, the post-covid group is at significantly higher risk of experiencing fatigue, shortness of breath, headache, sleep problems, and dizziness.

Conclusions: Individuals suffering from post-covid are at the highest risk of experiencing health symptoms, both based on self-reported symptoms as well as based on EHRs. The infected group generally experienced more self-reported symptoms than the non-infected, but on average, they experienced them at a shorter duration, and they also reported them to be less severe.

Key messages:

- Health symptom prevalence is higher in individuals with post-covid in the Netherlands.
- This effect is confirmed in self-reported health surveys as well as in primary care registries.

Abstract citation ID: ckae144.1494
Using English General Practice Patient Survey data to explore Long Covid prevalence

Mirembe Woodrow

M Woodrow[1], *N Ziauddeen*[1], *D Smith*[2], *NA Alwan*[1,3]
[1]Centre for Population Health Sciences, University of Southampton, Southampton, UK
[2]School of Geography and Environment, University of Southampton, Southampton, UK
[3]University Hospital Southampton NHS FT, Southampton, UK
Contact: m.woodrow@soton.ac.uk

Background: High global burden of Long Covid (LC) has significant implications for population wellbeing, health/social care and the economy. We aimed to assess prevalence of LC, the level of uncertainty general practice (GP) patients felt about whether they were experiencing it and patient characteristics associated with LC.

Methods: This is a secondary data analysis of GP Patient Survey 2023 data (759,149 participants aged 16+yrs in England). The outcomes included self-reported LC, and being unsure about having LC. Identity and socioeconomic characteristics were explored in relation to these outcomes using univariable and multivariable regression analyses.

Results: 4.8% of respondents described themselves as having LC, and 9.1% were unsure whether they had it. Patient age (highest odds at 35-54 years), sex (females more than males), ethnicity (highest odds in Gypsy or Irish Traveller), sexual orientation (increased odds in gay or lesbian or bisexual compared to heterosexual), religion, smoking, carer status, parental status, having a long-term condition, and area-level index of multiple deprivation (higher odds in more deprived areas) were all significantly associated with reporting having LC in the multivariable model compared to answering that question with 'no'. Generally, similar patterns of association to the above were observed in those who answered the Long Covid question with 'unsure' compared to those answering 'no', except for parental status and sexual orientation which were not significantly associated with the outcome in the multivariable model.

Conclusions: This study quantitatively highlights the high levels of uncertainty among primary care patients around experiencing LC, and the unequal distribution of LC burden among population groups. Our findings underline the need for better public health and primary care messaging to raise awareness around LC and ensure that those needing support can access services, particularly those already disadvantaged in society.

Key messages:

- There are high levels of uncertainty about having Long Covid among people attending primary care services.
- There is unequal burden of Long Covid in England underlining the need for improved awareness and access to support, particularly for minoritised groups.

Background: The COVID-19 pandemic has accelerated the use of digital health technologies. Digital health literacy (DHL) is essential for effectively understanding and applying electronic health information. However, unequal access and use of these technologies require interventions to improve DHL for fair healthcare access.

Objectives: This scoping review aimed to identify strategies to enhance DHL in patients and the general population.

Methods: The review used the Joanna Briggs Institute Scoping Review Methodology and PRISMA-ScR guidelines. Eligibility criteria included a wide population, interventions aimed at improving DHL, with no restrictions on outcomes. The search strategy included electronic databases (MEDLINE, PsycINFO, Web of Science), and AI-based software, AS Review, was used for screening.

Results: The review found 5149 articles, 44 met the eligibility criteria. Studies focused on different demographic groups and health conditions. Most interventions were in North America and Europe. The study designs varied. Interventions via mobile apps, online platforms, and in-person sessions aimed at various conditions yielded positive results, including increases in DHL, self-management skills, and health-related behaviors. These interventions involved either independent interventions that focused on DHL or integrated interventions that were part of another intervention that aimed at a health outcome and had an element of DHL enhancement.

Conclusions: The review highlights the importance of DHL in informed decision-making and navigating digital health environments. While many interventions had positive outcomes, methodological limitations challenge the findings, emphasizing the need for more rigorous study designs. Future research should address sustainability, scalability, and the impact of DHL on health disparities, considering cultural sensitivity when developing interventions.

Key messages:

- Scoping review identifies strategies to enhance Digital Health Literacy (DHL), crucial for effective use of health technology.
- Despite positive outcomes, methodological limitations exist. Future research should focus on sustainability and scalability.

Abstract citation ID: ckae144.1496
Adverse Reaction Reports for Skincare: Zero

Miranda Hernández Rico

D Morales Morales[1], M Espinosa Tabitas[1], JE Villegas Dominguez[1], V Cruz Duarte[1], JC Viñas Dozal[1], SD Chávez Castillo[1], GJ Carranza Promotor[1], M Perez Villenueva[1]
[1]Facultad de Medicina, Universidad Veracruzana, Veracruz, Mexico
Contact: zs19023068@estudiantes.uv.mx

Introduction: Suspicions of Adverse Drug Reactions (sADRs) facilitate public health authorities in making decisions regarding the safety of various drugs in the market, thus it is important to be acquainted with these data in our population.

Objectives: To identify suspicions of adverse reactions due to skincare product use among adults in Veracruz, Mexico.

Methods: A cross-sectional, prospective, and descriptive study was conducted, including subjects over 18 years old residing in the metropolitan area of Veracruz, Mexico. A self-administered questionnaire was utilized to identify suspicions of adverse reactions due to skincare product use and their notifications.

Results: 607 subjects participated, with a mean age of 24.61 (±9.85), comprising 78.25% females and 21.75% males. The prevalence of sADRs identified by patients was 37.2%; however, 44.3% reported experiencing skin redness, 42.7% reported burning sensation, and 31.6% noted changes in their skin becoming oilier. 70.20% claimed awareness of potential adverse effects of the products they use, and 37.2% reported experiencing some adverse reactions, with 76.6% indicating that adverse reactions noticed on their skin disappeared upon discontinuing the product. None of the participants notified sADRs upon identifying them.

Conclusions: Not all participants in this study recognize sADRs as adverse effects, indicating the possibility that patients may have experienced adverse reactions without being aware of them, as they may not relate the product to the reaction

Key messages:

- The notification of sADRs is a regulated activity in Mexico, so we must promote its implementation at all levels, since they are fundamental for public health decisions.
- We must carry out educational activities on skin care in order to prevent SADRs or so that the doctor provides care in a timely manner, since the patient does not recognize them.

Abstract citation ID: ckae144.1497
Measles outbreak under the Leaning Tower of Pisa in Italy

Alessandro Daole

A Daole[1], S Giorgi[2], G Cruschelli[1], L Bonaldo[1], A Gallo[2], C Rizzo[1]
[1]Translational Research and New Technologies, University of Pisa, Pisa, Italy
[2]Unità Funzionale Igiene Pubblica e Nutrizione, Azienda USL Toscana Nord Ovest, Pisa, Italy
Contact: aledaole@icloud.com

Background: Measles cases in Italy (58,9 mln population) were 8 in 2021, 15 in 2022 and 43 in 2023. Between January and April 2024 there were 213 cases in Italy, with higher incidence in children. Pisa Local Public Health Department (201073 population) experienced a measles outbreak in the same period.

Methods: Cases were classified according to Decision (EU) 2018/945. A bidirectional tracing (backward and forward) was conducted to identify transmission chain and contacts of cases. Immunization status was checked on Regional Vaccination Registry.

Results: 33 suspected measles cases were notified in Pisa between 21st January and 17th April 2024: 16 by General Practitioners and 17 by Hospital Emergency Room. Additionally, 1 undiagnosed case was found during the epidemiological investigation. 2 notifications were withdrawn by General Practitioner because of lack of the diagnostic criteria. Laboratory analysis confirmed 24 cases. Last confirmed case occurred on 23rd February, while not confirmed cases occurred mostly in the last part of the period (6 in a row from 3rd March to 17th April), suggesting an infodemic effect. Women were more affected than men (17 vs. 7). Except for 2 babies (9 months and 1 year old age), the outbreak affected young adults with a mean age of 40 yo. Hospitalization rate was 37,5%. The first 5 unrelated cases occurred between 19th and 21st January. A second wave involved 13 people, 12 of them were related to a single case. Transmission occurred in Emergency Room (7), in a mall (1) and in the neighborhood (4). A third wave involved 4 cases (family contacts). 2 cases were imported from Sicily and Spain. All cases were unvaccinated, 2 were migrants. Around 950 contacts were traced.

Conclusions: In Pisa, high vaccination coverage of children $<$ 2years of age ($\geq$95%) protected school population and cases to spread, but there are pockets of unvaccinated adults which could allow measles circulation.

Key messages:

- An effective public health response is required to contrast increasing measles cases in EU/EE countries.
- As recommended by ECDC, public health services need to close immunity gaps, addressing catch-up actions towards adults and vulnerable groups as migrants.

Abstract citation ID: ckae144.1498
Prevalence and incidence of chronic wounds in Austria - a population-based real-world data analysis

Kathrin Morasek

K Morasek[1,2,3], R Himmelsbach[2], C Schneider[2], V Ritschl[1,3], S Wieser[5], A Pötscher[4], T Stamm[1,3]
[1]Institute for Outcomes Research, Centre for Medical Data Science, Medical University of Vienna, Vienna, Austria
[2]Ludwig Boltzmann Research Group on Senescence and Healing of Wounds, Vienna, Austria
[3]Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Vienna, Austria
[4]Wound Centre Vienna 22, Vienna, Austria
[5]Austrian Health Insurance Fund, Vienna, Austria
Contact: kathrin.morasek@ar.lbg.ac.at

Background: Chronic wounds are associated with pain, odor, loss of mobility, an increased risk for infection and sepsis and a reduced quality of life. Treatment costs are rising due to the longevity of the population and increasing number of diabetes cases. For service planning in healthcare, it is thus necessary to describe patient characteristics and estimate the prevalence and incidence of chronic wounds. Currently, no data exists on this subject broken down by age group, gender, and province in Austria.

Methods: A retrospective analysis of real-world data was conducted using two merged datasets from an outpatient wound centre and the Austrian Health Insurance Fund. The study population consisted of people who resided in Austria and were covered by statutory health insurance from 2018 to 2022. We performed a descriptive, sociodemographic analysis of the data of patients, followed by a set of cluster analyses using the unsupervised K-means algorithm. From these clusters, we derived subgroup characteristics and patient trajectories and calculated prevalence and incidence rates for chronic wounds according to diagnoses, different age groups, gender, and different regions.

Results: Gender was almost evenly distributed in the wound centre's data set (n = 4963; 49.6% female). The age distribution revealed the age group from 71-80 years being the largest group. In general, more women than men are affected by chronic wounds from the age of 81 onwards. 31% of chronic wound patients had diabetes as an underlying condition. More men were affected by peripheral arterial occlusive disease and diabetic foot syndrome and, conversely, more women by chronic venous insufficiency. These are preliminary results of the analyses.

Conclusions: Chronic wound patients were characterised by older age and multi-morbidity. Interestingly, gender differences appeared in the occurrence of comorbidities.

Key messages:

- This study makes a crucial contribution in making routine data usable for the epidemiological study of chronic wounds, a cluster of diseases of complex aetiology.
- It thus contributes to filling a knowledge gap. The prevalence estimate serves as a basis of knowledge for health care planning and a basis for the health economic assessment of the problem.

Knowing the Antibody Status may influence compliance of health care workers to COVID-19 booster dose

Avi Magid

A Magid[1,2], *K Hussein*[2,3], *H Dabaja-Younis*[3,4], *M Szwarcwort-Cohen*[4], *R Almog*[4], *G Hyams*[4], *V Gepstein*[4], *NA Horowitz*[4], *M Halberthal*[2,3], *Y Shachor-Meyouhas*[2,3]

[2]Management, Rambam Health Care Campus, Haifa, Israel
[3]Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel
[4]Rambam Health Care Campus, Haifa, Israel
Contact: magid.avi@gmail.com

Background: Previous studies showed that the fourth SARS-CoV-2 vaccine dose has a protective effect against infection, as well as against severe disease and death. This study aimed to examine whether knowledge of a high level antibody after the 3rd dose may reduce compliance to the 4th booster dose among health care workers.

Methods: We conducted a prospective cohort study among health care workers vaccinated with the first three doses at Rambam Healthcare Campus, a tertiary hospital in northern Israel. Participants underwent a serological test before the 4th booster vaccine was offered to all of them, with results provided to participants. The population was divided into two groups: those with antibody below 955 AU/ml, and those with 955 AU/ml and higher, a cutoff found protective in a previous study. Multiple logistic regression was carried out to compare the compliance to the 4th booster between the two groups, adjusted for demographic and clinical variables.

Results: After adjusting for the confounding variables, the compliance was higher in those with antibody levels below 955 AU/ml (OR = 1.41, P = 0.05, 95% CI 1.10-1.96). In addition, male sex, and age of 60 years and above were also associated with higher vaccination rate (OR = 2.28, $P < 0.001$, 95% CI 1.64 - 3.17), (OR = 1.14, P = 0.043, 95% CI 1.06 - 1.75), respectively.

Conclusions: Knowledge of the antibody status may affect compliance with the booster dose. Considering waning immunity over time, reduced compliance may affect the protection of health care workers who declined the 4th dose.

Key messages:

- Knowing the antibody status may affect compliance of health care workers with the booster dose.
- Reduced compliance of health care workers may affect their protection.

Abstract citation ID: ckae144.1500
Happiness and all-cause mortality: the HAPIEE study

Hynek Pikhart

H Pikhart[1,2], *F Lin*[2], *A Tamosiunas*[3], *M Kozela*[4], *N Capkova*[5], *J Pikhartova*[1,2], *M Bobak*[1,2]
[1]RECETOX, Masaryk University, Brno, Czechia

[3]Lithuanian University of Health Sciences, Kaunas, Lithuania
[4]Jagiellonian University, Cracow, Poland
[5]National Institute of Public Health, Prague, Czechia
Contact: h.pikhart@ucl.ac.uk

Background: The evidence on the association between happiness and mortality is mixed. Similarly, the role of covariates in this association is not clear. Almost no evidence on the topic comes from the Central and Eastern Europe (CEE). This analysis aims to evaluate such association in longitudinal data from three CEE countries, and to investigate the role of other variables in this association.

Methods: The analysis is based on data from 18,362 men and women from the longitudinal Health, Alcohol and Psychosocial factors In Eastern Europe (HAPIEE) study conducted in the Czech Republic, Lithuania and Poland who were 45-70 years old at the start of the study. Happiness was based on 4-points Likert scale answers 'Very happy', 'Quite happy', 'Not very happy', and 'Not at all happy' to the question 'Taking all things together, would you say you are ...'. All-cause mortality was obtained from local or national mortality registers. Cox proportional hazards regression was used to estimate the hazard ratios (HRs).

Results: 2,718 deaths have been observed during the 11 years of follow-up. The mortality rates were 13.0, 14.1 and 20.7/1000 person years in very happy, quite happy and unhappy groups. After adjustment for country and age the HR comparing very happy and unhappy was 0.53 (95%CI: 0.43-0.67) in men and 0.66 (0.48-0.91) in women. This association was reduced after adjusting for socioeconomic characteristics, health behaviours and conventional risk factors (HR 0.78 in men and 0.84 in women); and was further reduced after controlling for health conditions at baseline. No strong evidence for country interaction was identified although the association was slightly stronger in Polish men than in other two countries.

Conclusions: Happiness has been shown to predict all-cause mortality in these three countries from CEE although it may be (at least partly) explained by established risk factors and underlying health conditions. This work was supported by the NPO SYRI (LX22NPO5101). #NGEU

Key messages:

- Happiness is shown to predict all-cause mortality in this CEE population.
- The association seems stronger in men than in women.

[3]Hepatology Unit, Pisa University Hospital, Pisa, Italy
[4]Careggi University Hospital, Florence, Italy
[5]Division of Infectious Diseases, Grosseto Hospital, Grosseto, Italy
Contact: erica.devita@unipi.it

Background: Chronic hepatitis C virus (HCV) infection is a major global public health problem. This study investigated the evolving landscape of HCV in Tuscany (Italy) from 2015 to 2022, considering demographic shifts, clinical profiles, treatment regimens, and outcomes.

Methods: The study was conducted in order to characterize HCV-positive patients who started treatment between 2015 and 2022 in Tuscan prescribing centers. The study was part of OPT-HepaC, a project funded by Regional Health Service. Data on demographics, clinical history and outcomes were collected. Three different temporal eras were analysed: the period before andfter the universal availability of direct-acting antivirals (DAA) and the COVID-19 era. Treatment's effectiveness was evaluated by the Sustained Virological Response (SVR12), assessed 12 weeks after the end of treatment. Outcomes included SVR12, non-SVR12 and lost to follow-up (LTFU). ANOVA, Kruskal-Wallis test and multinomial logistic regression were used for statistical analysis.

Results: 6882 HCV patients (age: 58.88±14.21) were treated by the centres participating at the study. Males (56.4%) and Italian (91.8%) were predominant. Sociodemographic and variable characteristics vary across the time. While the overall SVR12 remained stable over time ($\chi 2(2)=0.357$, $p = 0.837$), the LTFU rate significantly increased during the COVID-19 era. Facilitating factors for the non-SVR12 and LTFU outcomes were male gender (Odds Ratio (OR)=2.134, $p = 0.006$)/cirrhosis (OR = 1.713, $p = 0.040$)/HIV co-infection (OR = 3.251, $p = 0.005$) and DAA treatment of third generation (OR = 4.187, $p = 0.006$), respectively.

Conclusions: The study provides a comprehensive view of the HCV landscape, highlighting demographic changes, treatment regimens and outcomes. The COVID-19 pandemic affected service delivery, delaying HCV diagnosis/treatment and influencing the LTFU rate. Despite challenges, the region maintained high SVR12 rates, emphasizing the importance of sustained efforts in HCV care.

Key messages:

- The study highlights the dynamic nature of HCV management in Tuscany.
- The study emphasises the need for continuous adaptation to public health challenges, providing insights for future public health strategies.

Contact: elikagradschool@gmail.com

Background: Despite increasing rates of incarceration and sexually transmitted infections (STIs) among women globally, STI epidemiological data for this vulnerable at-risk population is limited. We therefore characterized patterns of STI symptoms and explored covariates and drivers of STI symptoms among incarcerated women in Peru.

Methods: Among 249 incarcerated women surveyed on substance use, depression, sexual behavior, STI symptoms and violence, univariate and bivariate analysis informed a latent profile analysis (LPA) and logistic regression assessing for syndemic associations between violence, substance use, and STI symptoms.

Results: Most participants were Peruvian (93.5%), in their late 30s (median=37; range:18-70 years), sentenced to < 5 years (86.6%) and had completed high school (78.7%). 36.9 had ≥ 2 STI; A minority were pregnant (2.6%), had children residing with them in prison (7.2%); symptoms. The LPA model with the best fit revealed the largest (39%) group with a 'syndemic' profile involving co-occurrence of multiple STI symptoms, substance use, and experiences of interpersonal violence (IPV); 86.6% of this latent class were <50 years old. The substance use and violence 'syndemic' profile was associated significantly higher likelihood of having multiple STI symptoms (2+ symptoms: PR = 1.88 (95% CI 1.18, 2.99) or 3+ symptoms PR = 2.55 (95% CI 1.32, 4.93).

Conclusions and Recommendations: The syndemic of younger incarcerated women with substance use and IPV with STI symptoms portends a group at substantially higher risk for HIV and given the structured setting of prisons, should be routinely screened for and treated for STIs. Moreover, these settings can and should screen for and address substance use and IPV and intervene before these women are released to community settings to not only improve individual but public health needs.

Key messages:

- In line with syndemic theory, incarcerated women presenting with multiple STI symptoms (≥ 2) were more likely to be engaged in substance use (illicit drug use and/or alcohol) and experience violence.
- Post-hoc analysis also revealed the rate of substance use was higher among women who engaged in commercial sex work (CSW) pre-incarceration compared to those who were not engaged in CSW.

[2]SIRC, University College Dublin, Dublin, Ireland
[3]School of Veterinary Medicine, University College Dublin, Dublin, Ireland
Contact: jwenish.kumawat@ucdconnect.ie

Background: This study describes the investigation and management of multiple outbreaks of SARS-Cov2 during the second and third wave of the pandemic at University College Dublin, Ireland from September 2020 to September 2021.

Methods: Relevant data were gathered as part of the public health outbreak investigations led by the UCD Internal Covid Control Team (ICCT) in collaboration with the public health teams of the Health Service Executive (HSE). Results are presented for PCR (polymerase chain reaction) confirmed cases and their close contacts, reported to the UCD ICCT between September 2020 to September 2021.

Results: There were 214 cases notified to ICCT. Among these, 153 cases were in residence on-campus cases. 73 epidemiologically linked clusters identified, where the number of cases linked with each cluster varied between 1 to 27. Additional cases during this period had no obvious epidemiological link to the identified clusters. Of 902 close contacts with PCR test results, 31.5% (n = 284) tested positive. 77% (n = 219) self-reported with mild to moderately symptoms while 23% (n = 65) self-reported as asymptomatic. Retrospective Whole Genome Sequence (WGS) analysis was undertaken after the outbreaks had subsided. The test positive cases were grouped into 6 clusters, and it was shown that many of the apparent sporadic cases were included in these clusters.

Conclusions: The proportion of close contacts testing positive varied significantly throughout the pandemic, with testing policy and type of exposure having the greatest impact. Whole genome sequencing can give a better understanding of webs of transmission to complement epidemiological investigations. It is now possible to undertake sequencing in real time where it can make a contribution to outbreak control and resolution. Public Health professionals should become familiar with WGS and bioinformatics as useful tools in their armory for the control of all communicable diseases not only SARS-CoV-2.

Key messages:

- Combined epidemiological investigations and Whole Genome Sequencing (WGS) provide crucial insights into campus COVID-19 outbreaks, guiding effective control measures.
- WGS integration enhances understanding of transmission patterns, identifies clusters, and equips public health professionals with data-driven approaches for outbreak management beyond SARS-CoV-2.

Abstract citation ID: ckae144.1504

Determinants of Long COVID illness duration and service use-an Irish retrospective cohort study

Patricia Carney

P Carney[1], F McGuire[1], C Carroll[1], P Kavanagh[2], U Fallon[1]
[1]Department of Public Health, HSE, Tullamore, Ireland
[2]National Health Intelligence Unit, HSE, Dublin, Ireland
Contact: patricia.carney1@hse.ie

The Follow-up After Disease Acquisition (FADA) study is a retrospective cohort study of COVID-19 recovery, aimed to characterise the nature and severity of Long COVID (LC) in an Irish community-based sample. Duration analysis is conducted applying Cox's proportional hazards model to those self-reported recovered from LC (n = 577) and a Gompertz distribution parametric model, determined best fit by AIC, for those still ill with LC (n = 928) at time of survey completion. A negative binomial model is estimated to understand the variation of services accessed for LC. The Hazard in this instance is recovery(<1 = contributing factor to duration). Factors significantly contributing to duration of illness are never married (Hazard Ratio (HR):0.689;p:0.01) higher physical activity levels prior to first C-19 infection (HR:0.964; p:0.06) and number of COVID-19 infections (H:0.926;p:0.07). Those that contract more recent variants are likely to recover quicker from their LC illness (baseline Wildtype. Alpha HR:1.7;p:0.0; Delta HR:3.36;p:0.0; Omicron HR:3.8; p:0.0). In variation of services used for LC, there are some major differences between those self-reporting as recovered from LC at time of survey completion and those still ill. Of those recovered, men, those sickest with LC and sick longest use a wider variation of services. Single people use a significantly narrower range of health services to combat their illness. For those still ill higher education, higher levels of physical activity pre COVID-19, healthcare workers, higher rates of comorbidity, those sick longest and those whose health has been most impacted by LC use a wider variation of services. A poorer health rating negatively impacts variation of services accessed for LC illness. More recent strains of COVID-19 are significantly less likely to lead to LC, this offers hope for the future, albeit more research is required to investigate factors to improve recovery rates for those already experiencing LC.

Key messages:

- Those with Long COVID that recover quickly are fundamentally different to those that do not.
- The number of COVID-19 infections is a key indicator of length of Long COVID illness, we need to protect our most vulnerable and put appropriate safeguards in place for healthcare provision.

Abstract citation ID: ckae144.1505

Revisiting COVID-19 Maps with Bayesian Hierarchical Modelling: Socioeconomic Insights from Istanbul

Hüseyin Küçükali

Objectives: This study explores the spatial disparities in COVID-19 incidence across neighborhoods in Uskudar, Istanbul, and examines the relationship between these disparities and neighborhood-level socioeconomic status.

Methods: This ecological study analyzed cumulative COVID-19 case data for 33 neighborhoods in Uskudar, collected up to 31 December 2020. Socioeconomic status was assessed using the Socioeconomic Development Index (SEDI) scores from Istanbul Metropolitan Municipality. Spatial analysis included Moran's I statistics and Local Indicators of Spatial Association (LISA) cluster analysis. Bayesian Hierarchical Modeling with the Besag-York-Mollie (BYM) model was employed to decompose spatially structured and unstructured variations, adjusting for SEDI scores and their sub-components. Model validation involved convergence diagnostics and Monte Carlo error assessments.

Results: A total of 29,834 COVID-19 cases were identified, with an incidence rate of 56.1 per 1000 residents. Spatial analysis revealed significant clustering of high incidence rates in peripheral and inner city neighborhoods. Moran's I statistic for COVID-19 incidence was 0.331 ($p = 0.003$), indicating positive spatial autocorrelation. SEDI scores were also spatially autocorrelated (Moran's $I = 0.293$; $p = 0.005$) and negatively correlated with COVID-19 incidence ($r = -0.570$; $p = 0.001$). Bayesian hierarchical models confirmed the association between lower socioeconomic status and higher COVID-19 incidence, even after adjusting for spatial autocorrelation.

Conclusions: The study highlights significant spatial and socioeconomic disparities in COVID-19 incidence in Uskudar, Istanbul. Lower socioeconomic status is associated with higher COVID-19 incidence, underscoring the need for region-specific public health strategies that consider socioeconomic factors. These findings can guide future interventions to mitigate the impact of the pandemic on vulnerable populations.

Key messages:

- Study reveals COVID-19 incidence in Uskudar is significantly influenced by socioeconomic status, highlighting need for targeted health interventions.
- Positive spatial autocorrelation found in COVID-19 cases and socioeconomic index suggests clustering in specific Uskudar neighborhoods.

Background: Systemic Inflammatory Response Syndrome (SIRS) is a rare disease often presenting emergency. While the aetiology varies, current diagnostic criteria do not allow differentiation. Hopes are placed on OMICs research and development of Artificial intelligence (AI) algorithms for personalised disease management. Our report aims at identification and analysis of AI-driven ethical issues within the bigger ERA PerMed funded project of development of tailored immunotherapy for paediatric SIRS patients (TIPS) coordinated by Prof. Catharina Schütz from Technic University Dresden.

Methods: Systematic literature review followed by qualitative research methodology. Ten experts with different backgrounds were interviewed. Subsequent thematic analysis was performed by two independent researchers.

Results: Experts were on the opinion that AI can lead to a depart from individual approach in the medicine, as the physician may be induced to only act based on algorithms that are more or less representative ($N = 2$). Interviewees were aware that AI can lead to changes in the assessment of reality, as it is dependent on data quality ($N = 4$). AI-aided decision-making might be useful for special therapeutic situations, although it may not always capture the subtleties of individual situations ($N = 2$). Positive implications of AI were significantly more emphasised, though current frameworks were perceived as more limiting than enabling.

Conclusions: Personalised therapy is making its first steps while the ethical apprehensions has already been there with a strong emphasis on precautionary principle and resulting limitations on the application of AI-algorithms. The multifaceted nature of the AI-driven ethical issues in personalised medicine research requires an interdisciplinary discourse, strengthened ethics training of all professionals involved in the technology development and more active involvement of physicians in the shaping of AI.

Key messages:
- AI algorithms promise therapeutic benefits, not achievable by other means, for specific categories of vulnerable pediatrics patients.
- The multifaceted nature of the AI-driven ethical issues in personalised medicine research requires an interdisciplinary discourse and further ethics training of all stakeholders.

Health innovation and research has become an economic and profitable activity. Market practices have exposed inequalities, scarcities and inequities in access to treatments and have significantly reduced the decision-making power of governments in the field of public health. Documentary research on the human right (HR) to health (Art. 12) and its interrelationship with the right to benefit from scientific progress (Art. 15, b) of the International Covenant on Economic, Social and Cultural Rights (CESCR) on access to medicines in three bodies of the UN system - the ICESCR Monitoring Committee (CESCR), the Human Rights Council (HRC) and World Health Organisation - over the last 10 years. The documents address three main topics. Market: marketing restrictions, price controls and using flexibility in pharmaceutical patents to reduce costs and produce generics. Innovation: patent protection without barriers to access to medicines for people in need. Health system interventions: giving priority to economic efficiency and sustainability by institutionalising health technology assessment, selecting essential medicines, developing clinical guidelines and integrating and linking regulatory agencies. These normative guidelines minimise the ethical, political and legal dimensions of the human right to enjoy scientific progress in access to medicines as a priority value that should guide public and private action, and emphasise technocratic and financial measures that seek to reconcile the liberal and social logic of the ICESCR.

Key messages:
- In order to maximise the guarantee of human rights in access to medicines, economic and financial considerations should play only a residual role in human rights.
- To give countries greater decision-making power at the global health, the scope of the right to benefit from scientific progress and its applications in health care needs to be expanded.

Issue/Problem: The World Health Organisation (WHO) and Association of Schools of Public Health in the European Region (ASPHER) roadmap for the professionalisation of the public health workforce has noted ethics as a pillar for professionalisation. It also highlights the need for code of ethics and professional conduct for all public health professionals and institutions. The Global Network for Academic Public Health (GNAPH), in collaboration with EUPHA, ASPHER, and the UK Faculty of Public Health has been working together for a code of ethics.

Description of the problem: The WHO/ASPHER group asked for a framework to be developed by the expert group as part of the rollout of the professionalisation agenda. The objective of this work was to develop a guide that is applicable to different countries within Europe to develop their own of code of ethics and conduct. A modified Delphi approach to building consensus amongst professionals in ethics included law, academia, and public health professionals. The questions sought to be answered were what and how to develop a framework and what should be included in the guide for creating a public health code of ethics.

Results: Throughout this method we developed five values, and twelve principles that are essential for the development of a code of ethics through a consensus building exercise. This framework was the first of its kind as part of the professionalisation agenda for different regions. There will be ongoing work piloting this framework in practice with various professional groups and institutions.

Lessons: Throughout this process, the need and demand across the public health community for ethical education and development of code of ethics was made evident. Collaboration between academics, ethicist, lawyers, and public health professionals and policy makers were key in developing a public health code of ethics. Identifying the challenges with monitoring and evaluating of its implementation a public health code of ethics.

Key messages:

- Ethics, and a code of ethics are an essential component of the professionalisation agenda of the public health workforce.
- There is need for continued collaboration and partnership with public health professionals and institutions in enacting its implementation and evaluation.

Issue: During the COVID-19 pandemic and subsequent outbreaks, health organizations have increased the use of social listening to inform infodemic management and outbreak response activities. This demonstrated the need to provide ethical guidance to organizations, and individuals engaging in social listening practices before, during and after public health emergencies, whilst protecting human rights.

Description of the problem: Social listening as a public health activity draws on analysis of conversations in social media, internet platforms, and feedback from geographically localized communities. Infodemic insights are generated rapidly, to support agile action by health organizations that improves outbreak response, health information delivery, community engagement, or reduction of unintended harm experiences by communities. Social listening involves use of social media and internet trace data, which were traditionally not used in public health for understanding community expressions, WHO convened a panel of experts to develop a framework on ethical considerations for social listening in infodemic management to provide recommendations for health authorities and researchers on practical tools that support setting up new data analysis and use of insights hereto not used in routine.

Results: The guidance framework has been structured into segments that vary from ethical principles and challenges in social listening and generation of infodemic insights, alignment with human rights, substantive principles, procedural principles, and practical guidance for translating these principles into real-world practice.

Lessons: This guidance aims to illuminate the intricate ethical dimensions of social listening and stress the urgent need for ethical guidance in this realm. The framework is a comprehensive inquiry of the ethical scope in social listening, providing valuable insights, practical guidance, and case studies to enhance understanding of this critical global health issue.

Key messages:

- While essential, social listening and infodemic insights come with ethical risks, including potential harm to populations in vulnerable situations, erosion of trust, and misuse of data.
- This ethical framework will govern social listening practices and ensure responsible and ethical social listening.
